This Series 9 Debenture is one of an authorized issue of debentures designated as 4.2% Senior Unsecured Debentures due [redacted], 20" (Series 9) and forming the series of debentures created and issued under a tenth supplemental trust indenture made as of [redacted], 2013 (the "Tenth Supplemental Trust Indenture") to a trust indenture (the "Indenture") made as of May 7, 2003, between the Corporation and BNY Trust Company of Canada (successor trustee of CIBC Mellon Trust Company) (the "Trustee"), as Trustee (the first supplemental trust indenture to the Indenture made as of May 7, 2003 between the Corporation and the Trustee, the second supplemental trust indenture to the Indenture made as of November 14, 2007 between the Corporation and the Trustee, the third supplemental trust indenture to the Indenture made as of November 12, 2009 between the Corporation and the Trustee, the fourth supplemental trust indenture to the Indenture made as of April 1, 2010 between the Corporation and the Trustee, the fifth supplemental trust indenture to the Indenture made as of April 1, 2010 between the Corporation and the Trustee, the sixth supplemental trust indenture to the Indenture made as of May 20, 2010 between the Corporation and the Trustee, the seventh supplemental trust indenture to the Indenture made as of September 20, 2011 between the Corporation and the Trustee, the eighth supplemental trust indenture to the Indenture made as of November 18, 2011 between the Corporation and the Trustee, the ninth supplemental trust indenture to the Indenture made as of April [redacted], 2013 between the Corporation and the Trustee, the Tenth Supplemental Trust Indenture and the Indenture (as amended, supplemented or restated from time to time) are collectively referred to herein as the "Trust Indenture"). The Trust Indenture specifies the terms and conditions upon which the Series 9 Debentures are created and issued or may be created, issued and held and the rights of the registered holders of the Series 9 Debentures, the Corporation and the Trustee, all of which terms and conditions are incorporated by reference in this Series 9 Debenture and to each of which the registered holder of this Series 9 Debenture, by acceptance hereof, agrees.

The aggregate principal amount of Series 9 Debentures that may be created and issued under the Trust Indenture is limited to "[redacted]" in lawful money of Canada. Series 9 Debentures are issuable as fully registered debentures in denominations of $1,000 and integral multiples thereof

and, subject to the terms and conditions set forth in the Trust Indenture, are issued as book entry only debentures.

The Series 9 Debentures are direct unsecured obligations of the Corporation and will rank equally with each other and with all other debentures of every other series from time to time issued and outstanding pursuant to the Trust Indenture and, except to the extent prescribed by law, with all other unsecured and unsubordinated indebtedness of the Corporation.

This Series 9 Debenture is redeemable, at the option of the Corporation when not in default under the Trust Indenture, in whole at any time, or in part at any time and from time to time, prior to ", 20", subject to the terms and conditions set forth in the Trust Indenture, at a price equal to the greater of the Canada Yield Price (as defined in the Trust Indenture) and par, together with accrued and unpaid interest to (but excluding) the date fixed for redemption.

This Series 9 Debenture is redeemable, at the option of the Corporation when not in default under the Trust Indenture, in whole, but not in part, at any time on or after ", 20", subject to the terms and conditions set forth in the Trust Indenture, at a price equal to 100% of the Principal Amount of the Series 9 Debentures outstanding, together with accrued and unpaid interest to (but excluding) the date fixed for redemption.

At any time when the Corporation is not in default under the Trust Indenture, the Corporation may, subject to the terms and conditions set forth in the Trust Indenture, purchase Series 9 Debentures in the open market, by tender or by private contract, at any price. Series 9 Debentures purchased by the Corporation shall be cancelled and not reissued.

The Principal Amount may become or be declared due before the Stated Maturity on the conditions, in the manner, with the effect and at the times set forth in the Trust Indenture.

The Trust Indenture contains provisions for the holding of meetings of registered holders of debentures issued by the Corporation pursuant to the Trust Indenture and the making of resolutions at such meetings and the creation of instruments in writing signed by the registered holders of a specified majority of debentures issued and outstanding pursuant to the Trust Indenture. Such resolutions and instruments will be binding on and may affect the rights and entitlements of all holders of debentures issued by the Corporation pursuant to the Trust Indenture, subject to the provisions of the Trust Indenture.

This Series 9 Debenture may be transferred only upon compliance with the conditions prescribed in the Trust Indenture relating to the transfer of a Global Debenture (as defined in the Trust Indenture), and upon compliance with such reasonable requirements as the Trustee or other registrar may prescribe, and such transfer shall be duly noted hereon by the Trustee or other registrar.

This Series 9 Debenture shall not become obligatory for any purpose until it shall have been certified by the manual signature of the Trustee in accordance with the Trust Indenture.

IN WITNESS WHEREOF TORONTO HYDRO CORPORATION has caused this Series 9 Debenture to be signed by its z and its z.

Ratings Score Snapshot

Related Criteria And Research

Summary:

Toronto Hydro Corp.

Rationale

Business Risk: Excellent	Financial Risk: Intermediate
• Transparent, predictable and stable regulatory regime • No input cost risks, because tariffs allow the pass-through of major expenses to customers • Stable customer base with no meaningful customer concentration risk	• Stable regulated cash flow • Sizable capital programs related to aging infrastructure • High leverage

Outlook: Stable

The stable outlook reflects Standard & Poor's Ratings Services' expectation that Toronto Hydro Corp. will continue to focus on the regulated utility business, which provides a stable and predictable stream of cash flow during our two-year outlook horizon. In addition, we believe the company will manage its capital expenditure cost to be within the approved amount set forth by the Ontario Energy Board (OEB) and maintain the deemed capital structure.

Downside scenario

We could downgrade the rating as a result of a material adverse regulatory decision, severe operational inefficiencies, or other changes that we believe might lead to long-term financial deterioration resulting in adjusted funds from operations [AFFO]-to-debt falling below 13%.

Upside scenario

We could upgrade the rating if we expect Toronto Hydro to demonstrate sustainable long-term financial growth or to improve its financial position that results in AFFO-to-debt of 23%-25%. This could require the utility to deviate from its financial policy, which we believe is highly unlikely. As a result, the prospect of an upgrade is limited during our two-year outlook horizon.

Standard & Poor's Base-Case Scenario

The key drivers in our analysis continue to be the regulatory framework and the performance of the utility operator within the regulatory framework.

Assumptions

- The regulatory system will be stable and Toronto Hydro will not experience any material, adverse regulatory decisions
- The utility will earn a standard return on equity of approximately 9.58%, operate within the deemed capital structure with 60% debt, and not spend any unapproved capital
- The company will have its rate base reset in 2015 under the new custom incentive rate-making (IR) method

Key Metrics

	2013A	2014E	2015E
AFFO/debt	16.7%	13%-16%	13%-15%
AFFO/interest	3.68x	3.3x-4.0x	3.3x-4.0x

AFFO--Adjusted funds from operations. A--Actual. E--Estimate.

Business Risk: Excellent

In our view, Toronto Hydro's business risk profile is "excellent." The main positive driver continues to be the OEB. The

regulator continues to provide a transparent regulatory framework that supports a stable and predictable cash flow model, which we view as a key credit strength. Historically, electricity rates are established under a cost-of-service framework with rates for subsequent three years under an incentive-rate mechanism. In 2012, the OEB proposed additional alternatives to electricity rate settings. We believe Toronto Hydro will adapt the custom IR method to reflect the revenue requirement based on the large multiyear capital programs the company is committed to in the next few years. Toronto Hydro most recently had its cost-of-service hearing in 2011 and is scheduled for a rate reset in 2015. The regulatory framework also limits the utility's exposure to commodity risk and associated cash flow volatility because price fluctuations in the commodity flow through directly to customers.

Further supporting the excellent business risk profile is Toronto Hydro's large and diverse customer base with no meaningful concentration risk Residential and small businesses account for more than 90% of the total. In our view this customer profile is less sensitive to macroeconomic stress and business cycles. Nevertheless, the residential customer base has some sensitivity to volume fluctuations, primarily weather-driven, although we do not believe the fluctuations would pressure credit metrics at the rating. We do not expect Toronto Hydro's customer composition to change materially over the next two-year horizon.

We believe the utility carries relatively low operating risk because it has no obligation to ensure an adequate supply of electricity and is not burdened with the procurement process or power purchase agreement, which reduces operating risks. We expect operational efficiency and reliability to remain within provincial industry norms to avoid regulatory risk linked to poor sustained performance.

Financial Risk: Intermediate

When evaluating the "intermediate" financial risk profile for Toronto Hydro, we take into the consideration of the company's lower-risk regulated business model and apply the low-volatility table. We expect the utility will continue generating stable cash flow, a key credit strength. The company has large capital programs in the next few years and relies on the combination of internal FFO and external debt to fund these capital expenditures. As a result, this has a downward pressure on the credit metrics, especially the AFFO-to-debt metric. However we believe the company will be able to maintain the AFFO-to-debt metric above the 13% threshold.

To further support the intermediate financial profile risk is that we expect Toronto Hydro to maintain its deemed capital structure established by the regulator, which includes about 60% debt. Furthermore, the company has a C$400 million commercial paper (CP) program with C$150 million outstanding. Supporting the CP program are liquidity facilities available under the utility's C$600 million revolving credit facility; hence, available borrowing under the credit facility is reduced by the amount of CP outstanding. In our opinion, the credit facility provides sufficient backup liquidity to protect Toronto Hydro in the event the company is unable to roll over the maturing paper with new notes.

Liquidity: Adequate

In our view, Toronto Hydro's liquidity "adequate". The company has sufficient liquidity sources to cover more than 1.1x its uses. Moreover, in the event of a 10% EBITDA decline, Toronto Hydro's sources of funds would still exceed its

uses. In our opinion, the company has sound relationships with its banks, generally satisfactory standing in credit markets and generally prudent financial risk management.

Principal Liquidity Sources	Principal Liquidity Uses
• FFO of approximately C$290 million • Undrawn committed credit facility of C$450 million expiring in October 2018, and two smaller facilities with total capacity of C$95 million, of which C$26 million is available	• A broad range of capital spending in 2014 that is estimated in the range of C$280 million to C$540 million • CP of C$150 million that matures in 2014 • Cash dividends of approximately C$61 million

Covenants

We expect Toronto Hydro to maintain sizable headroom below its 75% debt-to-capital covenant.

Other Modifiers

The modifying factors had no impact on the rating.

EB-2014-0166Toronto Hydro-Electric System Limit

Toronto Hydro Corporation

Report Date:
May 13, 2014

Rating Considerations

Strengths

(1) **Reasonable regulatory environment.** THC is predominantly a regulated electric distribution company that RSHUDWHV LQ D UHDVRQDEOH UHJXODWRU\ HQYLURQPHQW 7KH degree of stability to earnings and cash flow over the long term.

(2) **Strong franchise area.** THC is one of the largest municipally owned local distribution companies (LDCs) in Canada, serving a customer base of approximately 730,000 customers. Almost all RI 7+&¶V HOHF throughput is distributed to residential and general service customers, ZKR DFFRXQW IRU RI revenue (approximately 18% of the market in the Province of Ontario (rated AA (low)). Demand from these customers is relatively stable year over year, as they are less sensitive to economic cycles. Toronto is now the fourth-largest metropolitan area, by population, in North America.

(3) **Reasonable financial profile.** The Company¶V NH\ FUHGLW PHWULFV UHPDLQ consistent with the rating category. 7KH FRQILUPDWLRQ LQFRUSRUDWHV '%56¶V H[SHFWDWLRQV WKDW debt-to-capital ratio in line with the /'&¶V regulatory 60% debt-to-40% equity structure, and that in the event that debt leverage rises above the regulated capital structure, the Company will take necessary measures to restore its structure to the 60% debt level in a timely manner.

Challenges

(1) **Balance sheet pressure due to high capex.** Significant capital expenditure is needed to replace the &RPSDQ\¶V DJLQJ LQIUDVWUXFWXUH DSSURPLPDWHO\ $403 million planned in 2013), resulting in higher free cash flow deficits. In recent years, THC funded free cash flow deficits with a combination of proceeds from asset sales and debt, maintaining leverage close to the regulatory deemed capital structure (60% debt to 40% equity). However, as WKH &RPSDQ\¶V FDVK EDODQFHV going forward it will need to depend entirely on debt to fund its cash flow deficits. DBRS is concerned that this might DIIHFW WKH &RPSDQ\¶V IILQDQFLDO IOH[LELOLW\ DQG LWV DELOLW capital structure.

(2) **Earnings sensitive to volume.** Earnings and cash flow for electricity distribution companies are partially dependent on the volume of electricity sold, given that rates typically include a variable charge component. Seasonality, economic cyclicality and weather variability have a direct impact on the volume of electricity sold and, therefore, on revenue earned from electricity sales.

(3) **Limited access to equity markets.** 7+&¶V RZQHUVKLS VWUXFWXUH (the City; rated AA)) limits its ability to access the equity markets. As a result, 7+&¶V FDVK deficits are being financed largely through debt.

Earnings and Outlook

(CA$ millions where applicable)	For the year ended December 31 2013	2012	2011	2010	2009

(1) 2011 to 2013 financials based on USGAAP.

2013 Summary

- 7+&¶V HDUQLQJV DUH VXSSRUWHG E\ D UHDVRQDEOH UHJXODWHG diversified customer base.
- Net earnings before recurring items were higher due to lower operating costs resulting from cost reductions and staff restructuring in 2012, as well as lower financial charges.
- Reported net income was higher in 2013 due to: (1) OEB¶V -DQXDU\ disposition of the smart meter deferral account balances, permitting the recovery of return on assets since 2008 and providing for a one-time, non-recurring gain of $21 million in 2013, offset by higher operating expenses due to storm costs of $10.2 million; and (2) lower net income in 2012, resulting from a non-recurring restructuring charge of $27.8 million related to cost-reduction initiatives. DBRS has adjusted net sales and earnings to reflect these non-recurring items.

(1) Including operating leases. (2) 2011 to 2013 financials based on USGAAP.

2013 Summary

- 7+&¶V LQDQFLDO credit metrics remained reasonable for the assigned rating category.
- Capex has been steadily rising due to the replacement of aging electricity infrastructure, resulting in free cash flow deficits. Capital expenditures for the Copeland project were $43.5 million for 2013 (Total of $60.5 million spent on the project). The deficit in 2013 was financed with debt and cash on hand.
- Dividends are paid as per policy adopted by the City, that THC will pay the greater of $25 million per year (in segments throughout the year) or, if applicable, 50% of its consolidated net income for the year.

2014 Outlook

- In December 2013, the OEB approved a settlement agreement which correlates to the approval of capital expenditures amounting to $398.8 million for 2014.
- In February 2014, THC commenced tunneling for the Copeland Station project. The total capital expenditure required for the project is expected to be approximately $195 million.
- DBRS expects the Company to manage its balance sheet prudently, so that it continues to maintain its leverage in line with WKH /'& deemed capital structure. Should leverage rise above the deemed capital VWUXFWXUH RYHU RU LI NH\ FUHGLW PHWULFV ZHDNHQ DQG financial profile could deteriorate to a level that is no longer commensurate with the current A (high) rating.
- ,W UHPDLQV WR EH VHHQ ZKHWKHU 7+&¶V GLYLGHQG SROLF potentially weakening its financial profile.

Long-Term Debt Maturities and Bank Lines

(CA$ millions)	Amount	Drawn/CPs/LOCs	Available	Expiry
Cash & Cash Equivalents	-	-	-	-
Revolving Credit Facility	600.0	150.0	450.0	Oct 10, 2018
Prudential Facility	75.0	50.1	24.9	Demand
Working Capital Facility	20.0	19.1	0.9	Demand
		Total	**475.9**	

As at December 31, 2013

- On September 6, 2013, Toronto Hydro extended its $600 million committed credit facility by an additional year, to now mature in October 2018. As at December 31, 2013, $150 million was drawn under this facility.
- On December 17, 2013, Toronto Hydro launched a Commercial Paper program (DBRS rated R-1 (low)) for $400 million backstopped by its credit facility.
- The Company's liquidity profile remained strong and sufficient to cover all near- to medium-term obligations, with approximately $477 million of available funds.
- THC also has a $75 million Prudential Facility and $20 million Working Capital Facility.

Debentures

(CA$ millions)	Maturity	Outstanding

% of Total	0.0%	0.0%	0.0%	17.2%	82.8%	100.0%

As at December 31, 2013

- Debt maturities are reasonably staggered and THC continues to have good access to debt capital markets. The Company has access to a base shelf prospectus filed on December 10, 2012, for the issuance of up to $1.5 billion (approximately, $1.05 billion available as at December 31, 2013), active for 25 months following this prospectus date.
- On April 9, 2013, THC issued $250 million of 2.91% senior unsecured debentures due April 10, 2023 (Series 8), and $200 million of 3.96% senior unsecured debentures due April 9, 2063 (Series 9). Net proceeds from the issuances were used to repay a $300 million debenture that matured on May 7, 2013, and $200 million of debentures that matured on May 7, 2003 and May 6, 2013, respectively.

Corporate Structure

- THC is a holding company with the following two subsidiaries operating exclusively in the Toronto area:
  - Toronto Hydro Electric System Limited, one of the largest municipal distribution utilities in Canada, is responsible for regulated electricity distribution (99% of revenue).
  - Toronto Hydro Energy Services Inc., which has a contractual relationship with the City, owns and operates street lighting services (1% of revenue).
- Most of the energy produced in Ontario is generated by Ontario Power Generation Inc. (rated A (low)), then WUDQVPLWWHG WR 7+&¶V QHWZRUNV E\ +\GUR 2QH ,QF UDWHG to its customers via overhead and underground lines.
- The Company currently employs approximately 1,540 people, has a peak load of approximately 5,000 megawatts and distributes electricity to approximately 730,000 customers (approximately 18% of the market in the Province of Ontario (rated AA (low)).

Regulation

- THC operates under a reasonable regulatory environment regulated by the OEB (refer to Page 8), whose mandate is to approve and set rates for the distribution and transmission of electricity, as set out by the *Electricity Act, 1998*.
- The LDC operates with a deemed capital structure of 60% debt (divided into 56% long-term and 4% short-term) and 40% equity, and an allowed ROE of 9.58%.
- For rate setting, the Company currently operates under the third-generation IRM framework for the 2012-2014 rate years.
- For 2015 and onward, THC is expected to operate under a CIR, which is a hybrid between cost of service (COS) and IRM (minimum five-year term). 7KH UDWH VHWWLQJ IRU WKH WHUP LV and OEB ¶V R analysis, using productivity benchmarking.
- CIR is suited to distributors with large, broad, multi-year investment needs over a five-year period or more and distributors who require certainty of funding several years in advance.
- CIR requires THC to provide five-year histories and five-year forecasts, with emphasis on how the plan will vary from one application type to another. Benchmarking will likely include a combination of service quality, financial performance, asset management and Conservation and Demand Management (CDM) inflation factors. 3 2ff- U D P SfV +/- 300 basis points will be allowed and additional funding is available to compensate for unforeseen events costing over $1 million.
- In January 2014, the OEB approved the disposition of balances in its smart meter deferral account related to installations in 2008, 2009 and 2010. The two new rate riders approved are effective May 1, 2014.
- In 2015, the LDC will be allowed to seek recovery for capital spent in 2012 and 2013 that has not yet been approved by the OEB in the current ICM decision, due to the standard operation of the regulatory model.

Assessment of Regulatory Environment

Criteria	Score	Analysis
(1) Deemed Equity	Excellent Good Satisfactory Below Average Poor	The OEB allows LDC to have a deemed equity of 40%, which has been consistent historically.
(2) Allowed ROE	Excellent Good Satisfactory Below Average Poor	7KH 2(%¶V DOORZHG UHWXUQ RC LDC has been 9.58% in the past few years.
(3) Energy Cost Recovery	Excellent Good Satisfactory Below Average Poor	No power price risk, as the Company is allowed to pass through the entire cost of purchased power used by its customers.
(4) Capital Cost Recovery	Excellent Good Satisfactory Below Average Poor	Major capital costs are pre-approved by the OEB and added to rate base after project completion.
(5) COS vs. IRM	Excellent Good Satisfactory Below Average Poor	LDC is regulated under an incentive rate mechanism (IRM), with three years in between the COS rebasing year.

Criteria	Score	Analysis
(6) Political Interference	Excellent Good Satisfactory Below Average Poor	After years of a relatively stable political and regulatory environment, the utility sector in Ontario could face growing challenges. As generation costs potentially rise above and ultimately test the political ceiling (10% increase of the total bill annually), it may be difficult for the utilities to pass costs onto the ratepayers.
(7) Retail Rate	Excellent Good Satisfactory Below Average Poor	Retail rates in Ontario are at the mid-range of rates in other Canadian provinces. 7RURQWR +\GUR range between 11.2 cents/kWh to 13.5 cent/kWh on peak rates from May 2014. The economic environment in Ontario is stable (real GDP grew by 2.3% in 2013).
(8) Stranded Cost Recovery	Excellent Good Satisfactory Below Average Poor	Toronto Hydro has a limited history of stranded costs. Most prudently incurred or budgeted capital expenditures are approved by the OEB. DBRS notes that there can be some regulatory lag in the approval of capital expenditures under the renewed regulatory framework.
(9) Rate Freeze	Excellent Good Satisfactory Below Average Poor	)URP WR GXH WR ULVLQ experimental utility deregulation phase, a distribution rate freeze was imposed province-wide. There have been no subsequent province-wide rate freezes.
(10) Market Structure (Deregulation)	Excellent Good Satisfactory Below Average Poor	Electricity distribution in Ontario is largely regulated and the structure provides for stability and low risk associated with purchased energy costs and counterparty risk.

RATE BASE OVERVIEW

In accordance with s. 2.5.1.1 of the OEB's Filing Requirements for Electricity Distribution Rate Applications (July 17, 2013) (the "Filing Requirements"), this schedule provides an overview of Toronto Hydro's rate base and year-over year variance analysis of rate base and distribution assets for the following years: 2011 OEB-approved, 2011 to 2013 historical actuals, 2014 bridge year forecast, and 2015 test year forecasts. Continuity statements for Toronto Hydro's fixed assets, including interest during construction and all overheads, are filed at Exhibit 2A, Tab 1, Schedule 2.

1. RATE BASE

Table 1 below summarizes Toronto Hydro's rate base values for the historical (2011 to 2013), bridge (2014), and test year (2015), including opening and closing balances, the average of opening and closing balances for gross assets and accumulated depreciation, and the utility's working capital allowance.

Table 1: Rate Base Overview ($ Millions)

	2011 OEB Approved	2011 Historical CGAAP	2012 Historical UGAAP	2013 Historical UGAAP	2014 Bridge UGAAP	2015 Test MIFRS
Opening PP&E NBV	1,897.8	1,895.8	2,183.5	2,251.9	2,356.0	2,436.6
ICM	-	-	-	-	-	372.6
Street Lighting	-	-	-	-	-	39.8
Opening PP&E NBV Adjusted	1,897.8	1,895.8	2,183.5	2,251.9	2,356.0	2,849.0
Closing PP&E NBV	2,105.1	2,183.5	2,251.9	2,356.0	2,456.3[1]	3,161.0
Average PP&E NBV	2,001.5	2,039.7	2,217.7	2,304.0	2,406.1	3,005.0
Working Capital Allowance	296.7	318.1	316.6	354.4	369.5	241.5
Rate Base	2,298.2	2,357.7	2,534.3	2,658.4	2,775.6	3,246.5

/C

[1] The 2014 financial results have not been closed out and audited. However, Toronto Hydro's assessment is that the 2014 closing PP&E NBV is within approximately 1% of the forecast.

For the purpose of the test year revenue requirement (Exhibit 6, Tab 1, Schedule 1),[1] rate base includes the average of the opening and closing balances for the net book value of property, plant and equipment plus a working capital allowance. The net book value of property, plant and equipment ("PP&E") includes only assets that are associated with activities that enable the distribution of electricity ("distribution assets") and excludes non distribution assets. Working capital allowance is based on the cost of power and controllable expenses such as operations and maintenance, billing, collections and administration expenses. /C

1.1. Fixed Asset Continuity Statements

The continuity statements are filed at Exhibit 2A, Tab 1, Schedule 2. Toronto Hydro confirms that:

- the continuity statements provide year-end balance and include interest during construction, and all overheads;
- the opening and closing balances of gross assets and accumulated depreciation that are used to calculate the fixed asset component of rate base correspond to the respective balances in the fixed asset continuity statements; and
- continuity statements reconcile to calculated depreciation expenses (Exhibit 4B, Tab 1, Schedule 1) and are presented by asset account.

1.2. Working Capital Allowance ("WCA")

As can be seen in Table 1, WCA rises from $296.7 million in 2011 to $369.5 million in 2014, and then drops to $241.7 million in 2015. The main driver of the WCA increase from 2011 to 2014 is the cost of power expense. In 2015, Toronto Hydro forecasts a lower WCA due to a reduction in the allowance percentages based on the utility's latest /C /C

[1] Due to a last minute revision that could not be reflected in the Revenue Requirement Work Form (RRWF) (Exhibit 6, Tab 1, Schedule 2), the rate base value shown in the RRWF is $ 1.1M higher than the Rate Base Overview table above and the Fixed Asset Continuity statements (Exhibit 2A, Tab 1, Schedule 2). The impact on the Revenue Requirement is less than $0.1 million. /C

lead lag study conducted by Navigant Consulting Inc. Further details on WCA are provided at Exhibit2A, Tab 3 and Schedules 1 and 2.

2. RATE BASE VARIANCE ANALYSIS

2.1. 2011 OEB Approved vs. 2015 Test Year

Toronto Hydro's requested rate base for the 2015 test year is $3,246.7 million, which represents an increase of $948.5 million or 41.3 percent from the rate base amount of $2,298.2 million approved by the OEB in the utility's last rebasing application (EB-2010-0142). The average net book value ("NBV") of PP&E increased by $1,003.5 million and the WCA component of rate base decreased by approximately $55.0 million from that approved by the OEB. **/C** **/C** **/C**

2.2. 2011 OEB Approved vs. 2011 Actual

Toronto Hydro's 2011 actual rate base was $38.2 million less than the 2011 OEB-approved amount. Average NBV of PP&E in 2011 was $38.2 million higher than the OEB-approved level, primarily due to higher in-service additions than originally assumed and additional 2011 capital expenditure. Toronto Hydro's actual 2011 WCA was $21.4 million higher than OEB-approved because the cost of power expenses were $170.2 million higher than the original forecast, with most of the increase being attributable to commodity price increases.

2.3. 2011 Actual vs. 2012 Actual

Toronto Hydro's rate base increased by $176.6 million from 2011 to 2012. The net increase in average PP&E was $178.1 million. Continued investment in distribution assets contributed to this increase. WCA decreased by $1.5 million in 2012 primarily due to reduction in OM&A in 2012 compared to 2011.

2.4. 2013 Actual vs. 2012 Actual

In 2013, rate base increased by $124.1 million over 2012 levels. In 2013, the average PP&E NBV increased by $86.2 million. Continued investment in distribution assets contributed to this increase. In addition, in 2013, Toronto Hydro applied for and received approval for final disposition of its smart metering costs and investments. As a result of this decision, a total of $46.8 million in smart meter assets were transferred to rate base. The net book value of stranded meters related to the deployment of smart meters was also reclassified to regulatory assets resulting in a decrease in net assets of $17.3 million. WCA increased by $37.8 million due to cost of power expenses, which were $292.3 million higher in 2013 than the 2012, with most of the increase being attributable to commodity price increases.

2.5. 2013 Actual vs. 2014 Bridge Year

In 2014, rate base is forecasted to increase by $117.2 million. Average NBV of PP&E is expected to increase by $102.1 million due to increased investment in the distribution system. The level of increases in average NBV of PP&E is offset by the 2013 removal of the NBV of stranded meters related to Toronto Hydro's smart metering program. In this application, Toronto Hydro is proposing disposition of its stranded meter assets (Exhibit 2B, Tab 4, Schedule 1) and therefore has removed the amounts from the ending 2013 (opening 2014) NBV of PP&E. WCA increases by $15.1 million, primarily due to rising commodity costs. /C /C

2.6. 2014 Bridge Year vs. 2015 Test Year

In 2015 rate base is forecasted to increase by $471.1 million. Average NBV of PP&E increases by $598.9 million, while WCA decreases by $127.8 million. The increase in PP&E includes $372.6 million towards board approved ICM of 2013-2014 and $39.8 /C /C /C

million towards street lighting assets. Toronto Hydro has included ICM and street lighting in the opening balance of PP&E to capture the full year return.

3. DISTRIBUTION ASSETS

Table 2A below presents a summary of Toronto Hydro's distribution assets net of accumulated depreciation (excluding construction work-in-progress), based on the OEB's minimum reporting groups for the historical (2011 to 2013), bridge (2014), and test (2015) years.

Table 2A: Net Assets (2011-2015) – Years Ending December 31 ($ millions)

	2011 Historical CGAAP	2012 Historical UGAAP	2013 Historical UGAAP	2014 Bridge UGAAP	2014 Bridge MIFRS	2015 Test MIFRS
Land and Buildings	61.3	63.1	67.3	69.1	68.7	110.0
TS Primary Above 50	10.5	11.0	11.0	11.1	11.1	12.3

/C

The major drivers of the changes from 2011 to 2015 include:

- Continued investment in distribution assets;
- Inclusion of OEB-approved smart meter expenditures in net assets;
- Reclassification of stranded meters from net assets to regulatory assets;
- Inclusion of 2013 and 2014 ICM eligible in-service capital expenditures;

- Adjustments to decrease net assets related to the transition from UGAAP to MIFRS; and
- Completion of the Phase 1 Copeland TS project.

As directed by the OEB in its Partial Decision and Order in EB-2012-0064, Toronto Hydro transferred Incremental Capital Module ("ICM") in-service capital additions in the year 2013 and 2014 to a regulatory asset account. For the purpose of 2015 opening rate base, Toronto Hydro has included forecasted ICM in-service assets as at the end of 2014. To illustrate, Tab 2B below provides a separate view of net assets which includes ICM in-service additions in 2013 and 2014. For more information about Toronto Hydro's ICM True-Up process proposal, please refer to Exhibit 2A, Tab 9, Schedule 1.

Table 2B: Net Assets (2011-2015) – Years Ending December 31 ($ millions) Including Eligible ICM In-Service Capital Expenditures

	2011 Historical CGAAP	2012 Historical UGAAP	2013 Historical UGAAP	2014 Bridge UGAAP	2014 Bridge MIFRS	2015 Test MIFRS

/C

3.1. 2011 OEB-Approved vs. 2011 Actual

Toronto Hydro reached a settlement with intervenors in its last rebasing application in 2011 (EB-2010-0142), which resulted in the OEB approving the utility's capital expenditures for 2011 on an envelope basis.[2] Toronto Hydro therefore provides its variance analysis between 2011 OEB-approved and actual net fixed assets at a total level. 2011 OEB-approved net assets were $2,001.5 million compared to $2,183.5 million historical actual net assets. As explained in more detail below, the variance of $182.0 million of actuals over the OEB-approved amounts is attributable to higher in-service additions than originally assumed and additional capital expenditures in 2011:

- In-Service Additions: Consistent with previous years, the in-service amounts forecasted in the 2011 rebasing application were determined based on assumptions using historical averages. Actual in-service amounts were greater than assumed resulting in a higher value of actual ending 2011 net assets than the OEB-approved amount.
- Additional Capital Expenditures: 2011 capital expenditures exceeded the OEB-approved amount by $66.7 million. The related 2011 in-service amounts included unanticipated amounts related to a capital lease with Canadian Power Survey Corporation for the use of stray voltage scanning equipment, the purchase of land at 715 Milner and civil construction projects. These amounts contributed to higher actual net assets in 2011 compared to amounts approved by the OEB in Toronto Hydro's last rebasing application (EB-2010-0142).

3.2. 2011 Actual vs. 2012 Actual

As table 3 below illustrates, 2012 net assets were $2,251.9 million compared to 2011 net assets of $2,183.5 million, representing an increase of $68.4 million. Capital additions were $209.4 million and depreciation expense was $140.1 million in 2012. For more

[2] EB-2010-0142, Partial Decision and Order (July 7, 2011) at pages 2 and 3.

information, refer to the fixed asset continuity statement for 2012 UGAAP (Exhibit 2A, Tab 2, Schedule 1, Appendix A). Continued investment in distribution assets contributed to this increase. The primary driver contributing to the increase is poles and wires assets.

Table 3: 2011 Historical (CGAAP) versus 2012 Historical (UGAAP) ($ millions)

	2011 Historical CGAAP	2012 Historical UGAAP	Variance ($)	Variance (%)
Land and Buildings	61.3	63.1	1.8	2.9
TS Primary Above 50	10.5	11.0	0.5	4.6
Distribution System	222.6	226.5	4.0	1.8
Poles and Wires	2,893.6	3,037.9	144.3	5.0
Line Transformers	731.7	757.4	25.7	3.5
Services and Meters	303.7	317.2	13.5	4.4
General Plant	130.1	134.4	4.3	3.3
Equipment	180.1	178.5	(1.6)	(0.9)
IT Assets	44.6	50.5	5.9	13.2
Other Distribution Assets	323.9	348.9	25.0	7.7
Contributions and Grants	(294.5)	(316.6)	(22.1)	7.5
Gross Assets	**4,607.8**	**4,809.0**	**201.2**	**4.4**
Accumulated Depreciation	(2,424.2)	(2,557.1)	(132.8)	5.5
Net Assets	**2,183.5**	**2,251.9**	**68.4**	**3.1**

Note: Variances due to rounding may exist

3.3. 2012 Actual vs. 2013 Actual

As Table 4 below illustrates, 2013 net assets were $2,356.0 million compared to historical 2012 net assets of $2,251.9 million, representing an increase of $104.1 million or 4.6 percent. Capital additions were $381.3 million and depreciation expense was $143.1 million in 2013. For more information, refer to the fixed asset continuity statement for 2013 UGAAP (Exhibit 2A, Tab 2, Schedule 1, Appendix A). Continued investment in distribution assets contributed to this increase. The primary driver contributing to the increase is poles and wires assets. The net book value of stranded meters related to the deployment of smart meters was also reclassified to regulatory assets resulting in a decrease in net assets of $17.8 million. These reductions to net assets

were offset by an increase in net assets of $46.8 million related to the OEB ruling on smart meters permitting the recovery of the utility's allowed cost of capital on smart meters since 2008.

Table 4: 2012 Historical (UGAAP) versus 2013 Historical (UGAAP) ($ millions)

	2012 Historical UGAAP	2013 Historical UGAAP	Variance ($)	Variance (%)
Land and Buildings	63.1	67.3	4.1	6.6
TS Primary Above 50	11.0	11.0	(0.0)	(0.0)
Distribution System	226.5	229.3	2.8	1.2
Poles and Wires	3,037.9	3,179.0	141.0	4.6
Line Transformers	757.4	791.9	34.5	4.6
Services and Meters	317.2	278.1	(39.2)	(12.3)
General Plant	134.4	141.6	7.2	5.4
Equipment	178.5	181.8	3.3	1.9
IT Assets	50.5	56.3	5.8	11.5
Other Distribution Assets	348.9	380.2	31.2	9.0
Contributions and Grants	(316.6)	(338.8)	(22.2)	7.0
Gross Assets	**4,809.0**	**4,977.7**	**168.7**	**3.5**
Accumulated Depreciation	(2,557.1)	(2,621.7)	(64.6)	2.5
Net Assets	**2,251.9**	**2,356.0**	**104.1**	**4.6**

Note: Variances due to rounding may exist

Table 4 above reflects a reduction in net assets by $163.1 million related to ICM in-service capital expenditures, which were transferred to a regulatory asset account, as directed by the OEB in EB-2012-0064.[4]

3.4. 2013 Actual vs. 2014 Bridge

As Table 5 below illustrates, Toronto Hydro forecasts 2014 net assets at $2,456.3 million compared to historical 2013 net assets of $2,356.0 million, representing an increase of $100.3 million or 4.3 percent. Capital additions are forecasted at $470.6 million and accumulated depreciation additions are forecasted at $158.2 million in 2014. For more information,

/C

/C

Accumulated Depreciation	(2,621.7)	(2,771.3)	(149.6)	5.7
Net Assets	**2,356.0**	**2,456.3**	**100.2**	**4.3**

Note: Variances due to rounding may exist

/C

Table 5 above, reflects a reduction in net assets by $214.6 million related to forecasted ICM eligible in-service capital expenditures, which were transferred to a regulatory asset account as directed by the OEB. /C

3.5. 2014 Bridge vs. 2015 Test Year

Toronto Hydro forecasts 2015 net assets under MFIRS at $3,161.0 million compared to forecasted 2014 net assets of $2,456.3 million under UGAAP, representing an increase of $704.7 million or 28.7 percent. The 2015 opening balance net assets are adjusted for the following items, representing $393.3 million of the total net asset increase: /C

- \$372.6 million increase related to the addition of 2013 and 2014 ICM eligible in-service capital expenditures presented in the regulatory asset account for the duration of the IRM period. /C
- \$39.8 million increase for the transfer of former street lighting assets, which as proposed in Exhibit 2A, Tab 5, Schedule 1, will have a neutral effect on the utility's test year revenue requirement;
- \$19.1 million decrease related to the transition from UGAAP to MIFRS.

Table 5A: 2014 Bridge (UGAAP) versus 2015 Test (MIFRS) (\$ millions)

	2014 Bridge UGAAP	2015 Test MIFRS	Variance (\$)	Variance (%)
Land and Buildings	69.1	110.0	40.9	59.1
TS Primary Above 50	11.1	12.3	1.2	10.4
Distribution System	245.5	291.4	45.9	18.7
Poles and Wires	3,300.4	3,824.2	523.8	15.9
Line Transformers	810.3	835.5	25.3	3.1
Services and Meters	298.7	349.0	50.2	16.8
General Plant	167.2	153.3	(13.9)	(8.3)
Equipment	189.7	197.1	7.4	3.9
IT Assets	87.4	98.9	11.4	13.1
Other Distribution Assets	402.4	477.3	75.0	18.6
Contributions and Grants	(354.3)	(372.5)	(18.2)	5.1
Gross Assets	**5,227.6**	**5,976.5**	**749.0**	**14.3**
Accumulated Depreciation	(2,771.3)	(2,815.6)	(44.3)	1.6
Net Assets	**2,456.3**	**3,161.0**	**704.7**	**28.7**

Note: Variances due to rounding may exist

/C

Capital additions are forecasted at \$539.7 million. The increase in net assets is driven by the capital investments outlined in the Distribution System Plan (Exhibit 2B, Section E). /C

Land and Buildings are expected to increase \$40.9 million or 59.1 percent and TS Primary Above 50 assets are expected to increase \$1.2 million or 10.4 percent. The /C /C

increase in both of these major plant accounts is primarily due to the Phase 1 Copeland TS project which includes the station facility construction and installation of high voltage transmission connections. The Copeland TS project was approved by the OEB under the Toronto Hydro's 2012-2014 ICM application.[5] Refer to the Station Expansion Program (Exhibit 2B, E7.9) for additional details relating to this project.

Distribution System assets are expected to increase $45.9 million or 18.7 percent. The increase in distribution system assets is primarily due to the forecasted in-service stations switchgear projects. Municipal Station Switchgear and Transformer Switchgear work was filed and approved as part of Toronto Hydro's 2012-2014 ICM application and will continue as a program in 2015 to replace existing obsolete switchgear with a modern arc-resistant design. Refer to the Switchgear Renewal Program (Exhibit 2B, E6.13) for more information about this project. **/C**

Capital investment in poles and wires is expected to increase by $523.8 million or 15.9 percent and investment in line transformer assets are expected to increase by $25.3 million or 3.1 percent. The increase in these major plant categories is primarily attributed to the Underground Circuit Renewal (Exhibit 2B, E6.1), Overhead Circuit Renewal (Exhibit 2B, E6.4), Reactive Capital (Exhibit 2B, E6.20) and Customer Connections (Exhibit 2B, E5.2) programs. **/C**

- The Underground and Overhead Circuit Renewal programs are required to replace end of life and obsolete assets to mitigate failure and safety risks.
- The Reactive Capital program is required to restore power to customers and maintain system performance and reliability when assets fail.

[5] EB-2012-0064, Partial Decision and Order (April 2, 2013) at page 53.

- The Customer Connection program allows Toronto Hydro to satisfy its obligation to connect new customers in its service area.

Net additions to poles and wires and line transformers includes the 2013 and 2014 ICM eligible in-service capital expenditures presented in the regulatory asset account for the duration of the IRM period. Former street lighting assets are also included as part of the net addition increase to poles and wires.

Services and meter assets are expected to increase $50.2 million or 16.8 percent. The increase in services and meter assets is primarily related to the Metering program (Exhibit 2B, E6.1), the objective of which is to ensure compliance with Measurement Canada, OEB and IESO rules and regulations. **/C**

Equipment assets are expected to increase $7.4 million or 3.9 percent. The increase in equipment is primarily due to fleet. Refer to the Fleet and Equipment Services program (Exhibit 2B, E8.1) for additional details. **/C** **/C**

IT assets are expected to increase $11.4 million or 13.1 percent primarily due to computer hardware equipment investment which enables Toronto Hydro to efficiently and effectively plan and execute capital and operational programs and fulfill its obligations to customers and regulatory bodies. Refer to the IT Hardware program (Exhibit 2B, E8.4) for more information.

Other distribution assets are expected to increase $75.0 million or 18.6 percent primarily due to the in-service amount for computer software additions. For additional details related to the computer software investments refer to the IT Software program (Exhibit 2B, E8.5). **/C**

Contributions and grants are expected to increase $18.2 million or 5.1 percent related to realized contributions related to in-service assets.

The forecasted accumulated depreciation additions is $208.1 million in 2015, and includes $33.9 million of losses on derecognition of assets. For more information about Toronto Hydro's depreciation expense and derecognition losses, refer to Exhibit 4B, Tab 1, Schedules 1 and 2, respectively. /C

Net assets were reduced by $4.6 million related to eligible investment for the purpose of enabling the connection of a renewable energy generation facility to its distribution system. In accordance with s. 79.1 of the *Ontario Energy Board Act, 1998* and s. 2.5.2.5 of the OEB's Filing Requirements (July 17, 2013), Toronto Hydro proposes to recover the cost incurred for these investments from all provincial ratepayers. Refer to Exhibit 2A, Tab 8, Schedule 1 for more information about Toronto Hydro's proposed treatment of renewable enabling eligible investments.

GROSS ASSETS

1. BREAKDOWN BY FUNCTION

In accordance with section 2.5.1.2 of the OEB's Filing Requirements for Electricity Distribution Rate Applications (July 17, 2013) (the "Filing Requirements"), Table 1 below provides a breakdown of gross assets by function from 2011 historical actuals through to 2015 test year forecast. The amount for construction work-in-progress ("CWIP") has also been provided. The amounts for CWIP have not been included in gross assets for rate base.

In accordance with the Uniform System of Accounts ("USoA"), Toronto Hydro has included asset accounts 1805 to 1860 in the category of distribution plant, accounts 1905 to 1980, accounts 1609 to 1612 and account 2005 in the category of general plant, and account 1995 in the category of capital contributions.

Table 1: Breakdown of Gross Assets by Function

Gross Assets	2011 Historical CGAAP	2012 Historical UGAAP	2013 Historical UGAAP	2014 Bridge UGAAP	2014 Bridge MIFRS	2015 Test MIFRS
Distribution Plant	4,214.3	4,404.1	4,547.4	4,726.0	4,646.6	5,413.8
General Plant	687.9	721.5	769.2	855.8	858.2	935.2
Capital Contributions	(294.5)	(316.6)	(338.9)	(354.3)	(354.3)	(372.5)
Total Before CWIP	**4,607.8**	**4,809.0**	**4,977.7**	**5,227.6**	**5,150.5**	**5,976.5**
CWIP	257.8	336.9	401.3	515.5	516.1	507.4
Total Including CWIP	**4,865.6**	**5,145.9**	**5,379.0**	**5,743.1**	**5,666.6**	**6,483.9**

Note: Variances due to rounding may exist

/C

2. BREAKDOWN BY MAJOR PLANT ACCOUNT

In accordance with section 2.5.1.2 of the OEB's Filing Requirements (July 17, 2013), Table 2 below provides a breakdown of gross assets by major plant account from 2011 to 2015.

Table 2: Gross Assets Breakdown by Major Plant Account Summary

	2011 Historical CGAAP	2012 Historical UGAAP	2013 Historical UGAAP	2014 Bridge UGAAP	2014 Bridge MIFRS	2015 Test MIFRS

Note: Variances due to rounding may exist

/C

In accordance with the Uniform System of Accounts ("USoA"), Toronto Hydro's major plant categories are comprised of the following USoA accounts:

- **Land and Building**: 1805 Land; 1808 Buildings and Fixtures; 1810 Leasehold Improvements; 1905 Land
- **TS Primary Above 50**: 1815 Transformer Station Equipment
- **Distribution System**: 1820 Distribution Station Equipment
- **Poles and Wires**: 1830 Poles, Towers and Fixtures; 1835 O/H Conductors and Devices; 1840 U/G Conduit; 1845 U/G Conductors and Devices
- **Line Transformers**: 1850 Line Transformers
- **Services and Meters**: 1855 Services; 1860 Meters (including Smart Meters)
- **General Plant**: 1908 Buildings and Fixtures; 1910 Leasehold Improvements
- **Equipment**: 1915 Office Furniture and Equipment; 1930 Transportation Equipment; 1935 Stores Equipment; 1940 Tools, Shop and Garage Equipment; 1945 Measures & Test Equipment; 1955 Communication Equipment; 1960 Miscellaneous Equipment
- **IT Assets**: 1610 Miscellaneous Intangible Plant; 1920 Computer Equipment

- Other Distribution Assets: 1609 Capital Contributions Paid; 1611 Computer Software; 1612 Land Rights; 1970 Load Management-Customer; 1975 Load Management-Utility; 1980 System Supervisory Equipment; 2005 Property Under Capital Leases
- Contributions and Grants: 1995 Contributed Capital

Appendix A to this schedule provides a breakdown of gross assets by major plant account and USofA Account from 2011 to 2015.

Appendix A. Table 2 - Gross Assets Breakdown by Major Plant Account - Detailed by Uniform System of Account

WORKING CAPITAL ALLOWANCE (WCA)

Toronto Hydro determined the Working Capital Allowance ("WCA") included in its 2015 ratebase based on an updated Lead-Lag Study performed by Navigant Consulting Inc. ("Navigant"), which is filed as Exhibit 2A, Tab 3, Schedule 2. Navigant used Toronto Hydro's 2012 financial information to determine the revenue lead and expense lag for various detailed revenue and cost components. The methodology employed by Navigant in the current study is generally the same as that employed in the last Lead-Lag study which was filed in EB-2007-0680. Toronto Hydro confirms that for the purposes of the Lead-Lag Study, leads and lags were measured in days, and were dollar weighted.

The result of the Lead-Lag Study is a significant decrease in the WCA rate approved in the utility's last rebasing application (EB-2010-0142) from 12.88% of controllable expenses plus cost of power to 7.99% for the 2015 test year. The reduction was achieved primarily as a result of two changes: /C

1) a significant decrease in the revenue lag due to improved billing and collection activities, and
2) a change in the weightings applied to revenue lag days from customers to class revenues.

Table 1 below presents a detailed calculation of the WCA for 2015. To calculate the WCA, the Cost of Power was determined by using: the split between RPP and non-RPP customers, 2015 forecast RPP, HOEP, and UTR.

Table 1: Working Capital Allowance Calculation

	2015 Expenses ($ millions)	Working Capital Factor		Expenses * Working Capital Factor ($ millions)	
Cost of Power	2,751.9	6.1%		167.0	
OM&A	269.5	5.8%		15.6	
Interest on Long Term Debt	82.0	2.4%		2.0	
Income and Capital Taxes	24.0	28.4%		6.8	/C
DRC	171.2	5.9%		10.2	
SubrTotal Working Capital Requirement				201.7	/C
HST at 13%		Net Lag Days	Expenses * Net Lag Days/365 * 13% HST		
Revenue	3,403.1	r5.5	r6.6		
Cost of Power	2,751.9	45.9	45.0		
OM&A Expenses	103.2	41.5	1.5		
HST Working Capital Requirement				39.9	
Total Working Capital				241.5	/C
Working Capital as % of Cost of Power and Controllable Expenses				7.99%	

Table 2 below provides a comparison of the Working Capital Requirements for the 2015 test year which have been included in the utility's rate base calculations (Exhibit 2A, Tab 1, Schedule 1), and the last OEB-approved WCA in 2011. This table shows that since 2011, Toronto Hydro has achieved a reduction of just under $60M in its WCA.

Table 2: Working Capital Allowance ($millions)

	2011 OEB Approved	2015 Test Year	
Working Capital Allowance	296.7	241.5	/C

Working Capital Requirements of Toronto Hydro Electric System Limited's Distribution Business

Section 1: Executive Summary

Summary

This report provides the results of the working capital requirements of THESL's distribution business.

Performing a lead/lag study requires two key undertakings:

1. Developing an understanding of how the regulated distribution business operates in terms of products and services sold to customers/purchased from vendors, and the policies and procedures that govern such transactions; and,
2. Modeling such operations using data from a relevant period of time and a representative data set. It is important to ascertain and factor into the study whether (or not) there are known changes to existing business policies and procedures going forward. Where such changes are known and material, they should be factored into the study.

Results from the lead/lag study using 2012 data identify the following working capital amount in Table 1-1, below.

Table 1-1: Summary of Working Capital Requirements

Year	2012
Percentage of OMA	7.91%
Working Capital Requirement	$218,720,393

The results of the study indicate a lower working capital requirement compared to THESL's EB-2007-0680 distribution lead/lag study. A considerable amount of time has lapsed between the two studies. The primary reason for the difference is the decrease in retail revenue lag days due to the upgrade of THESL's Customer Information System since the prior study. The retail revenue lag days have decreased by approximately 20 percent. Table 2-1, below summarizes the detailed working capital requirements for 2012 calculated in the study.

Table 2-1: THESL Distribution Working Capital Requirements (2012)

Description	Revenue Lag Days	Expense Lead Days	Net Lag Days	Working Capital Factor	Expenses	Working Capital Requirements
Cost of Power	55.04	32.84	22.20	6.07%	$2,450,597,565	$148,654,316
OM&A Expenses	55.04	33.86	21.19	5.79%	$312,961,220	$18,115,434
PILS	55.04	(48.95)	103.99	28.41%	$7,831,100	$2,225,034
Interest Expense	55.04	46.17	8.87	2.42%	$176,173,950	$4,264,550
DRC	55.04	33.31	21.74	5.94%	$162,416,324	$9,645,577
Total					$3,009,980,059	$180,485,912
HST						$38,234,481
Total Including HST						$218,720,393
Working Capital as a Percent of OM&A (incl. Cost of Power)						7.91%

Organization of the Report

Section II of the report discusses the lag times associated with THESL's collections of revenues. The section includes a description of the sources of revenues and how an overall revenue lag is derived.

Section III presents the lead times associated with THESL's expenses. The section includes a description of the types of expenses incurred by THESL's distribution operations and how expenses are treated for the purposes of deriving an overall provincial expense lead.

Section IV presents a summary of the results from the study.

Section 4: Revenue Lags

A distribution utility providing service to its customers generally derives its revenue from bills paid for service by its customers. A revenue lag represents the number of days from the date service is rendered by THESL until the date payments are received from customers and funds are available to THESL.

Interviews with THESL personnel indicate that its distribution business receives funds from the following funding streams:

1. Retail Customers;
2. Other Sources (revenues from electricity retailers and revenues for miscellaneous services such as jobbing and contracting work performed by THESL); and,
3. The Ontario Clean Energy Benefit (OCEB).

The lag times associated with the funding streams above were weighted and combined to calculate an overall revenue lag time as shown below. Detailed data tables are provided in Appendix B.

Table 3: Summary of Revenue Lag

Description	Lag Days	Revenues	Weighting	Weighted Lag
Retail Revenue	54.78	$ 3,265,502,197	94.18%	51.59
Other Revenue	33.93	$ 25,540,425	0.74%	0.25
Ontario Clean Energy Benefit	62.98	$ 176,156,432	5.08%	3.20
Total		$ 3,467,199,054	100.00%	55.04

Retail Revenue Lag

Retail Revenue lag consists of the following components:

1. Service Lag;
2. Billing Lag;
3. Collections Lag; and,
4. Payment Processing Lag.

The lag times for each of the above components, when added together, results in the Retail Revenue Lag for the purpose of calculating the working capital requirements for THESL's distribution business. The components are intended to represent a continuous process from the end date of the customer's previous billing cycle to the date in which the payment is available to THESL. Figure 1 illustrates the start and end point for each component of THESL's retail revenue lag.

Figure 1: Retail Revenue Lag

Table 3, below summarizes the total Retail Revenue Lag.

Table 4: Summary of Retail Revenue Lag

Description	Lag Days
Service Lag	18.72
Billing Lag	12.52
Collections Lag	22.21
Payment Processing Lag	1.32
Total	54.78

The estimation of each component of the Retail Revenue Lag is described below.

Service Lag

The Service Lag is the time from THESL's provision of electricity to a customer, to the time the customer's service period ends, which is typically defined as when the meter is read. Customer Service staff at THESL provided data which documented that approximately 78% of revenues are billed monthly and 22% of revenues are billed bi-monthly. Using the information provided, the Service Lag was estimated to be 18.72 days.

Billing Lag

The Billing Lag is the time period from when the customer's service period ends, which is typically defined as when the meter is read, and the time that the customer's bill is generated in the customer information system (CIS). Interviews with billing staff at THESL and analysis of meter billing data indicated that THESL customers have an average billing lag of 12.52 days, which is significantly shorter than billing lag in the prior study due to the implementation of a new CIS.

Collections Lag

The Collections Lag is the time period from when the bill is generated in the CIS, until the time when the customer provides a payment to THESL. The Collections Lag is measured by analyzing the receivables aging data provided by THESL. THESL's Collection lag was calculated to be 22.21 days was determined for THESL's distribution operations.

Payment Processing Lag

The Payment Processing lag is the time period from when the customer provides a payment to THESL until such time as the funds associated with that payment are available to the company. The Payment Processing Lag is measured by analyzing the payment methods used by THESL customers. Some examples of the payment methods used include credit card, pre-authorized payment and branch payment. THESL provided the processing time associated with each method of payment and the number of customers using each method of payment. Using such data provided by THESL for the calendar year 2012, a customer-weighted average payment processing lag of 1.32 days was determined for THESL's distribution operations.

Section III: Expense Leads

Expense Leads are defined as the time period between when a service is provided to THESL and when payment is required for that service. Typically services are provided in advance of payment which reduces the capital requirement of the company. Therefore, in conjunction with the calculation of the revenue lag, expense lead times were calculated for the following items:

1. Cost of Power;
2. OM&A Expenses;
3. Interest on Long Term Debt;
4. Payments in Lieu of Taxes; and,
5. Harmonized Sales Tax.

Cost of Power

For the purpose of the distribution lead lag study, cost of power expenses were considered to consist of payments made by THESL to its vendors in the following categories:

1. Independent Electricity System Operator (IESO) Cost of Power Expenses;
2. Hydro One Low Voltage Charges;
3. Payments to Non Utility Generators; and,
4. Payments to Renewable Energy Standard Offer Program (RESOP), Micro Feed in Tariff (MFIT), and Feed in Tariff (FIT) customers.

Expense lead times were calculated individually for each of the items listed above and then dollar weighted to derive a composite expense lead time of 32.84 days for cost of power expenses.

Table 5: Summary of Cost of Power Expenses

Description	Amounts	Weighting	Expense Lead Time	Weighted Lead Time
IESO Cost of Power	$ 2,442,084,555	99.65%	32.80	32.68
Hydro One Low Voltage Charges	$ 352,519,111	0.01%	32.22	0.00
Payments to Non Utility Generators	$ 2,933,301,111	0.01%	32.26	0.00
Payments to RESOP, MFIT, and FIT customers	$ 7,186,760,111	0.32%	46.29	0.15
Total	$ 2,450,597,565	100.00%		32.84

IESO Cost of Power Expenses

THESL purchases its power supply requirements on a monthly basis from the IESO and pays for such supplies on a schedule defined by the IESO's billing and settlement procedures. Taking the information on actual payments made by THESL in 2012, a dollar weighted Cost of Power expense lead time of 32.801 days was calculated. Table 6 below summarizes the components of the Cost of Power expense lead calculation.

Table 6: Summary of IESO Cost of Power Expenses

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time
Jan-12	$ 201,741,673	8.26%	2/21/2012	15.50	21.00	31.50	2.60

Dec-12	$ 197,187,913	8.07%	1/21/2013	15.50	21.00	32.50	2.62
Total	$ 2,442,084,555	100.00%				32.801	

Hydro One Low Voltage Charges

THESL provides payment to Hydro One for low voltage charges on a monthly basis and pays for such charges on a monthly basis. Based upon information on payments made by THESL in 2012, a dollar-weighted Hydro One Low Voltage Charges Cost of Power expense lead time of 32.221 days was calculated. Table 7, below summarizes the components of the Hydro One Low Voltage Charges expense lead calculation.

Table 7: Summary of Hydro One Low Voltage Charges

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time

Payments to Non-Utility Generators

THESL purchases power supply from Non-Utility Generators on a monthly basis and pays for such supplies on a monthly basis. For the year 2012, a dollar-weighted expense lead time of 32.26 days was calculated. Table 8 below summarizes the components of the Non-Utility Generator payments expense lead calculation.

Table 8: Summary of Non-Utility Generator Payments

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time
Jan-12	$	11.59%	2/16/2012	15.50	16.00	31.50	3.65

Payments to RESOP, MFIT, and FIT Customers

THESL purchases power supply from RESOP, MFIT and FIT customers. Using payment information in 2012 and the service and billing lag values determined from the revenue analysis, a dollar weighted expense lead time of 46.29 days was calculated. Table 9 below summarizes the components of the RESOP, MFIT, and FIT payments expense lead calculation. Additional detail can be found in Appendix B.

Table 9: RESOP, MFIT, and FIT Customer Payments

Description	Amounts	Weighting	Expense Lead Time	Weighted Lead Time
RESOP	$ 113,497,711	1.44%	38.41	0.55
MFIT	$ 1,843,520	23.43%	43.31	10.15
FIT	$ 5,910,143	75.12%	47.38	35.59
Total	$ 7,867,160	100.00%	1	46.29

OM&A Expenses

For the purpose of the distribution lead lag study, OM&A expenses were considered to consist of payments made by THESL to its vendors in the following categories:

1. Payroll & Benefits;
2. Property Taxes;
3. Non-Resident Withholding Tax;
4. Corporate Procurement Card;
5. Lease Payments;
6. Outside Services; and,
7. Miscellaneous OM&A.

Expense lead times were calculated individually for each of the items listed above and then dollar weighted to derive a composite expense lead time of 33.86 days for OM&A expenses.

Table 10: Summary of OM&A Expenses

Description	Amounts	Weighting	Expense Lead Time	Weighted Lead Time
Payroll & Benefits	$ 207,829,884	66.41%	27.30	18.13
Property Taxes	$ 6,494,693	2.08%	(27.57)	(0.57)
Non-Resident Withholding Tax	$ 249,209	0.08%	29.44	0.02
Corporate Procurement Card	$ 187,473	0.06%	26.21	0.02
Lease Payments	$ 8,971,928	2.87%	12.85	0.37
Outside Services	$ 49,864,366	15.93%	53.51	8.53
Miscellaneous OM&A	$ 39,363,668	12.58%	58.56	7.37
Total	$ 312,961,220	100.00%	1	33.86

Payroll & Benefits

The following items were considered to be expenses related to the Payroll & Benefits of THESL:

1. Two types of payroll including basic and board of directors payroll;
2. Three types of payroll withholdings including the Canada Pension Plan, Employment Insurance, and Income Tax withholdings;
3. Contributions made by THESL to the THESL Pension Plan;
4. Group Health, Dental, and Life Insurance related administrative fees and claims, long term disability, accidental death and dismemberment, and employee assistance program;
5. Payments made by THESL on account of the Employer Health Tax (EHT); and,
6. Payments made by THESL to the Workplace Safety and Insurance Board (WSIB).

When all Payroll, Withholdings and Benefits were dollar weighted using actual payment data, the weighted average expense lead time associated with Payroll & Benefits was determined to be 27.30 days as shown in Table 11, below. Additional detail can be found in Appendix B.

Table 11: Summary of Payroll & Benefits Expenses

Description	Amounts	Weighting	Expense Lead Time	Weighted Lead Time
Payroll	$ 102,963,943	19.68	49.54%	9.75
Withholdings	$ 152,044,775	33.58	25.04%	8.41
Pensions	$ 129,800,561	56.83	14.34%	8.15
Group Life Insurance	$ 2,760,101	(4.25)	1.33%	(0.06)
Group Medical & Dental Claims	$ 33,286,318	0.50	6.39%	0.03
Long Term Disability	$ 2,160,197	(4.25)	1.04%	(0.04)
Accidental Death and Dismemberment	$ 287,471	(4.25)	0.01%	(0.00)
Employee Assistance Program	$ 818,870	(4.10)	0.06%	(0.00)
EHT	$ 3,167,626	42.39	1.52%	0.65
WSIB	$ 1,498,062	57.96	0.72%	0.42
Total	$ 207,829,884	1	100.00%	27.30

Property Taxes

THESL makes property tax payments to the City of Toronto and taxing authorities in the Province of Ontario. These payments are made in the current year for the current year and are typically made in installments. Using the payment dates and amounts associated with THESL's distribution business for calendar year 2012, a dollar weighted expense lead (lag) time of negative 27.57 days was determined. Table 12, below summarizes the components of the property tax expense lead calculation. Additional detail can be found in Appendix B.

Table 12: Summary of Property Tax Expenses

Description	Amounts	Weighting	Expense Lead Time	Weighted Lead Time
PIL Property Tax	$ 135,851	0.83%	(15.39)	(0.13)
Property Tax	$ 16,140,842	99.17%	(27.67)	(27.44)
Total	$ 16,294,693	100.00%		(27.57)

Non-Resident Withholding Tax

THESL makes non-resident withholding tax payments to the relevant taxing authority. These payments are made on a monthly basis. Using actual payment dates and amounts provided by THESL, a dollar weighted expense lead time of 29.44 days was determined. Table 13, below summarizes the components of the non-resident withholding tax expense lead calculation.

Table 13: Summary of Non-Resident Withholding Tax Expenses

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time

Corporate Procurement Card

Procurement (or charge) cards are used by the THESL's employees for a variety of company related reasons including, and not limited to, purchases of materials in the field, incidental expenses, and to settle charges for travel and accommodation. Based on invoice and payment information provided by THESL, a dollar weighted expense lead time of 26.21 days was determined. Table 14 below summarizes the components of the corporate procurement card expense lead calculation.

Table 14: Summary of Corporate Procurement Card Expenses

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time

Lease Payments

Using actual payment dates and amounts provided by THESL, a dollar weighted lease expense lead time of 12.85 days was determined. Table 15, below summarizes the components of the lease expense lead calculation.

Table 15: Summary of Lease Expenses

Delivery Period	Amounts	Weighting Factor %	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time
Jan-12	$ 1,844,861	9.42%	48.81	0.51	49.32	4.64

Total	$ 21,971,928	100.00%				12.85

Outside Services

THESL engages outside services to provide assistance in the areas of engineering, information technology, receivables management, accounting, and general consulting. Based on 2012 transactions in THESL's accounts payable system under the outside services category, a dollar weighted expense lead time of 53.51 days was determined. Table 16, below summarizes the components of outside services expense lead calculation.

Table 16: Summary of Outside Services Expenses

Delivery Period	Amounts	Weighting Factor %	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time
Jan-12	$ 14,612,817	9.25%	14.38	37.70	52.08	4.82

Miscellaneous O&M&A

The Miscellaneous O&M&A category includes items such as product purchases, equipment rentals, and provision of general services to THESL. Based on 2012 transactions in THESL's accounts payable system under the Miscellaneous O&M&A category, a dollar weighted expense lead time of 58.56 days was derived. Table 17, below summarizes the components of miscellaneous O&M&A expense lead calculation.

Table 17: Summary of Miscellaneous O&M&A Expenses

Delivery Period	Amounts	Weighting Factor %	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time

Total	$ 159,363,668	100.00%				58.56

Interest on Short-Term and Long-Term Debt

THESL makes interest payments on long-term and short-term intercompany promissory notes out of current year revenues. Payments on long-term debt are generally made twice a year. Though short-term debt was not part of THESL's financing in the base year of the analysis (2012), discussions with THESL staff indicate that short-term debt is expected to be a part of THESL's financing in the 2015-2019 period. Payments for short-term intercompany promissory notes in 2013 were included to reflect a known and measurable change from the base year of the analysis. Table 18, below summarizes the components of the interest expense lead calculation. Taking into account the various long-term and short-term debt instruments, a dollar-weighted expense lead time of 46.17 days was determined for the 2012 calendar year.

Table 18: Summary of Interest Expenses

Description	Amounts	Weighting	Expense Lead Time	Weighted Lead Time
2012 Long-term debt	$ 175,272,180	98.82%	46.38	45.83
2013 Short-term debt	$ 101,769	1.18%	28.84	0.34
Total	$ 176,173,950	100.00%		46.17

Debt Retirement Charge (DRC)

THESL makes payments for the debt retirement charge on a monthly basis to the Ontario Electricity Financial Corporation. Using payment amounts that were made in calendar year 2012, a dollar-weighted expense lead time of 33.31 days was determined for DRC. Table 19, below summarizes the components of the DRC expense lead calculation.

Table 19: Summary of DRC Expenses

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time
Jan-12	$ 12,414,868	7.64%	1/18/2012	15.50	18.00	33.50	2.56

Dec-12	$ 13,026,281	8.02%	12/18/2012	15.00	18.00	33.00	2.65
Total	$ 162,416,324	100.00%					33.31

Payment in Lieu of Taxes (PILs)

THESL makes payments in lieu of taxes in installments to the relevant taxing authorities. Using payment amounts that were made in calendar year 2012, a dollar weighted expense lead time of negative 48.95 days was determined for PILs. Table 20, below summarizes the components of the PILS expense lead calculation.

Table 20: Summary of PILs Expenses

Delivery Period	Amounts	Weighting Factor %	Payment Date	Service Lead Time	Payment Lead Time	Total Lead Time	Weighted Lead Time
2012	$ 11,665,000	21.26%	1/31/2012	183.00	(335.00)	(152.00)	(32.32)

2012	$ 1,612,000	7.82%	10/31/2012	183.00	(61.00)	122.00	9.53
2012	$ 1,612,000	7.82%	11/30/2012	183.00	(31.00)	152.00	11.88
Total	$ 17,831,000	100.00%					(48.95)

Harmonized Sales Tax (HST)

The expense lead times associated with the following items that attract HST were considered in THESL's distribution lead/lag study.

1. Revenues;
2. Cost of Power; and,
3. OM&A [1].

A summary of the expense lead times and working capital amounts associated with each of the above items is provided in Table 21. Note that the statutory approach described at the outset was used to determine the expense lead times associated with THESL's remittances and disbursements of HST (i.e., remittances are generally on the last day of the month following the date of the applicable return).

Table 21: Summary of HST Working Capital Amounts

Description	HST Lead Time	Working Capital Factor	2012
Revenues	(5.47)	1.50%	$ (6,347,016)
Cost of Power	45.92	12.55%	$ 67,966
OM&A Expenses	41.50	11.34%	$ 13,513,531
Total			$ 7,234,481

[1] Costs within OM&A that attract HST include Corporate Procurement Card, Outside Services, and Miscellaneous OM&A.

Section IV: Conclusions

Using the results described under the discussion of revenue lags and expense leads, and applying them to THESL's distribution expenses for 2012, THESL's working capital requirements were determined. Table 22, below summarizes the working capital requirements for 2012 calculated in the study.

Table 22: THESL Distribution Working Capital Requirements (2012)

Description	Revenue Lag Days	Expense Lead Days	Net Lag Days	Working Capital Factor	Expenses	Working Capital Requirements
Cost of Power	55.04	32.84	22.20	6.07%	$ 2,450,597,565	$ 148,654,316
OM&A Expenses	55.04	33.86	21.19	5.79%	$ 312,961,220	$ 18,115,434
PILS	55.04	(48.95)	103.99	28.41%	$ 7,831,001	$ 2,225,034
Interest Expense	55.04	46.17	8.87	2.42%	$ 176,173,950	$ 4,265,501
DRC	55.04	33.31	21.74	5.94%	$ 162,416,324	$ 9,645,577
Total					$ 3,009,980,059	$ 180,485,912
HST						$ 38,234,481
Total Including HST						$ 218,720,393
Working Capital as a Percent of OM&A incl. Cost of Power						7.91%

The results of the study indicate a lower working capital requirement compared to THESL's EB-2007-0680 distribution lead/lag study. A considerable amount of time has elapsed between the two studies. The primary reason for the difference is the decrease in retail revenue lag days, due to the upgrade of THESL's Customer Information System since the prior study. The retail revenue lag days have decreased by approximately 20 percent.

Appendix A: Working Capital Methodology

Working capital is the amount of funds that are required to finance the day to day operations of a regulated utility and which are included as part of a rate base for ratemaking purposes. A lead lag study is the most accurate basis for determination of working capital and was used by Navigant for this purpose.

A lead lag study analyzes the time between the date customers receive service and the date that customers' payments are available to THESL (or "lag") together with the time between which THESL receives goods and services from its vendors and pays for them at a later date (or "lead") [2]. "Leads" and "Lags" are both measured in days and are dollar weighted where appropriate. [3] The dollar weighted net lag (lag minus lead) days is then divided by 365 (or 366 for leap years) and then multiplied by the annual test year expenses to determine the amount of working capital required. The resulting amount of working capital is then included in THESL's rate base for the purpose of deriving revenue requirements.

Key Concepts

Two key concepts need to be defined as they appear throughout the report:

Mid Point Method

When a service is provided to (or by) THESL over a period of time, the service is deemed to have been provided (or received) evenly over the midpoint of the period, unless specific information regarding the provision (or receipt) of that service indicates otherwise. If both the service end date ("Y") and the service start date ("X") are known, the mid point of a service period can be calculated using the formula:

$$\text{Mid Point} = X + \frac{(Y - X + 1)}{2}$$

When specific start and end dates are unknown, but it is known that a service is evenly distributed over the mid point of a period, an alternative formula that is generally used is shown below. The formula uses the number of days in a year (A) and the number of periods in a year (B):

$$\text{Mid Point} = \frac{1}{2} \times \frac{A}{B}$$

Statutory Approach

In conjunction with the mid point method, it is important to note that not all areas of the study may utilize dates on which actual payments were made to (or by) THESL. In some instances, particularly for the HST, the due dates for payments are established by statute or by regulation with significant penalties for late payments. In these instances, the due date established by statute has been used in lieu of when payments were actually made.

Expense Lead Components

As used in the study, Expense Leads are defined to consist of two components:

[2] A positive lag (or lead) indicates that payments are received (or paid for) after the provision of a good or service.

[3] The notion of dollar weighting is pursued further in the sub section titled "Key Concepts".

1

1

1. Service Lead component (services are assumed to be provided to THESL evenly around the mid point of the service period), and
2. Payment Lead component (the time period from the end of the service period to the time payment was made and when funds have left THESL's possession).

Dollar Weighting

Both leads and lags should be dollar weighted where appropriate and where data is available to accurately reflect the flow of dollars. For example, suppose that a particular transaction has a lead time of 100 days and has a dollar value of $100. Further, suppose that another transaction has a lead time of 30 days with a dollar value of $1 Million. A simple (un-weighted) average of the two transactions would give us a lead time of 65 days ([100+30]/2). However, when these two transactions are dollar weighted, the resulting lead time would be closer to 30 days which is more representative of how the dollars actually flow.

Methodology

Performing a Lead/Lag study requires two key undertakings:

1. Developing an understanding of how the regulated distribution business operates in terms of products and services sold to customers/purchased from vendors, and the policies and procedures that govern such transactions; and,
2. Modeling such operations using data from a relevant period of time and a representative data set. It is important to ascertain and factor into the study whether (or not) there are known changes to existing business policies and procedures going forward. Where such changes are known and material, they should be factored into the study.

To develop an understanding of THESL's operations, interviews with personnel within THESL's Accounts Payable, Customer Service, Wholesale Market Operations, Human Resources, Payroll, Treasury, and Tax Departments were conducted. Key questions that were addressed during the course of the interviews included:

1. What is being sold (or purchased)? If a service is being provided to (or by) THESL, over what time period was this service provided;
2. Who are the buyers (or sellers);
3. What are the terms for payment? Are the terms for payment driven by industry norms or by company policy? Is there flexibility in the terms for payment;
4. Are any changes to the terms for payment expected? Are these terms driven by industry or internally? What is the basis for any such changes;
5. Are there any new rules or regulations governing transactions relating to distribution operations that are expected to materialize over the time frame considered in this report; and,
6. How are payments made (or received)? Payment types have different payment lead times (i.e., internet payments have shorter deposit times than cheque deposit times)

TREATMENT OF STRANDED ASSETS RELATED TO SMART METER DEPLOYMENT

In accordance with section 2.5.1.4 of the OEB's Filing Requirements for Electricity Distribution Rate Applications (July 17, 2013) ("the Filing Requirements"), this schedule provides information about Toronto Hydro's proposed treatment of stranded assets related to smart meter deployment, which conforms with the guidance provided by the OEB in s. 2.5.1.4 of the Filing Requirements, and in section 3.7 and Appendix A-1 of the Guideline G-2011-0001: Smart Meter Funding and Cost Recovery – Final Disposition (December 15, 2011). A completed copy of OEB Appendix 2-S is filed as Exhibit 2A, Tab 3, Schedule 2.

1. BACKGROUND

Toronto Hydro began its Smart Meter program in 2006 and substantially completed installation of all smart meters by the end of 2010. In 2012, Toronto Hydro applied for and was granted approval by the OEB for recovery of all remaining Smart Meter costs.[1]

2. NET BOOK VALUE ("NBV")

As of December 31, 2014, the net value of the Stranded Meters is estimated at $15.8 million. This value reflects the NBV of the assets ($16.3 million) less recovery amounts through scrap sales ($0.5 million). No carrying costs have been calculated on the Stranded Meter assets.

3. RECORDED AMOUNTS

For the conventional meters stranded through the Smart Meter program, Toronto Hydro continued to record these amounts in Account 1860 – Meters, until they were transferred

[1] EB-2013-0287, Decision and Order, January 16, 2014.

to Account 1555 – Sub-account Stranded Meter Costs in 2013. Depreciation was recorded on these meters since the beginning of the program.

4. RATE RIDER RECOVERY

For the purposes of 2015 Revenue Requirement (Exhibit 6, Tab 1, Schedule 1), the NBV of the stranded smart meter assets is not included in the utility's rate base. Toronto Hydro is seeking recovery of this amount through a separate rate rider. Toronto Hydro confirms that the associated cost recovery from the separate rate rider will be recorded in Account 1555 – Sub-account Stranded Meter Costs to reduce the balance of the sub-account.

For more information about the proposed rate rider, and an explanation of Toronto Hydro's approach to allocating the NBV of the stranded meters to the applicable customer rate classes, please refer to Exhibit 9, Tab 1, Schedule 1.

Notes:

(1) *For 2014 Depercation, it is provided based on forecast basis.*

(2) *For the period of 2007 to 2012, Stranded Meters were included in Account 1860. Stranded Meters were moved to Account 1555*

STREET LIGHTING ASSET TRANSFER

In two decisions relating to the utility's Street Lighting Transfer Application (EB-2009-0180 et al.), the OEB found that a portion of the street lighting assets in the City of Toronto can be considered distribution assets. In a Decision and Order dated February 11, 2010, the OEB made a principled determination about the categories of street lighting assets which could be considered to serve a distribution function and could be transferred to Toronto Hydro (the "Classification Decision"). In a subsequent Decision and Order, /C dated August 3, 2011, the OEB approved a value of $28.9 million of the assets that were /C found to be eligible to be transferred (the "Valuation Decision").

This schedule provides information to support Toronto Hydro's proposal to transfer former street lighting assets into the utility's rate base effective January 1, 2015, at the revised value of $39.8 million. Toronto Hydro submits that the revised transfer value of /C the street lighting assets has no effect on the utility's revenue requirement for all rate classes other than the Street Lighting and Unmetered Scattered Load ("USL") rate classes because the costs associated with the street lighting assets are directly allocated to the Streetlighting (95%) and the USL (5%) rate classes. For the Streetlighting class, these costs are offset by revenues from a Service Agreement with the City of Toronto. For the USL class, the effects are minimal. In addition, Toronto Hydro notes that for the purpose of this application, the effect of the proposed transfer has been fully integrated into the utility's operating and capital expenses, and cost allocation model; this schedule provides a summary of those effects.

The evidence is organized as follows:

1) Background
2) Post Filing Assessment
3) Asset Transfer Valuation

/C

4) Summary of Capital and OM&A Programs relating to Street Lighting
5) Revenue Requirement and Cost Allocation

1. BACKGROUND

On June 15, 2009, Toronto Hydro together with Toronto Hydro Energy Services Inc. ("TH Energy") and related legal entities (collectively, the "Applicants") applied jointly to the OEB for authorization to effectively transfer the streetlighting and expressway lighting assets held by TH Energy to Toronto Hydro.

In the Classification Decision, the OEB found that only certain assets are appropriately considered distribution assets (based on purpose, functional or intended use) and are eligible to be transferred to Toronto Hydro. Essentially, the OEB found that assets which are dedicated only to the streetlighting function per se (including luminaires, brackets and conductors on the bracket, and poles, related pole foundations and conductors along poles on local roads fed by underground circuits) do not serve a distribution function, and therefore were ineligible to be transferred. However, other assets (including poles, related pole foundations and conductors fed by overhead distribution lines or by underground circuits in mixed use urban areas) were found to have, or be capable of having, a distribution function. These assets were eligible to be transferred, as were underground conductors in residential areas, and all handwells that formed part of the street lighting system.

In the Classification Decision, the OEB rejected, for regulatory purposes, the discounted cash flow valuation that underpinned the original purchase of the streetlighting assets by TH Energy from the City of Toronto in 2006, and found that the depreciated historic cost ("DHC") method was more appropriate for rate setting purposes. However, as described in the Applicant's evidence and acknowledged by the OEB in the Valuation Decision,

/C

DHC information on the existing street lighting assets did not exist and was too costly to create.[1] The OEB therefore directed Toronto Hydro to bring forward further evidence enumerating the assets that were eligible for transfer according to the principles and categories set out in the Classification Decision, and provide a "physical valuation" of those assets.[2]

In addition, the OEB found that it was unable to determine on the evidence the proper classification of expressway lighting. The Applicants subsequently withdrew their request for the transfer of the expressway lighting assets in light of the principles set out in the Classification Decision.

In response to the Classification Decision, Toronto Hydro and TH Energy undertook two studies. The first was an exhaustive cataloguing of the streetlighting (and expressway lighting) assets, carried out by their staff and contract resources. This cataloguing (the "Inventory Study") recorded asset location, condition, and other parameters (including street type with respect to type of supply) necessary to properly classify the assets according to the terms of the Classification Decision. Toronto Hydro then used the data collected in the Inventory Study to determine the classification of all individual assets according to the criteria set out in the Classification Decision.

The second study was a valuation study conducted by ValuQuest Limited (the "ValuQuest Study"), which used the Depreciated Replacement Cost ("DRC") method to provide a "physical valuation" of the assets based on information from the Inventory Study. The ValuQuest Study found a DRC value of $83.7 million for the streetlighting assets, and $99.1 million for the total of streetlighting and expressway lighting assets.

[1] Valuation Decision, at page 14. The information does exist for assets installed after the purchase.
[2] Classification Decision, at page 20.

The Applicants filed evidence including the ValuQuest Study on January 31, 2011 in response to the OEB's direction in the Classification Decision. The Applicants proposed a 2010 year end valuation for the transferable assets of $28.9 million. This value was arrived at by scaling the DRC amounts in each asset class by the ratio of the 2010 year-end total net book value ("NBV") of $63.5 million. TH Energy's financial records the DRC total of $99.1 million. The basis of this valuation is explained in further detail below.

In the Valuation Decision, the OEB accepted the figure of $28.9 million as the 2010 year-end value of the transferable assets; however, the OEB noted that it did not specifically endorse the scaling of the DRC values so that their total matched the 2010 year-end NBV value. The OEB decided that rate base, revenue requirement, and the consequences of the transfer would be determined in Toronto Hydro's next cost of service application.[4]

On November 7, 2011, Toronto Hydro filed evidence in its EB-2011-0144 cost of service application relating to the incorporation of the street lighting assets into the utility's rate base.[5] In that application Toronto Hydro proposed a slightly lower transfer price for the assets of $28.5 million, reflecting the forecast evolution of the assets (principally additions and depreciation) over 2011. However, the OEB ultimately dismissed the EB-2011-0144 application so the matter remained unresolved.

The Applicants proceeded as authorized by the OEB to complete the transaction effective January 1, 2012. At that time an Agreement of Purchase and Sale (the "Sale Agreement") was executed between the parties which initially provided for a transfer price of $28.5 million, subject to a detailed analysis of the NBV of the transferred assets, which analysis would then underpin an adjustment to the transfer price, if necessary.

[4] Valuation Decision, at page 15.
[5] EB-2011-0144, Application and Evidence, Exhibit P3 (November 7, 2011).

By February of 2012, Toronto Hydro and TH Energy completed the detailed analysis of the NBV of the transferred assets, and found that the true NBV of the transferred assets was in fact $44.2 million. The methodology of the detailed analysis is explained in detail below. As a result, the value of the assets transferred was recorded at $44.2 million in Toronto Hydro's books. There was no change to the total valuation of the combined streetlighting and expressway lighting assets, so the amount that remained un-transferred in TH Energy was correspondingly lower.

2. POST FILING ASSESSMENT

Toronto Hydro filed a previous version of this evidence on July 31, 2014. After the filing, Toronto Hydro conducted an assessment of the assumptions and methodology underlying the transfer, and determined that the evidence must be revised. The revised description below does not affect the proposed value of the asset transfer into Toronto Hydro's rate base.

Toronto Hydro determined that an additional data point was used in the detailed analysis of the NBV of the transferred assets. This data point was the Optimal Investment Portfolio ("OIP") study, which was conducted in 2004 to assess the vintages of all major assets in Toronto Hydro's system, and to implement IFRS-consistent changes related to the manner in which Toronto Hydro records and accounts for its assets. For the purpose of the street lighting transfer, the OIP Study was used to determine the vintages of the poles, pole foundations and handwells and to allocate these assets between Toronto Hydro and TH Energy. The OIP Study provided better information about the vintages of the street lighting assets than the Inventory Study which was used for the purpose of the Valuation Decision in 2011. To illustrate, the original valuation assumed that approximately 49% of poles which did not have an associated year, were fully

depreciated. The OIP Study, however, revealed that only 5% of poles were without an associated year. Similarly, the original valuation assumed that nearly 58% of poles were older than 1970 and were thus fully depreciated, but the OIP Study shows that there were less than half of this number of poles, approximately 27% of poles, in that vintage band.[6]

In addition, Toronto Hydro assessed the classification of assets into the transferable and non-transferable categories and determined that: 1) approximately 5900 poles and related assets transferred from TH Energy were not *prima facie* eligible to be transferred because they were located on local streets fed by underground supply; and 2) some handwells, namely those associated with poles that were not transferable from TH Energy, were not transferred to Toronto Hydro, as required by the OEB decision. The revenue requirement impact of these findings is estimated to be $0.2 million. Because the impact of the reassessment is significantly lower than the utility's materiality threshold of $1 million, Toronto Hydro has not updated the value of the assets that it proposes to transfer. For greater certainty, the utility confirms the reassessment does not adversely affect any of the utility's rate classes. For the Street Lighting class, the incremental costs would be offset by revenues from a Service Agreement with the City of Toronto. For the USL class, the effects are minimal, as only 5% of the costs are allocated to this class of customers.

PricewaterhouseCoopers LLP ("PWC") was retained to review and provide an independent assessment of the methodology used by Toronto Hydro to arrive at the revised transfer price of the street lighting assets. PWC issued a report on July 28, 2014, which was filed alongside the original version of this evidence on July 31, 2014. PWC has considered the changes to original evidence, and has issued an addendum to its report with respect to the noted revisions. The addendum is filed at Exhibit 2A, Tab 5, Schedule 2, Appendix A.

/C

3. ASSET TRANSFER VALUE

For purposes of the present application, Toronto Hydro requests OEB approval to transfer the former streetlighting assets into this utility's rate base at a value of $39.8 million, which represents the opening net book value of the assets in 2015. This amount reflects the actual cost incurred by Toronto Hydro to acquire the 2012 transferred assets from TH Energy, the additional assets that were put in service in the intervening period (i.e., 2012 to 2014), as well as depreciation on assets. A stepwise explanation of the derivation of this amount is set out below.

3.1. The Need For A Detailed Analysis Of The Transferred Assets

Several factors contributed to the need to perform a detailed analysis of the NBV of the transferred assets. First, accounting and financial reporting standards require Toronto Hydro to maintain its financial records in a manner that permits accurate recording of assets owned by the respective businesses and depreciation on those assets. In order to calculate depreciation, the companies must have accurate records of the vintage of their assets and of the remaining useful lives of those assets in cases where acquired assets are not new.

Given the structure and function of the fixed asset sub-ledgers of both companies, it was not possible from an accounting perspective to simply transfer an unassociated amount between the companies without linking that amount as closely as possible to the underlying assets. Doing so would have interfered with the process of recording depreciation on the remaining assets, as Toronto Hydro would have no way of calculating depreciation for different asset types and vintages based on a single unassociated value being transferred to it. Therefore, it was necessary to perform the detailed analysis outlined below in order to identify the types, quantities, and vintages of the assets being transferred from TH Energy to Toronto Hydro.

Second, as explained in further detail below, the definitions of asset classes differed between TH Energy's s fixed asset sub-ledger and the ValuQuest Study. The ValuQuest Study distinguished poles, pole foundations and handwells, whereas TH Energy's fixed asset sub-ledger considered those to be one asset class. Conversely, TH Energy's fixed asset sub-ledger distinguished underground from overhead conductors, while the ValuQuest Study did not. Since some poles were associated with either, or both of, foundations and handwells, while others were not, this meant that a detailed analysis was required to effectively disaggregate the pole asset class in TH Energy's fixed asset sub-ledger in order to properly reflect the assets that were transferred. Allocations were also required for other asset classes.

Third, while Toronto Hydro accepted the principles of asset classification set forth by the OEB in the Classification Decision, the fact remained that those principles did not correspond to the financial records associated with the assets. For the assets that were found to be eligible for transfer, no existing asset classes exclusively and exhaustively represented the assets that could be transferred. As mentioned above, TH Energy's financial records considered handwells, poles and pole foundation to be one asset class, whereas the OEB's Valuation Decision found that while all handwells could be transferred, only certain poles and poles foundation were eligible. Therefore, a detailed analysis was required to properly separate the assets that were eligible for transfer, according to the criteria set out by the OEB in the Classification and Valuation Decisions.

3.2. Initial Conditions for the Detailed Analysis

In late 2011 and early 2012, following the preparation of the evidence in EB-2011-0144, Toronto Hydro undertook the detailed analysis of plant records for the purpose of supporting the asset transfer. At that time, Toronto Hydro had available to it the following information:

- The initial 2006 purchase price for sale of the City of Toronto-owned streetlighting and expressway lighting assets to TH Energy of $60 million. This amount was subsequently recognized on TH Energy's books as the sum of amounts in five asset classes (poles; wires and fixtures; overhead distribution lines and feeders; underground conduit; underground distribution lines and feeders; and streetlight fixtures and luminaires).
- The continuity (additions and depreciation) for the assets originally acquired from the City of Toronto (the "originally acquired assets"), as well as the assets added from the date of the purchase (2006) to the end of 2011. However, TH Energy's fixed asset sub-ledger did not contain information on the location of any assets, and did not contain information on the vintage of the originally acquired assets.
- The Inventory Study database, containing information on all of the streetlighting (and expressway lighting) assets, including condition, and situation (i.e., location on distinguished street types in accordance with the Classification Decision). /C
- The GEAR (Geo-Spatially Enabled Asset Registry) database, which was used by the Inventory Study, and which associated a Feature Identification ("FID") Number and vintage information with each pole asset where available. /C
- The ValuQuest Study and related database.
- The Optimal Investment Portfolio ("OIP") Study that was conducted in 2004 to assess the vintages of all major assets in Toronto Hydro's system. /C
- The Sale Agreement, dated December 29, 2011.

3.3. Detailed Analysis of the Originally Acquired Pole Assets

In order to bring TH Energy's fixed asset sub-ledger vintage information on the originally acquired assets to a level comparable to that of the subsequently installed assets, Toronto Hydro used information in the Inventory Study to determine which pole assets were transferrable and to stratify the originally acquired pole assets into vintage bands. For example, TH Energy had a count of poles by 5-year vintage bands starting in /C

1971 and ending in 2005. (Vintage bands were designated by their mid-points, so that the 1971 – 1975 vintage band was designated 1973.) The useful life of pole assets was set at 40 years, so assets installed prior to 1972 were considered to be fully depreciated.

Location information for pole foundations and handwells was matched to location information for poles to associate those assets with the corresponding poles. As previously noted, not all poles were associated with foundations or handwells, while some poles were associated with either or both of foundations and handwells.

In 2006, the originally acquired assets were classified into five assets classes and were assigned estimated remaining useful lives. For financial statement purposes, poles, pole foundations and handwells were merged into one asset class, "poles".

In 2011, subsequent to the release of the Inventory Study, in which poles were stratified into eleven 5-year vintage bands TH Energy assessed the need to prospectively change the remaining useful lives of poles to reflect the new information. Hence in 2011, the originally acquired pole asset in the financial records was stratified according to the vintage bands as per the Inventory Study. To do this, TH Energy applied standard costs of poles from the ValuQuest Study, which was approximately $2,340.00.

For the purpose of applying standard costs to historical quantities, TH Energy deflated the pole standard costs by the CPI (2010=100) to the mid-points of each vintage to arrive at sets of deflated standard costs for each vintage band. The resulting figures are essentially estimates of, or proxies for, the unit gross acquisition costs for each vintage band, which TH Energy was required to use in the absence of information on actual historical acquisition costs.

/C

The last element to disaggregate the asset with vintage bands was to scale the results so that the sum of the initial disaggregated NBV by vintage to agree with the amounts carried in TH Energy's books at the end of 2010. To do so, the accumulated depreciated was allocated proportionally to the vintage bands.[7] In order to arrive at the NBV at the end of 2011, it was then necessary to roll forward and deduct from the proxy acquisition costs the corresponding derived accumulated depreciation.

As previously noted, Toronto Hydro had conducted an analysis of the Inventory Study database to determine which poles and related assets were transferable, and to stratify the acquired assets by vintage bands. The OEB Study was then used to determine the vintage of the pole assets eligible for transfer and to allocate pole assets between Toronto Hydro and TH Energy. A recalculation – based on the OEB Study – of the stratification of the originally acquired pole assets was completed and deemed immaterially different (less than $150,000). Therefore, although the OEB Study provided better information about the age of the assets than was available from the Inventory Study, Toronto Hydro determined that it was not necessary to restate the stratification of the acquired assets.

If a foundation or handwell was associated with the pole, they were assumed to be of the same vintage. With this information, Toronto Hydro was able to compile a list by vintage of the poles, foundations and handwells to be transferred.[8] The counts by vintage and type of each asset to be transferred were then divided by the corresponding total asset counts in each vintage, and multiplied by the corresponding adjusted NBVs to obtain the transferred NBV by vintage for all asset types. Using illustrative data, the

/C

[7] Due to the prospective treatment of the change in remaining useful life of the pole assets, it was not necessary to stratify the accumulated depreciation as the acquired assets at the close of December 31, 2010 were pooled and shared the same remaining useful life.

[8] As mentioned above in section 2, Toronto Hydro conducted an assessment and determined that a number of handwells were not transferred from TH Energy, as required by the OEB decision. Toronto Hydro has not updated the value of the transferred assets because the revenue requirement impact is immaterial.

process of determining the transferable proportion of each vintage's NBV by class is depicted in Table 4 below.

Table 1: Illustrative Determination of Asset Vintage NBV Proportion Transferred

		Transferred Assets			All Assets			Proportion of Asset Vintage NBV Transferred		
Vintage	Asset FID	Pole Count	Found. Count	Handw. Count	Pole Count	Found. Count	Handw. Count	Poles	Found's	Handw's

	5698632	1		1						
SubTota		2	1	1	5	2	1	0.4000	0.5000	1.0000

/C

This example illustrates that the poles, which are the 'anchor' assets, may be associated with foundations, handwells, both, or neither. The pole FID enables that association to be made. In the result, there is no constant relationship or proportionality within or across vintages between poles and the other assets in order to properly execute the transfer of

only the authorized assets, it was necessary to perform the detailed analysis to establish what other assets were associated with the transferable poles, and properly value the entire transferred asset base. While it is possible after the fact of the analysis to calculate the proportion of the transferred assets by class, it is not possible to proceed in the opposite direction to infer from a simple proportion what assets from what class and vintage are properly transferable. /C

With respect to the balance of the assets in TH Energy's "Poles" asset class installed after the 2006 asset acquisition from the City, the process of determining the transferable proportion of NBV by vintage was the same. However, because of the detailed records then being kept, it was not necessary to go through the stratification process, and the "vintages" in the post-acquisition period were individual years.

3.4. Determination of the Transferred Proportions of Other Assets

Several other asset classes were also transferable according to the Classification Decision. These included overhead and underground conductors, and conduits, but did not include conductors within untransferred streetlight poles and brackets. In addition, since Toronto Hydro withdrew its request to transfer any expressway lighting assets, all conductors and conduits associated with expressway lighting were excluded.

In the case of conductors, conduits, and vaults, there were again differences in classification as between the ValuQuest Study and TH Energy's fixed asset sub-ledger. The ValuQuest Study identified only conductors for the streetlighting assets, and conductors and conduit for expressway lighting assets. In comparison, TH Energy's fixed asset sub-ledger classified these assets as underground conduit, underground distribution lines and feeders, and overhead distribution lines and feeders.

With the information available to it, Toronto Hydro was not able to specifically separate in the fixed asset sub-ledge these secondary assets based on location in the fixed asset sub-ledger. Therefore, Toronto Hydro relied on information presented to the OEB at the time of the Valuation Decision, specifically as shown in 'Table 4: Derivation of NBV by Asset Group and Classification,' on page 19 of that evidence.[9] In that evidence, the Group NBV figures represented the Group RCV values found by ValuQuest, scaled down by approximately 36% such that their total would be equal to the then current total NBV on TH Energy's books. Toronto Hydro summed the "Group NBV" figures for streetlighting conductors, and expressway lighting conductors and conduits and considered those groups to be equivalent to the TH Energy asset classes of underground conduit, underground distribution lines and feeders, and overhead distribution lines and feeders.

The total Group NBV for those three asset classes was $4.7 million, of which streetlighting conductors represented $3.6 million, or 76.65%. Expressway conductors and conduit, which were categorically excluded, represented the balance. Toronto Hydro then multiplied the streetlighting conductor percentage by the percentage of transferable streetlighting conductors, 64.62%, which latter percentage was based on Toronto Hydro's physical classification of assets into the transferable and non-transferable categories. The product of the percentages (76.65% * 64.62%) is 49.53%. On this basis, Toronto Hydro determined that 49.53% of the total NBV of TH Energy's asset classes of underground conduit, underground distribution lines and feeders, and overhead distribution lines and feeders would be transferred to Toronto Hydro. For the assets transferred to Toronto Hydro on January 1, 2012, this amount was $7.281 million.

[9] EB-2009-0180 et. al, Application and Evidence (January 31, 2011) at page 19 of 21.

3.5. Determination of the Transferred Proportion of CWIP

At any point in time, there is a balance in the Construction Work in Progress ("CWIP") account. In the case of TH Energy's street lighting assets, a CWIP balance of $6.265 million at December 31, 2011 existed, but it was not possible to specifically trace that balance to transferable versus non-transferable assets. As an interim proxy, the transferred proportion of in-service streetlighting assets (68%) was applied to the then existing CWIP balance to divide that balance between Toronto Hydro and TH Energy. Toronto Hydro's assumed share of the CWIP balance was therefore $4.264 million.

For that purpose, a "top-sided" entry was made to show the transfer of the portion of CWIP to Toronto Hydro. In the intervening years from 2012 to the current time, as projects were closed to net fixed assets, they were recorded in the books of TH Energy or Toronto Hydro as appropriate and any necessary adjustments were made to the top-sided entry to reflect any variance from the assumed proportion of 68%, and to draw down that balance as projects were closed. The closure of projects to Toronto Hydro's net fixed assets is reflected in the asset continuity tables set out below.

3.6. Summary of the Assets Transferred as of January 1, 2012

The assets were transferred to Toronto Hydro in the same asset classes as they existed in TH Energy's books, and were distinguished by asset class and vintage. For example, poles, foundations, and handwells of the 1988 vintage were transferred to Toronto Hydro as an asset designated "1988 Poles".

The incurred cost to Toronto Hydro upon transfer was treated as Toronto Hydro's gross acquisition cost of the assets, and accumulated depreciation at the time of transfer was zero in all cases. However, to recognize the fact that a variable portion of the useful lives of the assets had elapsed for the majority of the assets, the remaining useful life was determinative of the rate of depreciation subsequently applied to the assets.

The useful lives of all assets except Conduits were set at 40 years, with Conduits set at 50 years. The remaining useful life figures for each vintage of asset were calculated based on the useful lives and the vintages of the assets. As an example, a 1973 pole with a useful life of 40 years had at the end of 2011 a remaining useful life of two years. Although the 1973 vintage notionally included the year 1971, all assets (in this case, only poles) installed in 1971 or earlier were deemed to be fully depreciated and none were transferred at any value to Toronto Hydro.

Because of the deferral of the ratemaking treatment of the transferred assets, the utility determined that it was necessary, as a temporary measure, to record the transferred assets along with other non-rate regulated portions of Toronto Hydro's business (i.e., Conservation and Demand Management and microgeneration). Had the transferred assets been recorded in Toronto Hydro's rate-regulated financial records along with other fixed assets that are part of the utility's rate base, it would have been impossible, practically, to separately track the assets' cost and evolution over the period until the rate making treatment was established. In this Application, Toronto Hydro proposes to transfer the street lighting assets to the utility's Property, Plant and Equipment ("PP&E") fixed asset register.

3.7. Summary of the Continuity of Assets: 2012 to 2014

Over the period from the beginning of 2012 to the (forecast) end of 2014, Toronto Hydro has added assets and has similarly recorded depreciation on all the assets that it acquired effective January 1, 2012. For the assets added since January 1, 2012, Toronto Hydro has the normal and exact information on gross book value, accumulated depreciation, and net book value.

3.8. Explanation of Variance in Asset Valuation

The overall variance between the proposed 2014 year end NBV of the former street lighting assets ($39.8 million) and the original amount approved by the OEB in the Valuation Decision ($28.9 million) is composed of normal asset evolution amounts occurring over the period January 1, 2011 to December 31, 2014, and the difference in valuation amounts for the transferred assets. /C

The Valuation Decision amount was based on 2010 year-end figures, while the January 1, 2012 transfer amount was based on 2011 year-end figures. Therefore, some part of the difference between the two is due to asset evolution over 2011. Since a Valuation Decision amount based on 2011 year-end figures does not exist, it is not possible to precisely quantify what the difference would be between that (hypothetical) amount and the transfer amount. Nevertheless, the bulk of the variance is due to factors other than asset evolution over 2011.

These factors stem from a data and information gap at the time of the Valuation Application and Decision. Toronto Hydro fully acknowledges the valuable information provided through the Inventory Study and the LVQuest Study. However, it is still the case that the proxy value of $28.9 million provided at the time was the result of two simplifying assumptions that had to be made due to the lack of more precise information. The first was that the values of the transferred assets were proportional to their counts, which is effectively the same as assuming that individual assets within a class are of equal value regardless of their vintage and composition. The detailed analysis revealed new information indicating that assumption was not valid in the case of the streetlighting asset transfer. /C /C /C

The OIP Study, which was used to allocate pole assets between Toronto Hydro and TH Energy, provided more accurate and complete information about the age of the assets /C

than was available in Toronto Hydro's geospatial asset registry ("GEAR") system at the time of the Inventory Study and the Valuation Application. /C

The second assumption was that the proportions of the total asset represented by the various asset classes in both the TH Energy fixed asset sub-ledger and the ValuQuest Study were (approximately) equivalent. However, because of the differences in asset classifications, it was not evident prior to the detailed analysis whether this was valid, and upon that analysis, some significant differences became apparent.

In combination, these factors led to variances caused both by differences in the percentages of assets transferred on a class-by-class basis, and by differences in the initial NBVs by class, as between TH Energy's fixed asset sub-ledger and the ValuQuest Study amounts, which after being prorated downward underpinned the Valuation Decision amount of $28.9 million. In addition, the ValuQuest Study did not take into account CWIP, a portion of which was transferred as explained above. /C

It was necessary for Toronto Hydro to perform the detailed analysis resulting in the revised valuation in order to properly implement the OEB's Valuation Decision, and provide an accurate basis for Toronto Hydro's and TH Energy's ongoing accounting and financial reporting obligations. No existing asset classes exclusively and exhaustively represented the assets eligible for transfer; instead, the transferable assets were co-mingled with non-transferable assets. Therefore, it was necessary for example to disaggregate the existing TH-Energy class of poles' into its components of poles, foundations, and handwells, in order to extract the transferrable assets together with their corresponding values. Furthermore, since depreciation accounting depends on asset vintages and depreciation rates, it was not possible to simply transfer an amount unassociated with asset types and vintages; else, by doing so the information required for ongoing accounting would have been lost.

The detailed analysis created new information pertaining specifically to the transferred assets that was not available at the time the Valuation Application was submitted or the Valuation Decision was rendered. The new information, resulting from the detailed analysis, provides a better proxy for the Depreciated Historic Cost of the transferred assets than does the Depreciated Replacement Cost approach, with its results scaled down to match the then existing asset value carried on THEnergy's books. This is because the detailed analysis specifically traces the vintage and remaining useful life of the transferred assets, rather than simply assuming that all assets of a particular type were of equal value, regardless of vintage. However, the detailed analysis does not increase the value of the overall asset; rather, it changes the proportion of the unchanged total amount that is transferred to Toronto Hydro.

/C

4. SUMMARY OF CAPITAL AND OM&A PROGRAMS

In its decision authorizing the transfer of certain former street lighting assets into Toronto Hydro's Distribution system, the OEB determined that these transferred assets are effectively distribution assets. As such, these former transferred street lighting assets will be managed through Toronto Hydro's distribution capital and maintenance programs, as described in Exhibit 2B, Section E6 and Exhibit 4A, Tab 2, respectively.

4.1. Capital Programs

Three of Toronto Hydro's capital programs are relevant to the replacement of the transferred assets when those assets reach the end of their lives. These programs are:

- Overhead Circuit Renewal (Exhibit 2B, E6.4), which funds the replacement of overhead assets such as poles and conductor on a planned basis;
- Underground Circuit Renewal (Exhibit 2B, E6.1), which funds the replacement of underground cables and conduit on a planned basis; and

- Reactive Capital (Exhibit 2B, E6.20), which funds the replacement of both overhead and underground assets on an unplanned and non-discretionary basis to restore functionality or mitigate an unsafe condition due to asset degradation, damage, or failure.

The sub-set of capital expenditures under each of these programs associated with the transferred assets are summarized in Table 2 below.

Table 2: Capital Expenditures Associated with Transferred Assets ($ millions)

Capital Program	2015	2016	2017	2018	2019
Overhead Circuit Renewal	1.9	2.1	2.5	2.3	1.5
Underground Circuit Renewal	0.4	0.4	0.3	0.4	0.5
Reactive Capital	0.4	0.4	0.4	0.4	0.4
TOTAL	**2.7**	**2.9**	**3.2**	**3.1**	**2.4**

4.2. Operations and Maintenance Programs

Four of Toronto Hydro's maintenance programs are applicable to the transferred assets. These programs are:

- Preventative & Predictive Maintenance (Exhibit 4A, Tab 2, Schedule 1), specifically the Line Patrols and Pole Inspections Segment, assesses the structural integrity of transferred street lighting poles and identifies deficiencies with overhead plant that may raise unacceptable safety and system reliability risks;
- Corrective Maintenance (Exhibit 4A, Tab 2, Schedule 2), undertakes the permanent repair and remediation of overhead and underground assets such as conductors and cables that have deteriorated or are defective as identified during

the normal course of operations (e.g., Line Patrols and Pole Inspections);

- Emergency Maintenance (Exhibit 4A, Tab 2, Schedule 3), specifically the Grid Response or Significant System Disturbance Segment, responds to emergency conditions such as downed conductors, immediate asset failures, and situations that pose significant safety risks; and
- Customer-Driven Work (Exhibit 4A, Tab 2, Schedule 7), specifically the Damage Prevention Segment, conducts locates upon request from property owners and contractors.

The sub-set of operational expenditures under each of these programs associated with the transferred assets are summarized in Table 3 below. /C

Table 3: Operational Expenditures Associated with Transferred Assets ($ millions) /C

Operational Program	2015
Preventative & Predictive Maintenance	0.1
Corrective Maintenance	1.6
Emergency Maintenance	0.2
Customer-Driven Work	1.7
TOTAL	**3.7**

5. REVENUE REQUIREMENT AND COST ALLOCATION

The revenue requirement consequences of the utility's proposal to incorporate the street lighting assets into the utility's rate base effective January 1, 2015 are summarized in Table 4 below. /C

Table 4: Revenue Requirement from Streetlighting Assets ($ millions)

Revenue Requirement Component	2015 Test Year
NBV of Assets – opening	39.8
NBV of Assets – closing	39.1
Average NBV	39.5
Working Capital Allowance	0.2
Streetlighting Ratebase	**39.7**
OM&A	3.7
Cost of Capital	2.5
Depreciation	1.6
PILS	0.3
Service Revenue Requirement	**8.1**
Revenue Offset – Contract Revenue	8.1
Base Revenue Requirement	**0.0**

5.1. Revenue Offset

Under existing agreements between TH Energy and the City of Toronto, TH Energy receives service fees for the maintenance and operation of the street lighting assets. Given the transfer of a portion of these assets into Toronto Hydro's rate base as distribution assets, Toronto Hydro proposes to allocate a portion of the revenue that it expects to receive to exactly offset the revenue requirement impacts arising from the transfer. Consequently, there is no overall change to the Base Revenue requirement for 2015 as a result of these assets being transferred into the utility's rate base.

5.2. Cost Allocation

For the purposes of Cost Allocation, Toronto Hydro has allocated all of the costs associated with the transfer of the streetlighting assets to a combination of the Street lighting rate class and the Unmetered Scattered Load ("USL") rate class. No other rate

class is affected by the transfer. This is the same treatment proposed by Toronto Hydro in the Streetlighting Transfer Application.

Between the two classes – Streetlighting and USL – the additional costs related to the transfer were allocated 95% / 5% to these classes, respectively. USL attracts some of the costs as the assets being transferred have in some cases served USL loads. Toronto Hydro's best estimate, based on informed judgment, is that 5% is a reasonable allocation to this class.

The revenue offset of $8.1 million is however allocated 100% to the Streetlighting class. /C Toronto Hydro submits that this is an appropriate allocation because the revenue offset is based on the contract with the City of Toronto to service the street lighting assets.

Assignment	1
Scope	3
Background	4
Summary of Findings and Conclusions	6
Question 1	8
Question 2	15
Appendix A	20
Appendix B	21

Assignment, Scope and Background

Assignment

1. Toronto Hydro Electric Systems Inc. ("THESL"), Toronto Hydro Energy Services Inc. ("THESI"), and 1798594 Ontario Inc. ("NewCo"), are all wholly owned subsidiaries of Toronto Hydro Corporation ("Toronto Hydro" or "the Company"). The City of Toronto ("the City") is Toronto Hydro's sole shareholder.

2. THESL owns and operates an electricity distribution system which delivers electricity to approximately 730,000 customers located in the City of Toronto. It is the largest municipal electricity distribution company in Canada and distributes approximately 19% of the electricity consumed in Ontario.

3. THESL is regulated by the Ontario Energy Board ("OEB") which regulates the province's electricity and natural gas sectors in the public interest.

4. THESL has filed a proposed rate application (EB-2014-0116) with the OEB which includes a revised purchase price for certain street lighting assets which THESL purchased from its unregulated affiliate, THESI on January 1, 2012 (the "Current Proposal"). Please refer to the background section of this report for further information on the original application and sequence of transactions.

5. Tory's LLP has engaged us, PricewaterhouseCoopers LLP ("PwC", "us" or "we"), to prepare a report to be used as evidence in the Current Proposal.

6. This report was prepared for the purpose of the rate application (EB-2014-0116) relating to the proposed 2015 distribution rates. Specifically, we have been asked to provide our opinion on the following two questions:

    1) Is the revised detailed analysis prepared by Toronto Hydro of the value of former street lighting assets to be included in rate base determined using a reasonable method of calculating the depreciated historical cost of such assets?

2) Does the revised method used to value the former street lighting assets provide a better proxy for the depreciated historic cost of the assets than was provided to the OEB at the time of the August 2011 decision?

7. This report has been prepared by Ken Goodwin to best of his knowledge, acting independently and objectively. A copy of Mr. Goodwin's credentials have been attached as Appendix A.

Scope

8. In preparing our report, we have reviewed relevant documents and relied upon their accuracy and completeness, including the following:

"Toronto Hydro Corporation – Street & Expressway Lighting Network – Estimate of Fair Market Value" prepared by Deloitte as at October 31, 2005;

OEB decision and orders dated February 11, 2010 (the "February Decision") and August 3, 2011 EB 2009-0180, EB 2009-0181, EB 2009-0182 and EB 2009-0183; (the "August Decision")

Additional evidence filed in EB 2009-0180, EB 2009-0181, EB 2009-0182 and EB 2009-0183 on January 31, 2011;

"Allocation of Street Lighting Assets for the Purpose of the Asset Transfer in 2011/2012" Provided by: Toronto Hydro to PWC on July 12, 2014;

Amended and Restated Asset Purchase Agreement between 1798594 Ontario Inc. and Toronto Hydro Energy Services Inc. (executed December 29, 2011);

Revised Purchase and Sale Agreement (with updated price) between THESI and THESL (dated October 10, 2012);

ValuQuest Street Lighting and Expressway Lighting Assets Valuation Report for Toronto Hydro-Electric System Ltd. and 1798594 Ontario Inc. as at November 1, 2010 (Issued December 1, 2010) (the ValuQuest Study);

Kinectrics Inc. Report No: K-418021-RA-0001-R002 – Toronto Hydro Electric System Useful Life of Assets (dated August 28, 2009); and

Interviews and discussions with Toronto Hydro management.

Background

9. We understand that all of the City's street lighting assets were sold to THESL's unregulated affiliate THESI, at a purchase price of $60 million in December 2006 (the "Acquired Assets"). We further understand that this purchase price was arrived at using a discounted cash flow analysis.

10. In 2009, three Toronto Hydro subsidiaries, THESL, THESI and NewCo filed applications with the OEB seeking approval for the Acquired Assets to be included in THESL's distribution system as defined by the Ontario Energy Board Act, 1998, S.O. 1998, c.15 (schedule B) (the "Act"). The applications collectively sought a declaration by the Board that streetlighting assets owned by THESI in the City of Toronto (the "SEL System Assets"), are deemed to be a distribution system and, ultimately, to make those assets part of a new amalgamated distribution company consisting of THESL and NewCo.

11. The OEB issued a decision in February 2010[1] (the "February Decision") which stated that THESL may only transfer street light assets which can be specifically identified as assets which are used to convey electricity at voltages of 50 kilovolts or less and meeting the specific criteria as set out in the February Decision (the "Distribution Assets"). The OEB also stated that that a valuation must be provided supporting the value of the Distribution Assets.

12. In January 2011, THESL submitted evidence[2] to respond to the OEB's request (the "Additional Evidence" or the "Original Application"). The evidence included an enumeration of all street lighting assets on public property including the characteristics required to classifiy the assets as Distribution Assets. This information was based on a detailed inventory count performed by a third party (the "Inventory Count"). The evidence also included a third party valuation of all street lighting assets purchased from the City using a depreciated replacement cost ("DRC") methdology (the "ValuQuest Study")[3].

13. In the period between the purchase of the Acquired Assets from the city in December 2006 and the submission of the Additional Evidence, THESI made additions to the street lighting assets (the "Additions") to meet the needs of the City. In addition, depreciation was recorded for both the Acquired Assets and the Additions (the

[1] EB-2009-0180, 0181, 0182, 0183, Decision and Order to Toronto Hydro-Electrical System Limited et al (February 11, 2010) Page 6 - 12
[2] EB-2009-0180, 0181, 0182, 0183, Additional Evidence Regarding The Transfer of Streetlighting Assets (January 31, 2011)
[3] EB-2009-0180, 0181, 0182, 0183, Additional Evidence Regarding The Transfer of Streetlighting Assets (January 31, 2011) Page 23 - 109

"Total Assets"). At the time of the submision of the Additional Evidence the net book value (the "NBV") of all street lighting assets in the books of THESI was $63.5 million[4].

14. The Inventory Count and the ValuQuest Study[3] were used by Toronto Hydro to determine what portion of the Total Assets' NBV of $63.5 million qualified as Distribution Assets. This resulted in $29.4 million of the Total Assets' NBV qualifying as Distribution Aseets which was included in the Additional Evidence. However, the OEB and the Intervenors challenged the amount of handwells and pole foundations to be included into the rate base, and Toronto Hydro agreed to reduce the transfer of Pole Foundations by 10%[5], hence the final approval from the OEB was $28.938 million of the Total Assets qualified as Distribution assets in the August Decision. This amount was then used as a basis of the transfer price on January 1, 2012 (the "Date of Transfer").

15. We understand that in 2012 THESL determined that the $28.938 million used as the transfer price for the Distribution Assets between THESI and THESL did not accurately reflect the actual NBV of the Distribution Assets and that further analysis was required.The Purchase and Sale Agreement between THESI and NewCo dated December 29, 2011 provided a provision to adjust the purchase price within 180 days of closing date. On October 10, 2012, the purchase price was adjusted to $42.473 million. As such, THESL submitted the Current Proposal detailing a revised methology to calcuate the transfer price of the Distribution Assets.

[5] EB-2009-0180, 0181, 0182, 0183, Decision and Order to Toronto Hydro-Electrical System Limited et al (August 3, 2011) Page 11 - 15

Summary of Findings and Conclusions

16. Based on our knowledge, experience and analysis, and subject to the Scope of Review and Restrictions and Qualifications noted herein, our findings and conclusions in respect of the two questions posed in this report are outlined below:

Question 1:

17. Based on our understanding, depreciated historic cost ("DHC") should reflect the actual cost incurred in the acquisition and construction of the subject assets adjusted for depreciation. The Distribution Assets should be reported at DHC to ensure that THESL is appropriately compensated at the regulated rate of return for the investment made on its assets.

18. The following three-step approach was used to determine the value of the Distribution Assets as follows:

    Classification of the Total Assets into asset classes;

    Valuation of each individual asset class; and

    Allocation of the Total Assets into Distribution and Non-Distribution Assets.

19. The detailed classification of the Distribution assets was performed based on two asset groupings, further broken down into 6 asset classes. The assets were then categorized by age based on the Inventory Study.

20. The valuation methodology utilized in the Current Proposal relies on actual costs, where available, and depreciation details to estimate the DHC for the Additions. With respect to the Acquired Assets additional analysis was performed by allocating said assets into groups based on age, determining the standard replacement cost of the individual assets and deflating those costs based on the Consumer Price Index and depreciating the asset over its service life.

21. Based on our knowledge, experience and review of the detailed analysis, it is our view that Toronto Hydro utilized a reasonable method of estimating DHC in order to determine the value of the former street lighting assets and to identify the value of the assets eligible to be transferred from THESI to THESL and be included into the rate base.

Question 2:

22. We note from our review and analysis that there are differences in the approach used to value the Distribution Assets in the Original Application and the Current Proposal, however the underlying data is consistent as it relies upon the Inventory Study, the ValuQuest Study and the NBV in Toronto Hydro's books and records.

23. Based on our review, we noted that the Current Proposal incorporates a more detailed approach to estimating DHC.

24. Specifically the Current Proposal reflects actual costs borne by Toronto Hydro for the Additions and detailed analysis was undertaken to estimate the historic cost of the Acquired Assets as described above. Further, the Current Proposal considers the installation date of the Distribution Assets which was not contemplated in the Original Application.

25. Finally, the Original Application did not take construction work-in-progress (CWIP) into consideration, whereas the Current Proposal does.

26. Based on our knowledge, experience and review of Toronto Hydro's analysis, it is our view that revised methodology used to value the former street lighting assets provides a better proxy for the DHC of the assets than was provided to the OEB at the time of the August 2011 Decision.

Analysis and Findings

Question 1

"Is the revised detailed analysis prepared by Toronto Hydro of the value of former street lighting assets to be included in rate base determined using a reasonable method of calculating the depreciated historical cost of such assets?"

Depreciated Historic Cost

What is Depreciated Historic Cost?

27. In the context of the street lighting assets, DHC reflects the actual cost incurred in the acquisition and construction of the Total Assets less depreciation.

28. The ValuQuest Study submitted in the January 31, 2011 filing[3] utilized DRC to value the Total Assets. Per the ValuQuest Study, DRC considers the cost to reproduce or replace and install the assets being appraised. Per the Additional Evidence[6], DRC was used due to the fact that "a conventional historic- cost valuation of the assets in question was not and could not be made available" and "DRC yields a result which most closely approaches the Board's requirement for 'an asset valuation to be prepared for the physical assets' "

29. As stated in the Additional Evidence[7], "A significant conceptual difference between these two approaches is that the DRC method adopts (as it must) the current replacement cost as the basis for the calculation, whereas historical cost accounting naturally reflects a lower nominal historical acquisition cost since that is built up over time as equipment is acquired, and partially reflects lower nominal acquisition costs prevailing several decades ago without the effect of intervening inflation".

[6] EB-2009-0180, 0181, 0182, 0183, Additional Evidence Regarding The Transfer of Streetlighting Assets (January 31, 2011) Page 16 - 17
[7] EB-2009-0180, 0181, 0182, 0183, Additional Evidence Regarding The Transfer of Streetlighting Assets (January 31, 2011) Page 17

Why is DHC important?

30. As stated in the February Decision[8] and the August Decision[9], the amount to be included in rate base should be based on physical valuation of the assets and not a revenue-based fair market value approach. Further, in the Additional Evidence[10] THESL indicated that they seek to transfer an amount no greater than the actual net book value of the eligible distribution assets.

31. Regulated assets need to be reported at DHC to reflect the real cost borne by the organization in order to ensure that the organization is appropriately compensated at the regulated rate of return for the investment made on its assets.

Toronto Hydro's Revised Detailed Analysis

Overview

32. Toronto Hydro used the following three step approach to determine the value of the Distribution Assets:

    1) Classification of the Total Assets into asset classes;
    2) Valuation of each individual asset class; and
    3) Allocation of the Total Assets into Distribution and Non-Distribution Assets.

Classification of the Total Assets into asset classes

33. Using the Inventory Study, the Company organized the Total Assets into asset classes (and installation year, if applicable and where available) in order to consider the purpose, functionality or intended use of the assets.

34. To this end, Total Assets were organized into the two main asset classes qualifying as Distribution Assets per the February Decision[11] (i.e. Poles and Conductors). The assets within these two categories were then further disaggregated in order to allow Toronto Hydro to determine if a particular asset met the Distribution Asset criteria per the February Decision[11]. This process resulted in the identification of the following six asset classes:

[8] EB-2009-0180, 0181, 0182, 0183, Decision and Order to Toronto Hydro-Electrical System Limited et al (February 11, 2010) Pages 16, 19
[9] EB-2009-0180, 0181, 0182, 0183, Decision and Order to Toronto Hydro-Electrical System Limited et al (August 3, 2011) Page 12 - 13
[10] EB-2009-0180, 0181, 0182, 0183, Additional Evidence Regarding The Transfer of Streetlighting Assets (January 31, 2011) Page 15
[11] EB-2009-0180, 0181, 0182, 0183, Decision and Order to Toronto Hydro-Electrical System Limited et al (February 11, 2010) Pages 7 - 12

1) "Poles", including:

   Poles;

   Handwells; and

   Pole Foundations.

2) "Conductors", including:

   Conduits;

   Overhead Lines and Feeders; and

   Underground Lines and Feeders.

35. There are two additional asset categories described in the February Decision, Streetlight Brackets and Conductors on Streetlight Brackets (including luminaires) and Expressway Lighting[11], which do not qualify as Distribution Assets and therefore were not considered by Toronto Hydro in the Current Proposal.

Valuation of each individual asset class

36. Asset valuation, in this context, refers to the process of estimating the DHC for each of the six asset classes noted above. We understand the asset valuation process was performed for both the Acquired Assets and the Additions.

Acquired assets

37. We understand based on discussions with Toronto Hydro management, and as stated in the August Decision, that the detailed historic cost information (by asset class and the year installed) of the Acquired Assets is not available. As such, an alternative approach was required to determine an estimate of the DHC of the Acquired Assets for the purpose of the Current Proposal.

38. We understand Toronto Hydro has utilized different approaches to estimate the DHC depending on the asset class and information available. A summary of the approaches by asset class follows below:

Poles, Handwells and Pole Foundations

39. In 2006, all poles, handwells, and pole foundations acquired as part of the transaction with the City were recorded as a single asset class named "poles, towers, fixtures" to which $24.5 million of the $60 million acquisition price was attributed.

40. The Inventory Study provided Toronto Hydro with physical information and installation year for each of the Acquired Assets in this class. The DHC of the Acquired Assets in this class was determined using the multi-step process described below.

Allocate Assets by Vintage Band

41. The first step was to allocate the Acquired Assets by age. Specifically, Toronto Hydro allocated the Acquired Assets into five year age bands ("Vintage Bands") ranging from 1971 to 2005, using the information in the Inventory Study. Each Vintage Band was designated and identified by the mid-point of the band (e.g. Assets installed between 1976 and 1980 would be designated as "1978 assets" for the purpose of this exercise).

Determine 2010 standard cost

42. The next step was to apply a standard cost per asset to the historic asset quantity in each Vintage Band. The standard cost was determined using the 2010 standard costs provided in the ValuQuest Study[3].

Calculate standard cost by installation year

43. In order to apply standard costs to historical quantities, Toronto Hydro deflated the current 2010 standard cost noted above, using 2010 Consumer Price Index rate, to the mid-points of each Vintage Band to arrive at sets of deflated standard costs for each Vintage Band.

Depreciate deflated standard cost

44. The final step in the process was to determine the accumulated depreciation for each Vintage Band based on the age and remaining useful life of each respective asset. The useful life of the assets was based on a 2009 useful life study conducted by Kinectrics Inc. entitled "Toronto Hydro Electric System Useful Life of Assets"[12] (the "Kinectrics Study"). The age of the assets (in years) was estimated using the mid-point of each Vintage Band.

[12] Report: K-418021-RA-0001-R0002, Toronto Hydro Electric System Useful Life of Assets (August 28, 2009) Page 80

Conductors

45. Unlike Poles, which can be separately identified, underground/overhead lines and feeders as well as conduit (together the "conductors") are difficult to count and validate as they are not separately identifiable. As such, in order to determine the quantity and value for the conductors which qualify as Distribution Assets, Toronto Hydro started with the total NBV of all conductors as at the Date of Transfer and eliminated the two asset categories considered ineligible for inclusion as Distribution Assets, being (i) Expressway Lighting conductors and (ii) conductors which are used exclusively for street-lighting.

46. The value of the Expressway Lighting conductors was excluded using information in Table 4[13] of Appendix B of the Additional Evidence "Derivation of NBV by Asset Group and Classification".

47. Additionally, Toronto Hydro used the proportion of assets deemed as distribution from the Table 4[13] of Appendix B of the Additional Evidence "Derivation of NBV by Asset Group and Classification". The proportion which qualifies as Distribution Assets was based on the detailed count from the Inventory Study.

Additions

48. Since the acquisition of the initial portfolio of street lighting assets from the City in 2006, Toronto Hydro has constructed and acquired additional street lighting assets.

49. We understand that as new street lighting assets were constructed and installed by THESI in the period between 2006 and 2011, the Company maintained detailed records of actual costs by installation year. We further understand that the Additions were depreciated based on the Kinectrics Study[12] as follows:

    Cabling is depreciated over a life span of 40 years; and

    Poles, Civil (Handwells, Tap Box), Conductors are depreciated over a life span of 50 years.

50. Based on the information above the Company has been able to calculate the DHC of the Additions based on the actual cost and depreciation details in its books and records.

[13] EB-2009-0180, 0181, 0182, 0183, Additional Evidence Regarding The Transfer of Streetlighting Assets (January 31, 2011) Page 19

Allocation of the Total Assets into Distribution Assets and non-Distribution Assets

51. The allocation process refers to the bifurcation of the DHC for each of the six asset classes between Distribution Assets and non-Distribution Assets.

Poles, Handwells and Pole Foundations

52. Allocation rates for poles, handwells, and pole foundations were determined based on the ratio of estimated number of assets eligible for transfer to THESL and total poles, handwells and pole foundations. Eligibility of poles was determined based on the Inventory Study and the criteria set by the OEB in the February Decision.

53. These allocation rates were then multiplied by the DHC of each asset in each Vintage Band to determine the DHC value to transfer to THESL.

    The following is an illustrative example of the allocation process:

Vintage Band	DHC ($ millions) A	Total Number of Assets B	Distribution Assets C	Percentage to be Transferred D = C/B	Value to be Transferred ($ millions) E = A x D
Band 1	8	2,000	1,800	90%	7.2
Band 2	12	2,400	2,200	92%	11.0
Band 3	13	4,000	3,500	75%	9.8
Total	33	8,400	7,500	89.3%	28.0

(The numbers in the table are for illustrative purposes only and do not reflect the actual amounts filed by THESL)

Conductors

54. For conductors, an allocation rate was estimated based on the Inventory Study. Specifically, Toronto Hydro, using the Inventory Count details determined that a certain percentage of conductors were Expressway Lighting and therefore excluded from the Distribution Asset pool. Of the remaining conductor assets, a further deduction was made to remove the percentage of conductors used exclusively for street lighting. The remaining percentage was determined to represent conductors which qualify as Distribution Assets.

55. The conductor allocation percentage was then applied to the total conductor DHC to arrive at the conductor DHC eligible for distribution which was included in the Current Proposal.

56. We understand the conductor allocation percentages remain unchanged from the Additional Evidence which was accepted by the OEB in the August decision.

Construction work-in-progress

57. In addition to the acquired and constructed assets discussed above, Toronto Hydro also included CWIP balances that qualify as Distribution Assets in the Current Proposal. To the extent possible, Toronto Hydro used the construction and capitalization records, which include actual costs, to identify which CWIP assets qualify as Distribution Assets based on the criteria set out in the February Decision. For the remaining CWIP, Toronto Hydro has applied an assumed percentage of Total Assets which qualify as Distribution Assets based on the processes described above.

Conclusion

58. Based on our knowledge, experience and review of the detailed analysis noted above, and subject to the Scope of Review and Restrictions and Qualifications noted herein, it is our view that Toronto Hydro utilized a reasonable method of calculating DHC in order to determine the value of the former street lighting assets to identify the value of the assets eligible to transfer from THESI to THESL and therefore be included into the rate base.

Question 2

"Does the revised method used to value the former street lighting assets provide a better proxy for the depreciated historic cost of the assets than was provided to the OEB at the time of the August 2011 decision?"

59. The methodology used to determine the transfer price of the street lighting assets in the Current Proposal has been summarized in Question 1. The response to this question will focus on the methodology used in the Original Application and the key differences between the two methodologies.

Methodology used in the Original Application

60. We understand the estimate of the transfer price of the Distribution Assets which was included in the Original Application was based on the following three pieces of information:

    1) The ValuQuest Study[3];
    2) The Inventory Study; and
    3) The total net book value of all street lighting assets[13].

61. There were no changes in the ValuQuest Study and the Inventory Study between the two applications. The NBV was adjusted to the date of the Current Proposal based on additions and depreciation during the period between the applications.

62. The classification of the assets into asset classes in the Original Application was based primarily on the ValuQuest Study. Specifically, Toronto Hydro used the DRC of each asset class per the ValuQuest study[3] and divided it by the total DRC of all street lighting assets to determine the DRC percentage by asset class[13]. The DRC percentage by asset class was then applied to the NBV of the Total Assets to arrive at the estimated transfer value by asset class.

63. The estimated DHC by asset class was then allocated between Distribution Assets and non-Distribution Assets. We understand the allocation methodology for conductors was consistent between the Original Application and the Current Proposal. With respect to the Poles, the Original Application determined the Distribution

allocation percentage using the total number of poles which met the distribution criteria in the February Decision[11] using the Inventory Study, divided by the total number of poles. We further understand that the installation date of said poles was not considered in arriving at the allocation percentage.

Key differences between the Original Application and the Current Proposal

64. Both applications were derived from the same sources of information being the ValuQuest Study, the Inventory Count and the NBV of the street lighting assets in THESI's books and records.

65. A significant conceptual difference between the Original Application and the Current Proposal is the reliance on DRC versus DHC as the basis for the valuation of the Distribution Assets. Both methods consider and incorporate the concept of depreciation. However, as previously stated, the starting point for DHC is the cost of the asset at the time of acquisition whereas the starting point for the DRC is the current cost of replacement.

66. The table below summarises the differences in approach used in the Original Application as compared to the Current Proposal.

	Original Application	Current Proposal
Classification	Considers the asset classes as required in order to determine the purpose, functionality or intended use of the assets and meet the OEB criteria.	Considers the asset classes as required in order to determine the purpose, functionality or intended use of the assets and meet the OEB criteria; and Considers classification into Vintage Band or, where available, installation year.
Valuation	Uses DRC per the ValuQuest Study as the basis for the valuation; and DRC is decreased to NBV based on a	Uses actual NBV by asset class and installation date where available (the Additions);

	Original Application	Current Proposal
	percentage of the DRC by asset class applied to the NBV of the Total Assets.	Estimates the historic cost for Acquired poles using the standard cost per the ValuQuest Study adjusted for inflation; Calculates the depreciation for the Acquired poles based on the Kinectrics Study and Vintage Band; Uses the purchase price for the Acquired conductors at the Date of Transfer adjusted for depreciation; and Includes a value for CWIP based on the actual books and records.
Allocation	Uses the Inventory Count to identify the percentage of poles which meet Distribution criteria; and Uses the information in the ValuQuest Study to exclude the Expressway Lighting conductors and conductors used only for street lighting.	Uses the Inventory Count by Vintage Band or installation year to identify the poles which meet the Distribution criteria where available; Uses the information in the ValuQuest study to exclude the Expressway Lighting conductors and conductors used only for Street Lighting; and Allocates CWIP to Distribution Assets based on completed construction and cost information, where available, uses an allocation percentage for the remainder.

67. Using the date of installation either by year or Vintage Band allows Toronto Hydro to perform the second two steps in their process at a more detailed level.

68. There is different information available for the Additions and the Acquired Assets therefore separating these two groups allows THESL to refine the calculations to utilize the best information available for each category of asset.

69. The Original Application estimated a deflated value of the Total Assets through the process of allocation the DRC to the NBV at the Date of Transfer on a total basis. The cost of the Acquired assets used in the Current Proposal is a better proxy of the historic cost due to the fact that the replacement cost is deflated to the mid-point of the Vintage band. Further this process is performed only for the Acquired Assets as the actual cost of the Additions is known.

70. Cost and depreciation details are readily available for the Additions. The Current Proposal incorporates actual historical costs and depreciation which is the most reflective method of calculating DHC. The Original Application applied an estimate using the process described above.

71. The inclusion of the CWIP in the Current Proposal also provides a holistic view of all distribution assets that may be deemed transferrable to THESL.

72. In the Current Proposal, Toronto Hydro performed the Allocation to Distribution Assets of the pole assets (i.e. poles, handwells, foundations) by Vintage Band and installation year rather than the high level allocation rate used in the Original Application. As such the allocation in the Current Proposal provides a better proxy of assets eligible for transfer to THESL.

Conclusion

73. Based on our knowledge, experience and review of the detailed analysis noted above, and subject to the Scope of Review and Restrictions and Qualifications noted herein, it is our view that revised methodology used to value the former street lighting assets provides a better proxy for the DHC of the assets than was provided to the OEB at the time of the August Decision.

Respectfully submitted,

Restrictions and Qualifications

We understand that this Report and related appendices are intended to be tendered into evidence by THESL in EB-2014-0116 and solely for the purposes described in the Assignment section. The release of this Report, in whole or in part, to any party outside of this proceeding will require our prior written consent. We do not assume any responsibility or liability for losses incurred by any party as a result of the circulation, publication, reproduction or use of this Report contrary to the provisions of this paragraph.

We caution that the calculations, estimates and statements made in this Report are based solely on the information reviewed and communicated to us to date. We reserve the right to review all calculations, estimates and statements made or referred to in this Report and, if we consider it necessary, to revise our Report in light of any relevant information that becomes known to us after the date of this Report.

Our Report and related analysis must be considered as a whole. Selecting only portions of the analysis or the factors considered by us, without considering all factors and analysis together, could create a misleading view of our findings. The preparation of our analysis is a complex process and is not necessarily susceptible to partial analysis or summary description. Any attempt to do so could lead to undue emphasis on any particular factor or analysis.

Our review does not constitute an audit as defined by Canadian generally accepted auditing standards. The primary sources of information reviewed and relied upon are referred to in the Scope of Review section of this report. We have indicated the sources of factual information relied upon. Unless otherwise noted, we have not sought external verification of the information provided by Toronto Hydro or other sources as listed.

Our analysis is financial in nature. We make no representation regarding questions of legal interpretation.

The individuals that prepared this report did so to the best of their knowledge, acting independently and objectively in accordance with Rule 13A of the OEB's Rules of Practice and Procedure.

PwC's compensation is not contingent on an action or event resulting from the use of this Report.

Toronto Hydro Street Lighting Assets

September 23, 2014

Assessment of the valuation methodology used by Toronto Hydro in EB-2014-0116 - Addendum

Introduction

A-1 PricewaterhouseCoopers LLP ("we", "us" or "PwC") was previously engaged by Tory's LLP on behalf of Toronto Hydro-Electric Systems Limited (Toronto Hydro) to author a report entitled "Toronto Hydro Street Lighting Assets; Assessment of the valuation methodology used by Toronto Hydro in EB-2014-0116" (the "Report") dated July 28, 2014. The Report provided an opinion on whether Toronto Hydro's analysis in support of its rate application EB-2014-0116 was a reasonable method of calculating depreciated historic cost ("DHC") of street lighting assets and whether the method provided a better proxy of the depreciated historic cost of the street lighting assets than that used by Toronto Hydro in support of the OEB decision related to filings EB-2009-0180, EB-2009-0181, EB-2009-0182 and EB-2009-0183 dated August 3, 2011 (the "August 2011 Decision").

A-2 Subsequent to issuing the Report, management of Toronto Hydro ("Management") informed us that better aging information for poles, handwells and pole foundations had come to their attention. Management has represented that this new aging information is better data than that used in support of the EB-2014-0116 application which was the basis of the Report.

A-3 The purpose of this addendum is to discuss the impact of this new information on the methodology employed and the resulting DHC estimate of the street lighting assets.

Original Aging Information

A-4 Management has represented to us that the original aging information related to poles, handwells and foundations used in the EB-2014-0116 application was from Toronto Hydro's Geo-Spatially Enabled Asset Registry ("GEARS") database.

A-5 This database contains a cataloge of the street lighting and expressway lighting assets by the asset's location, condition and other parameters necessary to properly classify the assets according to the terms of OEB decision related dto filings EB-2009-0180, EB-2009-0181, EB-2009-0182 and EB-2009-0183 dated February 11, 2010.

A-6 We understand that within the GEARS database a significant percentage of the poles had no installation date and were assumed by Management to have been installed prior to 1971, resulting in the majority of the poles having an assigned age greater than 40 years. Similarly the aging information for the handwells and foundations suggested that the majority of these asset categories were installed prior to 1971.

Revised Aging Information

A-7 The revised aging information is based on Toronto Hydro's Optimal Investment Portfolio ("OIP") study, which was conducted in 2004 to assess the vintages of all major assets in Toronto Hydro's system. We understand this information was also used to implement IFRS-consistent changes related to the manner in which Toronto Hydro accounts for it's assets. Specifically, the study assisted Toronto Hydro in attributing an installation date to poles, handwells and foundations for which no aging information was previously available.

A-8 The OIP data exists for poles, handwells and foundations for the relelvant vintage bands leading up to the original Toronto Hydro purchase of the street lighting assets from the City of Toronto (the "City") in 2006. The aging analysis is only necessary for pre-2006 assets as detalied records have been maintained for all assets installed subsequent to the initial purchase from the City.

Imapact of Revised Aging Information on Methodology

A-9 Toronto Hydro has informed us that no changes have been made to the methodology used to calculate DHC as described in EB-2014-0116 and that Management has recalculated the DHC estimates of the street lighting assets using the new aging information.

A-10 We have obtained the revised analysis and discussed the application of the methodology with Management and note that the methodology appears to have been applied in a manner consistent with that outlined in the Report.

Conclusion

A-11 As a result of the foregoing, and subject to the Restrictions and Qualifications noted in the Report, without commenting on the inputs and data used, we maintain our view that Toronto Hydro utilized a reasonable method of calculating DHC in order to determine the value of the former street lighting assets and that the methodology is a better proxy than that provided to the OEB at the time of the August 2011 Decision.

CAPITAL EXPENDITURES

In accordance with the OEB's Chapter 5 Filing Requirements, Toronto Hydro has filed a consolidated Distribution System Plan ("DSP") at Exhibit 2B. In this schedule, Toronto Hydro files OEB Appendix 2-AA (Capital Projects Table) and OEB Appendix 2-AB (Capital Expenditures Summary), as required by s. 2.5.5.2 of the OEB's Filing Requirements. In accordance with the Filing Requirements, this schedule also provides:

- a description of the proposed accounting treatment for projects that have a lifecycle greater than one year, including the treatment of the cost of funds; and
- the components of other capital expenditures, including a reconciliation of all capital components to the Total Capital Budget.

1. OEB-Required Appendices (2-AA and 2-AB)

Appendices 2-AA and 2-AB, which are filed at Exhibit 2A, Tab 6, Schedules 2 and 3, provide an overview of Toronto Hydro's capital expenditures from 2010 to 2019, by program and by investment category, respectively.

To maximize the usefulness of these appendices, Toronto Hydro mapped its historical and future capital expenditures to the investment categories, and programs presented in the DSP. Capital expenditures associated with historical programs that could not be mapped to an existing DSP program are only presented in the 2010 to 2014 timeframe, as applicable. Written variance explanations of Toronto Hydro's capital expenditures are provided at Exhibit 2B, Section E4.

Toronto Hydro's last rebasing application (EB-2010-0142) was settled, and the Settlement Agreement, which was approved by the OEB, reflected a reduction in capital expenditures of $119.2 million for the 2011 test year.[1] As a result, Toronto Hydro is

[1] EB-2010-0142, Partial Decision and Order (July 7, 2011) at pages 2 and 3 and at section 4.2 of the Settlement Agreement (Appendix C to the Partial Decision and Order).

unable to provide a granular variance analysis of actuals versus OEB-approved amounts. On a total basis, Toronto Hydro's 2011 OEB-approved capital expenditures were $378.8 million, and its actual capital expenditures were $445.5 million.

2. PROPOSED ACCOUNTING TREATMENT RE PROJECTS WITH A LIFE CYCLE GREATER THAN ONE YEAR

Some of Toronto Hydro's capital projects have a project life cycle greater than one year. Where large projects span multiple years, the construction costs are recorded in construction work in-progress ("CWIP") accounts until they are in-service. Under Canadian Generally Accepted Accounting Principles ("CGAAP") and United States Generally Accepted Accounting Principles ("USGAAP"), projects with a construction duration of greater than six months include a financing charge in the cost of assets capitalized. The financing charge is at the interest rate published quarterly by the OEB for CWIP. Under Modified International Financial Reporting Standards ("MIFRS"), projects expected to exceed a duration of greater than six months include a financing charge in the cost of assets capitalized. The interest rate used to calculate the financing charge for MIFRS is Toronto Hydro Corporation's weighted average cost of borrowing.

3. COMPONENTS OF CAPITAL EXPENDITURES

Toronto Hydro's capital expenditures under the Other Capital Expenditures investment category include engineering capital, roads, allowance for funds used during construction, inflation and miscellaneous, all of which are summarized below.

3.1. Engineering Capital

Engineering capital represents labour costs that are capitalized although they are not directly attributable to specific distribution system assets or projects. These costs consist of the labour costs of engineers, technologists, design technicians and power system controllers ("PSCs") for engineering, design and planning work that they perform on

distribution assets that are put in-service. Such planning and design work is non-discretionary and is critical to Toronto Hydro's ability to complete capital work as it continues its focus on the following key areas: the capital investment program to address aging equipment and legacy infrastructure, development and implementation of new approaches for engineering decision support for creation and optimization of capital programs, and modernization through new technologies and systems. Engineering capital expenditures are only included in Other Capital Expenditures from 2010 to 2011. From 2012 onwards, these costs were integrated with capital investment programs, and this is captured in the reduction of costs within this category from 2011 onwards to 2012.

3.2. Historical Road Cut Repairs

When Toronto Hydro installs equipment in the ground it generally must disturb the environment around the job site (such as sidewalks and roadways). Temporary repairs to the property are done when the utility completes construction. This is required to make the area safe for the public and provide continuity of the surface with the surrounding area. Permanent repairs are made later by contractors engaged by the City of Toronto, usually anywhere from one to four years after Toronto Hydro has completed construction. At that time, Toronto Hydro is invoiced at for the cost of the restoration work. The timing of these repairs is generally out of the utility's control. Most jobs tend to get tendered by the City anywhere from 18 to 30 months after job completion. As a result of the outstanding costs for road cut repairs related to historical jobs, Toronto Hydro continues to receive and be legally obligated to pay invoices for repairs for road cuts dating back as far as 30 months. Any variance between the historical estimated repair cost and actual City invoice represents an obligation to the City of Toronto, pursuant to its authority over highways (public roads) under sections 32 and 33 of the City of Toronto Act, 2006[2].

[2] S.O. 2006, C. 11, Sched. A, at sections 32-33 ["City of Toronto Act"]

3.3. Allowance for Funds Used During Construction (AFUDC)

The Accounting Procedures Handbook, Article 490, allows the utility to capitalize an allowance for funds used during construction ("AFUDC"). The AFUDC rate applied by Toronto Hydro for 2010 to 2013 actuals and 2014 forecast is based on the OEB-prescribed rate. The forecasted 2015 capital expenditures are based on MIFRS and thus include AFUDC calculated based on Toronto Hydro's weighted average cost of debt.

3.4. Inflation

From 2016 onwards to 2019, inflation costs at 2.07% per year, consistent with the Statistic Canada Consumer Price Index ("CPI") for Toronto,[3] are also included within this category.

3.5. Miscellaneous

Miscellaneous capital expenditures primarily include pre-capitalized inventory and major tools. Capital expenditures related to pre-capitalized inventory is dependent on the change in capital inventory levels year over year. Toronto Hydro invests in major tools and testing equipment to allow employees to continue to complete work effectively and efficiently. The utility invests in major tools on an ongoing basis to replace worn or broken tools, and as required to install, commission and maintain new technologies. These are regular utility expenses that are essential to being able to perform necessary capital and maintenance work.

CAPITALIZATION POLICY

This schedule addresses section 2.5.2.3 of the OEB's Filing Requirements for Electricity Distribution Rate Applications (July 17, 2013) (the "Filing Requirements") which requires applicants to file a copy of their capitalization policies and to identify changes to their capitalization policy.

1. BACKGROUND

In 2007, Toronto Hydro commenced its International Financial Reporting Standards ("IFRS") conversion project with the intention of converting to IFRS on January 1, 2011. However, given uncertainty around the timing, scope and potential adoption of a rate-regulated accounting standard under IFRS, Toronto Hydro decided to defer the adoption of IFRS, and filed its 2011 rate application in accordance with its Canadian Generally Accepted Accounting Principles ("CGAAP") accounting practices in use at that time.

Prior to January 1, 2011, Toronto Hydro recorded depreciation and amortization on assets in accordance with the guidelines provided in the OEB's 2006 Electricity Distribution Rate Handbook ("EDRH"). The use of the guidelines was permitted under the CGAAP as the prescribed useful lives represented "estimated service lives" of assets under the regulatory framework.

Effective January 1, 2011, following a detailed review of the useful lives analyses conducted by Kinectrics and other third-parties for Toronto Hydro for the purposes of the IFRS conversion, the utility implemented certain changes in accounting estimates related to the manner in which it records and accounts for its property, plant and equipment ("PP&E").[1] Although Toronto Hydro decided to defer the adoption of IFRS, it determined that these changes were required to be applied under CGAAP as additional and more relevant information had been made available.

[1] EB-2010-0142, Application and Evidence (February 9, 2011) at Exhibit Q1, Tab 2, Schedule 7-2; and EB-2010-0142, Partial Decision & Order, (July 7, 2011) at page 41.

These changes in the estimates of useful lives of assets were reflected in the corresponding depreciation and amortization balances in Toronto Hydro's financial statements effective January 1, 2011, and in its last rebasing application (EB-2010-0142).[2] Toronto Hydro's external auditor acknowledged the appropriateness of the changes in accounting estimates effective January 1, 2011 under CGAAP,[3] and the Ontario Energy Board ("OEB") approved, for rate-making purposes, the depreciation and amortization expense that resulted from these changes effective May 1, 2011.

On July 21, 2011, the Ontario Securities Commission ("OSC") granted Toronto Hydro an exemption to prepare its financial statements in accordance with USGAAP for its fiscal years beginning on or after January 1, 2012, but before January 1, 2015. Toronto Hydro adopted USGAAP for financial reporting and rate-making purposes effective January 1, 2012.

On March 19, 2014, the Board of Directors approved the adoption of IFRS for the year beginning on January 1, 2015 due to the pending expiration of the above exemption.

On June 23, 2014, Toronto Hydro presented the IFRS policies to its Audit Committee. Once the IFRS policies are approved by the Audit Committee, Toronto Hydro intends to adopt a revised Capitalization Policy.

2. CAPITALIZATION POLICY

A copy of Toronto Hydro's current capitalization policy is filed as Appendix A to this schedule. As explained above, Toronto Hydro's Audit Committee is in the process of reviewing the revised IFRS policies. Therefore, the current capitalization policy filed at Appendix A to this schedule is based on USGAAP.

[2] EB-2010-0142 Exhibit Q1, Tab 1, Schedule 1,
[3] Toronto Hydro Corporation Consolidated Financial Statements December 31, 2011

Toronto Hydro confirms that for purposes of calculating rate base for the 2015 Test Year (Exhibit 2A, Tab 1, Schedule 1), its capitalization practices conform with IFRS guidance. Toronto Hydro does not expect the new IFRS Capitalization Policy to have any material impact on its 2015 test year rate base values.

3. CHANGES TO CAPITALIZATION POLICY

With the exception of the items noted below, there are no material differences between USGAAP and IFRS capitalization practices. The incremental net impact of the items listed below to the 2015 test year rate base is $0.1 million. The following table summarizes the differences between USGAAP and IFRS.

Topic	Aspect	USGAAP	IFRS
Borrowing Costs	Applicability	Assets requiring a "period of time" to complete	Assets requiring a "substantial period of time" to complete
	Commencement Date	After inception, not retroactive	At inception, on all project spend
	Interest Rate	OEB prescribed rate	Weighted average cost of borrowing
	Calculation	Simple Interest	Compounding Interest
Assets Retirement Obligation	Discount Rate	Credit adjusted risk free rate	Risk free rate
	Presentation	Accretion Expense shown as Operating Expense	Accretion Expense shown as Interest Expense
	Timing	Legal obligation	Legal or Constructive Obligation

3 POLICY OVERVIEW

This document describes the accounting policy and specific criteria used to determine the appropriate classification of expenditures, in particular, whether expenditures should be capitalized on the balance sheet (capital assets) or expensed to operations in the period incurred (expense).

The purpose of recording expenditures as capital assets is to provide for an equitable allocation of costs among current and future periods. As capital assets are expected to provide future economic benefits for more than a year, expenditures incurred for the acquisition, construction or

development of capital assets should be capitalized and allocated over the estimated useful lives[1] of the associated capital assets in the form of amortization/depreciation. All other expenditures should be expensed in the accounting period incurred.

4 DEFINITIONS AND ABBREVIATIONS

TERM or ACRONYM	DESCRIPTION
AFUDC	Allowance for Funds Used During Construction
AP Handbook	Accounting Procedures Handbook for Electricity Distributors issued by the OEB
ASC	Accounting Standards Codification
CWIP	Construction Work In Progress
Corporation	Toronto Hydro Corporation and its affiliates
FASB	Financial Accounting Standard Board
OEB	Ontario Energy Board
On-cost	Materials handling costs
PASC	Policy Administration Steering Committee The committee members are: Chief Financial Officer VP, General Counsel & Corporate Secretary VP, Organizational Effectiveness and Environment Health & Safety VP, Information Technology and Strategic Management
PP&E	Property, Plant and Equipment
SLR	Standard Labour Rate
US GAAP	United States Generally Accepted Accounting Principles
VHR	Vehicle Hire Rate

5 SCOPE

5.1 This policy applies to Toronto Hydro Corporation and its affiliates.

6 OBJECTIVE

6.1 7R HQVXUH SURSHU FODVVLILFDWLRQ in accordance with US GAAP, and compliance with applicable regulations.

7 CRITERIA FOR CAPITALIZATION

7.1 **Asset Recognition ±Capitalization versus Expensing**

[1] Estimates of useful life are reviewed periodically and whenever events or changes in circumstances indicate that the current estimates or depreciation method are no longer appropriate. Changes in estimates are accounted for on a prospective basis.

In order to determine whether an expenditure should be capitalized or expensed, the expenditure must be evaluated based on the criteria discussed below. Subject to the threshold levels outlined in **Appendix A**, expenditures that meet the definition of an asset as well as a capital asset will be capitalized, while all remaining expenditures will be expensed. Below are the two definitions which must be met in order for an expenditure to be capitalized:

7.1.1 **Assets** are economic resources controlled by an entity from which future economic benefits may be obtained. Assets have three essential characteristics:

i) they embody a probable future benefit that involves a capacity, singly or in combination with other assets, to contribute directly or indirectly to future net cash inflows;
ii) the entity can obtain the benefit and control R W K H U V ¶ access to the benefit; and
iii) the W U D Q V D F W L R Q R U H Y H Q W J L Y L Q J U L V H W R W K H H Q W L benefit has already occurred.

7.1.2 **Capital assets** are expenditures for which the future benefits to the Corporation extend over a period greater than one year. Capital assets comprise property, plant and equipment and intangible assets. Property, plant and equipment consists typically of long-lived tangible assets used to create and distribute an H Q W L W \ ¶ V S U R G X F W V and include land and land improvements, buildings, machinery and equipment, and furniture and fixtures. Intangible assets are assets that lack physical substance.

For additional guidance, **Appendix B ±Decision Tree** illustrates the criteria that must be met in order for expenditures to be capitalized. Expenditures not meeting the criteria will be expensed in the period incurred. Additionally, **Appendix C** includes excerpts from the OEB AP Handbook outlining capital asset and expense account definitions. A review of these definitions provides practical references and examples to assist in the classification of various expenditures.

For complex transactions and when capital/operating decisions may be ambiguous, the Business Units will consult with the Finance group.

7.2 Betterments versus Repairs

When expenditures are incurred relating to existing capital assets, they should be evaluated against the criteria outlined below to determine whether the expenditure should be classified as a betterment or a repair. ***Expenditures that meet the definition of a betterment will be capitalized while expenditures that meet the definition of a repair will be expensed. If a cost has the attributes of both a repair and a betterment, the portion considered to be betterment will be included in the cost of the capital asset.***

7.2.1 **Betterments** are costs incurred to enhance the service potential of an existing capital asset. The service potential of an existing capital asset may be enhanced when:

i) there is an increase in the previously assessed physical output or service capacity;
ii) associated operating costs are lowered;
iii) the life or useful life is extended; or
iv) the quality of output is improved.

7.2.2 **Repairs** are costs incurred in the maintenance of the service potential of a capital asset. Frequently referred to as operating expenses or maintenance expenses, they are costs incurred more or less on a continuous basis to keep the capital asset in normal operating condition, but do not improve the value of the asset, nor prolong its life appreciably.

Operating expenses or maintenance expenses are the result of an activity that encompasses actions of a detective, preventive, and/or monitoring nature. They are normally planned or scheduled. They can also be reactionary, in response to an unscheduled breakdown in service function.

For those instances when professional judgement has to be exercised to determine the proper classification of the & R U S R U D W L R Q ¶ V H[SHQGLWXUH XQLW[will confirm W K H the classification as a betterment or repair with the Finance group.

8 ASSET COST COMPONENTS

8.1 Once it has been determined that an asset can be capitalized, below are the amounts that can be included in the cost of a capital asset:

i) A capital asset should be recognized at cost. Capital asset cost is the amount of consideration given to acquire, construct, develop, or better a capital asset and includes all costs directly attributable to the acquisition, construction, development or betterment of the capital assets including installing it at the location and in the condition necessary for the intended use. This would also include any borrowing costs and includes AFUDC captured in CWIP.

The AP Handbook provides for the inclusion of AFUDC when capitalizing CWIP, until such time the asset is substantially complete. The interest rate for capitalization is prescribed by the OEB and modified on a periodic basis and is applied to the eligible CWIP balance on a simple interest basis.

ii) For purchased capital assets, cost would include the purchase price and other acquisition costs, such as: broke U V ¶ F R P P L V V L R Q V L Q V W D O O D W L R Q F architectural, design and engineering fees; legal fees; survey costs; site preparation costs; freight charges; transportation insurance costs; duties; testing and preparation charges; and option costs when an option is exercised.

iii) For an electrical plant that is constructed, construction costs should include where applicable: the cost of labour; materials and supplies; transportation; work done by others for the utility; damages incurred in the construction work; privileges and permits; special machinery services; allowance for funds used during construction; and such portion of general engineering, administrative salaries and expenses, insurance, taxes and other similar items as may be properly included in construction.

8.2 Burdens

Four burden rates are specifically analyzed below with respect to the asset cost:

8.2.1 Time-sheeting of Indirect Labour

One of the methods of capitalizing labour costs is to allocate employee labour costs through the process of time-sheeting of indirect labour. Field crews are supported,

supervised and guided by those employees whose personnel costs are included in indirect labour.

The process of capitalizing costs of indirect labour includes labour costing (i.e. time-sheeting) which differentiates the time spent between capital, operating, and blend activities (i.e. a mix of capital and operating), in order to appropriately allocate costs across projects based on identified cost drivers.

Once time-sheeted hours are applied to specific activities, the calculated cost will be allocated to capital expenditures, operating expenses, or a blend of both based on the nature of the activity. Costs identified as capital or costs that are designated as capital in nature within a blend activity will be mapped to construction work-in-progress (CWIP) while costs identified as operating in nature within a blend activity will be mapped to operating expense.

8.2.2 Standard labour rate

Another method of capitalizing labour costs is to track direct labour costs for various employees and apply a SLR to time recorded to various jobs. There are three broad direct labour categories within the group of employees who currently submit time-sheets for direct labour and for whom SLRs have been calculated: inside workers, outside shift workers and outside hourly workers.

The SLRs are calculated by dividing the total employee compensation, including various types of benefits) by the total available hours (i.e. hours available for work during the course of the year on capital projects) for each SLR category. The total available hours consist of: a) the total working days in a year less b) leaves (such as vacation and statutory holidays) as well as c) various unproductive time (such as safety training, inclement weather, etc.).

All existing elements of employee burden are capitalized since these costs are all permissible as capital expense elements, however, adjustments are made to the pool of available hours related to various unproductive factors that should not be considered. Such unproductive factors to be removed from the SLR calculation include: meetings, training, modified duty time, supervisory relief time and overtime in lieu. Aside from training (which will always be an operating expense), time spent on these activities in relation to capital work will be capitalized through the time-sheeting mechanism.

8.2.3 On-cost

An on-cost charge is applied to all items issued from the Corporate Warehouses. Such items generally include transformers, poles, cables, etc. These items are then installed in their final locations throughout the City of Toronto and are then considered to be in use. If the items issued from the warehouse are associated with capital projects, the on-cost charge is capitalized, whereas if the items issued are associated with operating projects, the on-cost charge is expensed in the period in which it is incurred.

The on-cost charge associates the cost of warehousing and handling to the items themselves. The on-cost rate is calculated as the sum of budgeted expenses in four specific material handling responsibility centers divided by the budgeted dollar value of materials moving through the warehouse in a given year. This rate is then applied to the dollar value of all materials when issued to capital and operating projects.

Some of the budgeted expenses within the material handling responsibility centers are not capitalizable, thus should not be included in the on-cost calculation. The disallowed costs include:

- Payroll related to administrative staff supporting the procurement and warehousing functions;
- Inventory and direct purchases of materials used in the warehouse for internal purposes ±i.e. not used for capital projects;
- Utilities and communications related expenses;
- Office supplies used in procurement and warehousing;
- Employee expenses (i.e. reimbursed expenses for employee purchases); and
- Allocated IT charges related to telephone and computing equipment used by the procurement and warehousing departments.

8.2.4 Vehicle Hire Rate

Vehicles used in the construction of capital assets can be capitalized into the item of PP&E. This capitalization is applied to projects based on time-sheets for the use of each vehicle. A VHR is calculated for each vehicle class and applied to the hours time-sheeted to determine the amount capitalized to each project.

The VHRs are calculated by taking the sum of the total operating charges, fuel costs and depreciation, and dividing by the total available vehicle hours for each vehicle class. The total available vehicle hours are based on the number of working days in a year less a factor for vehicle repairs and maintenance. Some of the budgeted expenses are not capitalizable thus should not be included in the VHR calculation.

8.3 Asset retirement cost

The Corporation recognizes a liability, known as an asset retirement obligation, for future removal and handling costs for contamination in distribution equipment and for the future environmental remediation of certain properties. The liability is measured at present value and an offsetting amount is added to the carrying amount of the related asset as asset retirement cost. This cost is depreciated over the useful life of the related asset. Changes to an existing asset retirement obligation are added to or deducted from the cost of the related asset and depreciated prospectively over the remaining useful life of the asset.

9 POLICY ADMINISTRATION OWNERSHIP, APPROVAL AND RESPONSIBILITIES

Policy Owner

9.1 This policy is owned by the *Chief Financial Officer,* who is responsible for:

- Ensuring that this policy is comprehensive, clear and current.
- Ensuring that this policy is implemented and communicated to the departments and staff that are impacted.
- Ensuring consistency between referenced policies and this document.
- Ensuring on-going compliance with this policy.
- Approving any exceptions to this policy, as required.
- Reviewing this policy annually.

Policy Approver

9.2 This policy is approved by the *Policy Administration Steering Committee,* which is responsible for:

- Considering the impact of the policy to the associated risk.
- Reviewing and approving this policy annually.

Directly Responsible Person

9.3 This policy is managed by the *Controller* of each affiliate through *Business Unit Managers and Senior Financial Analysts.*

9.4 The *Affiliate Controller* is responsible for:

- Ensuring that this policy is communicated to the departments and staff that are impacted and that it is implemented.
- Immediately communicating any exceptions or violations of this policy to the *Manager, Financial Reporting* for approval upon review.
- Reviewing this policy annually.

9.5 The *Business Unit Managers* are responsible for:

- Ensuring that this policy is communicated to the staff impacted and that it is implemented.
- Ensuring ongoing compliance with this policy.
- Ensuring that a review of expenditures recorded in CWIP accounts is performed on a regular basis. Expenditures are recorded in CWIP until such time as the project is essentially complete and may be capitalized as allowed by US GAAP. It is expected that Business Unit personnel and Finance staff periodically review this account for stranded costs and other entries that may be capitalized or expensed.
- Ensuring that a review of projects is performed on a regular basis, so that projects W K D W D U H H V V H Q W L D O O \ F R P S O H W H K D Y H W K D W D U H L Q F R U U H F W O \ V W D W X V X S J U SAP. Updating the status field is the trigger that initiates timely capitalization of costs.
- Immediately communicating any exceptions or violations of this policy to the *Senior Financial Analysts*.

9.6 The *Senior Financial Analysts* are responsible for:

- Providing support to the Business Units for proper application of this policy.
- Monitoring compliance with this policy.
- Immediately communicating any exceptions or violations of this policy to the *Finance Manager* and the *Affiliate Controller*.

9.7 The *Supervisor, Financial Reporting* is responsible for:

- Ensuring the policy is maintained and kept up to date.
- Immediately communicating any exceptions or violations of this policy to the *Manager, Financial Reporting*.
- Reviewing this policy annually.

10 POLICY COMMUNICATION

COMMUNICATION TRIGGER	TYPE OF COMMUNICATION	PARTY RESPONSIBLE FOR POLICY COMMUNICATION	AUDIENCE	ACKNOWLEDGEMENT
Policy Change/ Review	Presentation and/or e-mail	Manager, Financial Reporting	Affiliate Controller, Business Unit Managers and Senior Financial Analysts	Sign Off
Policy Change/ Review	Scheduled Meeting Presentation	Business Unit Managers	All affected employees	Sign Off
Policy Update	E-Mail	Manager, Financial Reporting	All affected employees	No
New Hire in Finance	Discussion, e-mail	Immediate Supervisor/Manager	New hire	No

11 POLICY COMPLIANCE AND VIOLATIONS

11.1 All Toronto Hydro employees, officers, directors and affiliates are required to comply with this policy.

11.2 Any employee who fails to comply with this policy could be subject to disciplinary action, up to and including dismissal.

11.3 Failure to comply with this policy could lead to a material misstatement of the &RUSRUDWLRQ¶V H[SHQGLWXUHV RQ WKH ILQDQFLDO VWDWHPH regulatory agencies. This can result in legal, regulatory and reputational ramifications.

12 RELATED LAWS, REGULATIONS AND DOCUMENTATION

12.1 Refer to ASC 360 ³3URSHUW\ 3ODQW ,QGXVWULDO (TXLSPHQW Accounting Concepts No.6 for more definitions and accounting guidelines. These Sections are available from the Finance group.

12.2 Refer to the ³&RPSXWHU 6RIWZDUH Guidelines´ for more detailed accounting treatment of expenditures related to the acquisition and/or development of computer software.

12.3 The following appendices were referenced in this policy:

- Appendix A - Minimum threshold dollar amounts for capitalization and Depreciation rates
- Appendix B - Decision Tree - Classification of an expenditure
- Appendix C - Capital asset and repair and maintenance expense definitions - Excerpts from the OEB AP Handbook

These appendices can be found on the Toronto Hydro Plugged In intranet site at http://pluggedin.torontohydro.com/policy/Pages/FinancePolicies.aspx.

OVERHEAD EXPENSE

Appendix 2-DA of the OEB's Filing Requirements for Electricity Distribution Rate Applications (July 17, 2013) (the "Filing Requirements") requires the presentation of changes in the capitalization of overhead costs under modified International Financial Reporting Standards ("mIFRS") and the applicant's previous accounting standard. Toronto Hydro has not filed this Appendix because there are no differences between the capitalization of overhead expenditures upon adoption of mIFRS for the 2014 bridge and 2015 test years.

BACKGROUND

As noted in EB-2010-0142 Exhibit Q1, Tab 2, Schedule 1, Toronto Hydro commenced its IFRS conversion project in 2007 with the intention of converting to IFRS January 1, 2011. However, given uncertainty around the timing, scope and potential adoption of a rate-regulated accounting standard under IFRS, Toronto Hydro decided to file its rate application for 2011 in accordance with the Canadian Generally Accepted Accounting Principles ("CGAAP") in use at that time.

Toronto Hydro determined that certain changes in accounting estimates were required to be applied under CGAAP as additional and more relevant information had been made available through the IFRS project. Toronto Hydro's external auditor acknowledged the appropriateness of prospective application of the changes in accounting estimates effective January 1, 2011 under CGAAP.[1] The changes related to the manner in which Toronto Hydro records and accounts for its property, plant and equipment and were filed as an Accounting Update to the 2011 application.[2]

[1] Toronto Hydro Corporation Consolidated Financial Statements, December 31, 2011.
[2] EB-2010-0142, Application and Evidence (February 9, 2011), Exhibit Q1, Tab 2, Schedule 1.

As a result of the changes adopted under CGAAP, there are no differences between the capitalization of overhead expenditures upon adoption of MIFRS for the 2014 bridge and 2015 test years. Consequently, Toronto Hydro has not completed OEB Appendix 2-DA as part of this application. Refer to EB-2010-0142 Exhibit Q1, Tab 2, Schedule 1 for a description and quantification of the changes in the capitalization of overhead expenses applied prospectively under CGAAP commencing January 1, 2011.

COST OF ELIGIBLE INVESTMENTS FOR THE CONNECTION OF QUALIFYING FACILITIES

Section 2.5.2.5 of the OEB's Filing Requirements for Electricity Distributor Rate Applications (July 17, 2013) (the "Filing Requirements"), contemplates that a distributor will file for provincial rate protection associated with any costs incurred to make eligible investments, as described in section 79.1 of the Ontario Energy Board Act, 1998 (the "Act") and Regulation 330/09 (O. Reg. 330/09)[1] made under the Act.

Costs incurred by a distributor, in accordance with the cost responsibility rules in the OEB's Distribution System Code, for the purpose of connecting or enabling the connection of a Renewable Energy Generation ("REG") facility to its distribution system are considered to be eligible investments for the purpose of provincial rate recovery under s. 79.1 of the Act.[2]

1. REG CONNECTIONS

There is significant renewable generation activity across Toronto Hydro's distribution system. As of May 31, 2014, Toronto Hydro has connected over 860 renewable generation projects representing over 20 MW of capacity, and has undertaken approximately 325 MW of pre-assessment capacity reviews. Toronto Hydro expects to connect approximately 972 renewable energy generation facilities during the 2015 to 2019 rate period, with a corresponding capacity of 148.9 MW. In summary, by the end of 2019, the utility anticipates to have almost 2000 renewable generation facilities, with a corresponding capacity of approximately 203 MW, connected to its distribution system.

[1] O. Reg. 330/09.
[2] O. Reg. 330/09, at s. 1(2).

Some renewable generation projects are currently unable to connect due to interconnection constraints either at transmission level or distribution level. These interconnection constraints are short circuit capacity, thermal capacity or reverse power flow issues associated with legacy system design or legacy equipment. The breaker upgrades presently underway by Hydro One Networks Inc. ("HONI") are expected to remove constraints at the transmission level and to be completed by end of 2014.

2. ELIGIBLE INVESTMENTS SUMMARY

To address interconnection constraints at the distribution level, Toronto Hydro proposes to undertake a number of Renewable Enabling Improvement ("REI") investments as part of its 2015 to 2019 Distribution System Plan ("DSP"), which is filed at Exhibit 2B.

2.1. Generation Protection, Monitoring & Control

- Advanced Protection System To enable more renewable generation projects to connect, a high speed protection scheme has been developed for implementation on station buses with short circuit constraints. This advanced protection, monitoring and control system uses a high speed communication network with the associated protective equipment to isolate the generator from the distribution system before the main circuit breakers operate, thus maintaining system integrity for upstream customers. For additional details refer to the Generation Protection Control and Monitoring Program (Exhibit 2B, E5.5) in the DSP.
- Installation of Bus-Tie Reactors Bus-tie reactors lower the short circuit current on the station bus and distribution system by insertion of an impedance at the bus-tie point. This method of fault mitigation has been successfully applied by Powerstream and HONI. Toronto Hydro proposes to work with HONI to install a bus tie reactor at Richview TS to eliminate the existing fault current constraint, which will enable renewable generation connections which at present cannot

proceed. For additional details refer to the Generation Protection Control and Monitoring Program (Exhibit 2B, E5.5) in the DSP.

- Remote Monitoring and Control of Generation (SCADA): Toronto Hydro requires real-time monitoring and control of renewable generation resources via communication networks with the utility's supervisory control and data acquisition ("SCADA") system to enable safe operation of the distribution system and feeder management of bi-directional distribution grid flows. The system has the ability to forecast resources and coordinate with Toronto Hydro's distribution outage management system, thereby enabling greater penetration of renewable generation by providing real-time visibility. Toronto Hydro's requirement for monitoring and control is modelled after requirements developed by the Independent Electricity System Operator ("IESO"). Consistent with the Distribution System Code ("DSC"), the costs associated with this investment program pertains only to renewable generation resources, as conventional generation projects bear the cost of monitoring and control requirements. For additional details refer to the Generation Protection, Control and Monitoring Program (Exhibit 2B, E5.5) in the DSP.

2.2. Energy Storage

- Toronto Hydro plans to deploy 24 energy storage systems at various strategic locations across the distribution system. These energy storage systems represent a total aggregated peak capacity of 4 MW and aggregated energy capacity of 10MWh. Toronto Hydro's infrastructure was not designed to accommodate two-way, variable renewable generation resources and these energy storage systems will balance energy flows in specific areas, allowing renewable generation connections to proceed and helping defer the need for conventional infrastructure upgrades. For additional details refer to the Energy Storage Program in the DSP (Exhibit 2B, E7.11).

The Ontario Power Authority ("OPA") reviewed Toronto Hydro's plans for REG investments and found that: 1) the utility's plans are reasonably consistent with the OPA's information regarding REG, and 2) that the investments support and enable the connection of additional REG, which enhances the ability of local customers and proponents to participate in ongoing renewable programs, while contributing to the supply diversity within the Integrated Regional Resource Plan ("IRRP") study for the Central Toronto region. For more information, please refer to the OPA Comment Letter filed at Exhibit 2B, Section B.

3. ELIGIBLE INVESTMENTS COSTS

Table 1 below summarizes the costs associated with REI investments over the 2015 to 2019 rate period. Toronto Hydro is not proposing any specific Renewable Expansion ("RE") investments during the period 2015 – 2019. However, Toronto Hydro notes that certain investments in its Station Expansion program (Exhibit 2B, E7.9) are expected to improve the utility's ability to connect REG facilities.

Table 1: Renewable Enabling Improvements (REI) from 2015 to 2019 ($ Millions)

Capital Program	2015	2016	2017	2018	2019
Generation Protection Control and Monitoring	6.12	5.19	3.26	2.10	2.02
Energy Storage	0.54	1.09	2.16	3.24	3.78
Totals	**6.66**	**6.27**	**5.43**	**5.34**	**5.79**

/C

4. PROVINCIAL RATE PROTECTION

In accordance with s. 2.5.2.5 of Filing Requirements, Toronto Hydro applied the six percent direct benefit assumption provided by the OEB with respect to REI investments to calculate the provincial rate protection amounts summarized below in Table 2. A more detailed breakdown of these figures is provided in the OEB Appendices 2-FA and 2-FB at Exhibit 2A, Tab 8, Schedules 2 and 3, respectively. (Note that Appendix 2-FC provided in Schedule 4 is not applicable).

Table 2: Provincial Rate Protection Amounts from 2015 to 2019 ($Millions)

Year	2015	2016	2017	2018	2019
Provincial Rate Protection	0.31	1.00	1.69	2.31	2.93

OEB Appendix 2-FA
Renewable Generation Connection Investment Summary (over the rate setting period)

Enter the details of the Renewable Generation Connection projects as described in Section 2.5.2.5 of the Filing Requirements.
All costs entered on this page will be transferred to the appropriate cells in the appendices that follow.

For Part A, Renewable Enabling Improvements (REI), these amounts will be transferred to Appendix 2 - FB

For Part B, Expansions, these amounts will be transferred to Appendix 2 - FC

If there are more than **five** projects proposed to be in-service in a certain year, please amend the tables below and ensure that the formulae for the Total
Based on the current methodology and allocation, amounts allocated represent 6% for REI Connection Investments and 17% for Expansion Investments.

Part A

ICM TRUE-UP – DEFERRAL PROPOSAL

1. INTRODUCTION

This schedule outlines Toronto Hydro's proposal for the treatment of its 2012-2014 Incremental Capital Module ("ICM") true-up.

In its Accounting Order in Toronto Hydro's 2012-2014 ICM application, the Ontario Energy Board ("OEB") ordered the utility to true-up the revenue requirement which was used to derive the ICM rate rider revenues for the ICM funding at a future date, on the basis of total annual revenue requirements based on the actual in-service assets of OEB-approved ICM segments.[1] Toronto Hydro's accounting process is not expected to have a final report of actual in-service additions ("ISAs") for 2014 until the second quarter of 2015. Therefore, Toronto Hydro proposes to defer the ICM true-up and bring forward a separate application in 2015, once actual ICM amounts are known.

2. PROPOSED APPROACH TO TRUE-UP

Toronto Hydro's 2012-2014 ICM application provided a detailed view into the utility's planned capital work based on the following hierarchy:

- Projects (10): the highest-level of work that can consist of one or more segments;
- Segments (24): a medium-level of work that consists of multiple jobs, and
- Jobs (hundreds): the most granular and detailed description of Toronto Hydro's capital activities.

In its Partial Decision and Order, the OEB approved Toronto Hydro's capital program at the level of the ICM segments[3] filed by the utility, with rate riders determined for each year calculated using a forecast of ISAs for the funded ICM segments. For example, "B1

[1] EB-2012-0064, Rate Order, 9 May 2013, pages 2-3.
[3] As discussed in Exhibit 2B, ICM capital segments are comparable to DSP programs in this application.

Underground Infrastructure" and "B2 Paper Insulated Lead Covered Cable – Piece Outs and Leakers" were both approved ICM segments. Toronto Hydro's rate riders were determined based on the cumulative forecast ISAs of the segments that were approved for rate rider funding.

The OEB contemplated the need to true-up to accommodate differences between forecast and actual expenditures at the segment level. Individual jobs within each segment may vary for a number of reasons, including (i) difference between cost forecast and actuals; (ii) prudent addition and removal of jobs from segments; (iii) the fact that jobs may come into service in a different calendar year than originally forecast.[4]

Upon determining final expenditures and ISAs by segment, Toronto Hydro proposes to complete the ICM workforms using these actual in-service amounts, as stipulated in the OEB's Accounting Order. On an annual basis, the recalculated actual revenue requirement will be compared to revenues collected through the respective rate rider to determine variances due to under-spend or prudent over-spend. The OEB determined that these variances would be returned to, or collected from, customers through a separate rate rider.

The steps described above are necessary precursors to truing-up ICM revenue requirement and actual ISAs. Toronto Hydro does not expect to be able to determine the required 2014 actual expenditures or ISAs in accordance with the likely timeframe of this proceeding. Toronto Hydro therefore submits that the true-up of the 2012-2014 ICM activities is most appropriately undertaken in a separate proceeding from this application, following the determination of actual expenditures and ISAs for the full 2012-2014 ICM period.

[4] For a discussion of operational factors that may lead to variances between planned and actual work, please see the "Execution Challenges" section in Exhibit 1B, Tab 1, Schedule 4, Appendix A (Execution Challenges)

SERVICE QUALITY PERFORMANCE

Toronto Hydro's service quality performance has been steady in most metrics over the five previous years, meeting or exceeding OEB standards in all areas, with the exception of the Appointment Rescheduling and Emergency Response metrics. A summary table of Toronto Hydro's performance, OEB Appendix 2G, is provided in Tab 10, Schedule 3. Detailed explanations of notable variances and results below OEB standards are described below.

1. APPOINTMENT RESCHEDULING

This metric requires utilities to contact a customer in advance of missing an appointment and reschedule a replacement appointment within two business days. As discussed below, Toronto Hydro did not meet the OEB's 100% standard for this metric in 2009, 2012, or 2013. When these three years are combined, Toronto Hydro had 50,251 customer appointments, 235 of which were missed, and of these only three were not rescheduled within two business days. /C

Toronto Hydro's results under this metric are more a function of the mathematical data than an underlying performance issue. Toronto Hydro focuses its efforts primarily to meet as many appointments as possible, such that very few are actually missed on an annual basis. When one of these very few missed appointments is subsequently not rescheduled in accordance with the OEB's performance metrics, it results in a fairly dramatic impact in percentage terms. For example, in 2009 of 23,027 total appointments with customers, only 82 were missed, of which only 1 was not rescheduled within the parameters of this metrics. Similarly, in 2012 and 2013, of 12,547 and 14,677 total appointments with customers, only 91 and 61 were missed, of which only 1 each were not properly rescheduled. As shown in Table 1 below, the number of appointments not rescheduled within the parameters of the Appointment Rescheduling metric are /C

immaterial as a percentage of the total.

Table 1: Appointments Rescheduling Summary

Year	Total Appointments	Appointments Missed	Appointments Not Rescheduled within 2 business days	Appointment Rescheduling ESQR	Appointments Not Rescheduled as a percentage of Total Appointments
2009	23,027	82	1	98.8%	99.9999%
2012	12,547	91	1	98.9%	99.9999%
2013	14,677	61	1	98.4%	99.9999%

/C

2. TELEPHONE ACCESSIBILITY

This metric requires utilities to respond to a customer's call within 30 seconds at least 65% of the time. Toronto Hydro has consistently exceeded this standard. The utility did experience a slight decline in performance in 2010 and 2011. This was primarily a result of pre- and post-business activities and training associated with converting to a new Customer Information System. In 2012, Toronto Hydro introduced a new customer care business model to better serve customer needs and improve efficiency by directing residential calls and simple clerical tasks to an external call centre, while internally retaining the complex work associated with business customers. During the three-month transition to this new model, the service level response time was temporarily affected but continued to exceed the OEB standard. This period is reflected in the annual results.

3. WRITTEN INQUIRY RESPONSE

The written response metric requires utilities to respond to customers' written inquiries within ten days at least 80% of the time. Toronto Hydro has consistently exceeded this standard, but did experience a slight decline in performance in 2012. The transition to a new customer care business model, combined with a large increase in inquiries in the month of November regarding an issue related to ePost (an external electronic bill

presentment service) slightly affected the annual results, which still exceed the OEB standard.

4. EMERGENCY RESPONSE

The Emergency Response metric requires utilities to respond to emergency calls within one hour in urban settings at least 80% of the time. Toronto Hydro exceeded this metric in 2010 and 2011, but had difficulties meeting it in 2009, 2012 and 2013. In these years, Toronto Hydro underperformed by between 0.5% and 7.5%. In all three years, but in 2012 and 2013 in particular, the major contributing factor to underperformance were the timing and severity of Major Event Days ("MEDs") – typically storms – which may not allow for a timely response to all (often simultaneous) emergency calls.

In 2012, the weather originating from Tropical Storm Sandy alone was responsible for 8% of all emergency incidents in 2012. Given the severity of the storm, THESL was only able to achieve a response target of 20% during this event. In addition, five of the eight MEDs in 2012 occurred after-hours, during which fewer resources were available for immediate dispatch, and once these were fully-engaged there was an unavoidable time delay before additional crews could be mobilized. With even a portion of these MEDs excluded or normalized, THESL's performance would have exceeded the 80% standard in 2012.

Similarly, in 2013 Toronto Hydro's underperformance was also the result of MEDs (8 of 10 of which occurred after hours) particularly the ice storm in December. This five-day period alone accounted for 16% of the yearly volume of emergency events, meaning that Toronto Hydro achieved an hourly response rate of 15% during the month of December. As a result of the ice storm, Toronto Hydro's annual year-to-date performance dropped from 86% as of December 21 to 74% by December 31, only ten days later.

In addition to emergencies originating from Police, Fire, or Ambulance (as per the definition of this metric), Toronto Hydro responds with the same priority to any emergency situation reported by any other member of the public. Therefore, the number of true emergency incidents (i.e., any for which THESL dispatches a crew on an emergency basis) is substantially higher than reported.

Nonetheless, Toronto Hydro is committed to continuing to improve its Emergency Response during the 2015-2019 period, and has planned investments to allow for a more timely response by its emergency response crews. Please refer to Exhibit 4A, Tab 2, Schedule 3 for additional details.

RELIABILITY PERFORMANCE

1. INTRODUCTION

Toronto Hydro tracks reliability performance indicators System Average Interruption Frequency Index ("SAIFI"), System Average Interruption Duration Index ("SAIDI"), and Customer Average Interruption Duration Index ("CAIDI") in several ways:

1) including all events;
2) excluding Loss of Supply;
3) excluding Major Event Days ("MEDs") and Loss of Supply; and
4) excluding MEDs, Loss of Supply, and Scheduled Outages

Scenarios 1 and 2 provide SAIFI and SAIDI in the filing manner required by OEB Appendix 2-G (Exhibit 2A, Tab 10, Schedule 3). Scenarios 3 and 4 provide SAIFI and SAIDI values by excluding additional externalities and controllable outages, to give a more normalized reflection of total system reliability. Each of these values provides valuable information as to the causes, duration, and frequency of outages within Toronto Hydro's distribution system.

2. SYSTEM OVERVIEW

Figures 1 and 2 below show the system total SAIFI and SAIDI between 2009 and 2013, respectively under each of the four scenarios. The notable increase in SAIFI and SAIDI in 2013 under scenarios 1 and 2 can be attributed to the flooding of Manby TS in July and the Ice Storm in December, both of which were MEDs. Under scenarios 3 and 4, (which exclude MEDs and other externalities, as well as planned outages), there is actually a slight overall downward trend in both SAIFI and SAIDI, suggesting improving system performance. Toronto Hydro places greater value in these latter scenarios (which exclude MEDs) since they provide a better indication of the performance trend of the

system and the impact of recent investments, and are more commonly used across the industry for benchmarking against past performances.

Figure 1: System Level SAIFI

Figure 2: System Level SAIDI

3. LOSS OF SUPPLY

Loss of Supply events have a significant impact on the overall reliability of Toronto Hydro's distribution system, and being external to Toronto Hydro's operations and control, are generally excluded from a system reliability analysis. In 2013, a total of 54 Loss of Supply events affected the system, with 17 such events occurring in 2012. On a system level, Loss of Supply typically affects up to 13% of the SAIFI and 10% of the SAIDI. Figures 3 and 4 below show the SAIFI and SAIDI system impact due to Loss of Supply.

Figure 3: Loss of Supply Impact on Total SAIFI

Figure 4: Loss of Supply Impact on Total SAIDI

3.1. Major Event Days

Major Event Days ("MEDs") are defined by the Institute of Electrical and Electronics Engineers ("IEEE") as "events that are beyond the design and/or operational limits of a utility." Similarly to Loss of Supply events, MEDs are generally external to routine utility operation, and in addition, are highly volatile from year to year. The exclusion of MEDs allows a utility to normalize its reliability data to make trending and goal setting possible. MEDs experienced by Toronto Hydro since 2003 are shown in Table 1 below:

Table 1: Major Event Days

Date	Description	SAIDI
Aug 14 - 15, 2003	Blackout	2 days
Sep 19, 2003	Hurricane Isabel	8.01 minutes
Jul 26, 2005	Loss of Supply to Esplanade TS	6.93 minutes
Aug 19, 2005	Major storm (thunderstorm)	19.16 minutes
Aug 20, 2005	Major storm (thunderstorm)	6.44 minutes
Jul 17, 2006	Major storm (thunderstorm)	12.46 minutes
Aug 21, 2006	Loss of Supply to Scarborough TS	7.30 minutes

Date	Description	SAIDI
Mar 2, 2007	Major ice storm	24.21 minutes
Jun 8, 2007	Major storm (thunderstorm)	11.63 minutes
Jan 15, 2009	Dufferin TS flooding	54.98 minutes
Apr 25, 2009	Major storm (thunderstorm)	12.69 minutes
Aug 20, 2009	Major storm (thunderstorm)	13.69 minutes
Aug 22, 2009	Major storm (thunderstorm)	10.42 minutes
Jul 5, 2010	Loss of Supply to Manby TS	21.61 minutes
Oct 29, 2012	Hurricane Sandy	9.37 minutes
Oct 30, 2012	Hurricane Sandy	18.83 minutes
Jul 8, 2013	Major storm (thunderstorm)	197.26 minutes
Jul 9, 2013	Major storm (thunderstorm)	7.60 minutes
Dec 21, 2013	Freezing Rain Ice Storm	263.90 minutes
Dec 22, 2013	Freezing Rain Ice Storm	683.13 minutes
Dec 23, 2013	Freezing Rain Ice Storm	16.19 minutes
Dec 24, 2013	Freezing Rain Ice Storm	12.30 minutes
Dec 25, 2013	Freezing Rain Ice Storm	7.65 minutes
Dec 26, 2013	Freezing Rain Ice Storm	7.53 minutes

3.2. Scheduled Outages

Scheduled Outages are associated with construction and preventative maintenance activities. Assets that are at risk of failing in the near future may be taken out of service to be repaired or replaced. While this can lead to lengthy outages, the duration of the outage would generally be much shorter than those caused by the asset failing during regular operation. Such planned replacements are also often required to mitigate safety risks to Toronto Hydro's employees. Toronto Hydro provides customers advanced notification of any impending work prior to engaging the project, which gives them the opportunity to plan their activities around the repair work. As planned outages do not reflect the inherent performance of the distribution system, they are typically excluded from reliability analysis.

Figure 5: Scheduled Outages Impact on Total SAIFI

Figure 6: Scheduled Outages Impact on Total SAIDI

4. SYSTEM RELIABILITY EXCLUDING LOSS OF SUPPLY, MAJOR EVENT DAYS AND SCHEDULED OUTAGES

As noted above, Toronto Hydro has minimal control over Major Event Days and Loss of Supply events. As a result, these factors are typically excluded from analysis of the overall system performance. In addition, Scheduled Outages are required in order to replace assets that are at their end of life and are not a reflection of distribution system performance. As such, they are also typically excluded from the analysis of the overall system performance. Figures 7, 8, and 9 below show the adjusted SAIFI, SAIDI, and CAIDI (excluding Loss of Supply, MEDs, and Scheduled Outages).

The year over year adjusted values show steady improvement over the years, with a dramatic improvement in 2012 for both SAIFI and SAIDI. While a part of this is a result of Toronto Hydro's investment strategy, which has focused on replacing old and aging infrastructure and reducing outages caused by defective equipment, the majority of the 2012 improvement can be attributed to favourable weather conditions and a decrease in overall wind speeds. This is further shown in the cause code breakouts in Figures 10 and 11, and highlighted in the weather related breakouts in Figures 12 and 13.

Figure 7: System SAIFI Excluding MEDs, Loss of Supply and Scheduled Outages

Figure 8: System SAIDI Excluding MEDs, Loss of Supply and Scheduled Outages

Figure 9: System CAIDI Excluding MEDs, Loss of Supply and Scheduled Outages

5. CAUSE CODE ANALYSIS

Toronto Hydro tracks causes of service interruptions using the ten primary cause codes as specified in OEB's Reporting and Record Keeping Requirements. Figures 10 and 11 show the reliability performance for SAIFI and SAIDI by cause code from 2009 through 2013. Table 2 shows the percentage contribution of each cause code to overall system SAIFI and SAIDI.

Figure 10: SAIFI Cause Code Breakdown (Excluding MEDs)

Figure 11: SAIDI Cause Code Breakdown (Excluding MEDs)

Table 2: Five-Year Average SAIFI and SAIDI Contribution by Cause Code

Cause Code	Contribution % to SAIFI	Contribution % to SAIDI
Defective Equipment	41.1%	44.3%
Unknown	12.0%	2.6%
Loss of Supply*	9.6%	5.9%
Foreign Interference	9.3%	9.4%
Tree Contacts	9.0%	12.8%
Adverse Weather	8.7%	11.3%
Lightning	3.5%	5.2%
Scheduled Outage*	3.2%	6.2%
Human Element	2.7%	1.0%
Adverse Environment	0.8%	1.3%

* Excluded from typical system analysis when demonstrating the true condition of THESL's system

Between 2009 and 2013, defective equipment was the main contributor to SAIFI and SAIDI, at 41.1% and 44.3% respectively. As shown in Figures 10 and 11, the majority of improvement in SAIFI and SAIDI in 2013 over the previous years is in Defective Equipment and, to a lesser extent, Adverse Environment and Lightning. Outages due to Adverse Environment and Lightning are typically not reflective of the condition of the assets in the system, but rather the environmental stresses that the assets experience. Toronto Hydro views the Defective Equipment cause code as a primary indicator of the condition of its distribution system, and tracks this cause code as a measure of continuous improvement over the course of its capital expenditure and maintenance plans. Additional analysis of various relevant cause codes is provided below.

5.1. Weather Impacts

Three cause codes can generally be combined to reflect weather impacts on the system:

(a) Adverse Weather,

(b) Lightning, and

(c) Tree Contacts

Figures 12 and 13 show the cumulative weather reliability impacts on the system.

Figure 12: Weather Impacts to SAIFI

Figure 13: Weather Impacts to SAIDI

Weather impacts on the distribution system account for a significant portion of total system SAIFI and SAIDI. In 2013 weather related causes attributed 11% to the annual SAIFI and nearly 40% to the annual SAIDI. While volatile from year to year, the three cause codes combined provide a more accurate reflection of the impact of weather events on the system. Figures 12 and 13 above demonstrate that a large portion of the SAIFI and SAIDI improvements in 2012 can be attributed to favorable weather conditions, while part of the decline in 2013 relative to 2012 can be attributed to a return to more typically normal weather patterns.

5.2. Foreign Interference Impacts

Foreign interference consists of outages caused by animal contact, dig-ins, vehicles, and other foreign objects. Though there are different ways to mitigate foreign interference, such as installing animal guards or moving assets to more secure locations, the yearly performance is generally more volatile to single events. Figures 14 and 15 below show the foreign interference impacts on Toronto Hydro's distribution system.

Figure 14: Foreign Interference – Root Cause SAIFI

Figure 15: Foreign Interference – Root Cause SAIDI

Of the four sub-categories, animal contact is one of the most "controllable", in that Toronto Hydro is able to reasonably install measures to effectively militate against the risk. Toronto Hydro's capital programs include animal guard replacement activities for this purpose (see the Overhead Circuit Renewal program, Exhibit 2B, Section E6.4, and the Worst Performing Feeder program, Exhibit 2B, Section E6.21), with new standard animal guards that eliminate a physical point of contact with live equipment and insulate all critical components. Since the start of animal guard replacement activities in 2010, animal contact has had a slight downward trend for both SAIFI and SAIDI. The remaining sub-categories are far more variable and generally beyond Toronto Hydro's direct control. For example, 13% of the foreign interference SAIDI for the year 2012 was attributed to a single incident, occurring on August 20th 2012, where a construction crane fell onto Toronto Hydro overhead lines. Similarly, on January 31st, 2012, contractors dug into Toronto Hydro's underground cable causing repeated disruptions that added up to 12% of the foreign interference SAIFI for the year.

5.3. Defective Equipment Impacts

As shown in Figures 16 and 17, the contribution of defective equipment to Toronto Hydro's SAIFI and SAIDI has remained relatively stable, with the exception of the overhead system sub-cause code, which has seen a considerable reduction in outages.

Figure 16: Defective Equipment SAIFI

Figure 17: Defective Equipment SAIDI

5.4. Overhead Defective Equipment

In the overhead sub-cause codes (Figures 18 and 19 below) the majority of the customer interruptions are caused by pole and pole hardware failures, as well as overhead switches. This is mainly due to the magnitude of these types of failures, which often disable large sections of feeders. Toronto Hydro has experienced an improvement in the SAIFI and SAIDI trend across all sub-categories, but particularly poles and pole hardware. This can be attributed to the extensive investment program that Toronto Hydro has been undertaking over the past years, with many overhead rebuilds and an aggressive porcelain insulator replacement program. Programs such as Rear Lot Conversion (see Exhibit 2B, E6.6) and Box Construction Conversion (see Exhibit 2B, E6.7) have also contributed to the improvement of the Overhead System. To maintain this result, Toronto Hydro plans to continue this effective replacement program throughout 2015-2019.

Figure 18: Defective Equipment SAIFI - Overhead

Figure 19: Defective Equipment SAIDI - Overhead

5.5. Underground Defective Equipment

In the underground sub cause code (Figures 20 and 21 below), underground cable faults dominate both the SAIFI and SAIDI indices and are the biggest equipment related cause of interruptions in Toronto Hydro's system. The majority of these failures are due to direct buried cables. Despite a heavy emphasis on the replacement of these cables over the past few years, the number of these cables reaching end of life or showing accelerated deterioration continues to increase. This trend supports the need to continue investment in replacing Direct Buried Cables, as detailed in Exhibit 2B, E6.1.

Figure 20: Defective Equipment SAIFI - Underground

1 Introduction

Toronto Hydro produced this Distribution System Plan (DSP) in close accordance with Chapter 5 of the Ontario Energy Board's (OEB) Filing Requirements for Electricity Transmission & Distribution Applications (Chapter 5). As prescribed in Chapter 5, this DSP describes Toronto Hydro's asset management process and capital expenditure plan, while also providing information pertaining to Toronto Hydro's coordination with third parties, identification of customer preferences, and proposed performance measures to be applied over the course of the plan.

Toronto Hydro has produced a DSP designed to provide the OEB and customers with an accessible, plain-language view of the distributor's investment plans for the five year planning horizon (also referred to as the forecast period) of 2015-2019, while illustrating how the utility plans to meet the expectations set out in the Renewed Regulatory Framework for Electricity (RRFE). Toronto Hydro believes that its plan is designed to address the needs and preferences of the utility's customers by presenting optimized investments that support (1) the achievement of public policy objectives, (2) the need for a significant level of investment in Toronto's distribution system and (3) the overriding objective of delivering value for money.

(i) DSP Organization

The DSP provides the OEB and customers with detailed information and justification on the material investments that Toronto Hydro plans to make during the period from 2015 to 2019. Toronto Hydro has adopted the requirements set out in Chapter 5, dividing the DSP into the following five chapters:

- Chapter A – Distribution System Plan Overview: Provides an introductory overview of the DSP, including (1) the purpose, background and objectives, (2) declaration of capital investment drivers and expected cost savings and (3) an overview of Toronto Hydro's asset management (AM) process with discussion on what has changed within that process from previous filings.

- Chapter B – Coordinated Planning with Third Parties: Provides information on how Toronto Hydro's DSP aligns to broader regional planning efforts, and shares information with respect to the various consultation processes that were executed.

- Chapter C – Performance Measures for Continuous Improvement: Provides information with respect to the selected measures that Toronto Hydro plans to use in order to track

continuous improvement of planning, execution and outcomes of investments over the course of the planning horizon.

- Chapter D – Asset Management Process: Provides information with respect to Toronto Hydro's long-term, short-term and maintenance planning processes, which are used to produce the capital investment plan described in Chapter E.

- Chapter E – Capital Expenditure Plan: Provides information on how Toronto Hydro has applied its Asset Management Process to the utility's distribution system in order to produce the capital investments contemplated by the DSP. This section also contains the detailed description and justification of material investments planned for the five-year forecast period.

(ii) Capital Programs and Drivers

Chapter 5 includes incremental filing requirements for projects/activities that meet the distributor's materiality threshold. Toronto Hydro has applied these filing requirements to a series of 46 unique capital programs, all of which contain over $1 million in spending over five years, and which are grouped according to the OEB's defined investment categories (i.e. System Access, System Renewal, System Service and General Plant). These programs are groups of projects or activities that are similar in nature and that share the same basic justification and business case elements. In accordance with the organization framework established in Chapter 5, Toronto Hydro has assigned a single "trigger" driver to each capital program along with any applicable secondary drivers. With the exception of two programs in the General Plant category, Toronto Hydro has generally adhered to the example drivers provided for specific investment categories by the OEB in Table 1 of the Chapter 5. The following table illustrates how Toronto Hydro's chosen trigger drivers map to the drivers listed in Chapter 5. A summary of forecast expenditures by trigger driver is provided in section E1.2.2 of the DSP.

TABLE 1: OEB EXAMPLE DRIVERS AND TORONTO HYDRO EQUIVALENTS

	Example Drivers	Example Projects / Activities	Toronto Hydro Trigger Drivers
System Access	Customer service requests	• New customer connections • Modifications to existing customer connections • Expansions for customer connections	Customer Service Requests

	Example Drivers	Example Projects / Activities	Toronto Hydro Trigger Drivers
		or property development	
	Other third party infrastructure development requirements	ƒ System modifications for property or infrastructure development (e.g. relocating pole lines for road widening)	Third Party Requests
	Mandated service obligations (DSC; Conditions of Service.; etc.)	ƒ Metering ƒ Long-term load transfer	Mandated Service Obligations
System Renewal	Assets/asset systems at end of service life due to: ƒ Failure ƒ Failure risk ƒ Substandard performance ƒ High performance risk ƒ Functional obsolescence	Programs to refurbish/replace assets or asset systems (e.g.: batteries; cable (by type); cable splices; civil works; conductor; elbows and inserts; insulators; poles (by type); physical plant; relays; switchgear; transformers (by type); other equipment (by type)	ƒ Failure ƒ Failure Risk ƒ Functional Obsolescence
System Service	Expected changes in load that will constrain the ability of the system to provide consistent service delivery	ƒ Property acquisition ƒ Capacity upgrade (by type); e.g. phases; circuits; conductor; voltage; transformation; regulation ƒ Line extensions	Capacity Constraints
	System operational objectives: ƒ Safety ƒ Reliability ƒ Power quality ƒ System efficiency ƒ Other performance/	ƒ Protection & control upgrades; e.g. reclosers; tap changer controls/relays; transfer trip ƒ Automation (new/upgrades) by device type/function ƒ SCADA ƒ Distribution loss reduction	ƒ Safety ƒ Reliability ƒ System Efficiency

	Example Drivers	Example Projects / Activities	Toronto Hydro Trigger Drivers
	functionality		
General Plant[1]	ƒ System capital investment support ƒ System maintenance support ƒ Business operations efficiency ƒ Non-system physical plant	ƒ Land acquisition ƒ Structures & depreciable improvements ƒ Equipment and tools ƒ Supplies ƒ Finance/administrative/billing software and systems ƒ Rolling stock ƒ Intangibles (e.g. land rights; capital contributions to other utilities)	System Maintenance and Capital Investment Support

For a complete summary of capital programs, including brief descriptions and total program expenditures, please refer to Section 7 of this executive summary. Full details and justification for all capital programs is provided in sections E5 through E8 of the DSP.

2 Distribution System Plan Objectives

Toronto Hydro's 2015-2019 Capital Expenditure Plan (see Chapter E) reflects the utility's need for a sustained period of capital investment to replace and expand the City's aging distribution infrastructure. The suite of capital programs and projects within the DSP are based on system needs and opportunities as identified through Toronto Hydro's asset management process and informed by the utility's asset management policy objectives (discussed in detail in Chapter D).

Figure 1 illustrates the overall level of spending, grouped by the OEB's specified investment categories (for a detailed discussion of expenditures on a category basis, see Section E4). This level of investment is required primarily to address a large and growing backlog of end-of-life and obsolete assets, while also addressing critical system challenges and operational needs at a pace and in a manner that moderates rate increases and is consistent with customer preferences.

[1] Toronto Hydro elected to use Functional Obsolescence and Safety as trigger drivers for two General Plant programs.

FIGURE 1: CAPITAL INVESTMENT REQUIREMENTS BY CATEGORY[2] (2015-2019)

2.1 Capital Investment Needs and Opportunities

This section provides an overview of the system and operational investment needs facing Toronto Hydro during the 2015-2019 forecast period and a discussion of the utility's long-term asset management objectives. For a comprehensive discussion of Toronto's existing distribution system assets, configurations, climate and utilization please refer to Section D2.

(iii) System Pressures: Aging and Obsolete Assets

Toronto Hydro's distribution system faces a number of significant and evolving challenges that necessitate the proposed level of investment. The foremost of these challenges is the large and growing backlog of in-service assets that are operating beyond their expected useful lives, which is reflected in the large percentage of System Renewal investments in all five years of the expenditure plan. To illustrate the rate of system aging, Figure 2 breaks the existing in-service asset base into three portions:

[2] The "Other" investment category includes forecast expenditures related to inflation, road cut repairs, and other capital expenditures that are unrelated to specific capital programs. For a complete explanation of this expenditures, refer to Section E4.2.5.

1. the forecast percentage of assets that Toronto Hydro anticipates will be operating beyond end-of-life as of 2015;

2. the forecast percentage of assets that are expected to reach or surpass end-of-life by 2020 should Toronto Hydro adopt a "run-to-failure" approach (i.e. executing a capital expenditure plan with minimal proactive asset replacement); and

3. the percentage of assets that are forecast not to have reached end-of-life in 2020.

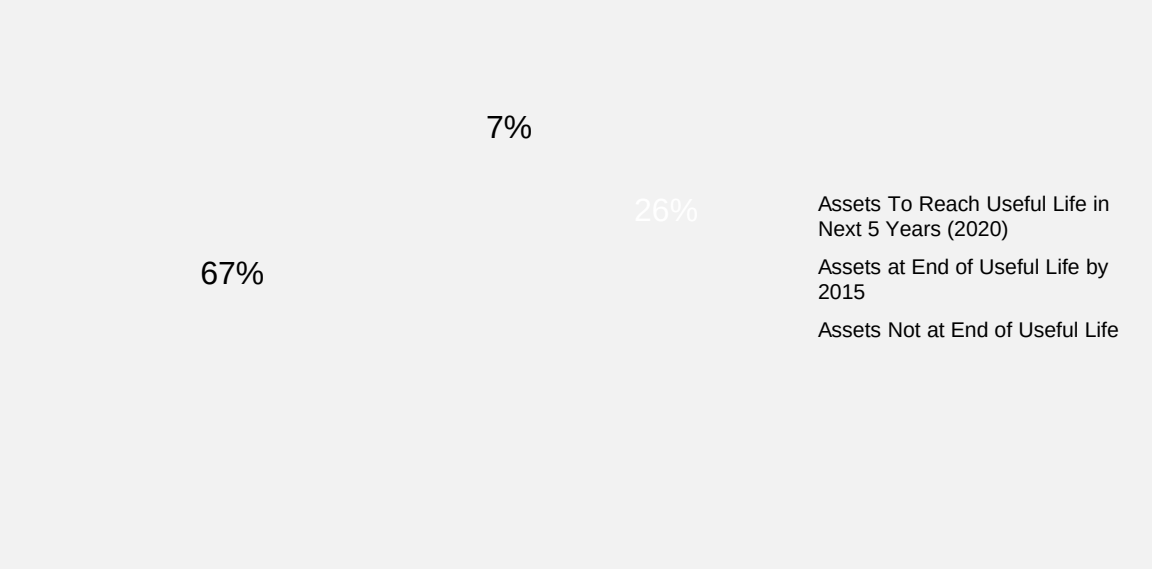

FIGURE 2: USEFUL LIFE DEMOGRAPHICS – 2015 TO 2020 ('RUN TO FAILURE' APPROACH)

The figure above shows that, without a proactive intervention strategy, approximately 32% of existing assets are forecast to be operating beyond end-of-life by the end of the five-year planning horizon contemplated by the DSP. As described later in this section, Toronto Hydro's long-term asset management objective is to reduce the percentage of assets operating beyond end-of-life at any given time until a theoretically optimal "steady-state" is achieved, at which point the capital needs of the system are generally balanced with the overall asset risk costs so that the cost of operating the system over time is minimized, in effect maximizing the value that customers and the utility derive from the existing asset base.

Setting aside this longer-term objective, the consequences of allowing the backlog of aging assets to continue to grow can be illustrated by comparing the forecast reliability outcomes of Toronto Hydro's proposed five-year capital plan to a run-to-failure approach over the same time period. Figures 3 and 4 illustrate these projections for the System Average Interruption Duration

Index (SAIDI) and the System Average Interruption Frequency Index (SAIFI). (A detailed discussion of these reliability forecasts is provided in Section E2).

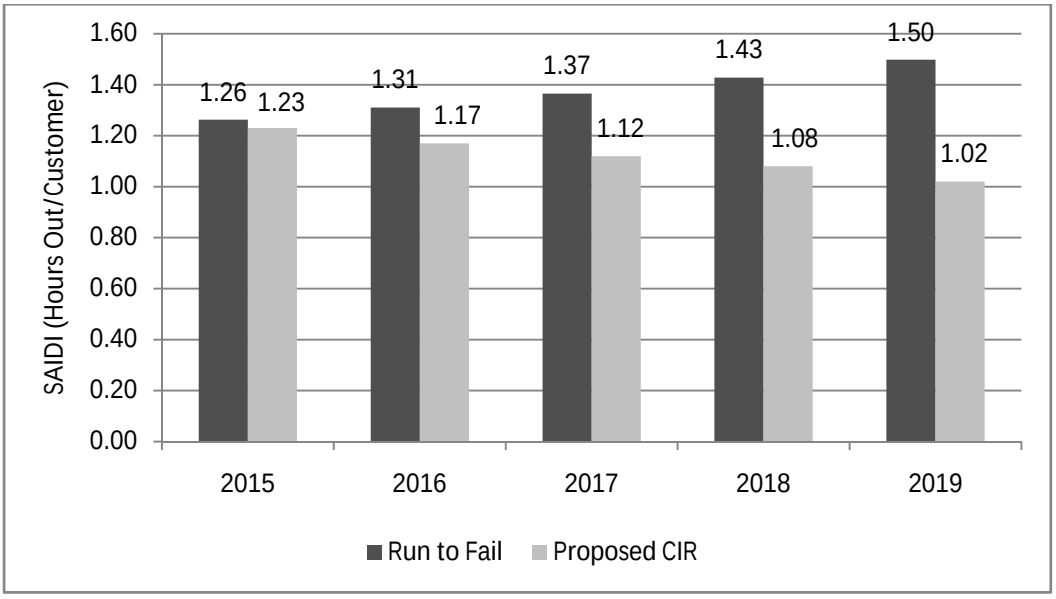

FIGURE 3: FIVE-YEAR SAIDI PROJECTION

IC

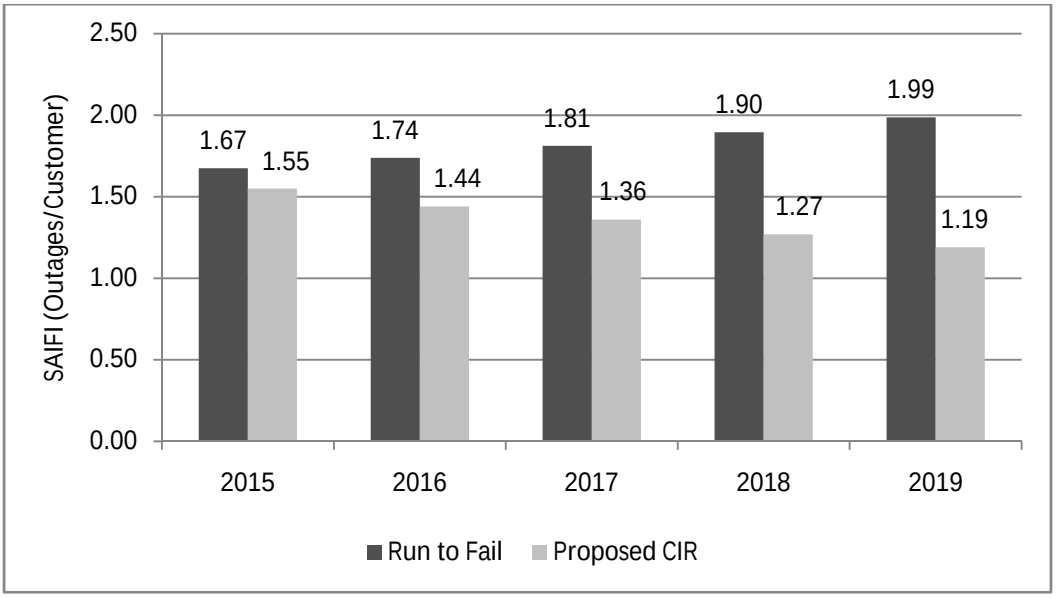

FIGURE 4: FIVE-YEAR SAIFI PROJECTION

The forecast improvement in reliability associated with Toronto Hydro's proposed capital plan is due in part to the ongoing renewal of aging and defective assets, but is also an expected outcome of a small number of targeted, high-value System Service programs such as Feeder Automation (E7.3) and Design Enhancement (E7.2), which are forecast to deliver significant improvements in system performance and operational efficiency for a level of annual investment that is relatively small compared to the typical renewal program. These cost-effective interventions should allow Toronto Hydro to enhance customer value through system reliability and efficiency improvements while executing core renewal programs at a moderate pace.

(iv) System Pressures: Economic Growth and Capacity Constraints

Toronto's distribution system continues to face utilization pressures related to economic growth and evolving system use. Examples of this include the following.

- Capacity constraints (System Access and System Service): A number of Toronto Hydro's station busses are currently overloaded; forecast load growth is expected to exacerbate these issues during the 2015-2019 planning horizon and beyond. The DSP proposes to address these concerns through targeted, near-term interventions (Load Demand, E5.4); medium to long-term capacity expansions (Stations Expansion, E7.9); and other, targeted means (e.g. Local Demand Response, E7.10).

- Externally initiated projects (System Access): The number of large third party infrastructure renewal and expansion projects across the City of Toronto is expected to significantly increase the amount of externally initiated plant relocations projects that Toronto Hydro will be required to carry-out during the 2015-2019 forecast period. Major projects that could drive investment during this period include the Metrolinx light rail transit projects and the electrification of the GO rail service between Pearson airport and Union Station.

- Accommodating distributed generation (DG) (System Access): DG connections, consisting mostly of renewable energy generation (REG) facilities, are expected to more than triple in total capacity by 2019, reaching over 625 MW. Toronto's distribution system is not presently equipped to accommodate this level of DG penetration, and a series of renewable enabling improvements will be required within the forecast period in order for Toronto Hydro to continue fulfilling its obligation to safely and reliably connect generators.

For a comprehensive discussion of forecast system development, including load and customer growth, smart grid development and capacity to accommodate forecast renewable energy

generation growth, see Section E1.3.

(v) System Pressures: Critical Issues

Toronto Hydro also plans to address a number of critical distribution system issues that go beyond core renewal and capacity/utilization concerns. These System Service investments include potential safety issues (e.g., Polymer SMD-20 Switch Renewal, E7.6), system design deficiencies (e.g., Contingency Enhancement, E7.1), and reliability issues (e.g., Customer-Owned Substation Protection, E7.8).

(vi) System Pressures: Climate Change

On July 8, 2013, and December 22, 2013, the City of Toronto was hit with two different types of extreme weather (a flood and an ice storm, respectively) that had widespread adverse affects on the distribution system. An AECOM-Toronto Hydro report entitled Future Impacts of Climate Change on Toronto Hydro's Distribution System (E8.8, Appendix A) concludes that weather and climate change can be expected to impact the reliability of the distribution system going forward, and that Toronto Hydro will be required to manage assets that may not have been designed for future climate conditions. Climate change forecasts anticipate growing pressures such as increases in extreme maximum temperatures and increases in intensity of rainfall events.

FIGURE 5: HEAVY RAINS WASH-OUT THE BASE OF A POLE IN THE DON VALLEY (JULY 2014)

A number of Toronto Hydro's planned investments in the DSP are expected to improve system performance during major storm events. For example, the Overhead Infrastructure Relocation program (E6.5), as part of end-of-life asset renewal, relocates vulnerable and difficult to access pole lines from areas such as heavily treed ravines and highway crossings. Other renewal programs that replace obsolete and difficult to access feeders (e.g., Rear Lot Conversion, E6.6; Box Construction Conversion, E6.7) are expected to have similar performance benefits during storm events.

Non-renewal programs are also expected to improve system and operational performance during storm events. For example, Feeder Automation (E7.3) is expected to significantly improve fault isolation, location and restoration on feeder trunks, simplifying restoration efforts during certain types of major storm events and freeing up resources for reactive repairs on lateral sections of feeders. Targeted, high-value programs such as Contingency Enhancement (E7.1), Downtown Contingency (E7.7) and Design Enhancement (E7.2) are expected to improve system performance during storms by ensuring that operators and crews have full flexibility to transfer and restore load and by hardening vulnerable parts of the system with more optimal fusing arrangements and the installation of assets such as tree-proof overhead conductors.

During the 2015-2019 planning horizon, Toronto Hydro intends to conduct climate adaptation studies to assist with engineering analysis, informed decision-making and standards development for overhead and underground capital programs. These studies are expected to focus specifically on identifying areas of the distribution system that are vulnerable to extreme weather and climate change, and include pilot projects for assessing study recommendations. These pilot projects are intended to help Toronto Hydro finalize climate adaptation solutions before programs are carried out at a system level.

(vii) Business Operations Needs (i.e. General Plant investments)

Toronto Hydro must also continue to maintain and enhance its non-distribution system assets to allow the utility to efficiently and effectively execute the proposed capital program, maintenance activities and other business functions. In addition to routine fleet, facilities and IT asset renewal investments, Toronto Hydro has identified several additional, one-time capital projects that are required during the forecast period.

- Toronto Hydro's current enterprise resource planning (ERP) system, installed in 2002 and last upgraded in 2006, has reached obsolescence due to lack of vendor support and other functional deficiencies. Toronto Hydro plans to replace the existing system with a

new, fully-supported ERP, which would incorporate new functional requirements that can deliver incremental benefits such as cost savings and process improvements.

- Toronto Hydro's voice radio system is not supportable beyond 2016 and must be upgraded in order to maintain safe and effective work practices.

- Toronto Hydro is executing an Operating Centers Consolidation Program (E8.3) to achieve permanently and significantly lower operating center costs.

Complete details and justification for all of the aforementioned system and non-system investments (as well as additional investment programs not highlighted in this section) are available in sections E5 through E8 of the DSP. A detailed discussion of the pacing of investment and its alignment to longer-term objectives is provided below.

2.2 Long-term Objective: Achieving "Steady-State"

The pace of investment during the 2015-2019 period is driven by system needs. The detailed rationale and decision-making frameworks that ultimately yielded this proposed pacing are described in Toronto Hydro's asset management policy and processes in Section D. At a high level, the long-term objective of Toronto Hydro's asset management policy is to achieve an optimal "steady-state", in which the number of assets that are past their economic end-of-life (explained below) is minimized. When the system is in that theoretical steady state, the total operating (or lifecycle) costs associated with the broader in-service asset population is minimized, meaning that customer value is effectively maximized.

The concept of a steady state can be better understood by examining Toronto Hydro's risk-based optimization approach to investment planning. Using the Feeder Investment Model (FIM), Toronto Hydro determines the optimal asset renewal timing based on the economic end-of-life criteria for each asset. The economic end-of-life of an asset is derived from two offsetting cost curves:

1. Annualized risk cost (red line below): increases as the asset ages; represents the quantifiable costs of asset failure (including customer interruption costs) multiplied by the probability of failure.

2. Annualized capital cost (green line below): decreases as the asset ages; represents the capital cost of replacement, annualized over the asset's projected life.

(For a detailed explanation of the FIM and how it is used within Toronto Hydro's asset management process, refer to Section D3.)

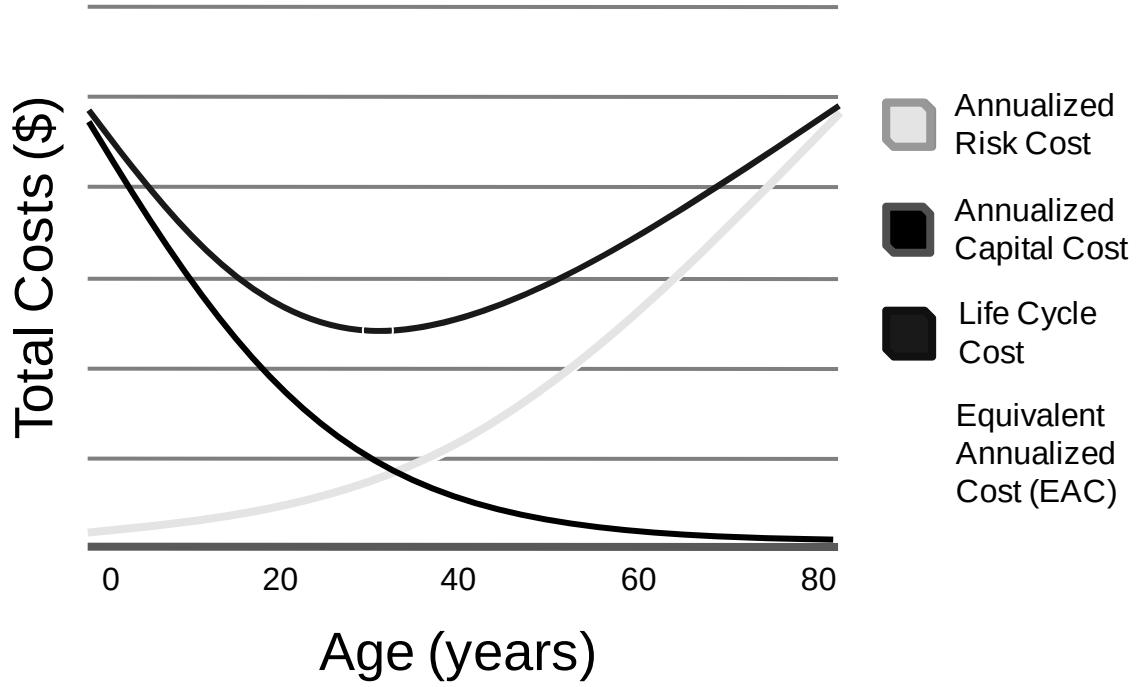

FIGURE 6: LIFECYCLE COST OF A DISTRIBUTION ASSET

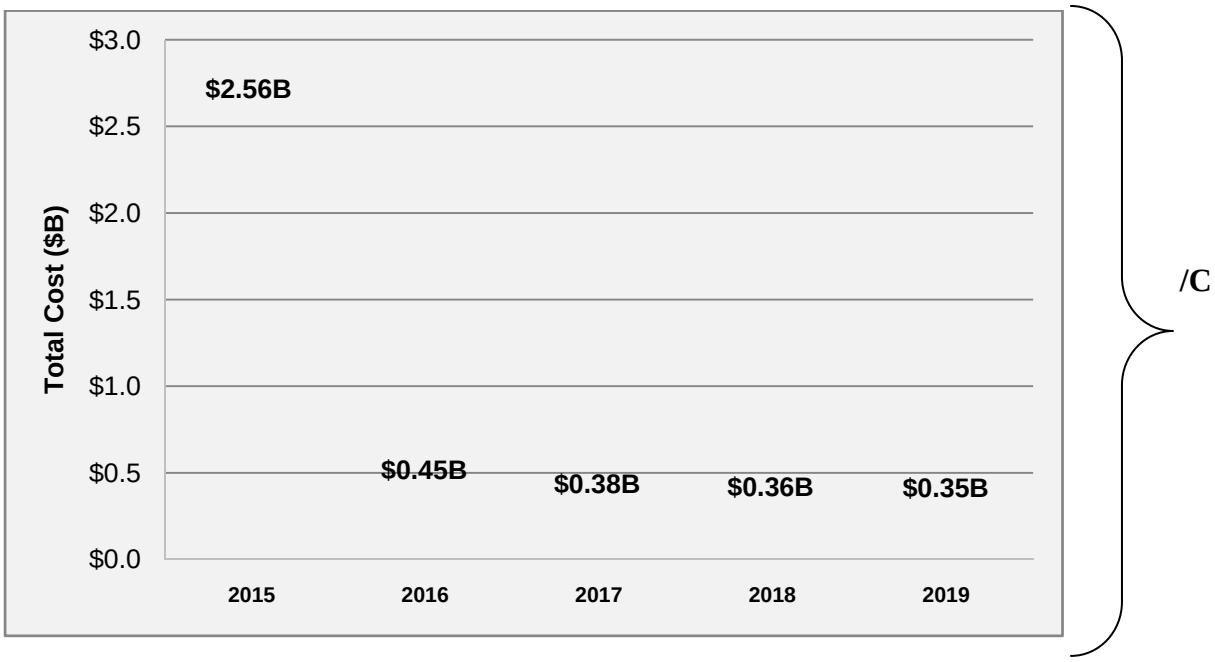
An asset reaches its economic end-of-life when the annualized capital cost of replacing the asset becomes less than the annualized risk cost of continuing to operate the asset. Put another way, the asset has reached its economic end-of-life when the total life cycle cost – i.e. the sum of the annualized risk cost and the annualize capital cost (depicted as the blue line in the above figure) – is at its lowest point. This is referred to as the optimal intervention time. Replacing the asset any sooner than the optimal intervention time risks wasting the remaining useful life of the asset, while replacing the asset after the optimal intervention time risks incurring unnecessary and avoidable costs associated with asset failure.



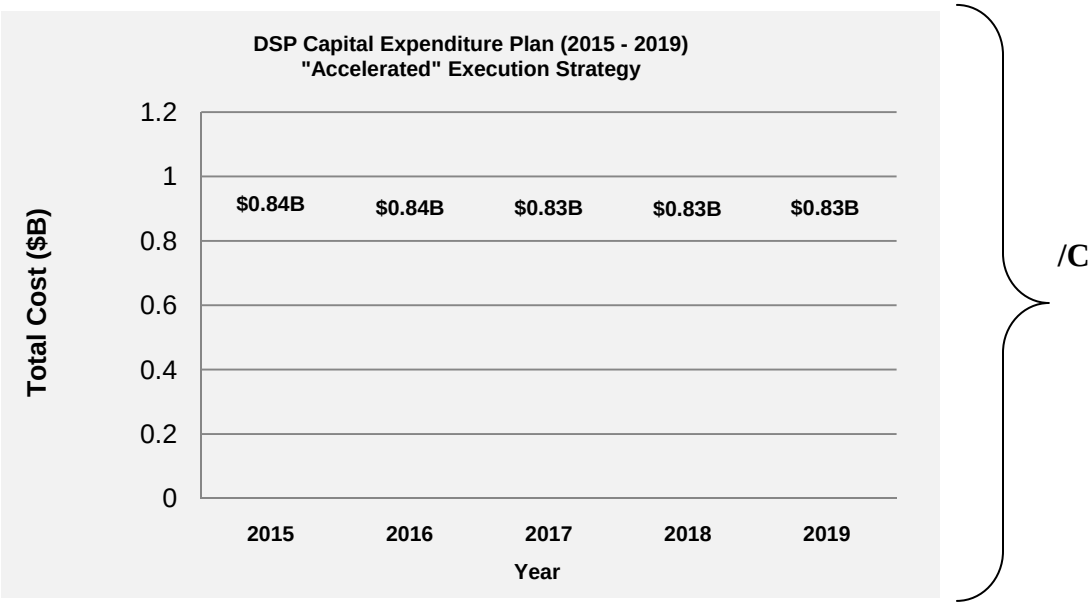
The objective of this risk-based approach is to minimize the total lifecycle or operational cost of the equipment in order to maximize the value derived from the assets. Of course, any given asset is likely to fail earlier or later than the optimal intervention time prescribed by the probabilistic FIM approach. The aggregate benefits of this risk-based approach are realized by applying the asset-level approach to a broader population of assets. Doing so means that, on average, Toronto Hydro is replacing assets in a manner that minimizes total lifecycle costs, and therefore the cost of service over time.

Theoretically, Toronto Hydro's risk based model defines the ideal steady state as the scenario where, on a system level, no assets are allowed to operate beyond their optimal intervention time, and all assets are replaced at exactly the optimal intervention time and no earlier (except those that inevitably fail prematurely). In reality, this approach would not be feasible as it would limit Toronto Hydro's ability to group assets into geographic, feeder, or station based renewal projects. Project-based asset renewal allows Toronto Hydro to undertake capital replacement cost-effectively by realizing design, scheduling, procurement and construction efficiencies. Toronto Hydro will therefore, in appropriate circumstances, elect to replace some assets prior to or following the optimal intervention time if doing so will allow the utility to realize project-based efficiencies. (Toronto Hydro's FIM tool includes functionality that helps planning engineers determine asset groupings that result in economically optimized renewal projects.) The OEB commended Toronto Hydro for developing this approach to asset management in the utility's previous distribution rates application (EB-2012-0064).

Taking these practical considerations into account, Toronto Hydro estimates that the optimal steady state for the distribution system will include a small percentage of assets operating beyond their economic end-of-life criteria in any given year, and that this percentage will change from year to year depending on the mix of projects. The following section includes a forecast of the percentage of assets that Toronto Hydro estimates will be operating beyond their economic useful lives if the proposed capital investment program is extended until steady state is reached.

Achieving Steady State

As explained above, the steady state approach represents the system state in which the total aggregate lifecycle cost of the existing asset base is minimized. Once the steady state is achieved, it must be maintained by continuing to renew assets as they reach economic end-of-life. This purely risk-based approach is indifferent to year-over-year changes in the level of investment required. In theory (i.e., without considering other practical constraints like bill impacts and resource constraints), the risk-based model recommends the following capital spending profile for the 2015-2019 planning horizon:



/C

FIGURE 7: ECONOMICALLY OPTIMAL CAPITAL INVESTMENT APPROACH (2015-2019)

This economically optimal capital investment approach would theoretically achieve steady state by 2016. However, this approach would constitute an unprecedented single-year capital investment that Toronto Hydro recognizes would result in large step-increases in rates, and, in any event, could not be completed as a practical matter. In short, this backlog of investments cannot be reasonably addressed in one year when considering bill impacts, system constraints and available resources.

For a more reasonable investment program, Toronto Hydro considered two alternatives: an "accelerated" strategy and a "paced" strategy. The accelerated strategy would allow for the backlog of investments to be managed over the five-year DSP period, such that "steady state" is achieved by 2019 with a level of investment of approximately $830 million on average per year, for a total of $4.17 billion over five years.

/C

FIGURE 8: ACCELERATED CAPITAL INVESTMENT STRATEGY (2015-2019)

One of the benefits of the accelerated strategy is that the system would be forecast to reach steady state in time for Toronto Hydro's next five-year rate filing, delivering more predictable rate impacts and system performance beginning in 2020.

However, the accelerated strategy would still feature levels of investment that do not immediately align to Toronto Hydro's current resources and system constraints, and, most importantly, would result in steeper rate increases over the DSP forecast period that would likely be unacceptable to customers. For this reason, Toronto Hydro's DSP is based on a paced strategy, which is illustrated in the figure below and represents the level of capital investment in the proposed 2015-2019 DSP. (Note that the annual investment amounts vary in this scenario. This is because these amounts are based on detailed DSP program level forecasts of assets to be replaced and projects to be executed within the DSP forecast period. For the reasons described above, the utility has not developed the accelerated strategy to this level of detail.)

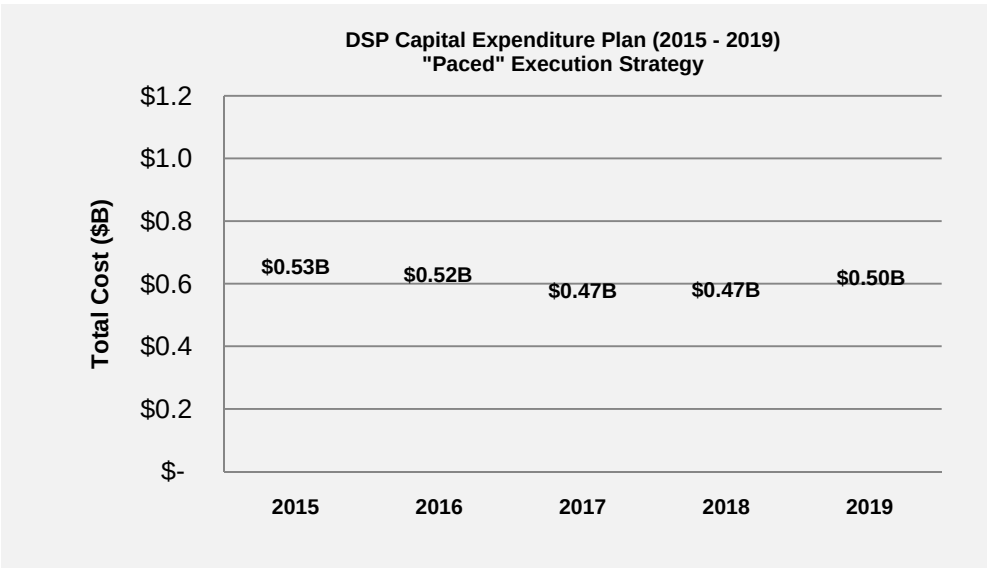


FIGURE 9: PACED CAPITAL INVESTMENT STRATEGY (2015-2019)

The paced execution strategy features an average annual investment of just under $500 million, which, as the DSP evidence in Chapters D and E demonstrates, is the minimum level of investment that is appropriate given the magnitude of the asset backlog and other critical system issues and operational needs. If Toronto Hydro were to continue at this annual pace beyond 2019, the system is forecast to reach steady state by approximately 2037.

The disadvantage of this strategy is that customers are exposed to greater total asset lifecycle costs during the entire period of 2015 to 2037. However, this approach has the advantage of more predictable and tolerable bill increases during the 2015-2019 period and alignment with Toronto Hydro's immediate execution capacity.

The paced strategy has another significant advantage over the accelerated strategy: bill impacts and system performance are forecast to be more predictable beyond the achievement of steady-state. This is because the paced strategy takes a more gradual or dispersed approach to clearing the backlog of end-of-life assets. While achieving steady-state faster would maximize customer value sooner, the rapid renewal of aging assets would likely result in another large "lump" of end-of-life assets in the future, which would require another period of significantly large, multi-year investment needs.

To illustrate the overall impact on the system of reaching steady state, Figure 10 shows the forecast useful life demographics of the system as of 2037. The projected steady state in 2037

features a 15 percentage point reduction in the percentage of assets operating beyond end-of-life versus the current state of the system illustrated in Figure 2.

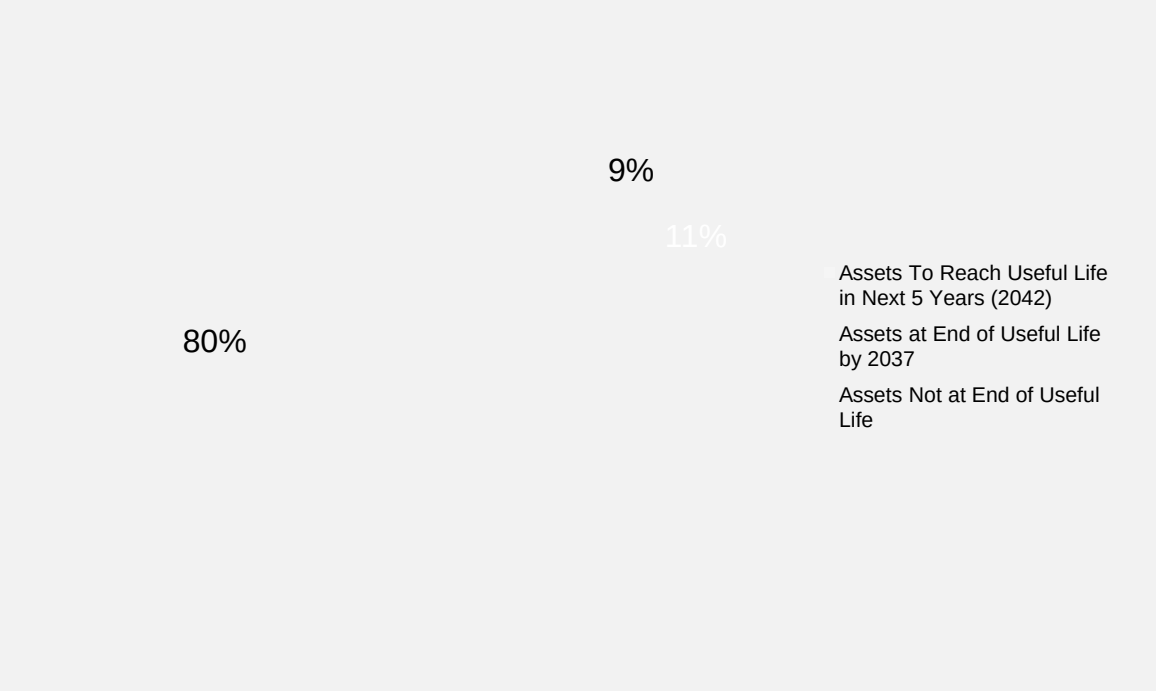

FIGURE 10: PROJECTED ASSET AGE DEMOGRAPHICS AS OF 2037

3 Coordinated Planning with Third Parties

Toronto Hydro recognizes the importance of coordinated regional planning between licensed distributors and transmitters and agrees with the view articulated in the RRFE that regional planning is an essential input to the cost-effective development of electricity infrastructure. The OEB's RRFE report and associated filing requirements place an emphasis on the integration of regional issues and requirements into utility planning processes.

Toronto Hydro, through its participation in the Central Toronto Integrated Regional Resource Plan led by the OPA, and in its participation in the Needs Screenings for Metro Toronto Northern sub-region and GTA North Western sub-region led by Hydro One Networks Inc. (HONI), has coordinated its planning efforts and subsequent DSP with the outcomes of the completed plans. The utility continues to coordinate with regional plans that are under development.

Transmitter Consultations

HONI consulted with Toronto Hydro and neighbouring distributors through a Needs Screening of two electrical areas:

- Metro Toronto Northern Sub-region, and
- GTA North Western Sub-region.

The Needs Screening Report for the Metro Toronto Northern Sub-region was completed on June 12, 2014 and is provided as Appendix A of Chapter B. The Needs Screening Report for the GTA North Western Sub-region was completed on June 27, 2014 and is provided in Appendix B to Chapter B. Neither of these Needs Screening Reports identified any transmission infrastructure needs during the planning horizon. There is no impact on the DSP due to either report.

Regional Planning Process

The Metro Toronto Region has been divided into two sub-regions for ease of planning: Central Toronto and the Northern sub-regions. The two sub-regions are shown in Figure 11.

FIGURE 11: INTEGRATED REGIONAL RESOURCE PLAN REGIONS

The Central Toronto sub-region study in December of 2011 was started before the introduction of the Regional Planning Process. Previously known as the Toronto Regional Plan, it is now the Central Toronto Integrated Regional Resource Plan (IRRP).

The Ontario Power Authority is the lead in this process and the following organizations are the study participants:

- Toronto Hydro
- Hydro One Networks Inc. (HONI)
- Independent Electricity System Operator (IESO)

The purpose of the IRRP is to help ensure that the electricity service requirements of the central Toronto community are served by an appropriate combination of demand and supply options that reflect the priorities of the community. The Central Toronto IRRP is still in progress but the Ontario Power Authority (OPA) has confirmed a long identified issue of capacity shortfalls in the

Runnymede TS, Manby TS and Copeland TS areas. Toronto Hydro has been planning remedies for these shortfalls and has discussed and shared alternatives with the OPA and HONI as part of the planning effort. The projects contained within the Stations Expansion capital investment program, further detailed in Section E7.9, reflect the regional planning consultations to date for Central Toronto.

The Central Toronto IRRP is currently expected to be completed by December 2014.

4 Performance Measurement for Continuous Improvement

In section 5.2.3 of the filing requirements, the OEB requests that distributors identify and define the methods and measures that will be used to monitor the quality of their planning process, the efficiency with which their plans are implemented, and/or the extent to which their planning objectives are met. Following the OEB's guidance, Toronto Hydro has developed a set of 12 measures to monitor quality and drive continuous improvement in its distribution system planning and implementation work over the 2015-2019 planning horizon. The measures cover several distinct dimensions of the utility's capital planning and implementation processes and/or speak directly to the outcomes of such processes, motivated by customer needs, regulatory compliance obligations, or the utility's efficiency objectives.

Table 2 outlines Toronto Hydro's proposed DSP performance measures, grouped by primary category.

TABLE 2: PROPOSED PERFORMANCE MEASURES FRAMEWORK

Customer-Oriented Performance	Cost Efficiency/ Effectiveness of Planning and Implementation	Asset/System Operation Performance
1. System Average Interruption Duration Index (SAIDI). 2. System Average Interruption Frequency Index (SAIFI). 3. Customer Average Interruption Duration Index (CAIDI). 4. Feeders Experiencing Sustained Interruptions (FESI). 5. Momentary Average Interruption Frequency Index (MAIFI).	1. Distribution System Plan Implementation Progress. 2. Planning Efficiency: Engineering, Design and Support Costs. 3. Supply Chain Efficiency: Materials Handling On-Cost. 4. Construction Efficiency: Internal vs. Contractor Cost Benchmarking. 5. Construction Efficiency: Standard Asset Assembly Labour Input.	1. Outages caused by defective equipment. 2. Stations capacity availability.

For a detailed discussion of these measures, their technical definitions, and the expected outcomes over the DSP forecast period, please refer to Section C of the DSP.

For each proposed measure, (with the exception of new measures) Toronto Hydro provides performance results along with the associated trend over the recent years, describes the methodology used to calculate the measure and its implementation, and outlines the ways in which the measure informs and/or otherwise interacts with the utility's DSP and the related processes. Where relevant, Toronto Hydro also describes the unique planning and implementation considerations that shape the measure's design and the utility's expectations as to its future performance levels.

5 Asset Management Process

Toronto Hydro's AM Process, which is explained in detail in Section D, can be broken down into five major components: (i) the planning process, (ii) the associated decision-support systems, (iii) the enterprise databases that support both the planning process and systems, the (iv) distribution

system plan itself that is supplied by outputs from the planning process, and finally (v) a measurement and enhancement process that supports continuous improvement. Figure 12 depicts the AM process and its various elements and support systems.

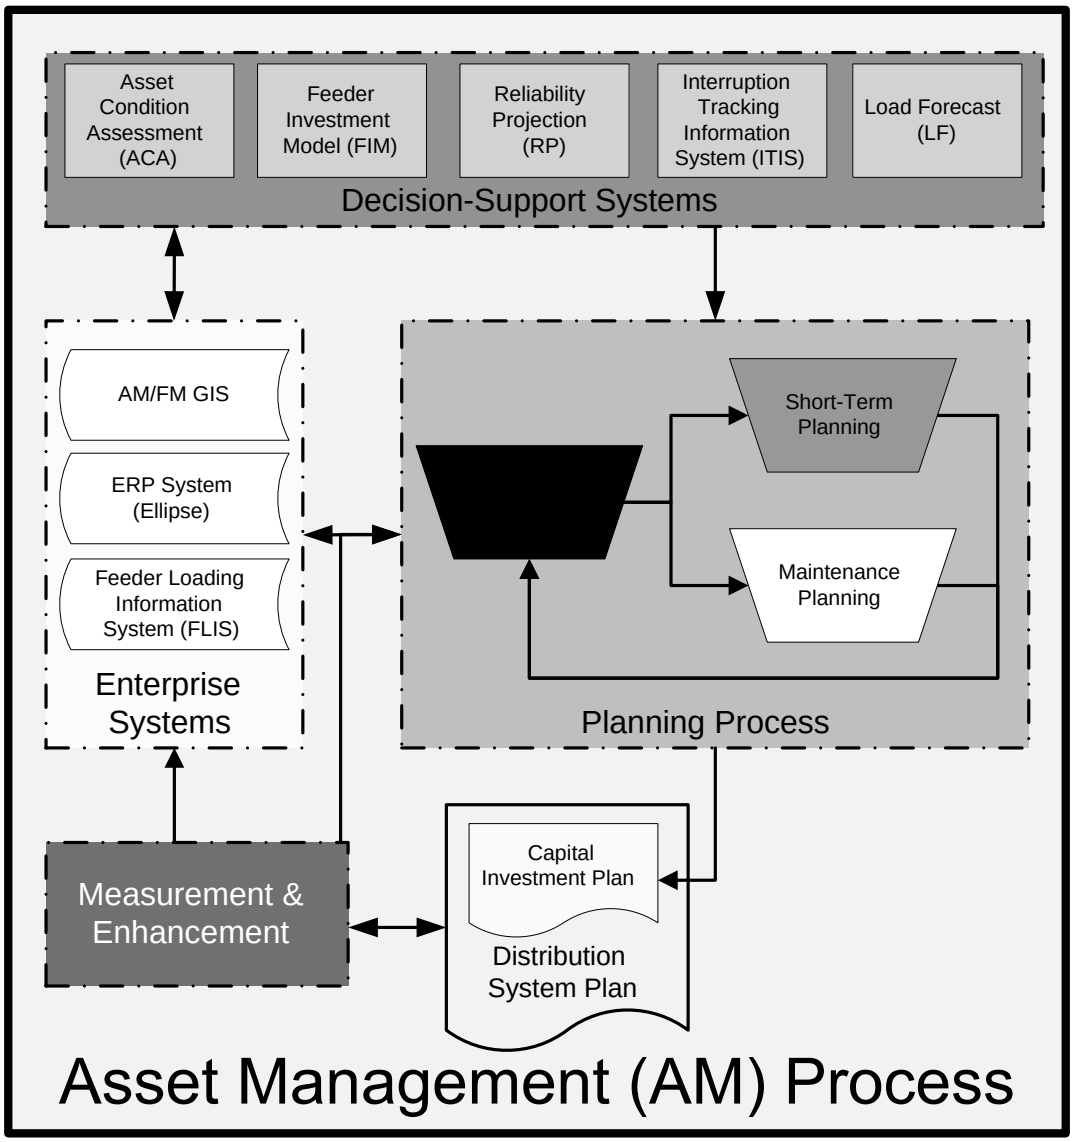

FIGURE 12: ASSET MANAGEMENT PLANNING PROCESS OVERVIEW

The planning process element of the AM process can be further subdivided into three stages:

(i) Long-term planning, discussed in detail in Section D1.2.1, results in the development of a capital investment approach and execution strategy along with corresponding investment programs that align to AM objectives.

(ii) Short-term planning, discussed in detail in Section D1.2.2, results in the production of discrete projects within each investment program.

(iii) Maintenance planning, discussed in detail in Section D1.2.3, focuses on extracting the maximum value out of Toronto Hydro's distribution system assets, through inspections, upkeep and repair activities. The outputs from the AM Planning Process as a whole are integrated into the DSP.

Toronto Hydro is continually monitoring and improving decision-support systems, enterprise systems and various inputs that support the AM planning process. Recent improvements include the following:

- Kinectrics, in their independent audit of Toronto Hydro's Asset Condition Assessment program (Chapter D, Appendix A), notes that Toronto Hydro has worked to improve its maintenance practices in a number of ways, including improved asset inspection forms and an expanded scope for transformer oil testing.
- Toronto Hydro introduced additional quantifiable benefits as an enhancement to the business case evaluation process. This allows for a broader set of benefits to be considered in the quantified analysis, thereby allowing for a more accurate and robust analysis of the proposed program. This enhancement is further discussed in detail in Section D3.
- Toronto Hydro has made efforts to improve data quality within its enterprise geographical information system (GIS) and enterprise resource planning (ERP) system respectively such that improved decision making can be performed at both the long-term and short-term planning levels. This includes development of data quality reporting processes, consolidation of data from the two systems, improvement of connectivity of information within systems, etc.
- Toronto Hydro has improved on various elements of the Asset Condition Assessment process. Key improvements include increased sample size of each asset category and improvements to the Business Intelligence Calculator

6 Customer Needs and Preferences

In accordance with the OEB's requirement to obtain information on customer preferences, Toronto Hydro has engaged with its customers specifically around the utility's DSP for 2015-

2019. As explained in detail in Exhibit 1B, Tab 2, Schedule 7, Toronto Hydro engaged Innovative Research Group Inc. ("Innovative"), a national consultancy with expertise in public opinion research, to design and carry-out a consultation process intended to provide the utility with meaningful information to assist in preparing the DSP.

Innovative's final report (Appendix B to Exhibit 1B, Tab 2, Schedule 7) documents the process and findings of this consultation in detail. Overall, Toronto Hydro has found that customers' preferences and values align with central pillars of the utility's DSP. Toronto Hydro learned that, while its customers expect the utility to make prudent investment decisions, the majority accept the need for timely renewal of the distribution system, while acknowledging that this will mean an increase in their monthly bills. A detailed discussion of how the results of this consultation are reflected in Toronto Hydro's 2015-2019 Distribution System Plan is provided in section E2.4.

7 Capital Expenditure Plan

Table 3 shows the level of spending for the System Access, System Renewal, System Service and General Plant investment categories, as well as the System O&M expenditures over the historical period from 2010 to 2014 and over the forecast period from 2015 to 2019. This table aligns to "Table 2 – Capital Expenditure Summary" in Chapter 5 of the Filing Requirements.

Expenditures within the 2010-2013 historical period are actual expenditures, whereas expenditures for 2014 are forecast (i.e. bridge year) expenditures, as the 2014 year has not yet concluded as of this writing.

For a complete analysis of year-over-year historical and forecast variances within each category, refer to Section E4 of the DSP.

TABLE 3: CAPITAL EXPENDITURE SUMMARY

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
System Access	$44.37	$58.31	$53.15	$86.62	$76.01	$86.13	$93.54	$100.93	$90.41	$85.47
System Renewal	$215.00	$219.25	$157.25	$231.08	$286.37	$251.74	$234.99	$246.35	$260.08	$265.49
System Service	$35.32	$75.63	$38.35	$83.67	$101.34	$76.45	$69.60	$62.51	$49.54	$73.95
General Plant	$55.53	$67.71	$29.28	$33.77	$109.47	$104.63	$99.44	$28.93	$32.13	$27.88
Other CAPEX	$50.36	$24.63	$9.92	$10.52	$12.73	$12.18	$21.22	$28.65	$37.89	$49.37
Total	**$400.58**	**$445.53**	**$287.95**	**$445.66**	**$585.92**	**$531.13**	**$518.79**	**$467.36**	**$470.05**	**$502.16**
System O&M	$114.64	$111.89	$109.03	$119.84	$118.94	$128.76	-	-	-	-

IC

The following sections provide a summary of System Access, System Service, System Renewal and General Plant programs as well as System O&M expenditures. For full details and justification of the programs listed throughout these sections, see Sections E5 through E8 of the DSP. For a detailed explanation of System O&M expenditures, see Section E4.2.6.

7.1 System Access

Toronto Hydro's capital expenditures under the System Access investment category are driven by statutory, regulatory or other obligations that require Toronto Hydro to provide customers with access to the distribution system or to otherwise respond to service requests.

TABLE 4: SUMMARY OF SYSTEM ACCESS PROGRAMS

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E5.1	**Metering**	Enable Toronto Hydro to meet its mandatory service obligations with respect to revenue metering and wholesale metering. This will be accomplished by testing meters, replacing damaged and obsolete meters, and upgrading the under-capacity and obsolete collector stations. Upgrading Toronto Hydro's Interval Metering MDM software will help customers manage their energy use and costs by providing them with timely access to their data.	**$81.5 M**	Mandated Service Obligations	Failure Risk

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E5.2	**Customer Connections**	Toronto Hydro is obligated to connect new customers or upgrade existing customers to a larger service if requested, as required under the terms of Toronto Hydro's distribution license, the Distribution System Code and the *Electricity Act, 1998*. On average, 10,000 requests for new services, upgrades, and removals are made each year and the amount is expected to increase with current and proposed development.	**$261 M**	Customer Service Request	Mandated Service Obligations
E5.3	**Externally-Initiated Plant Relocation & Expansion**	Toronto Hydro is required to modify/relocate its system to accommodate property or infrastructure development (e.g., requests from a road authority to move a pole line). Toronto Hydro works with the external agency in question to accommodate the project, and investigates opportunities for cost-efficient expansion work. Note that the cost listed in the DSP is significantly below forecast costs. Due to the externally-driven natures of this work, Toronto Hydro proposes to seek rates funding only for this sub-forecast base amount, with a variance account to record differences from this forecast.	**$20.1 M**	Third Party Request	
E5.4	**Load Demand**	With increased load in concentrated areas due to the city's growth, equipment (such as undersized cables) in the system must be upgraded in the short-term to address contingency issues to accommodate this increased demand. The problem is expected to be addressed by transferring loads to stations with available capacity, upgrading undersized equipment and cables, and ensuring civil infrastructure can support increased demand, allowing Toronto Hydro to continue connecting customers in these areas without harming system reliability, customer value, and operational flexibility.	**$74.9 M**	Customer Service Requests	Mandated Service Obligations - Reliability - System Efficiency
E5.5	**Generation Monitoring, Protection and Control**	Toronto Hydro is mandated to make every reasonable effort to connect distributed generation users. This program involves installation of bus-tie reactors at station buses, advanced protection systems, and monitoring and control systems to handle the increasing DG penetration in the City of Toronto, including renewable energy generation (REG) projects.	**$18.7 M**	Mandated Service Obligations	Safety - Reliability

/C

7.2 System Renewal

Capital expenditures in the System Renewal investment category are driven by the need to maintain distribution system asset performance at an acceptable standard. These investments will serve to renew those assets that are nearing, at, or exceeding their end-of-life criteria, along with assets that are functionally obsolete due to accessibility or serviceability deficiencies.

TABLE 5: SUMMARY OF SYSTEM RENEWAL PROGRAMS

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E6.1	Underground Circuit Renewal	Replace end-of-life and obsolete underground assets with new ones on a "like-for-like" basis. The assets include switches, transformers, and cables. Replacing the assets is forecast to help improve system reliability and efficiency.	$459 M	Failure Risk	Safety - Functional Obsolescence
E6.2	Paper-Insulated Lead-Covered (PILC) Piece-outs and Leakers	Program will address two issues related to underground PILC cable. PILC cables are aging and a number have developed cracks and pinholes and must either be replaced or repaired. The program will also increase cable length to address unsafe congested areas and allow the cables to be safely and properly routed.	$6.88 M	Failure Risk	Safety - Reliability
E6.3	Underground Legacy Infrastructure	Targets non-standardized equipment that is at or near end-of-life and poses a failure risk. Many of these assets are now obsolete and will be replaced with standardized equipment, helping to improve safety and system reliability.	$27.4 M	Functional Obsolescence	Safety - Reliability - Failure Risk
E6.4	Overhead Circuit Renewal	Focuses on replacing poles, switches, transformers, overhead accessories and street lighting assets that are either aged, in poor condition, or functionally obsolete on a “like-for-life” basis. Toronto Hydro expects the program to mitigate significant sources of outages that negatively impact service reliability to customers and may pose potential safety risks for employees and the general public.	$147 M	Failure Risk	Safety - Functional Obsolescence

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E6.5	Overhead Infrastructure Relocation	Provide a modern and efficient configuration to replace feeders that are past end-of-life and functionally obsolete from a design perspective to mitigate the number of system outages. Feeders will be relocated to eliminate difficult-to-access overhead plant, overhead egress plant and overhead plant crossing highways.	$9.87 M	Functional Obsolescence	Safety - Reliability
E6.6	Rear Lot Conversion	This program replaces the existing, end-of-life rear lot distribution service configuration with an underground front lot access system to eliminate challenges in performing maintenance activities and to mitigate the increased risk of long duration outages inherent in the existing plant design. The conversion eliminates operational constraints and reduces the safety and reliability risks associated with this obsolete connection configuration.	$59.3 M	Functional Obsolescence	Safety - Reliability - Failure Risk
E6.7	Box Construction Conversion	This program transitions customers from functionally obsolete 4.16 kV box construction feeders to the current standard 13.8 kV or 27.6 kV overhead infrastructure. By eliminating box construction feeders, Toronto Hydro anticipates that the program will reduce safety concerns for crew members dealing with restricted working spaces, improve restoration times and mitigate costs related to load capacity constraint when connecting new customers in the downtown area.	$103 M	Functional Obsolescence	Safety - Efficiency - Reliability

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E6.8	SCADA-MATE R1 Replacement	This program replaces malfunctioning switches. Moisture has caused internal switch components to corrode. The corrosion poses significant safety hazards to the public and Toronto Hydro employees due to misrepresentation of the switch state; therefore, core functions of the switch can no longer be used. The new R2 design improves remote functionality and reliability of the switch, thereby reducing prolonged outages and failure risk for customers.	$12.9 M	Functional Obsolescence	Safety - Failure Risk
E6.9	Network Vault Rebuild Program	Rehabilitation of vaults that were identified to be high-risk (through asset condition assessment studies) to protect the assets that are housed within and to mitigate potential safety hazards for crews, pedestrians and emergency response crews in busy downtown areas. Rehabilitation options include decommissioning the vaults, rebuilding the vault roofs, or rebuilding the entire vault.	$45.1 M	Failure Risk	Safety
E6.10	Network Unit Renewal Program	Replacement of obsolete and poor condition Network Units that are at risk of failure with new submersible Network Units. Toronto Hydro anticipates that this program will increase service reliability, improve employee safety and reduce environmental concerns by mitigated oil leaks.	$34.4 M	Failure Risk	Safety
E6.11	Legacy Network Equipment Replacement (ATS & RPB)	Replacement of automatic transfer switches (ATSs) and reverse power breakers (RPBs) with manual secondary switches, stand alone network protectors (SANPs), or network units. The ATSs and RPBs are no longer supported by their original manufacturer, making it difficult to comply with prudent maintenance practices and policies. These assets are also not submersible by design and are subject to a high risk of equipment failure.	$4.62 M	Functional Obsolescence	Failure Risk - Safety

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E6.12	Network Circuit Reconfiguration	Reconfiguration of the functionally obsolete network system by splitting a large secondary grid into enhanced mini grids. Increasing grid flexibility is expected to enhance the utility's ability to supply new classes of customers, to operate under different contingency events and decrease the necessity to drop the entire network during failure.	$9.14 M	Functional Obsolescence	Reliability - System Efficiency - Safety
E6.13	Stations Switchgear Renewal	Replacement of existing switchgears that have become functionally obsolete and that have passed the end of their useful lives. The existing non-arc resistant switchgear at municipal stations and transformer stations will be replaced with type C, arc resistant switchgear with vacuum circuit breakers.	$106 M	Functional Obsolescence	Reliability - Safety
E6.14	Stations Power Transformer Renewal	Replacement of power transformers located at municipal stations across the city to mitigate the failure risk of prolonged outages due to assets at the end of their useful lives. This program is expected to directly benefit customers connected to the transformers identified for replacement by reducing outage risk and increasing system reliability in their respective areas.	$12.3 M	Failure Risk	
E6.15	Stations Circuit Breaker Renewal	Replacement of obsolete oil circuit breakers, which are no longer supported by manufacturers, with stand-alone vacuum circuit breakers. Vacuum circuit breakers are cheaper to maintain and are less likely to fail catastrophically.	$9.13 M	Functional Obsolescence	Failure Risk - Safety
E6.16	Stations Control & Monitoring	This program aims to replace aging and obsolete remote terminal units (RTUs) and install SCADA systems at substations with no SCADA capabilities. Existing RTUs and radio communications networks at Etobicoke MS and downtown Toronto TS will be replaced while modern SCADA systems at Scarborough MS will be installed.	$5.05 M	Functional Obsolescence	Reliability - Cyber Security

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E6.17	Stations Ancillary Systems	Replacement of end-of-life and outdated ancillary systems (air compressors, station service power supply systems, fire alarm systems, and fire barriers) that are at risk of failure and functionally obsolete with more reliable modern technologies.	$2.29 M	Failure Risk	Functional Obsolescence - Safety
E6.18	Stations Buildings	This program focuses primarily on the structural integrity of 11 TS and MS buildings in which electrical stations assets are housed. The program takes a proactive approach to improve existing station buildings to extend their serviceable lives. Toronto Hydro anticipates that this will help it deliver uninterrupted service, improve the safety of crews and the public, and help protect nearby customer property.	$11.1 M	Failure Risk	Safety
E6.19	Stations DC Battery Replacement	Replacement of end-of-life DC batteries and chargers systems with new ones at various stations locations to mitigate battery failure risk and ensure faults are isolated to the local feeder. These batteries are used to provide the necessary power supply to operate the associated circuit breaker assets if the main power supply to the entire station is lost.	$3.14 M	Failure Risk	Safety
E6.20	Reactive Capital	Accounts for unplanned, non-discretionary capital expenditures required to repair or replace assets. With proper budgeting and resource allocation, timely reactive work improves safety, reduces the backlog of assets to be maintained, avoids depriving other capital programs of planned resources and reduces strain on the distribution system.	$166 M	Failure	Safety - Reliability

Program Index and Name		Description	Total (5 yrs)	Trigger Driver	Secondary Drivers
E6.21	Worst Performing Feeder	This program analyses the performance of feeders that are at risk of seven or more outages in a year and determines the root cause of the outage trend. Condition of the equipment will be assessed during feeder patrols and appropriate mitigation work will be performed to alleviate outages caused by design or environmental disturbances. The program is expected to improve the reliability of feeders, minimizes power outages for customers experiencing especially poor service, and mitigates the risk of additional asset failures.	$8.49 M	Failure Risk	
E6.22	Distribution System Communication Infrastructure	This program renews and improves the telecommunications system by identifying gaps in the communication service platform, updating the obsolete SONET technology and SCADA infrastructure. An updated telecommunication system reduces failure risk an provides safe, efficient and reliable supply of electricity to customers.	$16 M	Functional Obsolescence	System Capital Investment Support - System Maintenance Support - Safety

7.3 System Service

Capital expenditures under the System Service investment category are driven primarily by the need to resolve critical system-wide issues, including capacity and operational constraints, security-of-supply risks, potential safety risks, system reliability deficiencies and other inefficiencies within the existing grid. Beyond the safety and capacity-driven investments in this category, a number of the programs were selected as cost-effective means of enhancing customer value (in the form of improved service and service efficiency) during the 2015-2019 period while maintaining a relatively modest pace of System Renewal work.

TABLE 6: SUMMARY OF SYSTEM SERVICE PROGRAMS

Program Index and Name	Description	Total (5 years)	Trigger Driver	Secondary Drivers

Program Index and Name		Description	Total (5 years)	Trigger Driver	Secondary Drivers
E7.1	**Contingency Enhancement**	Make improvements to feeders in the existing distribution systems that are currently unable to quickly restore power to affected customers under a contingency situation.	**$48.9 M**	Reliability	System Efficiency - Safety
E7.2	**Design Enhancement**	Implementing fusing enhancements to resolve the issues of undersized fuses, mis-coordinated fuses and redundant trunk sections that lack fusing. Replacement and strategic location of fuses and the implementation of tree proof conductors to mitigate sustained interruptions caused by tree contact outages.	**$7.27 M**	Reliability	System Efficiency
E7.3	**Feeder Automation**	Facilitating faster and less labour intensive system restoration procedures by replacing existing switches with autonomously operating Supervisory Control and Data Acquisition switches, reducing the impact of trunk outages to customers and isolating the faulted section of the feeder in less than a minute.	**$54.1 M**	System Efficiency	Reliability
E7.4	**Overhead Momentary Reduction**	Installation of reclosers to provide flexibility to the system, fault protection and improve the distribution feeder reliability performance by limiting outage times and containing the outage to a minimum area.	**$1.91 M**	Reliability	System Efficiency - Safety
E7.5	**Handwell Upgrades**	Replacing the remaining legacy handwells with new standard handwells made from non-conducting composite materials to remove the risk of contact voltage to the public.	**$4.98 M**	Safety	Functional Obsolescence
E7.6	**Polymer SMD-20 Switch Renewal**	Targets SMD-20 switches that were installed between 2006 and 2011, as breakages inhibit these switches from functioning safely as designed. New switches utilize a fiberglass core that has five times the strength of the previous design. Replacement of the switches eliminates the known safety risk to the public and Toronto Hydro employees.	**$4.84 M**	Safety	Substandard Performance - Reliability

/C

Program Index and Name		Description	Total (5 years)	Trigger Driver	Secondary Drivers
E7.7	**Downtown Contingency**	Providing distribution load transfer capability between stations in the downtown Toronto area by tying feeders from one station with feeders from an adjacent station. This program addresses a risk in the downtown area where no back-up is provided for certain low probability, high impact events.	**$3.36 M**	Reliability	Operational Constraints - Safety
E7.8	**Customer Owned Station Protection**	Installation of utility-owned protection devices upstream of customer-owned substations to isolate any faults occurring at customer owned substations.	**$4.04 M**	Reliability	Safety
E7.9	**Stations Expansion (including HONI contributions)**	Upgrades to either Toronto Hydro or Hydro One Networks Inc. owned transformer stations. These upgrades address recent trends in customer connection requirements and loading, by mitigating system limitations imposed by existing station equipment.	**$188 M**	Capacity Constraints	Reliability
E7.10	**Local Demand Response**	Providing medium-term capacity relief to Cecil TS by implementing a targeted and localized demand response strategy which primarily leverages new and existing demand response resources.	**$4.06 M**	Capacity Constraints	Reliability
E7.11	**Energy Storage Systems**	To provide a conventional support for local capacity constraints and service reliability issues throughout Toronto Hydro's distribution system. These systems are also categorized as a renewable enabling improvement to accommodate the increasing numbers of renewable energy generation (REG) connections.	**$10.8 M**	System Efficiency	Reliability - Power Quality

IC

7.4 General Plant

Capital expenditures under the General Plant investment category represent necessary routine and one-time investments into the backbone assets that support Toronto Hydro's operational activities. These investments are essential to the execution of the capital and O&M related activities and expenditures discussed in the DSP and elsewhere.

TABLE 7: SUMMARY OF GENERAL PLANT PROGRAMS

Program Index and Name		Description	Total (5 years)	Trigger Driver	Secondary Drivers
E8.1	**Fleet and Equipment Services**	As Toronto Hydro's fleet ages, regular vehicle replacement and repair is necessary. This program replaces 24-95 vehicles a year as well as installing new equipment on existing vehicles requiring refresh or replacement, all to ensure the fleet is safe, reliable, and cost-efficient.	**$17.9 M**	System Maintenance and Capital Investment Support	Safety - Reliability - Business Operations Efficiency
E8.2	**Facilities Management & Security**	Security enhancements are necessary to ensure assets, employees and the general public are protected by up-to-date security equipment and technologies. Additionally, facilities program is needed to improve the safe, reliable and efficient operation of the work centers and stations as well as increase the overall asset value for all of Toronto Hydro	**$31.8 M**	System Maintenance and Capital Investment Support	Safety - Failure Risk - Reliability
E8.3	**Operating Centers Consolidation**	Consolidation of Toronto Hydro's operating centers is required to secure tenure for Toronto Hydro in the northwest and northeast areas of the City while delivering benefits to ratepayers. Toronto Hydro plans to vacate four facilities, two of which it currently owns, and relocate staff, equipment and operations to three facilities already owned by Toronto Hydro to achieve efficiencies and improve space utilization. The utility plans to sell the two surplus Toronto Hydro-owned facilities, crediting the net after-tax gains on sale and related tax savings to ratepayers through rate riders.	**$52.2 M**	System Maintenance and Capital Investment Support	Business Operations Efficiency
E8.4	**IT Hardware Refresh**	The program addresses the renewal and maintenance of core backend infrastructure (e.g. servers, storage disks) and endpoint assets (i.e. laptops, desktops) that enable Toronto Hydro to plan and execute capital and operational programs and to fulfill its obligations to customers and applicable regulatory bodies.	**$36.7 M**	System Maintenance and Capital Investment Support	Cyber Security Risks - Business Operations Efficiency
E8.5	**IT Software**	The Software program covers planned IT upgrades to more than 70 software applications that support Toronto Hydro's core functions and processes. Toronto Hydro must upgrade these applications to ensure their availability to meet operational needs, and to protect itself against cyber threats that	**$81.0 M**	System Maintenance and Capital Investment Support	Cyber Security - IT Systems Compatibility -

/C

Program Index and Name		Description	Total (5 years)	Trigger Driver	Secondary Drivers
		could jeopardize the security of the distribution system and the privacy of sensitive operational, customer and employee information. The program also includes initiatives to enhance, modify or implement new software applications that are necessary to optimize business operations, or to comply with external requirements imposed by entities such as Measurement Canada, the OEB and the IESO.			Regulatory Compliance
E8.6	ERP Implementation	The current end-of-life ERP, Ellipse, will soon no longer be supported by its vendor, introducing a number of technical risks. The program will replace Ellipse and 30 other legacy applications with a new ERP that meets functional requirements.	$51 M	Functional Obsolescence	Business Operations Efficiency
E8.7	Voice Radio System	The voice radio system is critical to Toronto Hydro's ability to safely and effectively deliver its planned capital and maintenance programs and to respond to trouble calls in a safe, timely and efficient manner. The current voice radio system cannot be supported by the vendor beyond 2016 and must be upgraded to mitigate safety and operational risks.	$20 M	Safety	System Capital and Maintenance Program Support - Functional Obsolescence
E8.8	Program Support	This program will perform two studies to enhance the asset management process and improve the long-term and short-term strategy. The first will be a climate adaption study, focusing on at risk areas to extreme weather and climate change. The second will be a customer interruption study to estimate outage costs.	$1.7 M	System Maintenance and Capital Investment Support	

7.5 System Operating & Maintenance (O&M)

System Operational and Maintenance (O&M) expenditures represent the following five functional areas:

- Supply Chain Services;
- Control Centre;
- Operations Support;

- Distribution Maintenance Programs; and
- Fleet and Equipment Services.

Specific O&M programs within these areas are explained in detail in Exhibit 4A, Tab 2.

Capital and System O&M programs are interrelated. Ageing and deteriorated assets that are not replaced through capital work typically result in deteriorating conditions over time that are managed through System O&M work. These activities place upwards pressure on expenditures within certain segments of System O&M programs. The opposite also typically holds true as increases in capital work can result in reductions in certain System O&M work. Examples of this include capital replacements and enhancements for legacy distribution assets such as fibertop network units, reverse power breakers, and porcelain insulators. Examples also include corrective maintenance expenditures, which during the 2010 to 2013 period, experienced a reduction in part due to increases in planned capital expenditures on ageing and deteriorated assets. Corrective maintenance is expected to rise in 2015, however it is forecast to remain below the peak levels experienced in 2011.

Although System O&M and capital investments are interrelated, a significant portion of System O&M expenditures are directed to activities that are independent of particular capital expenditure levels, including routine maintenance to preserve asset performance over its expected life; vegetation management to maintain minimum clearance requirements for overhead conductor and equipment; cyclical patrols and inspections undertaken to comply with minimum Distribution System Code requirements; corrective maintenance activities to address deficiencies caused by animal, pest, or tree contacts; and emergency maintenance following severe weather and storm damage. In addition, System O&M programs are necessary to provide the information that is used to plan Toronto Hydro's capital programs, such as asset health and condition information. This is particularly important given Toronto Hydro's ageing asset base, which cannot be feasibly replaced through capital work in a short time frame due to a variety of factors such as resource and logistic constraints, as well as potentially intolerable bill increases. The information captured through Toronto Hydro's System O&M programs is necessary to enable the prioritization of assets for capital work and to maximize the likelihood that assets that remain in-service have not surpassed end-of-life.

The projected budgets from 2016 to 2019 for System O&M are expected to increase in line with inflation.

Distribution System Plan (DSP)

A DISTRIBUTION SYSTEM PLAN OVERVIEW

ID	Section
A1	Introduction
A2	Capital Investment Drivers and Expected Cost Savings
A3	Asset Management Process Summary & Enhancements

A1 INTRODUCTION

Toronto Hydro produced this Distribution System Plan ("DSP") in close accordance with Chapter 5 of the Ontario Energy Board's (OEB) Filing Requirements for Electricity Transmission & Distribution Applications.[1] As prescribed in Chapter 5, this DSP describes Toronto Hydro's asset management process and capital expenditure plan, while also providing information pertaining to Toronto Hydro's coordination with third parties, identification of customer preferences, and proposed performance measures to be applied over the course of the plan.

Toronto Hydro has produced a DSP designed to provide the OEB and customers with an accessible, plain-language view of the distributor's investment plans for the five year planning horizon (also referred to as the forecast period) of 2015-2019, while illustrating how the utility plans to meet the expectations set out in the Renewed Regulatory Framework for Electricity (RRFE). Toronto Hydro believes that its plan is designed to address the needs and preferences of the utility's customers by presenting optimized investments that support (1) the achievement of public policy objectives, (2) the need for a significant level of investment in Toronto's distribution system and (3) the overriding objective of delivering value for money.

The DSP has been subdivided into five chapters. Section A serves to provide an introductory overview of the DSP, including the purpose, background and objectives, declaration of capital investment drivers and expected cost savings and an overview of Toronto Hydro's asset management (AM) process. Section A includes discussion on what has changed within that process from previous filings. Section A1.1 provides further detail into the remaining four chapters in the DSP.

A1.1 Purpose

The main purpose of the DSP is to provide the OEB and customers with detailed information and justification on the material investments that Toronto Hydro plans to make during the period from 2015 to 2019. Toronto Hydro has adopted the requirements set out in Chapter 5, dividing the DSP into the following five sections:

[1] Ontario Energy Board, Filing Requirements for Electricity Transmission and Distribution Applications, (Toronto: Ontario Energy Board, 2013). ["OEB Filing Requirements"]

- Section A – Distribution System Plan Overview: Provides an introductory overview of the DSP, including (1) the purpose, background and objectives, (2) declaration of capital investment drivers and expected cost savings and (3) an overview of Toronto Hydro's asset management (AM) process with discussion on what has changed within that process from previous filings.

- Section B – Coordinated Planning with Third Parties: Provides information on how Toronto Hydro's DSP aligns to broader regional planning efforts, and shares information with respect to the various consultation processes that were executed.

- Section C – Performance Measures for Continuous Improvement: Provides information with respect to the selected measures that will be adopted by Toronto Hydro to track continuous improvement of planning, execution and outcomes of investments over the course of the planning horizon.

- Section D – Asset Management Process: Provides information with respect to Toronto Hydro's long-term, short-term and maintenance planning processes, which are used to produce the capital investment plan described in Chapter E.

- Section E – Capital Expenditure Plan: Provides information on how Toronto Hydro has applied its Asset Management Process to the utility's distribution system in order to produce the capital investments contemplated by the DSP. This section also contains the detailed description and justification of material investments planned for the five-year forecast period.

A1.2 Background & Objectives

Toronto Hydro has developed a capital investment plan designed to (i) renew grid systems (overhead, underground, secondary network, stations) infrastructure at or beyond their useful life or economic end-of-life criteria, (ii) mitigate critical system-wide issues such as capacity constraints, downtown contingency, security of supply and safety issues while also making (iii) necessary and mandatory investments supporting Toronto Hydro's 24/7 operations, including customer connections, metering, fleet, facilities, information technology (IT), externally-initiated plant relocations and expansion, and system capital and maintenance investment support to ensure that these investment plans are executed and mandated obligations to customers are satisfied.

It is important that Toronto Hydro's DSP address the significant renewal, critical issues and other investment pressures on Toronto's distribution system, as well as deliver value to customers and reflect prudent utility investments. Among other things, Toronto Hydro plans to achieve these goals through the long-term planning processes described in Section D. These planning processes enable the utility to (i) assess the current state of the distribution system; (ii) derive a capital investment approach from this current state foundational data and select an execution strategy that allows for alignment to AM objectives; and (iii) develop capital investment programs that target prioritized assets and issues for intervention.

The derived capital investment approach and execution strategy aligns to asset management objectives. Those objectives, which are described in detail in Section D1.1 aim to: (i) maximize value to the customer; (ii) minimize or eliminate potential safety risks; and (iii) enable the eventual achievement of an optimal balance between required annual capital investment and aggregate risk costs associated with asset failure, also referred to as a "steady state".

As discussed in Section E2.1.2, the produced capital investment approach has revealed a substantial backlog of investments that must be performed in 2015, comprised of assets at or beyond their useful life or economic end-of-life coupled with critical issues. From a purely system-focused perspective, an optimal execution strategy would be to address this backlog of investments in 2015.

However, Toronto Hydro also considers the pacing of those investments and its effect on customers. The utility has therefore proposed a "paced" execution strategy, designed to achieve a steady state in a gradual manner. This "paced" strategy allows for steady capital investments and predictable rate impacts for customers during the 2015-2019 period and beyond. While it would be possible, and optimal from a system perspective, to invest more aggressively today to eliminate the backlog of investments sooner, Toronto Hydro believes that its proposed plan, which is more moderate and predictable, fairly balances the needs of current and future customers and will help mitigate future surges in capital commitments for the long-term.

As explained in Section E2.1.3, the proposed capital expenditure plan and "paced" execution strategy results in a forecasted SAIFI reduction from 1.53 outages in 2014 (target) to 1.13 outages in 2019, and a projected SAIDI reduction from 1.21 hours in 2014 (target) to 0.97 hours in 2019 respectively. Were Toronto Hydro not to execute this investment approach and instead adopt a run to failure approach, SAIFI and SAIDI are forecasted to worsen by another 30%, and 24% respectively over the period from 2015 to 2019.

Toronto Hydro has also engaged with its customers specifically on the needs addressed and the investments proposed in the DSP, as well as the anticipated bill impacts of those investments. Further information on the various customer engagement activities that Toronto Hydro has carried out in relation to the DSP is available in Section E2.4.

In order to monitor the benefits produced by this DSP within the filing period from 2015 to 2019, Toronto Hydro is proposing a series of customer-oriented, cost efficiency and effectiveness-oriented and asset/system operations performance-based metrics. Further details are available in Section C.

Finally, Toronto Hydro has undertaken a variety of coordination and communication efforts with third parties, including the Ontario Power Authority (OPA) and Hydro One Networks Inc. (HONI) as part of the Chapter 5 requirements.

A2 CAPITAL INVESTMENT DRIVERS & EXPECTED COST SAVINGS

A2.1 Capital Investment Drivers

In this DSP, Toronto Hydro proposes capital investment programs with specific drivers. Toronto Hydro developed a list of capital investment drivers based on the OEB's example drivers. Each program includes its own trigger and secondary drivers. Each program is classified under its respective investment category, as shown in Table 1, according to its trigger driver. In the case where one program has multiple drivers from different investment categories, its trigger driver is what determines which investment category it is placed in. Table 1 also provides clarification on the application of these categories to Toronto Hydro's capital investments.

TABLE 1: CAPITAL INVESTMENT CATEGORIES

System Access	ƒ Modifications that the utility is obligated to perform or that are otherwise necessary to provide customers with access to electricity services, driven by statutory, regulatory or other obligations.
System Renewal	ƒ The replacement and/or refurbishing of assets at, or approaching, end of life to extend the service life of the assets, and/or replacement of those assets that no longer align to current operating practices such that accessibility and serviceability conflicts are produced.
System Service	ƒ Modifications to the system to ensure that operational objectives are met while addressing system-wide critical issues and future electricity service requirements.
General Plant	ƒ Modification, replacements or additions to assets that are not part of the distribution system, but represent the backbone of Toronto Hydro's 24/7 operations, including capital and maintenance supporting activities.

Capital investment drivers were developed based on the needs of maintaining reliable services of Toronto Hydro's distribution system. The utility's descriptions for each driver are shown below in Table 2. The core issues addressed by work under each driver can be found in Sections E5 though to E8. Program-specific descriptions are provided in the evidence relating to each program. While the issues identified in the description (both in the table below and in DSP programs themselves) are reasonably illustrative of the issues addressed under each driver, they are not exhaustive lists. The basis and justification for each program is ultimately found in the substantive information provided in the program.

TABLE 2: TORONTO HYDRO DRIVER DESCRIPTIONS

	Driver	Description
System Access	Customer Service Requests	ƒ The fulfilment of Toronto Hydro's obligation to connect a customer to its service. This includes both traditional demand customers and distributed generation (DG) customers. The obligation to connect holds as long as there are no safety concerns for the public or employees and there is no adverse affect on the reliability of the distribution system. ƒ Expansion or enhancements to the system when a connection cannot be made with existing infrastructure.
	Mandated Service Obligation	ƒ Compliance with all legal and regulatory requirements and government directives. ƒ Compliance with Measurement Canada (Gas and Electricity Inspection Act[2]), the Ontario Energy Board (Standard Supply Service Code for Electricity Distributors[3]) and the Independent Electricity System Operator (Wholesale Revenue Metering Standard[4]) and other regulations
	Third Party Request	ƒ Mandated system modifications for property or infrastructure development by government agencies and other entities.
System Renewal	Functional Obsolescence	ƒ Assets/asset installations that no longer align to Toronto Hydro's current operating processes and practices including those assets with accessibility (ravines, rear lots, highway crossings) or serviceability (e.g. Lack of spare parts, lack of ability perform maintenance, operational constraints) conflicts, which can result in increased reliability and/or safety related risks.
	Failure	ƒ Failures have already taken place that Toronto Hydro must reactively respond to as part of capital investment activities.
	Failure Risk	ƒ There is the imminent risk of failure due to age or condition deterioration ƒ The potential failures will result in severe reliability impacts to customers as well as potential safety risks to crew workers or to the public.

[2] R.S.C. 1985, c. E-4.[" Gas and Electricity Inspection Act"]
[3] Ontario Energy Board, Standard Supply Service Code for Electricity Distributors (Toronto: Ontario Energy Board, 2011). ["Standard Supply Service Code"]
[4] Independent Electricity System Operator, Whole Revenue Metering Standard – Hardware (Issue 10.0) (Toronto: Independent Electricity System Operator, 2012). ["Wholesale Revenue Metering Standard"]

	Driver	Description
System Service	Safety	ƒ Assets are exposing known safety-related hazards/risks to crew workers or the general public, or assets are an integral part of maintaining safe work practices, and the failure of those assets would result in safety-related hazard/risk exposure.
	Reliability	ƒ Maintain or improve reliability at a local, feeder-wide or system-wide level.
	System Efficiency	ƒ The need to improve restoration capability, ultimately resulting in substantial reliability and customer experience improvements. ƒ The need to reduce losses in distribution lines.
	Capacity Constraints	ƒ Expected changes in load that will constrain the ability of the system to provide consistent service delivery. ƒ Current or potential incapability of the system to handle demand requirements.
General Plant	System Maintenance and Capital Investment Support	ƒ Renewal and enhancement of critical backbone assets (vehicles, buildings), systems (IT) and systems supporting Toronto Hydro's 24/7 operations, including capital and maintenance investment activities (e.g. Feeder Investment Model)

In Toronto Hydro's planning process, and consequently in this DSP, the trigger driver indicates the primary reason that a particular program must be carried out. However, secondary drivers may be as or more consequential than the trigger driver. For example, a program's trigger driver may be functional obsolescence, meaning that a type of asset can no longer be maintained due to age, availability of parts, and other issues. However, that functional obsolescence may also result in serious safety or reliability issues. The safety or reliability issues would be listed as secondary drivers for the program because they are a consequence of the functional obsolescence of those assets. However, addressing the resulting safety or reliability issues may ultimately be the most pressing reason for Toronto Hydro to proceed with that program, even though those drivers are listed as "secondary".

Table 3 illustrates the association of Toronto Hydro's trigger drivers to each of the four capital investment categories as defined in Table 1 of OEB's Chapter 5 documentation.

TABLE 3: OEB EXAMPLE DRIVERS AND TORONTO HYDRO EQUIVALENTS

	Example Drivers	Example Projects / Activities	Toronto Hydro Trigger Drivers
System Access	Customer service requests	ƒ New customer connections ƒ Modifications to existing customer connections ƒ Expansions for customer connections or property development	Customer Service Requests
	Other third party infrastructure development requirements	ƒ System modifications for property or infrastructure development (e.g. relocating pole lines for road widening)	Third Party Requests
	Mandated service obligations (DSC; Conditions of Service.; etc.)	ƒ Metering ƒ Long-term load transfer	Mandated Service Obligations
System Renewal	Assets/asset systems at end of service life due to: ƒ Failure ƒ Failure risk ƒ Substandard performance ƒ High performance risk ƒ Functional obsolescence	Programs to refurbish/replace assets or asset systems (e.g.: batteries; cable (by type); cable splices; civil works; conductor; elbows and inserts; insulators; poles (by type); physical plant; relays; switchgear; transformers (by type); other equipment (by type)	ƒ Failure ƒ Failure Risk ƒ Functional Obsolescence
System Service	Expected changes in load that will constrain the ability of the system to provide consistent service delivery	ƒ Property acquisition ƒ Capacity upgrade (by type); e.g. phases; circuits; conductor; voltage; transformation; regulation ƒ Line extensions	Capacity Constraints
	System operational objectives:	ƒ Protection & control upgrades (e.g. reclosers; tap changer controls/relays;	ƒ Safety ƒ Reliability

	Example Drivers	Example Projects / Activities	Toronto Hydro Trigger Drivers
	ƒ Safety ƒ Reliability ƒ Power quality ƒ System efficiency ƒ Other performance / functionality	transfer trip ƒ Automation (new/upgrades) by device type/function ƒ SCADA ƒ Distribution loss reduction	ƒ System Efficiency
General Plant	ƒ System capital investment support ƒ System maintenance support ƒ Business operations efficiency ƒ Non-system physical plant	ƒ Land acquisition ƒ Structures & depreciable improvements ƒ Equipment and tools ƒ Supplies ƒ Finance/administrative/billing software and systems ƒ Rolling stock ƒ Intangibles (e.g. land rights; capital contributions to other utilities)	System Maintenance and Capital Investment Support

A2.2 Expected Sources of Cost Savings

Cost savings that are realized through the execution of the DSP have been captured within each capital investment program through the development of a business case evaluation (BCE) per Toronto Hydro's Investment Planning process. Key inputs into the BCE process, including asset risk and non-asset risk variables are derived from the Feeder Investment Model (FIM). The FIM, discussed in detail in Section D3.1.2, is a risk-based analytical model that is used to establish the economic end-of-life for the major asset classes within Toronto Hydro's distribution system. It also establishes an optimal time for intervening on a particular asset by balancing the risk associated with asset failure against the capital cost of intervention.

Two different BCE approaches are applied for the capital investment programs within the DSP. For in-kind renewal programs, where existing assets are replaced with their standardized equivalents without any changes to asset configuration, an Avoided Risk Cost (ARC) BCE is

applied. For non-in-kind renewal programs - where existing assets are removed and new assets are installed as per a completely new configuration or where new technologies are introduced such that some form of benefit is introduced to the existing assets in the form of reduced outage durations or reduced overall risks - a Cost of Ownership (COO) BCE is applied. These BCE results are calculated for the first year of activities in each program (for which necessary asset-level details are generally available) and demonstrate cost savings that are achieved through the execution of this work in the form of reduced asset risk or non-asset risk costs, reduced maintenance costs or other efficiencies that can be quantified as Additional Quantifiable Benefits (AQB's). These BCE approaches are discussed in detail in Section D3.3.

As seen in Sections E6.6 and E6.7, execution of the Box Construction and Rear Lot Conversion programs in 2015 result in reductions of maintenance costs of approximately over $3.1 million. BCE's have been applied to the majority of capital investment programs where practicable, and a total NPV of approximately over $380 million is produced through the execution of these programs in 2015.

In addition to the cost savings captured through the BCE process, the majority of Toronto Hydro's proposed DSP programs also include elements that are expected to deliver some form of system efficiency benefit. Some of the specific programs that are expected deliver efficiency to both the customer and Toronto Hydro are:

- Within the Station Expansion program, as outlined in Section E7.9, the completion of the Strachan TS transformer upgrade is expected to prevent Toronto Hydro from having to pay the full cost to replace the transformer again when additional capacity is required. New customers being connected are more likely to be serviced from the station that is geographically closest, thus reducing the connection costs.

- The Box Construction Conversion program, as outlined in Section E6.7, presents reduction in line losses by upgrading from 4.16kV to 13.8kV. The upgrade in overhead feeders is expected to present a three-fold capacity increase, which can accommodate more connections with reduced costs.

- Within the Stations Circuit Breaker Renewal program, as outlined in Section E6.15, the vacuum circuit breakers that Toronto Hydro plans to install through this program entail fifty percent less maintenance cost compared to the oil circuit breakers, since the oil handling expenses associated with oil circuit breakers is eliminated and vacuum circuit breakers have less moving parts to maintain.

In addition, the following table lists the major cost-saving factors with brief explanations into how programs are achieving a more efficient process within Toronto Hydro and reducing costs:

TABLE 4: COST SAVING FACTORS

Cost Saving Factors	Description
Tree trimming	• Use of tree proof conductor in areas where it is expected to reduce the pace of tree trimming cycles by mitigating tree contact outages
Maintenance	• Increased capacity is expected to allow for more flexibility in scheduling planned outages for maintenance at the effected stations • Limiting the number of different types of assets in the system is expected to result in savings in maintenance since there are fewer equipment types with different maintenance needs • Improved availability of spare parts for equipment repair • Automatic switching capability is expected to help achieve maintenance efficiency by reducing maintenance crew hours to complete the same work through a more effective streamlining of functions • Analysis of SCADA monitoring data may help Toronto Hydro make adjustments and corrections, which may result in corrective maintenance cost savings
Control and Monitoring	• Improved restoration time by replacing older and unreliable assets with modern equipment capable of remote troubleshooting and switching capabilities at with no SCADA connection • Installation of sensors providing Toronto Hydro's Control Room the ability to remotely view real time statuses such as flooding, temperature and loading. This is expected to reduce the number of visits to vaults and stations
Operation Efficiencies	• Improved productivity for power system controllers and system response crews – Crews will not have to patrol the entire feeder, only the faulted section, reducing time for restoration • Deploying SCADA enabled tie point and sectionalizing switches reduces the need to send crews to perform the extensive switching work that would otherwise be needed to restore power during outages; is expected to result in labor cost savings by eliminating manual switching

Cost Saving Factors	Description
	ƒ Automated switches allow system controllers to make more efficient use of their time. Since switching actions on automated feeders would be able to occur autonomously, they would be able to focus on other areas requiring restoration
Elimination of Functionally Obsolete Assets	ƒ Provide better access to distribution equipment and allowing for use of standard equipment in the future (i.e. bucket trucks); this is expected to reduce operational costs ƒ Expenditure of engineering resources to deal with asset failure on a reactive basis is avoided, improving organizational efficiency ƒ Installing a current standard asset, opposed to like for like legacy asset – if it is even available, is better for the system and is more efficient from a cost/procurement/standards perspective ƒ Reduce cost associated with repairing obsolete assets and supporting assets (e.g. communications systems)
Reduction of Failure Risk	ƒ Saving cost by planned replacements compared to reactive replacements of failed assets
Project coordination with external parties	ƒ Reduction in capital costs during the installation of infrastructure through cost sharing agreements, as well as shared construction efforts between Toronto Hydro and other organizations
Grouping assets together in projects	ƒ Coordinate work with other asset replacement projects where optimization of work program can be achieved through time and material saving efforts. This includes pole/transformer coordinated replacements to reduce truck rolls, executing work on adjacent feeders to minimize manual switching efforts, etc.
Future Planning	ƒ Enhanced condition monitoring on automated feeders is expected to allow day to day operating decisions and long term asset investment decisions to be made more efficiently and effectively ƒ Implementing the best the technology and material used in construction to extend asset and civil life

As the DSP is executed, Toronto Hydro expects to continue to refine its AM planning processes, which should result in further improvements to capital investment programs. This refinement is performed through a measurement and enhancement process that is further discussed in Section D3.1.2.3. Section C, in particular, highlights a series of performance measures that Toronto Hydro has proposed in order to demonstrate savings and successes that will be realized over the course of the five-year period from 2015 onwards to 2019.

A3 ASSET MANAGEMENT PROCESS SUMMARY & ENHANCEMENTS

This section provides a brief overview of Toronto Hydro's AM Process, along with a summary of recent changes and enhancements to the elements contained within this process from previous EDR filing applications submitted by Toronto Hydro.

A3.1 Asset Management Process Summary

The AM Process, which is presented in Section D, can be broken down into five major components: (i) the planning process; (ii) the associated decision-support systems; (iii) the enterprise databases that support both the planning process and systems' the (iv) distribution system plan itself that is supplied by outputs from the planning process; and (v) a measurement and enhancement process that supports continuous improvement.

The planning process itself can be further subdivided into three stages:

(i) Long-term planning, discussed in detail in Section D1.2.1, results in the development of a capital investment approach and execution strategy along with corresponding investment programs that align to AM objectives.

(ii) Short-term planning, discussed in detail in Section D1.2.2, results in the production of discrete projects within each investment program.

(iii) Maintenance planning, discussed in detail in Section D1.2.3, focuses on extracting the maximum value out of Toronto Hydro's distribution system assets, through inspections, upkeep and repair activities.

The outputs from the AM Planning Process as a whole are integrated into the DSP.

A3.2 Asset Management Process Enhancements

Enhancements to the Asset Management Process can be broken down into two categories: (i) enhancements that have taken place since previous filing periods, and (ii) future enhancements and the processes associated with fulfilling those enhancements. The following sections provide further details on these two forms of enhancements.

A3.2.1 Recent Enhancements from Past Filing Periods

Toronto Hydro has continually monitored and improved decision-support systems, enterprise systems and their respective inputs that support the asset management planning process. This section further provides a breakdown of (i) process-related improvements and (ii) data quality & system improvements.

A3.2.1.1 Process-Related Improvements

Asset Condition Assessment (ACA) represents a core decision-support system used to monitor the condition of core asset classes within Toronto Hydro's distribution system and produce a Health Index (HI) score to support the development of capital investment programs and projects. ACA, which is further explained in Section D3.1.2.1(ii) is driven by inspection information coming out of Toronto Hydro's maintenance program.

As identified by Kinectrics within their independent audit of Toronto Hydro's Asset Condition Assessment program (Appendix A to Section D3), Toronto Hydro has worked to improve its maintenance practices in the following ways:

- Expanded the scope of transformer oil testing (e.g. oil quality tests, furan analyses, dissolved gas analysis (DGA) to include transformers outside of Toronto Hydro's transformer stations. Toronto Hydro-owned transformers at customer locations are now subject to such oil tests).

- Use of enhanced inspection forms for all station assets, network vaults, cable chambers, and overhead switches. In the new forms, there is increased use of dropdown comments as opposed to free-form text. These changes will improve data quality and accuracy.

- Improved record keeping for assets, namely line disconnects, bus disconnects, fuse compartments, and relays. Inspections and maintenance records for these assets are now in the Ellipse database.

- Improvement of inspection forms for wood poles and migration of data into Ellipse. Inspectors will also provide remaining pole strength in PSI.
- Improvements have been made to maintenance inspection training program in order to improve inspection data quality and consistency.

More broadly, Toronto Hydro has enhanced its short-term and long-term planning processes such that specific requirements detailed in OEB's Chapter 5 documentation are satisfied. This includes:

- The use of capital investment drivers for each investment program
- Organizing each capital investment program to one of the four capital investment categories as defined in Chapter 5
- Explaining of timing and pacing of the capital investment program, based upon historical and forward spending
- Alignment of each capital investment program to the program/activity evaluators as defined in Chapter 5, including customer value, reliability, efficiency and safety.

Finally, Toronto Hydro introduced additional quantifiable benefits as an enhancement to the business case process. This allows for a broader set of benefits to be considered in the quantified analysis, thereby allowing for a more accurate and robust analysis of the proposed program. This enhancement is further discussed in detail in Section D3.

A3.2.1.2 Data Quality & System Improvements

Toronto Hydro has worked to improve data quality within its enterprise geographical information system (GIS) and enterprise resource planning (ERP) system respectively such that improved decision making can be performed at both the long-term and short-term planning levels. This includes the following initiatives:

- Development of a data quality reporting process that allows for the discovery, monitoring and repair of data quality issues within various systems.
- Consolidation of data from enterprise systems (GEAR, Ellipse) such that data integrity can be improved.

- Improvement of connectivity of information within various enterprise systems and decision-support systems. For instance, a process was developed to introduce linkages between the GEAR enterprise system and associated asset photos.

A3.2.1.3 Asset Condition Assessment Improvements

Toronto Hydro has improved on various elements documented in the Asset Condition Assessment report. Key improvements include increased sample size of each asset category and improvements to the Business Intelligence Calculator. Other improvements but not limited to include the following:

- Improved maintenance practices – Improvement to inspection data quality and consistency has been made with the enhanced maintenance practices.
- Maintenance tools – New maintenance tools are being used as prototypes and may potentially be incorporated as part of the main maintenance program such as SF_6 sniffer tool for SF_6 equipment and Ultrasonic inspection tools for station switchgears.
- Training of inspectors – The training program has been improved in order to enhance the data quality, such as restructuring the maintenance manuals with updated photos and technical information.

A3.2.2 Future Enhancements

Toronto Hydro is also examining and exploring future enhancements to further improve upon its AM planning process. These include:

- Potential enhancements to the Feeder Investment Model (FIM) in order to respond to feedback provided as part of the 2012-2014 IRM Filing submission. These include:
  - Geospatial tracking of non-asset-related outage events to further improve the calculation of non-asset-related risks
  - Improvements to link customer data to assets in order to improve asset-level load impact data used as part of the outage cost calculation procedure
  - Improvements to customer interruption costs used as part of the outage cost calculation procedure. These have been further defined as part of the Program Support capital investment program in Section E8.8.
- Introduction of performance measures as described in Section C to measure progress and effectiveness of Toronto Hydro's Distribution System Plan. These measures will be used to further enhance Toronto Hydro's AM process.

Distribution System Plan (DSP)

B

COORDINATED PLANNING WITH THIRD PARTIES

ID	Section
B1	Overview of Coordi nated Planning Approach
B2	Regional Planning Process
B3	OPA Comments on Renewable Energy Generation

B1 OVERVIEW OF COORDINATED PLANNING APPROACH

On October 18, 2012, the Ontario Energy Board (OEB) issued its Report of the Board – A Renewed Regulatory Framework for Electricity Distributors: A Performance Based Approach.[1] The RRFE Board Report concluded a consultation process aimed at promoting the cost-effective development of electricity infrastructure through coordinated planning on a regional basis between licensed distributors and transmitters.

In the RRFE Board Report, the OEB concluded that infrastructure planning on a regional basis is required to ensure that regional issues and requirements are effectively integrated into utility planning processes. The OEB also noted that the effective use of Regional Infrastructure Planning and the inclusion of regional considerations in distributors' and transmitters' plans will be key in ensuring that the development and implementation of the smart grid in Ontario is carried out on a coordinated basis and that smart grid investments are made at the system level (distribution or transmission) that will best serve the interests of the region.

Toronto Hydro, through its participation in the Central Toronto Integrated Regional Resource Plan led by the OPA, and in its participation in the Needs Screenings for Metro Toronto Northern sub-region and GTA North Western sub-region led by Hydro One Networks Inc. (HONI), has coordinated its efforts and DSP with the outcomes of the completed plans and continues to coordinate with the plans that are under development.

B1.1 Coordinated Planning Approach

Planning for the electricity system in Ontario is done at essentially three levels:

- Bulk system planning
- Regional system planning
- Distribution system planning

[1] Ontario Energy Board, Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach (RRFE) (Report of the Board) (Toronto: Ontario Energy Board, 2012), online: Ontario Energy Board < http://www.ontarioenergyboard.ca/oeb/_Documents/Documents/Report_Renewed_Regulatory_Framework_RRFE_20121018.pdf>. [the "RRFE Board Report"]

These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Bulk system planning typically looks at the broader power system. The bulk power system transfers large quantities both within Ontario (as between major generation sources and load centres) as well as between the provincial grid and neighbouring power systems external to the province via the interconnections. The Ontario Power Authority (OPA) has the accountability for the integrated planning of the bulk power system.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the portions of the power system that supply various parts of the province. There are portions of the power system which can be electrically grouped together due to their bulk supply points and their electrical interrelationships whereby common facilities may impact many connected customers.

Regional planning focuses on the facilities that provide electricity to transmission connected customers such as distributors and large directly-connected customers. This typically includes the transformer load stations and the transmission supply circuits to these stations. It also includes the 115/230 kV auto-transformers and their associated switchyards. From a resource perspective, regional planning considers the local generation and/or Conservation and Demand Management (CDM) that could be developed to address supply and reliability issues in a region or local area.

Local Distribution Companies (LDCs) conduct wires (and resource) planning at the distribution level and coordinate with the Transmitter and the OPA mainly on transmission supply facilities. Toronto Hydro has coordinated new/enhanced transmission supply facilities for some of its stations. These are discussed in more detail in Section B2.

Regional planning can overlap with bulk system planning and distribution system planning. Overlaps with distribution system planning occur largely at the transformer load stations which deliver power to distributors and at large directly-connected customers. In the case of building transformer load stations, this planning can sometimes take place at the distribution level. Another example where regional planning may require coordination with distribution planning occurs when a distribution solution may address the needs of the broader local area or region, for example, by providing load transfer capability between transformer stations.

B1.2 Transmitter Consultations

HONI consulted with Toronto Hydro and neighbouring distributors through a Needs Screening of two electrical areas:

- Metro Toronto Northern Sub-region, and
- GTA North Western Sub-region.

The scope of these Needs Screening processes was to consider whether transmission infrastructure potential transmission needs within these The Needs Screening process produces a Needs Screening Report. The Needs Screening Report for the Metro Toronto Northern Sub-region was completed on June 12, 2014 and is provided as Appendix A. The Needs Screening Report for the GTA North Western Sub-region was completed on June 27, 2014 and is provided in Appendix B.

B1.3 Other Distribution Consultations

Toronto Hydro is the largest LDC in Ontario, is not an embedded distributor and does not supply any embedded distributors. Therefore, the utility does not typically carry out formal planning consultations with other LDCs. Regional system planning processes that are coordinated by HONI and the OPA are generally sufficient in addressing the needs of Toronto Hydro's service area and adjacent regions.

B1.4 OPA Consultations

Toronto Hydro is in active consultation with the OPA, the Independent Electricity System Operator (IESO) and HONI to develop a Central Toronto Integrated Regional Resource Plan (IRRP). The purpose of the IRRP is to ensure that the electricity service requirements of the central Toronto community are served by an appropriate combination of demand and supply options, which reflect the priorities of the community. The plan forecasts the expected growth in electricity demand and investigates the costs and benefits of conservation, distributed generation, and transmission and distribution options in meeting the future electricity needs of customers in the central Toronto area for the next 25 years. The outcome is expected to be an integrated plan with a long-term perspective - one which recommends a balance of options that account for costs, the contribution to reliable electricity service, and mitigation of environmental impacts.

B2 REGIONAL PLANNING PROCESS

The province of Ontario is divided into 23 regional areas for planning purposes. Toronto Hydro's service territory is within the Metro Toronto Region. Toronto Hydro also receives supply from outside of its service territory and this is from the GTA North Region.

The regional planning process is an important input to distribution system planning (stations planning in particular) and the regional planning process is informed by Toronto Hydro's plans. The regional planning process for Toronto is characterized by:

- A large load that is dynamic in the city area
- A significant number of transmission lines and stations
- The presence of a large generator
- A customer base that has experienced and is sensitive to major events that disrupt continuity of service

B2.1 Central Toronto Integrated Regional Resource Plan

The Metro Toronto Region has been divided into two sub-regions for ease of planning: Central Toronto and the Northern sub-regions. The two sub-regions are shown in Figure 1.

The Central Toronto sub-region study in December of 2011 was started before the introduction of the Regional Planning Process. Previously known as the Toronto Regional Plan, it is now the Central Toronto Integrated Regional Resource Plan.

The Ontario Power Authority is the lead and the following organizations are the study participants:

- Toronto Hydro
- Hydro One Networks Inc. (HONI)
- Independent Electricity System Operator (IESO)

FIGURE 1: INTEGRATED REGIONAL RESOURCE PLAN (IRRP) REGIONS

The purpose of the Integrated Regional Resource Plan (IRRP) is to ensure that the electricity service requirements of the central Toronto community are served by an appropriate combination of demand and supply options that reflect the priorities of the community. Planning activities include forecasting the expected growth in electricity demand for the next 25 years, investigating the costs and benefits of conservation, distributed generation, and transmission and distribution options in meeting the future electricity needs of customers in the central Toronto area. The outcome of the planning process will be an integrated plan, with a long-term perspective, which recommends a balance of options that account for costs, reliable electricity service, and mitigation of environmental impacts. The plan has not been completed yet, and is currently

expected to complete by April 2015 (see Exhibit 2B, Appendix D). The impact of the regional plan on the Distribution System Plan is discussed in Section E1.4 - Regional Planning Considerations. ***IC***

B2.2 Metro Toronto – Northern Sub-Region Needs Screening

The purpose of the Needs Screening report was to undertake an assessment of the Metro Toronto Northern Sub-Region and determine if there were regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required. No need for coordinated regional planning was identified. Impacts to the Distribution System Plan are described in Section E1.4 (Regional Planning Considerations).

B2.3 GTA North – Western Sub-Region Needs Screening

The purpose of the Needs Screening report was to undertake an assessment of the Greater Toronto Area (GTA) North, Western Sub-region and determine if there were regional needs that would lead to coordinated regional planning. Where regional coordination is not required and a "wires" only solution is necessary, such needs will be addressed between the relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required. No need for coordinated regional planning was identified. Impacts to the Distribution System Plan are described in Section E1.4 (Regional Planning Considerations).

B3 OPA COMMENTS ON RENEWABLE ENERGY GENERATION

B3.1 OPA Comment Letter

In compliance with section 5.1.4.2 of the OEB's Filing Requirements for Electricity Transmission and Distribution Applications, Toronto Hydro formally requested a letter of comment from the Ontario Power Authority with respect to the utility's planned renewable energy generation (REG) investments. Toronto Hydro received the OPA Letter of Comment on July 24, 2014. This letter can be found in Appendix C.

B3.2 Toronto Hydro's Response to OPA Letter

The OPA found that Toronto Hydro's REG investment plan is consistent with the OPA's information regarding REG applications to date and that the investments in Toronto Hydro's plan support and enable the connection of additional REG.

The OPA also confirmed that the Integrated Regional Resource Plan (IRRP) is currently under development that Toronto Hydro has participated in all required technical meetings, and that, in early 2013, Toronto Hydro provided the IRRP Working Group (which includes the OPA, Hydro One Networks Inc. and the Independent Electricity System Operator) with a detailed long-term load forecast for the utility's service area in support of the assessment of needs.

Hydro One Networks Inc. (Distribution)	Charlie Lee

Disclaimer

This Needs Screening Report was prepared for the purpose of identifying potential needs in the Metro Toronto Northern Sub-Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Screening Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Screening Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Screening Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Screening Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Screening Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Screening Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS SCREEN EXECUTIVE SUMMARY

NAME	Metro Toronto Northern Sub-Region Study Team		
LEAD	Hydro One Networks Inc.		
REGION	Metro Toronto Northern Sub-Region		
START DATE	April 14, 2014	END DATE	June 11, 2014

1. INTRODUCTION

The purpose of this Needs Screening report is to undertake an assessment of the Metro Toronto Northern Sub-Region and determine if there are regional needs that require coordinated regional planning.

Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Ontario Power Authority (OPA) will initiate the Scoping process to determine whether a OPA-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE/TRIGGER

The Needs Screening for the Metro Toronto Northern Sub-Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process that was approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, with Group 1 Regions being reviewed first. The Metro Toronto Northern Sub-Region belongs to Group 1 and the Needs Screening for this Sub-Region was triggered on April 14, 2014 and was completed on June 11, 2014.

3. SCOPE OF NEEDS SCREENING

The scope of this Needs Screening assessment was limited to the next 10 years because relevant data and information was collected up to the year 2023. Needs arising over the near-term (1-5 years) and mid-term (6-10 years) should be further assessed as part of the Needs Scoping Assessment and/or IRRP, or in the next planning cycle to develop a 20 year IRRP with strategic direction for the Sub-Region.

The assessment included a review of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis, system reliability, and operational issues such as load restoration, and any relevant asset replacement plans.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the OPA, the Independent Electricity System Operator (IESO), and Hydro One transmission provided information for the Metro Toronto Northern Sub-Region. The information included historical load, forecast, conservation and demand management (CDM), distributed generation (DG), load restoration and performance information along with identification of major equipment approaching end-of-useful life. See Section 4 for further details.

5. ASSESSMENT METHODOLOGY

The assessment's primary objective over the study period (2014 to 2023) is to identify the electrical infrastructure needs in the Sub-Region over the study period (2014 to 2023). The assessment reviewed available information, including load forecasts, and included contingency analysis to confirm the need(s), if and when required. See Section 5 for further details.

6. RESULTS

Transmission Capacity Needs

A. 230 kV Transmission Lines

- Circuit C10A is a 230 kV radial circuit from Cherrywood TS that supplies both Agincourt TS and Cavanagh TS. Following certain contingencies, flow on this circuit may exceed its long-term emergency (LTE) rating. Further assessment is required.

B. 230kV Connection Facilities

- The following DESN stations approach their normal supply capacity in the study period based on the gross demand forecast, but the net demand forecast shows that there is sufficient capacity at these stations throughout the study period. No action is required at this time and the capacity needs will be reviewed in the next planning cycle.
  - Sheppard TS (T3/T4)
  - Leslie TS (T1/T2, 27.6kV windings)
  - Cavanagh MTS

System Reliability, Operation and Restoration Needs

Generally speaking, there are no significant system reliability and operating issues identified for one or two elements out of service in this sub-region. There are contingencies where the loss of load exceeds 150 MW by configuration which must be restored within 4 hours as per the Ontario Resource and Transmission Assessment Criteria (ORTAC). Further assessment is required.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace major equipment do not affect the needs identified. Planned replacement of the T3/T4 DESN at Sheppard TS may provide opportunities for additional capacity at that station.

7. RECOMMENDATIONS

The study team recommends that "local" wires only solutions be developed in the near-term to adequately and efficiently address the needs associated with 230 kV circuit C10A and replacement/upgrading of Sheppard TS through planning between Hydro One Networks Inc. and the impacted distributors.

1 INTRODUCTION

This Needs Screening report provides a summary of needs that are emerging in the Metro Toronto Northern Sub-Region (“Sub-Region”) over the next ten years. The development of the Needs Screening report is in accordance with the regional planning process as set out in the Ontario Energy Board’s (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the “Planning Process Working Group (PPWG) Report to the Board”.

The purpose of this Needs Screening report is to undertake an assessment of the Metro Toronto Northern Sub-Region to identify near-term and/or emerging needs in the area and determine if these needs require a “local” wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with local distribution companies (LDC) or other connecting customer(s) will further undertake planning to develop options and recommend solution(s). For needs that require further regional planning and coordination, the Ontario Power Authority (OPA) will initiate the Scoping process to determine whether an OPA-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required.

This report was prepared by the Metro Toronto Northern Sub-Region Needs Screening study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, the OPA and the Independent Electricity System Operator (IESO).

2 REGIONAL ISSUE/TRIGGER

The Needs Screening for the Metro Toronto Northern Sub-Region was triggered in response to the Ontario Energy Board's (OEB) new Regional Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, where Group 1 Regions are being reviewed first. The Metro Toronto Northern Sub-Region belongs to Group 1. The Needs Screening for this Sub-Region was triggered on April 14, 2014 and was completed on June 11, 2014.

The Metro Toronto Region can be divided into two sub-regions: Metro Toronto Northern Sub-Region and Metro Toronto Central Downtown Sub-Region. The Metro Toronto Central Downtown Sub-Region currently has an IRRP under development, which was initiated prior to the new Regional Infrastructure Planning process.

3 SCOPE OF NEEDS SCREENING

This Needs Screening covers the Metro Toronto Northern Sub-Region over an assessment period of 2014 to 2023. The scope of the Needs Screening includes a review of transmission system connection facility capability which includes transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this Needs Screening.

3.1 Metro Toronto Northern Sub-Region Description and Connection Configuration

The Metro Toronto Northern Sub-Region comprises the northern portion of the municipality of Toronto. It includes the area roughly bordered geographically by Highway 401 on the south, Steeles Avenue on the north, Highway 427 on the west and Regional Road 30 on the east in addition to the area east of the Don Valley Parkway and north of O'Connor Dr. The boundaries of the Metro Toronto Northern Sub-Region are shown below in Figure 1.

Figure 1: Metro Toronto Region

Electrical supply to the Metro Toronto Northern Sub-Region is provided through 230 kV transmission lines and step-down transformation facilities. Supply to this sub-region is provided from a 230 kV transmission system consisting of the Richview TS to Parkway TS, the Richview TS to Cherrywood TS, the Richview TS to Claireville TS, as well as the Cherrywood TS to Leaside TS system. The distribution system in this sub-region is predominantly at 27.6 kV and small pockets at 13.8 kV.

The 230-115kV autotransformers at Leaside TS and Manby TS, the 115 kV transmission lines in Toronto, the Richview TS to Manby TS 230 kV transmission lines, and the stations supplied from all of these lines are not included in the Metro Toronto Northern Sub-Region, but are included in the Metro Toronto Central Downtown Sub-Region. In the Cherrywood TS to Leaside TS system only the station capacity needs are reviewed in this report; the transmission line and all other needs for this system are part of the Metro Toronto Central Downtown Sub-Region.

A single line diagram of the 230 kV system in the Metro Toronto Northern Sub-Region is shown in Figure 2 below.

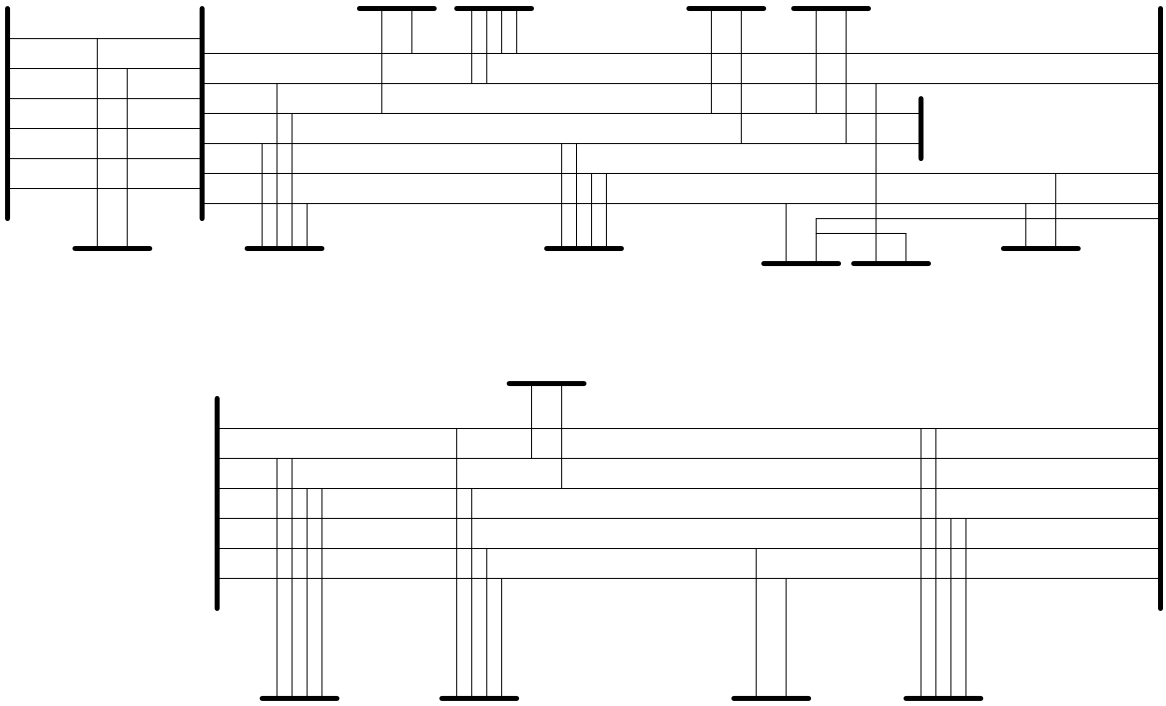

Figure 2: Single Line Diagram – Metro Toronto Northern Sub-Region

4 INPUTS AND DATA

In order to conduct this Needs Screening, study team participants provided the following information and data to Hydro One:

- IESO:
  - i. Historical 2013 regional coincident peak load and station non-coincident peak load
  - ii. List of existing reliability and operational issues
- LDCs and Transmission Connected Customers: Historical (2011-2013) net load, gross load forecast (2014-2023) and any relevant planned distribution investments;
- Hydro One (Transmission): Circuit and transformer ratings
- OPA: Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- Hydro One: Any relevant planned transmission investments.

4.1 Load Forecast

As per the data provided by the LDCs the load in the Metro Toronto Northern Sub-Region is expected to grow at an average of approximately 1.6% annually from 2013-2018, and 0.6% from 2018-2023.

5 ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Screening assessment:

1. The Sub-Region is summer peaking, so this assessment is based on summer peak loads.

2. Forecast loads are provided by the LDCs.

3. The LDC's load forecast is translated into load growth rates, and is applied onto the 2013 summer peak load as a reference point.

4. The 2013 summer peak loads are adjusted for extreme weather conditions according to Hydro One's methodology.

5. The needs were first identified based on the gross demand forecast which is deemed to be the worst case scenario. Both the gross demand forecast and the net demand forecast (which includes forecasted CDM and DG contributions) were used to determine the timing of the needs.

6. Review and assess impact of any on-going and/or planned development projects in the Sub-Region during the study period.

7. Review and assess impact of any critical elements planned/identified to be replaced at the end of their useful life such as lines and stations.

8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this Sub-Region is determined by the summer 10-Day Limited Time Rating (LTR).

9. To identify the emerging needs in each Sub-Region, the study was performed observing all elements in service and one or two elements out of service, in accordance with ORTAC.

10. Transmission adequacy assessment is primarily based on but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer 10-Day LTR.
    - All voltages must be within pre and post contingency ranges as per ORTAC criteria.
    - With two elements out of service, the system is capable of meeting the load loss limits and restoration guidelines of ORTAC.

6 RESULTS

This section summarizes the results of the Needs Screening in the Metro Toronto Northern Sub-Region.

6.1 Transmission Capacity Needs

6.1.1 230 kV Transmission Lines

C10A is a 20 km long radial circuit from Cherrywood TS. This circuit's capacity is thermally limited by a section approximately 4 km long between Duffin Jct. and Agincourt Jct. This need was also identified in the IESO's System Impact Assessment for Clarington TS (CAA ID 2012-462) which states that flow on this circuit may exceed its LTE rating under peak load conditions.

The conductor on this section is comprised of 795 kcmil, 26/7 ACSR and the Long-Term Emergency (LTE) rating for this type of conductor is typically based on 127ºC. However, the thermal limit for this section is based on a lower temperature of 63ºC and a technical assessment is required to to determine if and how this limit can be removed.

6.1.2 230kV Connection Facilities

The 230kV connection capacity needs identified during the study period include, but may not be limited to the following:

- Sheppard TS consists of two DESN stations and the T3/T4 DESN may reach its normal supply capacity in the near term based on the gross demand forecast.

However, the normal supply capacity is not exceeded in the study period based on the net demand forecast.

It is worth noting that the Sheppard TS T3/T4 DESN is currently scheduled for replacement and upgrade options should be considered. Additionally, the T1/T2 DESN can also be expanded, if needed, by connecting the second pair of transformer secondary windings and adding feeder breakers.

- In the near term (1-5 years), Leslie TS T1/T2 DESN (27.6kV windings) is forecast to reach its normal supply capacity based on the gross demand forecast. However, the normal supply capacity is not exceeded in the study period based on the net demand forecast. No action is required at this time and the capacity need will be reviewed in the next planning cycle.
- In the medium term (6-10 years), Cavanagh MTS is forecast to reach its normal supply capacity based on the gross demand forecast. However, the normal supply capacity is not exceeded in the study period based on the net demand forecast. No action is required at this time and the capacity need will be reviewed in the next planning cycle.

The station capacity needs outlined above are not expected to require further coordinated regional planning.

6.2 System Reliability, Operation and Load Restoration

Generally speaking, there were no significant system reliability and operating issues identified for this sub-region. Load loss exceeding 250 MW and 150 MW for design criteria contingencies must be restored within 30 minutes and 4 hours respectively, according to ORTAC. Based on the net coincident demand forecast, there were no contingencies identified in this sub-region where more than 250 MW would be lost by configuration. Some contingencies may result in load loss at this approaching 250 MW in the study period, and this should be reviewed in the next planning cycle. However, there are contingencies in the sub-region where load lost by configuration may exceed 150 MW. Further assessment is required by the transmitter.

Based on the net demand forecast there are contingencies in the Cherrywood x Leaside transmission system that may result in loads in excess of 250 MW. Load restoration issues for this system are being further assessed as part of the Metro Toronto Central Downtown study.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any auto-transformers, power transformer and high-voltage cables. There are no major refurbishment or replacement plans that will affect capacity needs in the

Sub- Region with the exception of transformers (T3 and T4) and associated switchyard at Sheppard TS.

7 RECOMMENDATIONS

The study team's recommendations are as follows:

a) At this time, the potential needs identified above do not require further regional coordination. Rather, these potential needs can be adequately and more efficiently addressed by Hydro One Networks Inc. and the relevant LDCs.

The Metro Toronto Central Downtown Sub-Region currently has an OPA-led IRRP study underway. OPA will later append the results of this sub-region's Needs Screening to the Regional IRRP.

The needs that have been identified through this Needs Screening may be re-evaluated based on the findings of subsequent analysis.

8 NEXT STEPS

Following the Needs Screening process the next regional planning step, based on the results of this report, is for Hydro One Transmission and impacted LDCs to develop and implement local solutions for the aforementioned near-term needs.

Disclaimer

This Needs Screening Report was prepared for the purpose of identifying potential needs in the GTA North, Western Subregion and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Screening Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Screening Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Screening Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Screening Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Screening Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Screening Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS SCREEN EXECUTIVE SUMMARY

REGION	GTA North, Western Subregion (the "Subregion")		
LEAD TRANSMITTER	Hydro One Networks Inc. ("Hydro One")		
START DATE	April 28, 2014	**END DATE**	June 27, 2014

1. INTRODUCTION

The purpose of this Needs Screening report is to undertake an assessment of the GTA North, Western Subregion and determine if there are regional needs that would lead to coordinated regional planning. Where regional coordination is not required and a "wires" only solution is necessary, such needs will be addressed between the relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Ontario Power Authority (OPA) will initiate the Scoping process to determine whether an OPA-led Integrated Regional Resource Planning (IRRP) process or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution) is required, or whether both are required.

2. REGIONAL ISSUE/ TRIGGER

The Needs Screening for the Subregion was triggered in response to the Ontario Energy Board's (OEB) new Regional Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups - Group 1 Regions are being reviewed first. The GTA North, Western Subregion belongs to Group 1 and the Needs Screening for this Region was triggered on April 28, 2014 and was completed on June 27, 2014.

3. SCOPE OF NEEDS SCREENING

The scope of this Needs Screening assessment was limited to the next 10 years because relevant data and information was collected up to the year 2023, as per the recommendations of the Planning Process Working Group Report to the Board. Needs emerging over the near-term (0-5 years) and mid-term (6-10 years) should be further assessed as part of the OPA-led Scoping Assessment and/or IRRP, or in the next planning cycle to develop a 20-year plan and strategic direction for the Region.

The assessment included a review of transmission system connection facilities capacity which covers station loading, thermal and voltage analysis, system reliability, operational issues such as load restoration and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from relevant LDCs, the OPA, the IESO, and Hydro One transmission provided information for the GTA North, Western Subregion. The information included historical load, load forecasts, Conservation and Demand Management (CDM) information, Distributed Generation (DG) information, and load restoration and performance information along with end-of-useful-life of any major equipment. See Section 4 for further details.

5. ASSESSMENT METHODOLOGY

The assessment's primary objective over the study period (2014 to 2023) was to identify the electrical infrastructure needs in the region. The study reviewed available information and load forecasts and conducted single contingency analysis to confirm needs, if any, and when they may be required. See Section 5 for further details.

6. RESULTS

Transformer stations and transmission facilities in the Subregion have sufficient capacity to accommodate the expected load over the study period.

Inherent to radial configuration, loss of two radial 230 kV circuits V43 and V44 will result in loss of load. Load restoration for the loss of these two circuits as per the ORTAC guidelines is being further assessed as part of the OPA led Integrated Regional Resource Plan (IRRP) for the GTA West, Northern Subregion.

See section 6 for details.

7. RECOMMENDATIONS

Based on the findings of the Needs Screening process, the study team recommends that further coordinated regional planning is required to assess load restoration for the loss of two radial elements (230 kV circuits V43 and V44). OPA will coordinate the assessment of this need currently underway as part of GTA West Northern Subregion IRRP process with the study team.

1 INTRODUCTION

This Needs Screening report provides a summary of needs that are emerging in the GTA North, Western Subregion (the "Subregion") over the next ten years. The development of the Needs Screening report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC), Distribution System Code (DSC) and the Planning Process Working Group (PPWG) Report to the Board.

The purpose of this Needs Screening report is to undertake an assessment of the Subregion, and determine if there are regional needs that would lead to coordinated regional planning. Where regional coordination is not required and a wires-only solution is necessary such needs will be addressed between the relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required. For needs that require further regional planning and coordination, the Ontario Power Authority (OPA) will initiate the Scoping process to determine whether an OPA-led Integrated Regional Resource Planning (IRRP) process or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution) is required, or whether both are required.

The preparation of this report was carried by the GTA North, Western Subregion Needs Screening study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by the LDCs, the Ontario Power Authority (OPA) and the Independent Electricity System Operator (IESO).

Table 1: Study Team Participants for GTA North, Western Subregion

Figure 1: GTA North, and Western Subregion (shown in yellow highlight).

2 REGIONAL ISSUE/TRIGGER

The Needs Screening for the GTA North, Western Subregion was triggered in response to the Ontario Energy Board's (OEB) new Regional Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, where Group 1 Regions are being reviewed first. The GTA North region belongs to Group 1. The Needs Screening for this Subregion was triggered on April 28, 2014 and was completed on June 27, 2014.

3 SCOPE OF NEEDS SCREENING

This Needs Screening covers the Subregion over an assessment period of 2014 to 2023. The scope of the Needs Screening includes a review of system capability which covers transformer station loading and transmission line thermal and voltage analysis. System reliability, operation, load restoration and asset sustainment issues were also reviewed as part of this screening.

3.1 Subregion Description and Connection Configuration

The GTA North, Western Subregion includes the area roughly bordered geographically by Steeles Avenue on the south, King-Vaughan Rd on the north, Highway 50 on the west and Weston Road on the east. The GTA North Western Subregion comprises the Western portion of the City of Vaughan.

Electrical supply to the GTA North Western Subregion is provided through 230 kV transmission lines and step-down transformation facilities as shown in Figure 1 above and Figure 2 below. Supply to this Subregion is provided through the 230 kV Claireville TS to Kleinburg TS transmission lines (V43 and V44). The distribution systems supplied by this Subregion operate at 27.6 kV and 44 kV.

The 230 kV Claireville TS to Brown Hill TS and the Claireville TS to Parkway TS transmission lines and the stations supplied from these lines are not included in the GTA North Western Subregion but are included in a the York Subregion of GTA North.

Table 2 below lists the substations in the GTA North, Western Subregion, the LDCs supplied by each station and the stations' actual 2013 non-coincident summer peak demand as per IESO data.

Table 2: 2013 Summer Peak Station Demand

Station	2013 Peak Station Demand (MW)	LDCs
Woodbridge TS	151	Enersource Hydro Mississauga Inc.
		Hydro One Brampton Networks Inc.
		PowerStream Inc.
		Toronto Hydro-Electric System Limited
Vaughan MTS #3	152	Powerstream Inc.
Kleinburg TS	136	Hydro One Networks Inc. (Distribution)
		PowerStream Inc.

A single line diagram of the Subregion's transmission supply and transformer stations is shown in Figure 2 below. Goreway TS is not part of this Subregion, but its loading is considered due to the impact on the V43 circuit which supplies the Subregion. The 2013 coincident summer peak demand supplied by the 230 kV V43/V44 circuits is approximately 500 MW, which includes the portion of Goreway TS coincident summer peak demand supplied by the V43 circuit.

* Goreway TS is not part of the GTA North, Western Sub-Region study but its loading is considered due to impact on loading of circuit V43.

Figure 2: Single Line Diagram – GTA North, Western Subregion

4 INPUTS AND DATA

In order to conduct this Needs Screening, study team participants provided the following information and data to Hydro One:

- IESO provided:
  i. Historical regional coincident peak load and station non-coincident peak load.
  ii. List of existing reliability and operational issues.
- LDCs and Transmission Connected Customers provided historical (2011-2013) net load and gross load forecast (2014-2023).
- Hydro One provided transformer, station, and line ratings.
- OPA provided Conservation and Demand Management (CDM) and Distributed Generation (DG) data.
- Any relevant planned transmission and distribution investments were provided by the transmitter and LDCs, etc.

4.1 Load Forecast

As per data provided by the study team, gross load in the GTA North, Western Subregion is expected to grow at an approximate rate of 1.1% annually between 2014 and 2023. The near term growth rate, between 2014 and 2018, is expected to be approximately 1.17% per year and the medium term growth rate, between 2018 and 2023, is expected to be 1.03% per year.

The Needs Screening assessment considered gross loads at individual stations based on the 2013 summer peak non-coincident demand and the summer peak non-coincident demand forecasts for stations within the Subregion. The station load forecast was developed by applying load growth rates derived from the LDCs' load forecasts.

5 ASSESSMENT METHODOLOGY

The following methodology and assumptions were made in this Needs Screening assessment:

1. The Subregion is summer peaking so this assessment is based on summer peak loads.
2. The coincident load forecast is based on the forecast growth rates provided by the Subregion's LDCs and historical 2013 summer peak loads as the reference point. The 2013 historical peak loads are adjusted for extreme weather conditions according to Hydro One methodology.
3. The Subregion's non-coincident peak load forecast for station capacity assessment was developed from load forecasts provided by LDCs.

4. Gross coincident peak load forecast is used to develop a worst-case scenario to identify needs. Where applicable, net coincident peak load forecast, which includes forecasted CDM and DG contributions, is used to determine the timing of needs.
5. Review and assess the impact of any on-going or planned development project in the Subregion during the study period.
6. Review and assess the impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as auto transformers, cables and stations.
7. To identify the emerging needs in each area, the study was performed observing all elements in service and one element out of service.
8. Station capacity adequacy is assessed by comparing non-coincident peak load with the station's normal supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
9. Normal supply capacity for transformer stations is the summer 10-Day Limited Time Rating (LTR).
10. Transmission adequacy assessment is primarily based on but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer 10-Day LTR.
    - All voltages must be within pre and post contingency ranges as per ORTAC criteria.

6 RESULTS

This section summarizes the results of the Needs Screening in the GTA North, Western Subregion.

6.1 230kV Supply in the Subregion

The 230kV transmission system in the Subregion consists of two radial transmission circuits, V43 and V44 which originate from Claireville TS and supply the three stations in the region: Woodbridge TS, Vaughan #3 MTS and Kleinburg TS. In addition to supplying the three stations in the Subregion, V43 supplies Goreway TS which is not within the GTA North, Western Subregion. Loading of Goreway TS has been considered in performing the Needs Screening for the 230 kV transmission supply.

With the expected load growth in the Subregion, the V43 and V44 circuits are expected to remain within their normal supply capacity over the period covered by the Needs Screening. Line voltages under regional peak loading conditions are within the limits specified in ORTAC.

6.2 Transformer Stations in the Subregion

Transformer Stations in the Subregion include the following:

i) Woodbridge TS: Capacity at Woodbridge TS is sufficient to accommodate the expected load growth over the study period.

ii) Vaughan MTS #3: This station is loaded to its normal rated supply capacity as of 2013. Vaughan MTS #4, which is expected to be in service in 2017, will relieve Vaughan TS #3. The 230 kV transmission lines between Claireville TS and Minden TS, which are expected to supply Vaughan MTS #4, are not part of this Subregion.

iii) Kleinburg TS: Capacity at Kleinburg TS is sufficient to accommodate the expected load growth over the study period.

6.3 System Reliability, Operation and Load Restoration

Generally speaking, there are no significant system reliability and operating issues for one element out of service.

Inherent to radial configuration, loss of two radial 230 kV circuits V43 and V44 will result in loss of load. Load restoration for the loss of these two circuits as per the ORTAC guidelines is being assessed as part of the OPA led Integrated Regional Resource Plan (IRRP) for the GTA West, Northern Subregion.

6.4 Aging Infrastructure and Replacement Plans for Major Equipment

During the study period:

- None of the sub-station step-down transformers are expected to reach the end of their useful life.
- No high voltage cables in the area are expected to reach the end of their useful life.

7 RECOMMENDATIONS

Based on the findings of the Needs Screening, the study team recommends that further coordinated regional planning is required to assess load restoration for the loss of two radial elements (230 kV circuits V43 and V44). OPA is assessing this need as part of its GTA West, Northern Subregion IRRP and will coordinate the assessment with the study team.

8 NEXT STEPS

Based on the findings of the Needs Screening process, the next steps for this Subregion include:

a) OPA to include relevant LDCs in the GTA West, Northern Subregion IRRP process to participate in the assessment of load restoration needs identified for this Subregion.

b) Revisit the Subregion's needs during the next regional planning cycle, which is expected to be within the next five years.

OPA Letter of Comment

Toronto Hydro-Electric System Limited

Renewable Energy Generation Investments Plan

July 24, 2014

region in the PPWG report, and the Central Toronto IRRP was initiated prior to the formalization of regional planning in Ontario by the OEB. THESL has been working with the OPA, Hydro One Networks Inc., and the Independent Electricity System Operator as part of an IRRP Working Group. The OPA confirms that THESL has participated in all required technical meetings, and in early 2013, THESL provided the IRRP Working Group with a detailed long-term load forecast for the area to support the assessment of needs.

THESL has also been a lead partner in developing an engagement plan and supporting materials in preparation for the stakeholder engagement phases of the Central Toronto IRRP. THESL has been a key contributor to the planning and logistics and will jointly conduct the engagement in partnership with the OPA.

The first phase of the engagement is currently set to be undertaken in 2014, and the information can be found at: http://powerauthority.on.ca/power-planning/regional-planning/toronto/central-downtown. An engagement workbook, providing information on key plan objectives, needs and a review of potential options, has been developed to provide interested stakeholders with context in advance of more detailed in-person discussions with key stakeholders. THESL played a central role developing the list of invitees for the engagement. Stakeholders invited to the engagement sessions will include a diverse group of customer representatives from commercial, public sector, City of Toronto, ratepayer groups, environmental groups, and others.

Options for the IRRP include conservation and demand management, distributed generation development (including REG), and transmission and distribution system expansion to both enable the incorporation of distributed generation and to accommodate growth in the city. Many opportunities exist in the context of an integrated resource plan for Central Toronto. The investments identified in THESL's Plan support and enable the connection of additional REG, which enhances the ability of local customers and proponents to participate in these ongoing renewable programs, while contributing to the supply diversity within the IRRP study area. The outstanding IRRP process steps include the identification and consideration of local community preferences and the economic comparison of technically viable options.

The final deliverable, an IRRP report, is scheduled to be issued by the end of 2014.

A Needs Screening for the remainder of Metro Toronto area, including the areas outside of Central Toronto, has been completed by Hydro One, and has been posted to their website at: http://www.hydroone.com/RegionalPlanning/Toronto/Pages/default.aspx. The Needs Screening concluded that, at this time, there is no further need for regional coordination to address the potential needs identified in the Needs Screening report, and that the needs can be addressed by Hydro One and the relevant local distribution companies.

The OPA looks forward to working further with THESL in the Regional Planning process, and appreciates the opportunity to comment on the information provided.

February 3, 2015

Mr. Jack Simpson
Toronto Hydro-Electric System Limited
500 Commissioners Street
Toronto, Ontario M4M 3N7

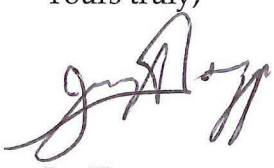
Dear Jack:

Re: Update to July 24, 2014 Letter of Comment regarding THESL's Renewable Energy Generation Investments Plan

In response to your request for an update to the OPA's[1] July 24, 2014 Letter of Comment, I am pleased to provide THESL with updated information as follows.

The FIT and microFIT applications referenced in the Letter of Comment remain consistent with the renewable energy generation information that was received from THESL, as of May 31, 2014.

With respect to the Central Toronto Integrated Regional Resource Plan ("IRRP"), since July 2014, the IESO and THESL, with Hydro One Networks, have completed a stakeholder engagement process that included:



- the release of an online discussion workbook,
- two public webinars,
- three stakeholder workshops with representatives from the City of Toronto, Board of Trade, environmental non-governmental organizations and major consumers,
- focus group sessions with residential and small business customers,
- public open houses, and
- customer telephone surveys.

[1] On January 1, 2015, the Ontario Power Authority ("OPA") merged with the Independent Electricity System Operator ("IESO") to create a new organization that will combine the OPA and IESO mandates. The new organization is called the Independent Electricity System Operator.

THESL was a full partner in developing and delivering the engagement plan. This included developing supporting materials in preparation for the stakeholder engagement, and the planning and logistics. The IESO has archived the engagement materials which can be found at the following link: http://powerauthority.on.ca/power-planning/regional-planning/toronto/central-downtown.

The completion date of the IRRP has been revised to April 2015 to allow time for incorporating the impact of new customer connection inquiries and meaningful consideration of input from the stakeholder engagement.

Yours truly,

Joe Toneguzzo
Director, Transmission Integration

Metro Toronto Region – Northern Subregion

The Need Assessment report for this Subregion was completed in June 2014 and is available on Hydro One's Regional Planning website. From a regional planning perspective, THESL has little impact from this Subregion. In addition, the study team determined that the needs identified for this Subregion can be addressed directly by Hydro One and LDCs and further regional coordination is not required.

GTA North Region – Western Subregion

The Need Assessment report for this Subregion was completed in June 2014 and is available on Hydro One's Regional Planning website. Based on the findings of the Need Assessment, the study team determined that further coordinated regional planning is required to assess load restoration issues for the loss of two radial elements (230 kV circuits V43 and V44). The IESO (formerly OPA) will coordinate the assessment of this need as part of GTA West Northern Subregion IRRP process currently underway. Other needs identified for the rest of the Subregion will be addressed directly by Hydro One and the relevant LDCs, and further regional coordination is not required.

Hydro One looks forward to working with THESL in executing the new regional planning process. If you have any further questions, please feel free to contact me.

Sincerely,

Ajay Garg, Manager – Regional Planning Coordination
Hydro One Networks Inc.

Distribution System Plan (DSP)

C PERFORMANCE MEASUREMENT FOR CONTINUOUS IMPROVEMENT

ID	Section
C1	Overview of Continuous Improvement Principles and Approach
C2	Customer Oriented Performance
C3	Cost Efficiency and Effectiveness
C4	Asset and System Operations Performance

C1 OVERVIEW OF CONTINUOUS IMPROVEMENT PRINCIPLES AND APPROACH

C1.1 Introduction

The purpose of this exhibit is to describe Toronto Hydro's proposed Distribution System Plan (DSP) measures that the utility plans to track and periodically report on over the 2015-2019 ratemaking period.

Toronto Hydro has developed a set of 12 measures to monitor quality and drive continuous improvement in its distribution system planning and implementation work over the 2015-2019 planning horizon. The measures cover several distinct dimensions of the utility's capital planning and implementation processes and/or speak directly to the outcomes of such processes, motivated by customer needs, regulatory compliance obligations, or corporate efficiency objectives.

Table 1 outlines Toronto Hydro's proposed DSP performance measures, grouped by primary category.

TABLE 1: PROPOSED PERFORMANCE MEASURES FRAMEWORK

Customer-Oriented Performance	Cost Efficiency/ Effectiveness of Planning and Implementation	Asset/System Operation Performance
1. System Average Interruption Duration Index (SAIDI).	1. Distribution System Plan Implementation Progress.	1. Outages caused by defective equipment.
2. System Average Interruption Frequency Index (SAIFI).	2. Planning Efficiency: Engineering, Design and Support Costs.	2. Stations capacity availability.
3. Customer Average Interruption Duration Index (CAIDI).	3. Supply Chain Efficiency: Materials Handling On-Cost.	
4. Feeders Experiencing Sustained Interruptions (FESI).	4. Construction Efficiency: Internal vs. Contractor Cost Benchmarking.	
5. Momentary Average Interruption Frequency Index (MAIFI).	5. Construction Efficiency: Standard Asset Assembly Labour Input.	

In developing the proposed measures, Toronto Hydro referred to the Section 5.2.3, Chapter 5 of the Ontario Energy Board's (OEB) Filing Requirements for Electricity Transmission and Distribution Applications[1], which sets out the key parameters for measures or metrics supporting the applicants' Distribution System Plan filings. Toronto Hydro's proposed framework of measures is consistent with the OEB's expectations set out in the Chapter 5 Filing Requirements, and should provide the OEB with useful insights into the quality and sophistication of the utility's distribution planning and implementation activities, as well as Toronto Hydro's improvement in recent years.

For each proposed measure, (with the exception of new measures) Toronto Hydro provides performance results along with the associated trend over the recent years, describes the methodology used to calculate the measure and its implementation, and outlines the ways in which the measure informs and/or otherwise interacts with the utility's Distribution System Plan and the related processes. Where relevant, Toronto Hydro also describes the unique planning

[1] Ontario Energy Board, Filing Requirements for Electricity Transmission and Distribution Applications, (Toronto: Ontario Energy Board, 2013). ["OEB Filing Requirements"]

The table would be accompanied by a discussion document which provides: additional context for Toronto Hydro's performance on each of the measures, including year-over-year variance explanations; a discussion of planned and completed activities that may have a bearing on the utility's performance on one or more of the measures; and such other information as may be relevant to the explanation of the utility's annual results. /C

Consistent with the OEB's decision to treat information relating to the cost difference between internal and external construction of projects in a confidential manner as part of this application,[3] Toronto Hydro proposes to file the annual results of the Construction Efficiency: Internal vs. Contractor Cost, in a confidential manner as well.

[3] EB-2014-0116, Decision on Confidentiality And Procedural Order No. 4 (January 7, 2014). /C

C2 CUSTOMER ORIENTED PERFORMANCE

C2.1 Reliability Measures – SAIDI, SAIFI, CAIDI

C2.1.1 Measure Description

Toronto Hydro tracks its results on the System Average Interruption Duration Index (SAIDI), System Average Interruption Frequency Index (SAIFI), and Customer Average Interruption Duration Index (CAIDI) in accordance with the OEB-mandated measurement and reporting practices specified in Section 2.1.4.2 of the Reporting and Record Keeping Requirements (RRR) as established by the OEB. The methodology used to calculate and report on these metrics is consistent with the requirements in the OEB's RRR document and IEEE 1366-2012. Calculation of SAIDI, SAIFI, and CAIDI is as follows:

`

Each outage is captured in Toronto Hydro's Interruption Tracking Information System (ITIS), further described in Section D3.1.2.1 (iii) of the DSP. Outage statistics such as Customers Interrupted (CI), Customer Minutes Out (CMO) and Duration are kept as individual entries in each individual report. The ITIS tool was developed in-house to facilitate Toronto Hydro's operational and reporting requirements with respect to outage information tracking and analysis. The CI values, used for SAIFI, and the CMO values, which are an input for SAIDI are tracked in ITIS and aggregated on a monthly basis to derive the Total Number of Customer Interruptions and Minutes Out. To calculate monthly SAIDI and SAIFI values, Toronto Hydro uses the most recent customer count data from its Customer Care and Billing (CC&B) system. At the end of the year, Toronto Hydro aggregates the monthly SAIDI and SAIFI values to calculate the annual reliability measure

values. All SAIFI, SAIDI, and CAIDI values showcased further in this document are based on year-end calculations. Toronto Hydro excludes the major event days (MEDs), as defined by IEEE 1366-2012 2.5 beta method, from all representations of reliability metrics.

C2.1.2 Historical Performance Trends

Figures 1, 2, 3, and 4 respectively illustrate Toronto Hydro's SAIDI, SAIFI and CAIDI over the past five years both including and excluding loss of supply. For SAIDI and SAIFI, the trend over the five year historical period can be attributed to the capital investments made over that time. CAIDI, on the other hand, has remained stable over the five-year historical period, as it is proportional to SAIDI and inversely proportional to SAIFI. As such, when it comes to CAIDI, the improvement of SAIDI is negated by a similar improvement to SAIFI. Toronto Hydro notes that improvements made towards SAIDI and SAIFI can lag the investments by a year or more.

Activities such as rear lot conversion and direct-buried cable replacement that reduce the number and duration of outages are among the investments that have contributed to the historical improvements shown.

FIGURE 1: HISTORICAL SAIDI EXCLUDING MEDS – 2009-2013

FIGURE 2: HISTORICAL SAIFI EXCLUDING MEDS – 2009-2013

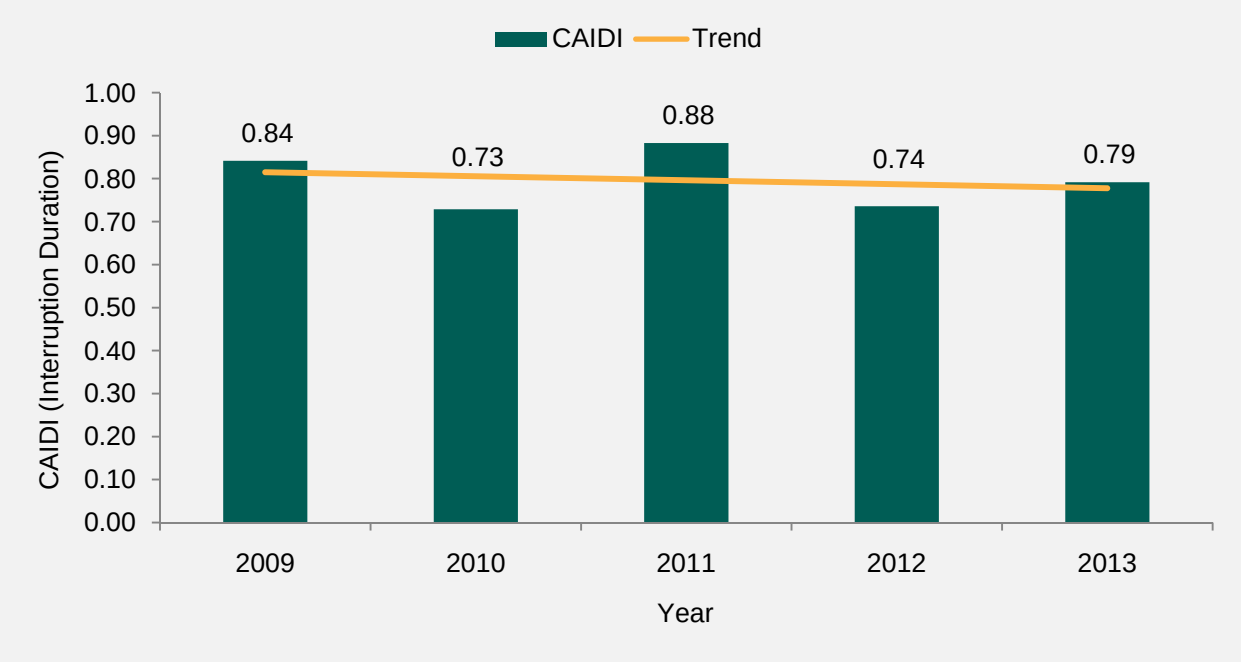

FIGURE 3: HISTORICAL CAIDI EXCLUDING MEDS – 2009-2013

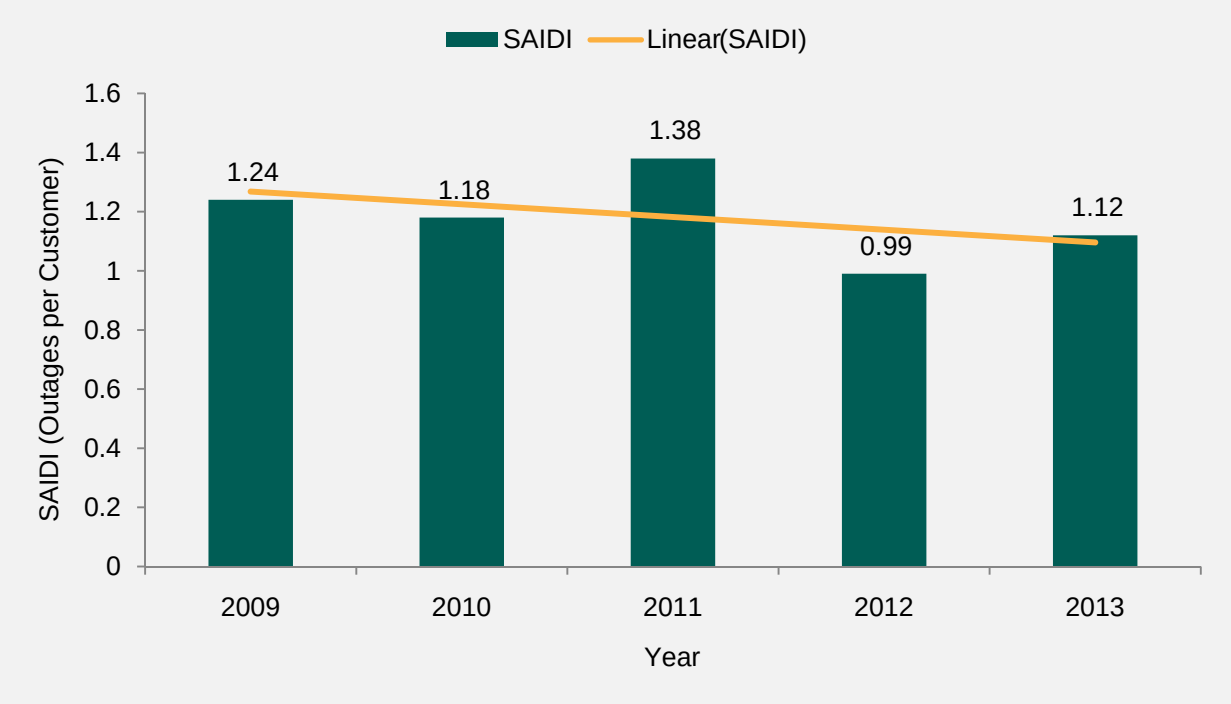

FIGURE 4: HISTORICAL SAIDI EXCLUDING MEDS AND LOSS OF SUPPLY – 2009-2013

FIGURE 5: HISTORICAL SAIFI EXCLUDING MEDS AND LOSS OF SUPPLY – 2009-2013

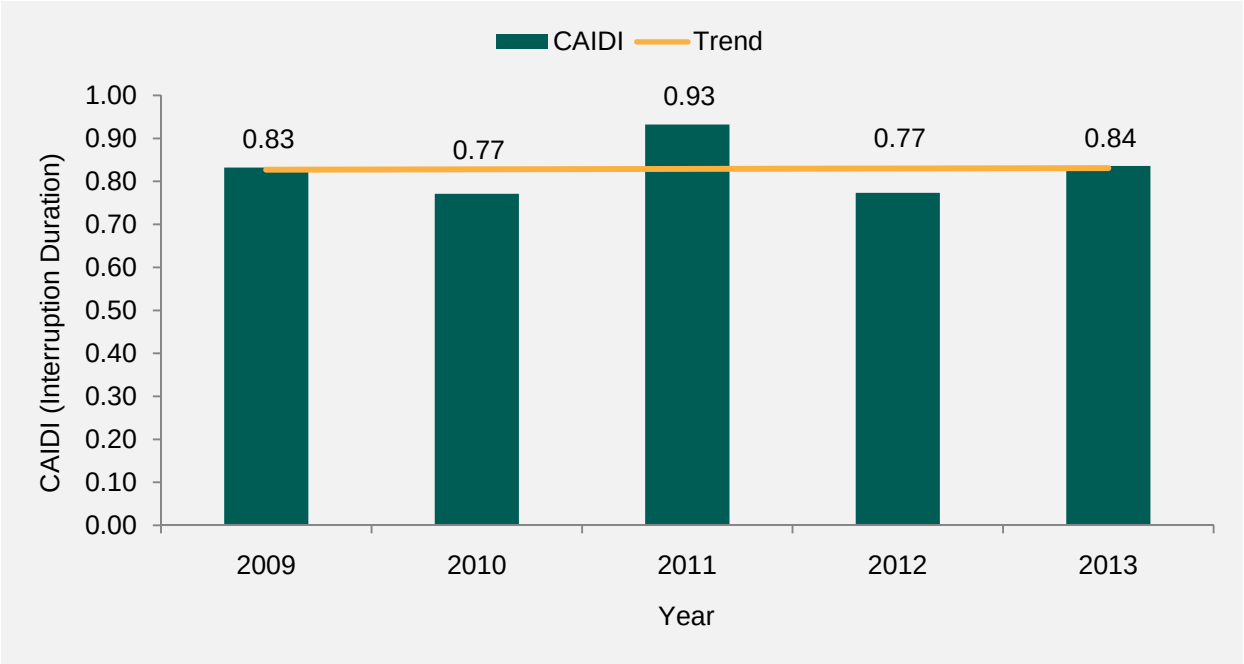

FIGURE 6: HISTORICAL CAIDI EXCLUDING MEDS AND LOSS OF SUPPLY – 2009-2013

C2.1.3 Interaction with the Distribution System Plan

Toronto Hydro uses historical reliability data as a key input into its Asset Management Process, discussed in further detail in Section D of the DSP. Within the long-term asset management policies, described in Section D3.1.1, reliability data serves as a key input to develop investment programs that will target key assets and manage critical issues. As part of short-term asset management policies, further defined in Section D3.1.2, reliability data is used at a local level to identify opportunities for capital projects.

On a system-wide level, the measures inform the asset management process to identify assets and programs required to address the root issues across the system, including activities such as direct-buried cable replacement, air insulated PMH switchgear and others. At the local or project level, historical SAIDI and SAIFI performance and anticipated improvements are considered when selecting individual assets to be replaced, enhanced or modified. On a system level, SAIDI and SAIFI are projected to improve by about 20% and 26% respectively by the end of the CIR period due to the investment programs proposed. Once again, Toronto Hydro expects CAIDI to remain relatively stable as SAIDI and SAIFI are improving in a similar trend.

C2.2 Feeders Experiencing Sustained Interruptions

C2.2.1 Measure Description

The Feeders Experiencing Sustained Interruptions (FESI) measure tracks the number of times Toronto Hydro's feeders (and by extension, some of the customers served by these feeders) are interrupted in a given rolling 12-month period. FESI aims to identify and develop mitigating strategies for the areas with the largest number of annual interruptions. Similar to other reliability metrics, FESI's source of outage data is ITIS. For some tracking measures, such as FESI, the number of feeder interruptions are aggregated by feeder. The measure focuses on interruptions that can be addressed at the feeder level and excludes value such as MEDs, loss of supply, planned interruptions and bus-level interruptions so as to focus on the performance of the feeder itself.

FESI is valuable because it measures pure distribution equipment performance by excluding external non-distribution related events that also impact the feeder level performance. Unlike SAIFI, SAIDI and CAIDI, which are effective for measuring the overall system performance, FESI focuses on specific areas of the distribution system that are underperforming relative to the system averages. Accordingly, the tracking of FESI allows Toronto Hydro to gain insights into the performance of smaller neighbourhoods and individual streets so that the overall customer experience can be improved.

As described in the Worst Performing Feeder Program (E6.21), Toronto Hydro's current management approach related to issues measured by FESI focuses on feeders that have experienced seven or more interruptions in a given 12-month period. Toronto Hydro established the threshold of seven outages based on a review of its historical feeder-level performance statistics, which determined that 3.5% of all feeders (those with seven or more annual outages) in the system were responsible for about half of the total system SAIDI and SAIFI. For the purposes of annual tracking, Toronto Hydro proposes to normalize the annual results by excluding Major Event Days and Loss of Supply events.

C2.2.2 Historical Performance Trends

Figure 7 shows Toronto Hydro's historical FESI-7 performance over the last five years, along with the associated trend. The number of feeders sustaining seven or more interruptions has

decreased from 38 in 2009 to 33 in 2013, and declining to as low as 29 in 2012. The average number of feeders with seven or more interruptions in 2009-2013 was 35.

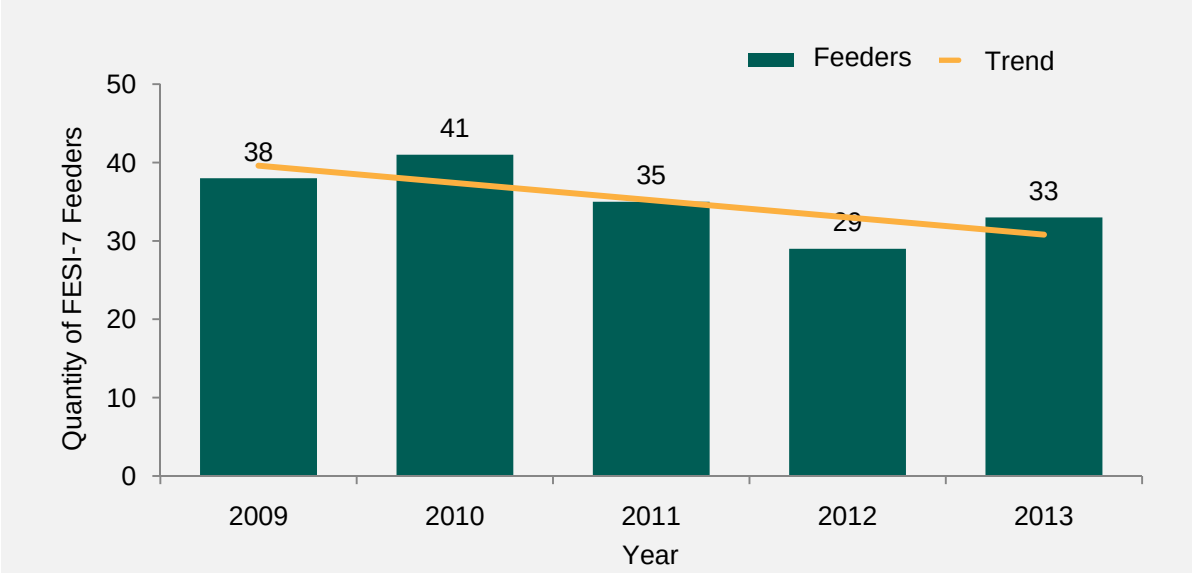

FIGURE 7: QUANTITY OF FESI-7 FEEDERS –2009-2013

C2.2.3 Interaction with the Distribution System Plan

The declining trend illustrated above speaks to the effectiveness of Toronto Hydro's Worst Performing Feeder program over the recent years, including specific reliability-driven capital and maintenance programs, such as tree trimming, targeted asset replacement, insulator washing and animal guard replacement. Toronto Hydro plans to continue monitoring the outcomes of its investments targeted towards service improvements on the utility's worst performing feeders. The Worst Performing Feeder Program (E6.21) contains a detailed list of maintenance and capital work planned to target FESI feeders. However, beyond the specific work planned as part of the Worst Performing Feeder program, which deals with primarily short term mitigation, every aspect of the Toronto Hydro's Capital Expenditure plan that is driven to some degree by reliability (e.g. circuit renewal work), and will ultimately contribute to the improvement of the FESI performance.

Based on the scope and volume of investments proposed within the utility's 2015-2019 Distribution System Plan, Toronto Hydro anticipates that its average number of feeders experiencing seven or more interruptions will continue to decline, or at least remain in line with the 2009-2013 average. At the same time, and as seen from the historical data, some year-over-

year volatility in single year results can be expected. This volatility stems mainly from large events such as thunder storms or a single failure mode that can cause a single feeder to fail in rapid succession.

C2.3 Momentary Average Interruption Frequency Index

C2.3.1 Measure Description

Momentary Average Interruption Frequency Index (MAIFI) measures the average frequency of momentary interruptions that affect Toronto Hydro's customers. Similar to SAIFI, MAIFI is an aggregation of the number of CI month–over-month, normalized to the number of customers served. Unlike SAIFI, MAIFI tracks only those interruptions lasting less than one minute. MAIFI is calculated as follows:

Avoidable momentary outages arising from defective equipment or other controllable factors can be a concern for certain customers. Industrial customers can experience interruptions to their normal production schedules, retail customers may experience interruptions to their ability to serve customers, and residential customers can be affected in a number of ways associated with downtime of household appliances or other technology. In extreme cases, a momentary interruption can result in significant damage to customer equipment or machinery.

C2.3.2 Historical Performance Trends

Figure 8 shows Toronto Hydro's historical MAIFI performance over the 2009-2013 period, and the associated trend. As the figure shows, the average frequency of momentary interruptions has decreased from 3.3 per year in 2009 to 2.37 interruptions in 2013 (a 28% improvement), with the five-year average frequency value of 2.74. Toronto Hydro attributes its improved MAIFI performance to the same factors that have led to a decreasing trend in SAIFI. While the two metrics measure different types of events, the activities aimed at reduction of SAIFI can also lead to improvements in MAIFI. Maintenance and capital work such as insulator washing and tree proofing can improve both SAIFI and MAIFI.

Toronto Hydro currently performs MAIFI tracking using a manual data entry process and resource-intensive background analysis, but plans to address this limitation over the 2015-2019 timeframe. In light of these potential process enhancements, Toronto Hydro notes that its MAIFI performance calculated through fully automatic processes may be materially different from the data collected using the manual approach currently employed. At this point, Toronto Hydro is not in a position to assess the direction or magnitude of potential performance changes following automation of the tracking process.

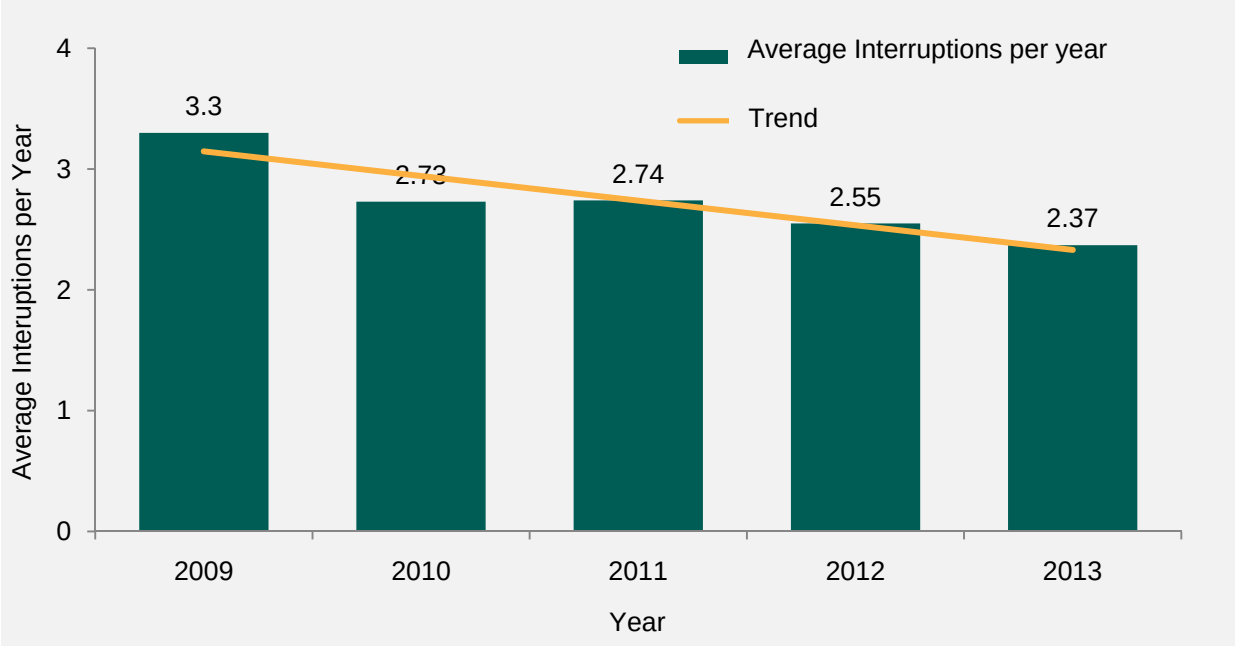

FIGURE 8: MAIFI PERFORMANCE – 2009-2013

C2.3.3 Interaction with the Distribution System Plan

Toronto Hydro's Distribution System Plan and planned maintenance expenditures include a number of programs and projects that are expected to directly and indirectly impact the number of momentary interruptions across the utility's service territory. Programs and activities such as the Overhead Momentary Reduction program, insulator washing, tree trimming and tree proofing are expected to assist in the reduction of avoidable momentary outages. For the purposes of the 2015-2019 planning timeframe, however, Toronto Hydro anticipates its MAIFI levels to improve in line with SAIFI improvements. Both measures reflect the frequency of interruptions, with the key

difference that SAIFI measures outages over one minute and MAIFI outages less than one minute. Given the similar measurement criteria, Toronto Hydro expects that its MAIFI results will follow a similar trend to SAIFI projections, subject to the above-noted measurement considerations. As the utility continues to track its momentary events over the 2015-2019 period, it expects to work with its customers affected by momentary outages and with industry colleagues to devise more precise MAIFI reduction objectives.

C3 COST EFFICIENCY & EFFECTIVENESS

C3.1 Distribution System Plan Implementation Progress

C3.1.1 Measure Description

Toronto Hydro plans to measure the overall progress of its Distribution System Plan implementation as a rolling ratio of total capital expenditures made over the plan years completed to date, divided by the five-year total amount of OEB-approved capital expenditures approved as a part of the utility's 2015-2019 Distribution System Plan, Including the System Access, System Renewal, System Service, and General Plant investment categories. The proposed measure will be calculated using the following formula:

$$\frac{\text{Actual Capital Expenditures for Completed Plan Years}}{\text{OEB-Approved Capital Expenditures for Completed Plan Years}} \geq \text{Actual Capital Expenditures for Plan Year}$$

According to this formula, if Toronto Hydro's total five-year approved capital envelope was approved to be $2.47 billion and the utility's Year 1 (2015) and Year 2 (2016) capital expenditures amounted to $524 million, and $502 million respectively, then the utility's plan implementation progress metric at the end of the 2016 rate year would be:

$$\frac{\text{\$524 million + \$502 million}}{\text{\$2.47 billion}} = 42.1\%$$

Toronto Hydro's preference for using the rolling measure of plan implementation progress stems from the fact that the utility operates in a dynamic business environment, where a number of issues can emerge over the course of any given year that require the utility to advance,

postpone, or otherwise amend the schedule, sequencing or pacing of projects slated for completion in that year. These considerations are often outside of the utility's control, and include the following factors:

- Major weather events (floods, ice storms);
- Atypical seasonal conditions (shorter construction seasons or limited switching capability);
- Urgent third-party work requests (e.g. plant relocations for transit);
- City and/or third-party (e.g. Hydro One Networks Inc. (HONI)) dependencies (resulting in longer project timelines);
- Changes in labour force availability (job action, higher than anticipated retirement rates, changes in the contractor community);
- Actions of HONI or the IESO (e.g. outage coordination challenges);
- Other related circumstances.

While these activities can have a significant affect on Toronto Hydro's ability to implement certain programs or projects in any specific year, that potential impact is significantly reduced over a longer (five-year) timeframe, providing the utility sufficient flexibility to adjust the pace on the affected projects, while redeploying its resources towards the work that can be completed in the immediate term. The aggregate five-year target ensures that the utility will work towards delivering the entirety of the capital program approved for the 2015-2019 planning period.

C3.1.2 Historical Performance Trends

The proposed 2015-2019 Distribution System Plan is the first time that Toronto Hydro expects to implement an approved medium-length multi-year capital plan. Accordingly, the utility is not in a position to provide the comparable historical results in a similar format, in light of the variety of circumstances under which Toronto Hydro's capital plans for 2009 through 2014 were prepared, amended and subsequently reviewed and approved by the OEB.

C3.1.3 Interaction with the Distribution System Plan

The proposed plan implementation progress measure is expected to allow Toronto Hydro and the OEB to gauge the utility's progress towards the completion of its entire 2015-2019 capital plan at

regular intervals. Reviewing the progress at one-year intervals will assist in providing the OEB regular updates regarding the plan progress.

C3.2 Planning, Engineering & Support Efficiency

C3.2.1 Measure Description

Planning, engineering, and other eligible administrative costs associated with capital program or project development are a component of Toronto Hydro's total capital costs. For the purposes of its 2015-2019 Distribution System Plan, Toronto Hydro proposes to track the proportion of its total capital expenditures on distribution plant and associated civil infrastructure that is comprised of indirect planning, engineering and support labour costs related to this portion of the utility's capital expenditures. By measuring the resulting ratio and taking steps to ensure that it remains within or below the historical levels, Toronto Hydro plans to drive the efficiency and productivity of these processes, ultimately resulting in more cost-effective assets being put into service.

The eligible costs to be tracked for the proposed measure include capitalized labour costs associated with long-term, short-term planning functions, including development of the long-term system studies, capital investment programs and specific projects. Section D1 provides a high level summary of each of the planning processes, while Section D3 provides details with respect to the elements and outputs produced by each planning process. The work to develop and refine the utility's decision support systems is also included in Section D3.1.2.1. The formula for the proposed performance measure is as follows:

$$\text{Ž ƒ • • ‹ • ‰ á • ‰ ‹ • ‡ ‡ " ‹ • ‰ ¬ — ' ' : " ÷ ' • – ^ Ð ‹ … ‹ ‡ • … ›}$$
$$L = \frac{\text{D ƒ ' ‹ – ƒ Ž Ž ƒ • • ‹ • ‰ á • ‰ ← • ‡ ‡ " ‹ • ' ‡ • † : š Ž ƒ • – ;}}{\text{D ' – ƒ Ž ƒ ' ‹ – ƒ Ž ' ‡ • † : š Ž ƒ • – ;}}$$

Using a hypothetical example to illustrate the mechanics of this formula, if Toronto Hydro's total capitalized indirect labour costs related to electric distribution plant amounted to $5 million in a year, while the utility's total capital expenditures attributable to the distribution plant and associated civil infrastructure were $50 million, the resulting metric for the year in question would be:

$$\frac{\text{D w}}{\text{D w r}} \text{ L s r ¨}$$

Toronto Hydro tracks the eligible costs through a thorough time-sheeting process. This process assigns indirect labour costs to capital, operating, or blended activities, in accordance with a detailed set of pre-established criteria. These criteria are approved by Toronto Hydro's senior management and reviewed for compliance with the applicable accounting frameworks. Given that the utility has had no experience in explicitly tracking its performance on this measure in the past, Toronto Hydro proposes to track the yearly results on a rolling five-year average starting in 2015, in order to reduce the effects of any one-time events that may affect the results. While a portion of eligible indirect labour costs such as regular salary and burden of full-time employees is typically "fixed" year-over-year, subject to headcount changes, a significant portion of these costs can vary year-over-year. The variability is caused by circumstances such as overtime use, implementation of new tools or process streamlining, or additional hiring to support the changes in the utility's capital program. Accordingly, by commencing the measurement of its indirect labour costs supporting its electrical distribution plant and the associated infrastructure, Toronto Hydro plans to be in a better position to assess and improve the efficiency of its indirect labour costing and resourcing through a variety of potential management decisions.

C3.2.2 Historical Performance Trends

While Toronto Hydro has not explicitly tracked the proposed metric in the past, the application of the proposed formula to the eligible portion of the utility's historical capital expenditures produces the results presented in Figure 9.

Over the past five years, the portion of Toronto Hydro's indirect labour costs relative to the total distribution plant-related capital expenditures has decreased from 13.1% in 2009 to 7.1% in 2013, for the average five-year value of 9.9%. Toronto Hydro attributes the improvement in this measure's results to the increasing size of the utility's capital work program and subsequent optimization of the available labour resources. Although part of this improvement is attributed to the staffing reductions and certain accounting changes (2011), Toronto Hydro has generally been able to manage an increasing capital work program with the smaller work force. In addition, the performance improvements are attributable to the increased efficiency of asset management processes through automation of many manual procedures and the use of decision support systems, detailed in Section D3.

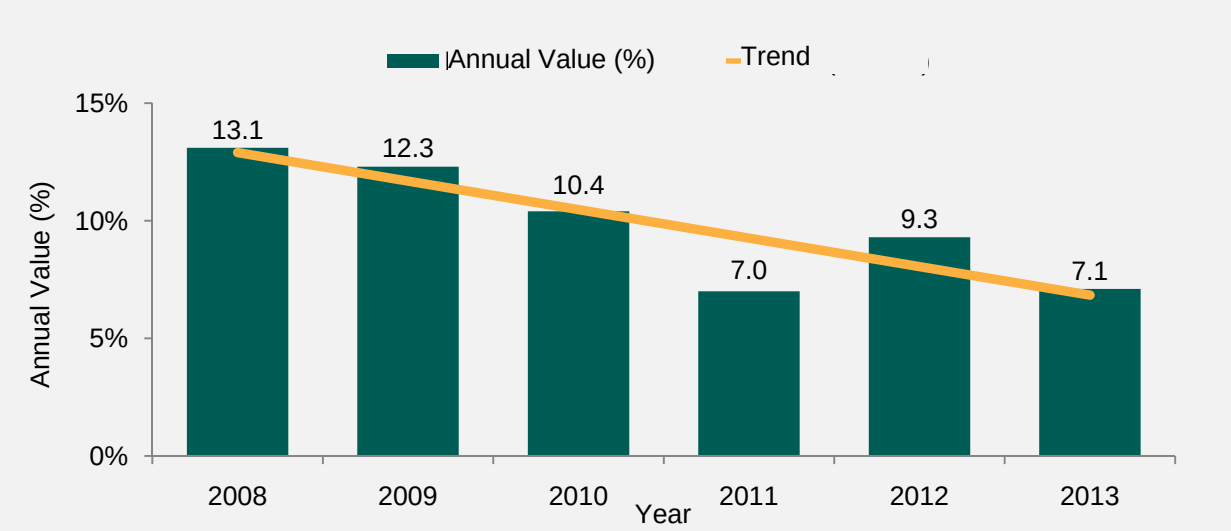

FIGURE 9: INDIRECT LABOUR % OF DX PLANT EXPENDITURES – 2009-2013

To gauge the appropriateness of its historic performance levels, Toronto Hydro consulted the 2014 edition of the RSMeans Electrical Cost Data Book[2] that provides the electric contractor industry with estimate ranges for a variety of electrical construction activities, including the proportion of total project costs made up of specific activities. A copy of the relevant information from this document can be found in Appendix A to this section of the DSP. According to the RSMeans data, the suggested total range of engineering costs as a portion of total project costs is within the 4.1% - 10.1% range. While Toronto Hydro's historical average result of 9.9% falls within the acceptable range, the utility notes that its indirect labour costs include other activities, such as management and support costs beyond the scope of activities captured by the RSMeans range.

For the purposes of its 2015-2019 capital plan, Toronto Hydro proposes to track the proportion of its indirect labour costs associated with electrical distribution plant relative to the total electrical distribution plant expenditures on a rolling five-year basis, with the 2009-2013 average value serving as a reference point. As the utility and the OEB gain more experience in this performance measurement area, Toronto Hydro may set more concrete targets in its future applications.

[2] RSMeans Electrical Cost Data Book, 2014 Edition, p 8. (See Appendix)

C3.2.3 Interaction with the Distribution System Plan

Toronto Hydro has no previous experience in tracking the proposed metric. Accordingly, the utility's current Distribution System Plan was not explicitly informed by any assumptions as to the capital planning, engineering, and support efficiency. By measuring these activities over the 2015-2019 timeframe, Toronto Hydro expects to gain valuable insights into this dimension of its capital work, while ensuring that the amount of supporting labour costs included in its distribution plant capital project costs remains appropriate.

C3.3 Supply Chain Efficiency: Materials On-Cost

C3.3.1 Measure Description

In accordance with the applicable accounting frameworks, Toronto Hydro adds the eligible portion of its supply chain and warehousing activities costs directly to the capital projects and programs that these activities support. The supply chain and warehousing costs are added to the total costs of capital projects through the service charge referred to as "On-Cost," which is applied as a percentage of the project's total costs. Since capitalized warehousing activities make up a material portion of each project's final costs, Toronto Hydro proposes to track the annual On-Cost value as a measure of efficiency of the utility's supply chain and warehousing activities.

Toronto Hydro calculates the On-Cost rate as the sum of budgeted eligible expenditures (e.g. warehouse employee labour costs), divided by the budgeted dollar value of materials moving through the utility's warehouses (including the recently outsourced warehousing operation) in a given year. The utility then applies the resulting rate to the dollar value of all materials when issued to capital and operating projects. At the end of each year, Toronto Hydro calculates the final on-cost rate on the basis of actual warehouse expenditures and the value of materials processed through the warehouse, and makes the appropriate adjustments to the capital costs of all projects.

Not all warehousing expenditures are included in the on-cost rate. For example, the inventory of materials used for internal warehousing purposes, utilities and communications-related expenses, and administrative staff costs are excluded. As with the indirect labour costs measure discussed above, Toronto Hydro's On-Cost calculation methodology is based on pre-determined parameters that are periodically evaluated.

C3.3.2 Historical Performance Trends

Figure 10 illustrates Toronto Hydro's historical On-Cost rates and the associated performance trend. Toronto Hydro's On-Cost charges remained relatively flat between 2009 and 2013, with a 2009-2013 historical average of 11.8%. The utility attributes its generally steady On-Cost levels to better utilization of available resources, the increase of the overall volume of capital program and a number of efficiencies detailed in the Supply Chain Program OM&A evidence (Exhibit 4A, Tab 2, Schedule 12). Over the 2015-2019 planning horizon, the utility expects its On-Cost rate to decline because of anticipated attrition and other productivity and efficiency improvements, including the deployment of a third-party warehousing outsourcing model that began in 2013.

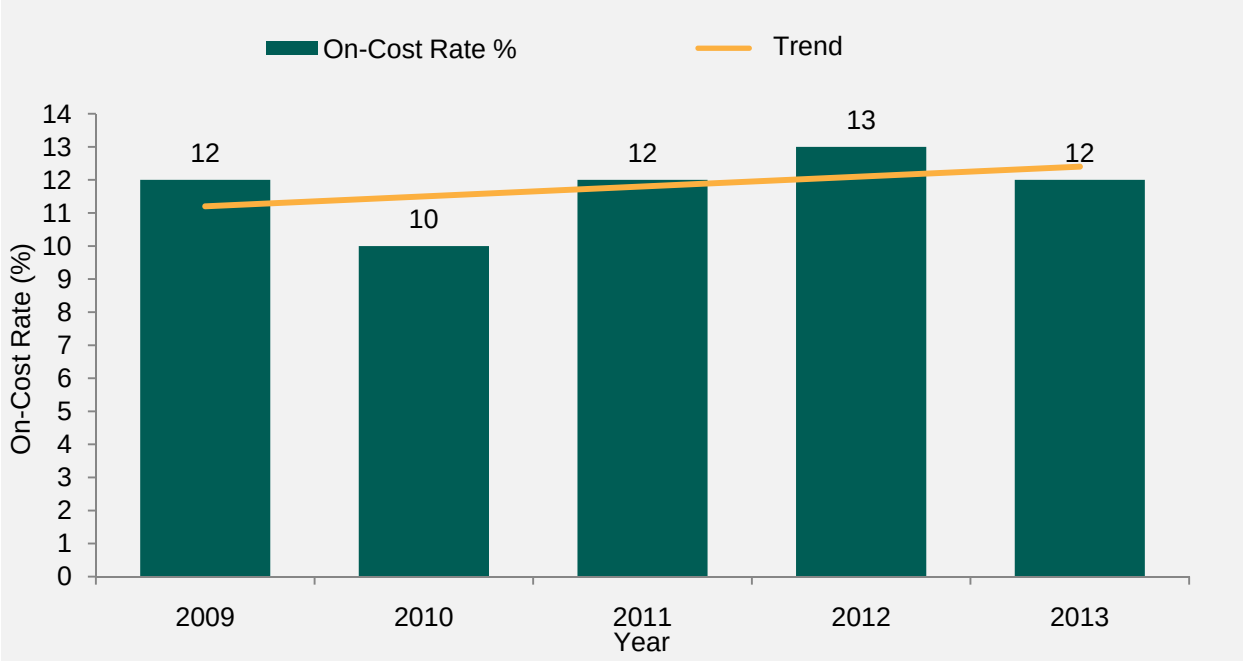

FIGURE 10: ON-COST PERFORMANCE (%) – 2009 – 2013

C3.3.3 Interaction with the Distribution System Plan

Subject to any developments outside of Toronto Hydro's control, Toronto Hydro's supply chain and warehousing efficiencies tracked through the On-Cost measure is expected to facilitate more cost-effective completion of the utility's capital program, enabling higher volumes of capital work to be completed for the same cost, thus directly benefiting Toronto Hydro ratepayers.

C3.4 Construction Efficiency: Internal vs. Contractor Cost

C3.4.1 Measure Description

To assess the reasonableness of the costs of capital construction projects completed by the utility's internal construction crews, Toronto Hydro compares the cost of select projects constructed "in-house" to the unit prices charged for similar work performed by external contractor crews. Toronto Hydro currently employs six full-service design and construction contractors that provide the utility with turnkey electrical project design and construction services. This service enables the utility to complete the requisite volume of capital work in a safe and efficient manner, while providing the resourcing scalability and flexibility to account for the changing capital program funding levels.

When presented with individual project designs, contractors break down each project into the number and type of applicable activity-based units, which are based on Toronto Hydro's certified Distribution Construction Standards. The aggregation of unit prices determines the total price that the contractors are paid for delivering the project. As such, contractors are ultimately responsible for managing the variances between the unit cost estimate and their actual costs.

Once properly adjusted for the differences in cost structures between Toronto Hydro's operations and those of external contractors, the comparative results show Toronto Hydro the cost gap between internally and externally executed projects. Given that Toronto Hydro's external contractors operate in the same environment as the utility's internal crews, and use materials paid for and procured by the utility, comparisons between the costs of externally and internally constructed projects constitute an appropriate form of construction cost benchmarking. Operating in the Canadian and Toronto construction markets, the cost structures of Toronto Hydro's external contractor partners must reflect the optimal efficiency levels across both its operating and support activities in a competitive market. Accordingly, the unitized cost estimates provided to Toronto Hydro by its construction partners at the time of contract negotiation reflect the competitive market costs to complete the projects of the scope, scale and complexity characteristic of Toronto Hydro's aging and dense urban distribution system.

C3.4.1.1 Comparison Methodology

Beginning in 2011, each year Toronto Hydro selects up to ten reference capital projects constructed by its internal crews over the previous year. To date, the projects have been selected from three of the utility's larger capital portfolios, namely Direct Buried Cable Replacement, Overhead and Underground Rehabilitation. To establish a consistent baseline for cost comparison, the selected internally delivered projects have minimal cost and scope variations from the original design.

The reference project design packages are divided among several of Toronto Hydro's participating contractors, who disaggregate them into individual units. To better reflect the range of contractor costs available to Toronto Hydro, the utility applies the unit costs of all six contractors to the number and type of units identified for each project. This provides Toronto Hydro with six unique contractor cost estimates for each of the ten reference projects.

Prior to undertaking comparisons, Toronto Hydro's actual project costs and the contractor estimates require adjustments to account for a number of differences inherent in the respective entities' business models. The most significant of these adjustments is necessitated by the fact that Toronto Hydro's capital costs do not capture the full extent of the utility's expenses, as a significant portion of the utility's costs is recovered through the OM&A expenditures and other means of cost recovery available to regulated distributors in Ontario. At the same time, Toronto Hydro assumes that the contractors must recover and earn profit on the entirety of their operating activities through the prices charged for project delivery. To correct for this important distinction, Toronto Hydro's capital costs require adjustments to include the relevant overhead, burden and regulated return components.

In performing the above adjustment Toronto Hydro accounts for the fact that it performs a number of functions which the contractors do not perform at all (e.g. feeder switching), or which they perform on a smaller scale than the LDCs (customer care, finance, HR, etc). Because of these distinctions, certain components of Toronto Hydro's overhead and burden costs are either explicitly excluded from the capital cost adjustment, or are proportionally allocated to reflect the costs associated with Toronto Hydro's internally executed capital construction costs. The end product of the adjustment process is an all-in cost estimate of Toronto Hydro's construction costs for internally executed projects, inclusive of all the relevant support functions that may not be intuitively associated with construction. In other words, the resulting adjusted estimate represents a approximation of a hypothetical price that Toronto Hydro would charge its customers if it were a design and construction-only utility, as opposed to a regulated distributor.

In a similar manner, contractor project estimates require adjustments to account for the project-related cost drivers that are incremental to their project costs, including costs of audit and verification mandated by Toronto Hydro, and administration charges from the utility's Program Support Office that manages the design and construction contractors. After the completion of the adjustment process, Toronto Hydro's reference project costs are reasonably comparable to the contractor estimates..

C3.4.2 Historical Performance Trends

Based on the above comparison methodology, the costs of Toronto Hydro's internal project construction were on average [redacted] higher[3] than the costs of the same projects had they been constructed by the six design and construction contractors. The cost gap value was calculated using the weighted average of individual estimate variances commensurate to the proportion of external contract work performed by each of the six contractors in a reference year.

Toronto Hydro's analysis indicates that a significant portion of fully burdened construction cost variance stems from the higher overhead and burden expenditures associated with the scale and scope of the utility's operations as compared to the analogous cost drivers for the external contractors. Some of these costs are driven by the terms of Toronto Hydro's collective agreements and by the need for Toronto Hydro to have specialized trades to work on unique aspects of its distribution system (downtown network, lead cable, box construction etc.). Contractors, on the other hand, generally employ high voltage workers with generic qualifications and experience needed for more standard overhead and underground systems most prevalent across their customer base. However, with respect to other cost drivers, such as facilities expenditures and the On-Cost rate, Toronto Hydro anticipates overall improvement due to the planned or ongoing productivity and efficiency initiatives. For the purposes of the 2015-2019 CIR period, Toronto Hydro will use the results of its historical analysis as a general point of reference. The utility notes, however, that it has recently issued a Request for Proposals (RFP) with the goal of awarding and re-negotiating its contracts with all external design and construction service providers for the 2015 – 2018 timeframe. The outcomes of the RFP may materially affect the results of future comparative efforts relative to the past year assessments. This is especially relevant in light of the high demand for qualified services currently characterizing Toronto Hydro's electrical construction market, and expected to remain a significant factor in the medium term. This is primarily due to a large number of construction projects planned or underway in the city

[3] The redacted information has been filed confidentially pursuant to the OEB's Practice Direction on Confidential Filings

including the residential high rise real estate developments, the PanAm/ParaPan Games construction, waterfront redevelopment, major transportation projects, and outsourcing work undertaken by other utilities.

C3.4.3 Interaction with the Distribution System Plan

Toronto Hydro uses the results of its external project construction cost benchmarking as a general reference for the reasonableness of the cost of projects completed by the utility's internal construction crews. As the utility continues conducting these comparative exercises over the 2015-2019 planning horizon, it may undertake more detailed assessments of individual cost drivers that make up the cost gap between contractor-delivered and internally constructed projects. At present, Toronto Hydro does not plan to expand the scale of this annual comparative activity, in part because of the complexity of conducting these assessments.

C3.5 Construction Efficiency: Standard Asset Assembly Labour Inputs

C3.5.1 Measure Description

Toronto Hydro is in the early stages of investigating the possibility of developing a comprehensive framework for tracking the total number of labour hours required to stage, install and energize a fully assembled unit corresponding to each major asset class of the utility's electricity distribution plant (e.g. transformers, switchgear etc). The project's envisioned scope entails developing a framework of about 25 major "Asset Assemblies," which in aggregate account for over 80% of the utility's planned capital program executed by internal resources.

At present, Toronto Hydro's engineers and designers use a fragmented framework of over 180 discrete labour activity cost estimates to prepare project scopes and develop associated designs, by taking into account the varying job-specific field conditions and circumstances that impact installation timeframes. While this framework enables Toronto Hydro to prepare extremely detailed cost estimates, it is not optimally suited for easy and effective tracking in the field by the utility's crews conducting the work. Accordingly, Toronto Hydro's objective is to augment the existing system with a more uniform, yet sufficiently flexible, labour hours input framework that would meet all of Toronto Hydro's planning, design and project tracking needs.

While the project is currently in an early testing stage, the envisioned end-state scope includes about 25 discrete estimates of total labour and "non-wrench" hours (e.g. driving, set-up/take-down, breaks) required to fully complete a single installation of a major asset class unit. The estimates of total hours will be developed based on system averages derived through analysis of past results, pilot time studies, and other activities determined as necessary during the subsequent project stages. To provide the requisite flexibility and scalability in light of the diversity of conditions and configurations inherent in Toronto Hydro's distribution system, the core Asset Assemblies framework will be augmentable through a standardized and centrally managed set of Project Adjustment Factors. These additional estimate adjustment capabilities are expected to allow the engineers and designers to customize the expected project completion estimates to account for specific engineering, topographic or other related circumstances applicable to each individual project.

To faciliate the core labour and non-wrench hours estimates continuing to reflect the reality of field conditions, the underlying numbers will undergo periodic updates on the basis of actual results obtained from the field. This periodic update process is expected to effectively create a positive feedback loop, allowing Toronto Hydro to reflect the emerging improvements in crew productivity levels in its future estimates. This process will enable Toronto Hydro to maintain realistic capital construction targets and foster a culture of continuous improvement. To enable effective day-to-day tracking of project progress by individual construction crews, the project scope includes the development of a user-friendly IT application for use on handheld devices issued to crew leaders.

Toronto Hydro chose to focus on labour input hours rather than any other units (e.g. dollars), because labour hours are a commodity that is not affected by inflation, is generally comparable across the utility's field resources, and has inherent potential for improvement through adoption of more efficient work execution practices and the introduction of new tools or other process improvements.

C3.5.2 Historical Performance Trends

Toronto Hydro is in the early stages of the Asset Assemblies project implementation and testing, so the utility does not have any historical results associated with this measure.

C3.5.3 Interaction with the Distribution System Plan

Given the early stages of what Toronto Hydro estimates to be a three-year project implementation timeline, Toronto Hydro's tracking of this measure will amount to annual updates on the project status, based on the following anticipated timeline:

- 2015-2016: develop and test the conceptual framework and implement the tracking system;
- 2017-2018: collect actual data and establish initial labour and non-wrench time benchmarks;
- 2019: begin reporting on performance related to a subset of specific Asset Assemblies.

While Toronto Hydro acknowledges that the above project tracking schedule is general in its nature, the utility is not in a position to provide a more detailed schedule at this time. Accordingly, Toronto Hydro plans to provide more detailed project development schedule forecasts with each annual update. Once Toronto Hydro is in a position to track the adherence to specific labour targets for Asset Assemblies completion, it plans to track approximately three to five individual asset categories for the purposes of any single Distribution System Plan performance measurement.

More generally, Toronto Hydro anticipates that the successful implementation of the Asset Assemblies framework will allow the utility to effectively benchmark its internal construction inputs (and by extension costs), thus driving continuous improvement. Among other things, the Asset Assemblies labour hours tracking framework may prove to be a useful way to inquire further into the utility's internal labour costs as compared to the results of benchmarking of its internal construction costs to the prices charged by the external construction contractors (See Section C3.4).

C4 ASSET & SYSTEM OPERATIONS PERFORMANCE

C4.1 Outages Caused By Defective Equipment

C4.1.1 Measure Description

For the purposes of measuring the performance of its equipment over the 2015-2019 planning horizon, Toronto Hydro plans to track the number of outages occurring over a rolling 12-month period due to defective or otherwise malfunctioning equipment. These outages are distinct from other outage causes such as vegetation/animal contacts, upstream supply interruptions or weather-related events. On average over the past five years, defective equipment-related outages were responsible for approximately 44% of total SAIDI and 41% of SAIFI results. Toronto Hydro tracks its equipment-related outages using ITIS, where each event is assigned a specific cause code. The count or number of outages caused by failed equipment speaks to the general condition of the utility's assets. Toronto Hydro proposes to track the number of equipment related-outages on a rolling 12-month basis.

C4.1.2 Historical Performance Trends

Figure 11 provides a summary of Toronto Hydro's historic performance on the equipment-related outages measure over the 2009-2013 timeframe. As seen in the chart, Toronto Hydro's performance on this measure has steadily improved over the past five years from 728 events in 2009 to 636 in 2013 – an improvement of over 11%. The utility attributes this performance improvement to the high level of System Renewal investments made in recent years, but notes that as with SAIDI and SAIFI, improvements in the defective equipment-caused outages often lag behind the investments to rectify them by several years. Accordingly, to maintain and/or improve on the current trend, Toronto Hydro plans to continue investing in System Renewal and other programs facilitating equipment performance improvements.

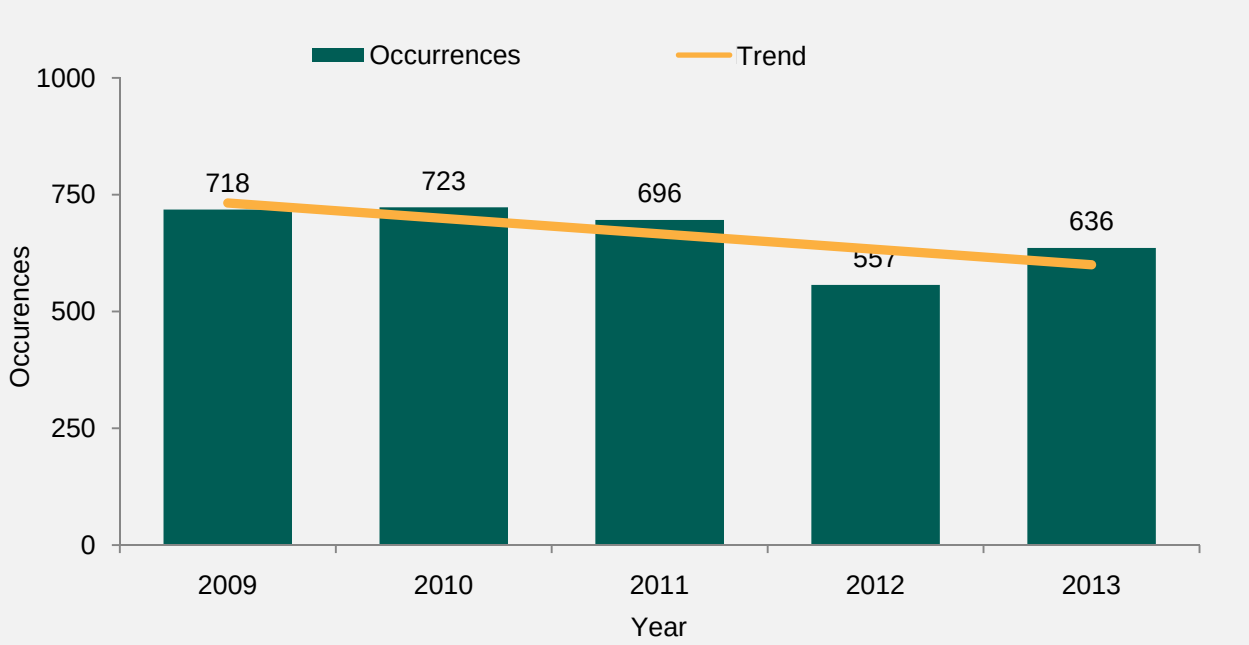

FIGURE 11: OUTAGES CAUSED BY DEFECTIVE EQUIPMENT – 2009-2013

C4.1.3 Interaction with the Distribution System Plan

As stated above, Toronto Hydro attributes performance improvement as illustrated in Figure 11 to the level of System Renewal investments made in recent years, but notes that given the current system demographics, continued focus on the system renewal investments is required to avoid a reversal of this trend.

Toronto Hydro plans to continue improving the general health of the system assets and ensure the historical trend continues so as to improve the system reliability. Given the proposed levels of System Renewal investments in its 2015-2019 Distribution System Plan, Toronto Hydro anticipates that the number of defective equipment-related outages will improve in line with the expected improvement in asset demographics. As a pure failure metric that does not consider imact and duration, the trajectory of this metric is expected to be affected by system renewal but not significantly changed by modernization. Overall, Toronto Hydro expects the historic trend to continue during the 2015-2019 period.

The results of this measure will inform Toronto Hydro as to the effectiveness of its asset replacement strategies and preventive maintenance activities. Should the results over the future years display trends significantly different from the historical levels, Toronto Hydro plans to investigate the underlying reasons and make the appropriate adjustments as necessary and feasible. Customers that are interrupted due to failed equipment can typically expect extended outages as Toronto Hydro crews replace the failed asset. By reducing the volumes of equipment at risk of failure across its system, Toronto Hydro will be assisted delivering more reliable system performance to its customers.

C4.2 Stations Capacity Availability

C4.2.1 Measure Description

As its final performance measure for the purposes of its 2015-2019 Distribution System Plan, Toronto Hydro proposes to track the availability of capacity at its Transformer Stations (TS). The utility regularly monitors its available station capacity across the service territory to ensure that sufficient capacity exists to satisfy system peak demand, accommodate new customer connections, and provide a reasonable amount of operating flexibility to the Control Centre for the purposes of load transfers. These monitoring activities enable the planned and reactive capital and maintenance work, and facilitate outage restoration efforts.

Toronto Hydro forecasts station-specific demand on an annual basis and compares the forecasts against the available equipment capacity. Where forecasts indicate potential capacity shortages, Toronto Hydro develops and executes the plans to transfer the incremental load to adjacent stations or increase the existing equipment's capacity. Given the pace of the recent and projected economic growth across the utility's service territory, stations capacity monitoring represents a crucial dimension of Toronto Hydro's asset management activities.

For the purposes of the 2015-2019 Distribution System Plan performance monitoring, Toronto Hydro proposes to track the number of stations where peak demand exceeds 90% of station capacity over the next five years. Given that a number of station expansion activities are currently underway (including construction activities at Copeland TS), Toronto Hydro proposes to track this measure based on a five-year rolling outlook starting in 2015. Since Toronto Hydro is not always in a position to unilaterally affect the station capacity limitations (e.g. due to upstream

transmission system constraints), the utility proposes to narrow the scope of this measure to include the stations where capacity limitations are at the station bus and/or switchgear level.

C4.2.2 Historical Performance Trends

Figure 12 shows the historical data for the proposed Stations Capacity measure for the 2009-2013 period. As evidenced by the chart, the number of stations with capacity limitations has increased from three to five over 2009-2013, with a historical high of six stations in 2011-2012. This trend reflects ongoing load growth and new connections throughout the city. Over the time period shown, no new stations or additional station busses have been put into service. The metric drops from 2012 to 2013 primarily as a result of load transfer projects that have been planned since the 2013 load forecast was issued.

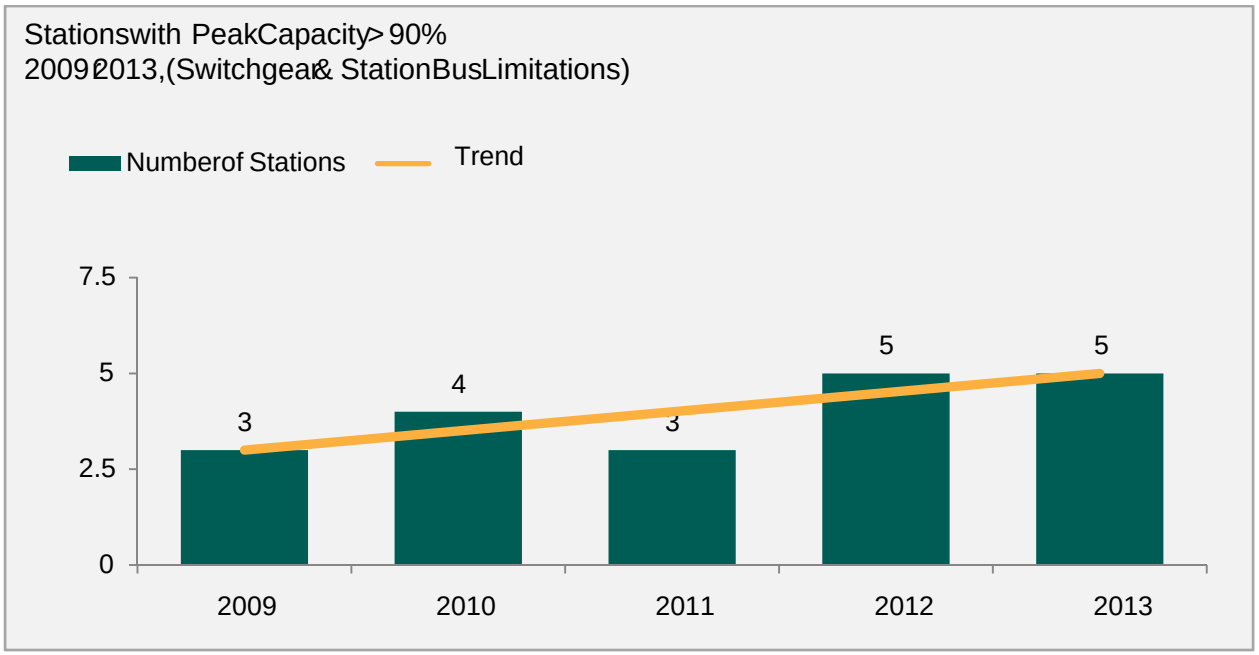

FIGURE 12: STATIONS WITH PEAK CAPACITY > 90% – 2009-2013, (SWITCHGEAR & STATION BUS LIMITATIONS)

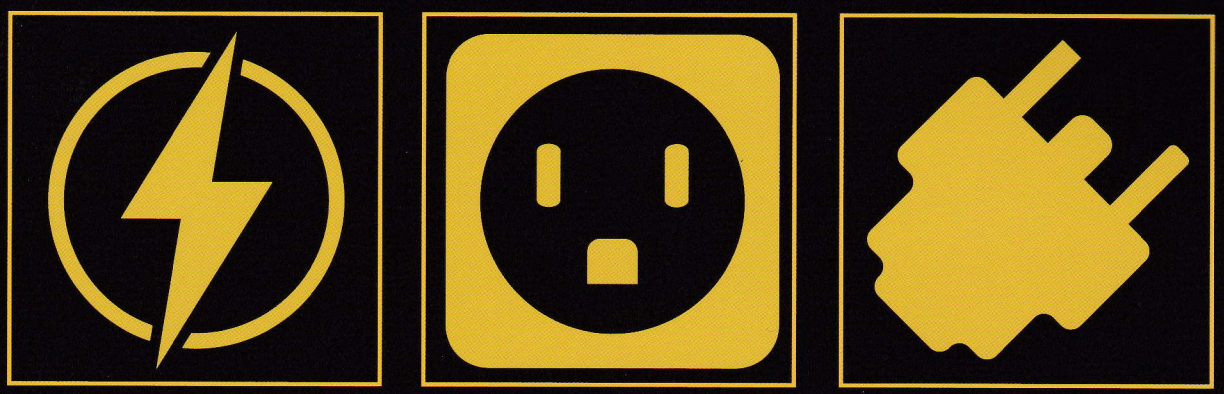

C4.2.3 Interaction with the Distribution System Plan

Tracking the number of stations with peak capacity exceeding 90% will allow Toronto Hydro to gauge the effectiveness of its capacity planning processes and the timeliness of the associated

constraint mitigation measures, including permanent load transfers, capacity increases, targeted CDM programs and other related activities. The Station Expansion Program specifically targets stations at which peak demand is approaching available capacity through upgrades and expansion of station infrastructure. The Load Demand program also aims to mitigate capacity shortfalls by balancing station bus loading through permanent load transfers.

Over the course of the 2015-2019 period, Toronto Hydro expects the measure and associated trend to remain generally constant, or potentially trend further upward, as more station busses approach their peak demand. Toronto Hydro's ability to maintain this trend is closely linked with the Station Expansion (E7.9) and Load Demand (load transfers) (E5.4) programs, which are expected to alleviate the most pressing concerns and add flexibility to the system to enable us to balance load between stations. Absent the investment levels proposed in either of these two programs, the measure would trend upward at a significantly higher pace.

Distribution System Plan (DSP)

D ASSET MANAGEMENT PROCESS

ID	Section
D1	Asset Management Process Overview
D2	Overview of Assets Managed
D3	Asset Lifecycle Optimization Policies & Practices
D4	Information Technology (IT) Asset Management Process

D1 ASSET MANAGEMENT PROCESS OVERVIEW

Section D of the Distribution System Plan provides both a summary as well as full details of the Asset Management (AM) Process that is applied at Toronto Hydro in order to produce the Capital Expenditure Plan, which is discussed in Section E.

Toronto Hydro's AM Process forms the foundational architecture for long-term, short-term and maintenance planning functions, bringing together input data and decision support systems to produce load, system performance and capital investment forecasting, investment programs and investment projects as part of the capital expenditure plan.

Section D1 provides an overview of the elements that form the AM process, including process maps that conceptualize the interactions between long-term, short-term and maintenance planning. Section D2 provides current information and challenges associated with Toronto Hydro's distribution system. Section D3 provides further details of the policies and practices associated with the AM process elements, including long-term, short-term and maintenance planning components contained within the planning process. Section D4 provides an overview of Toronto Hydro's distinct Information Technology (IT) Asset Management Process, which consists of a set of business principles and practices that support prudent IT asset life cycle management and IT investment planning.

D1.1 Overview of Asset Management Objectives

Toronto Hydro's asset management process proactively identifies, manages and mitigates deficiencies and risks to the electrical distribution system in order to (i) maximize value to the utility's customers, (ii) minimize or eliminate safety risks, and (iii) strike an optimal balance between required capital investment and risk costs associated with asset failure (on a system level, Toronto Hydro refers to this balance as "steady state").

The AM process described in this section allows Toronto Hydro to meet these AM objectives while also aligning to its corporate pillars as described below:

- People: Strive to foster a fully engaged, safe and healthy workforce that meets the changing requirements of the utility's business. This includes developing a skilled and knowledgeable workforce and keeping that workforce engaged and productive.

- Customer: Provide value for money. This includes providing long-term value for rate payers, helping customers conserve energy, providing customers with tools and technology, and making it easier to work with Toronto Hydro.

- Operations: Work to improve reliability through optimal and sustainable system management. This includes keeping the lights on, keeping the system safe, building a grid that supports a modern city in an environmentally responsible manner, and maintaining above-average productivity.

- Financial: Aim to meet the financial objectives of Toronto Hydro's shareholder, the City of Toronto.

Toronto Hydro's AM process provides a foundation for the execution of long-term, short-term and maintenance planning functions. This process takes into account requirements established in both the Electricity Act, 1998,[1] and the Distribution System Code (DSC). Among the purposes of the Electricity Act, are:

- "[Ensuring] the adequacy, safety, sustainability and reliability of electricity supply in Ontario through responsible planning and management of electricity resources, supply and demand"[2] and

- "[Protecting] the interests of consumers with respect to prices and the adequacy, reliability and quality of electricity service"[3]

Among other things, the DSC requires a distributor to follow good utility practices for system planning to ensure reliability and quality of electricity service on both a short-term and long-term basis.[4]

Toronto Hydro used its AM process to develop the 2015-2019 Capital Expenditure Plan, which is discussed in detail in Section E of this 2015-2019 Distribution System Plan. To promote continued alignment with changing legislative and regulatory requirements (including the Ontario Energy Board Act, 1998,[5] Toronto Hydro's Distribution License, the Standard Supply Service Code, and relevant City of Toronto By-laws), Toronto Hydro is continually refining and enhancing its AM process and improving its practices.

[4] DSC, at section 4.4.1.
[5] S.O. 1998, c. 15, Sched. B. ["Ontario Energy Board Act"]

D1.2 Asset Management Process Overview

This section outlines the major elements of Toronto Hydro's AM process, the inter-relationships between these elements, and the key inputs and outputs between these elements.

As illustrated in Figure 1 below, the AM process consists of five elements: (i) the planning process itself; (ii) the enterprise systems that support both the planning process and decision-support systems; (iii) the decision-support systems; (iv) the produced Distribution System Plan; and (v) measurement and enhancement activities that are conducted during the term of the CIR filing period (2015-2019).

The first element – the planning process – can be further subdivided into three stages:

- Long-term planning
- Short-term planning
- Maintenance planning

Long-term planning involves the development of a capital investment approach, execution strategy and associated investment spending levels, derived from long-term system studies and current-state assessments of the distribution system, which ultimately allow for the production of capital investment programs targeting prioritized assets and issues. This long-term planning process is further discussed in Section D1.2.1, with specific details on the process elements provided in Section D3.2.1.

Short-term planning involves the development of discrete projects that intervene upon prioritized assets and issues identified within the long-term investment programs. These projects are scheduled based upon system, resource and external constraints, and are executed accordingly. Project development, scheduling and execution result in further refinement and finalization of the investment spending levels for each capital investment program. The short-term planning process is further discussed in Section D1.2.2, with specific details on the process elements provided in Section D3.2.2.

Maintenance planning focuses on extracting the maximum value out of Toronto Hydro's distribution system assets through regular inspections, upkeep and repair activities. Maintenance planning also produces condition-related data which feeds back into enterprise databases and

planning tools. This process is further discussed in Section D1.2.3, with specific details on the process elements in Section D3.2.3.

The second element of the AM process is the collection of enterprise systems that contain nameplate asset information (age, asset type, etc), locations, historical reliability and loading data. This information is used either directly within the planning process or as inputs to the decision-support systems. Enterprise systems are as follows:

- Automated Mapping/Facilities Management Geographic Information System (AM/FM GIS): Provides locations and nameplate information associated with assets.
- Enterprise Resource Planning (ERP) System (Ellipse): Provides asset nameplate information, inspection data and project estimates.
- Feeder Loading Information System (FLIS): Used to capture raw load readings from supervisory control and data acquisition (SCADA) devices.

The third element of the AM process is the collection of decision-support systems, which are used in long and short-term planning processes to make informed decisions when producing capital investment programs and corresponding projects respectively. Decision-Support Systems are discussed in more detail in Section D3.1.2.1.

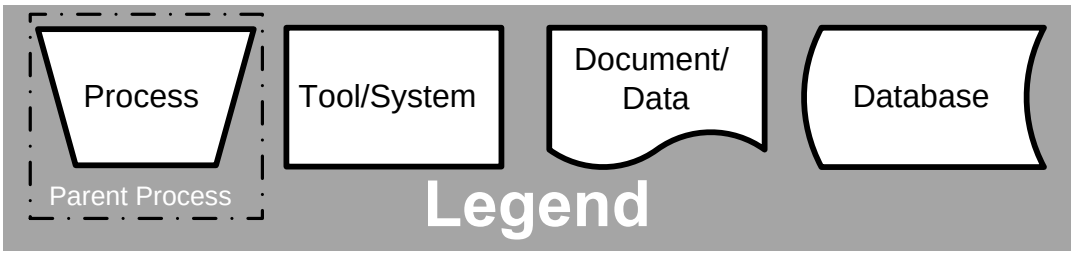

FIGURE 1: PROCESS LEGEND

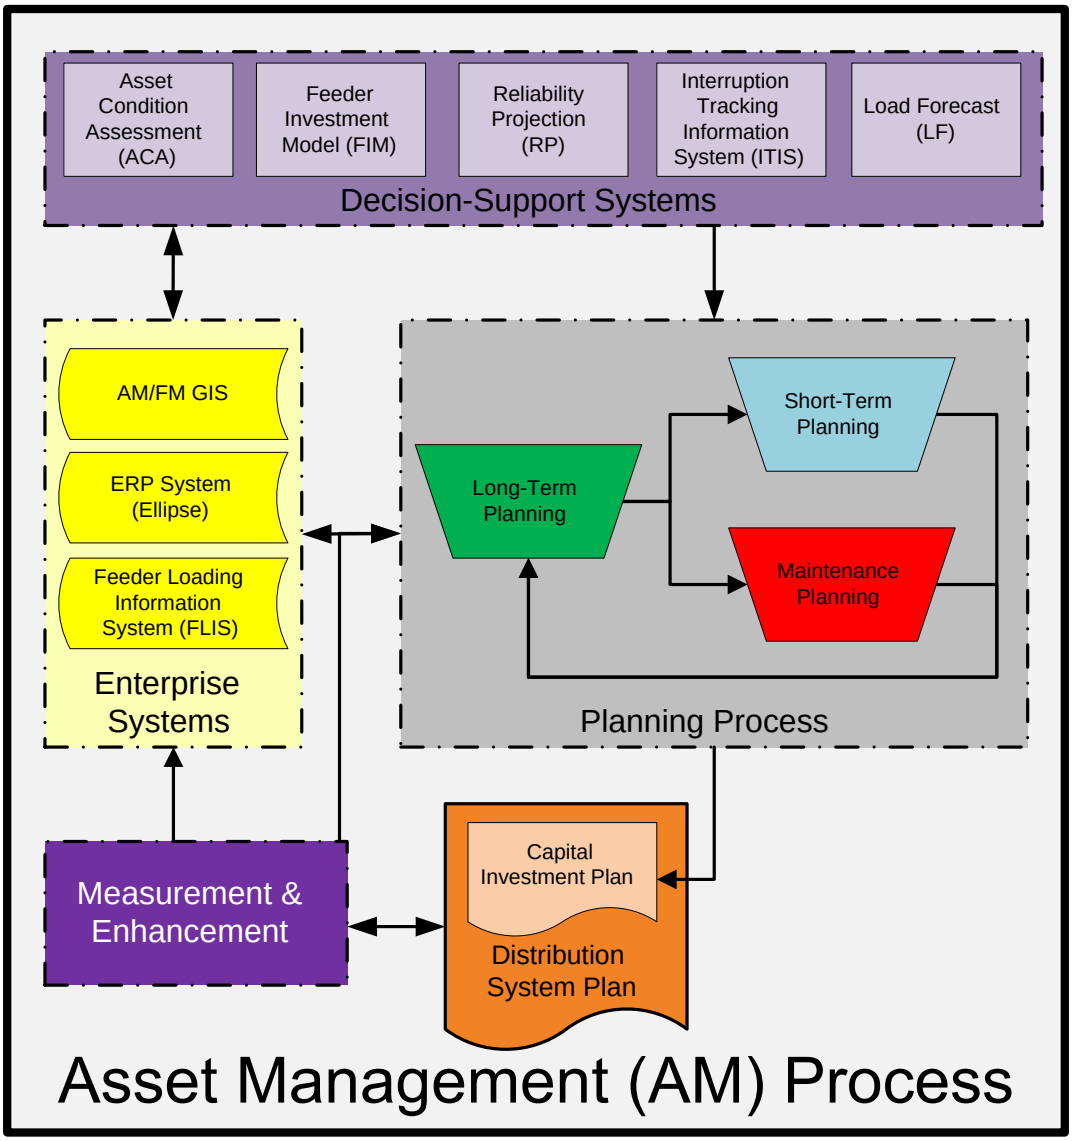

FIGURE 2: ASSET MANAGEMENT PLANNING PROCESS OVERVIEW

The fourth element in the AM process is the Capital Expenditure Plan, published within the DSP (Section E), which is produced based on the outputs derived from the planning process.

The fifth and final element of the AM process is the collection of measurement and enhancement activities whereby the Distribution System Plan itself is monitored and measured in order to produce continuous improvements and enhancements to the planning process and to input data within the enterprise systems. This is further discussed in Section D1.2.4, with specific details

discussed in Section D3.1.2.3. Legends for all figures provided in the proceeding content are in Figure 3.

D1.2.1 Long-Term Planning Process

The long-term planning process is a systematic process involving a current-state system analysis and long-term system review process, which ultimately results in the production of a long-term investment approach and execution strategy, followed by the development of investment programs with associated investment levels.

The current-state system analysis (CSA) is a foundational analysis performed to understand the current state of the distribution system in terms of asset performance (age, condition), asset properties and quantities, historical reliability and remaining useful life. This analysis is further detailed in Section D3.1.1.1. Outputs of the CSA produced for the 2015-2019 Distribution System Plan are provided in Section D2.

Data from the CSA is used as part of the long-term system review process, in which the following deliverables are produced:

(a) a proactive capital investment approach that addresses all known challenges and enables progress toward achievement of a system “steady state”;

(b) evaluation and selection of an execution strategy that is responsive to customers’ price sensitivity while being practical to execute; and

(c) comparison of reliability outcomes for the proactive capital investment approach and selected execution strategy against a “do nothing”/”run to failure” approach.

A proactive capital investment approach is designed based upon the necessary forms of investment that are required over the DSP planning period. These necessary forms of investment will be informed by the results of the CSA, coupled with known system challenges that must be addressed. The forms of investment defined as per the 2015-2019 Capital Expenditure Plan include: (i) asset renewal; (ii) system-wide critical issues; and (iii) mandatory operational investments. These are further defined and discussed in Section E2.1. This proactive capital investment approach must enable progress toward a “steady state”, which represents an optimal balance between required capital investment and aggregate risk costs associated with asset failure, such that the distribution system exists in an economically optimal composition. Section E2.1 further details the results of the capital investment approach produced for the 2015-2019

Capital Expenditure Plan, which shows a backlog of investments, mostly comprised of assets that are past their economic end-of-life criteria. Mitigating this backlog will permit the achievement of steady state, such that the total aggregate lifecycle costs of the system are minimized.

The final deliverable within the long-term system review process involves a comparison of the reliability outcomes of the proactive capital investment approach and selected execution strategy against a run-to-failure/"do nothing" approach. Section D3.1.1.2 provides further details on the Long-Term System Review Process, while Section E2.1 provides the results of the long-term system review process that were applied as part of the 2015-2019 Capital Expenditure Plan.

Outputs from the long-term system review process are used to develop capital investment programs as part of the Investment Planning process. Capital investment programs are produced by prioritizing system assets and issues based upon their alignment to associated program trigger drivers. Prioritization factors will vary depending on the program driver. For instance, programs driven via Failure Risk adopt factors such as asset age, condition, economic end-of-life criteria and historical reliability in order to prioritize assets. On the other hand, programs driven by Safety address specific asset types and sub-types that introduce known safety risks into the system. Enterprise and decision-support systems are used to aid in the identification and prioritization of assets and issues at the system level, depending on the program drivers. Outputs produced by the Investment Planning process include:

- the individual capital investment programs, which are aligned to the forms of investment identified within the long-term system review process;
- the prioritized assets and/or issues that are to be addressed within each capital investment program across the DSP planning period; and
- the associated investment spending levels for each capital investment program.

Each investment program takes into consideration the maintenance activities that are occurring in parallel. Ultimately, each capital program represents required investments above and beyond what current maintenance practices are able to accomplish. The Investment Planning process is further detailed in Section D3.1.1.3.

Once investment programs have been established at the long-term planning level, and discrete projects are established at the short-term planning level, a business case evaluation (BCE) is produced at the investment program level, where practicable. The BCE identifies the most cost-

effective solution for mitigating the associated challenges and issues to help ensure that the program is providing value to customers over its life-cycle.

This BCE relies upon knowledge of discrete assets to be intervened upon and specific locations where issues are to be mitigated. A BCE cannot be produced practicably for those investment programs that are dynamic in nature. For dynamic investments, the exact discrete assets are yet to be determined as of the DSP publication (e.g., customer connections and reactive capital).

The BCE approach is further defined in Section D3.3. Capital investment programs along with their respective BCE results are provided in Sections E5 through to E8.

As illustrated in Figure 3, outputs of the long-term planning process, including the considered capital investment approaches, execution strategies and the produced capital investment programs are integrated into the produced Distribution System Plan. The produced capital investment programs are also used as a key input to the short-term planning process in order to develop projects as further explained in Section D1.2.2.

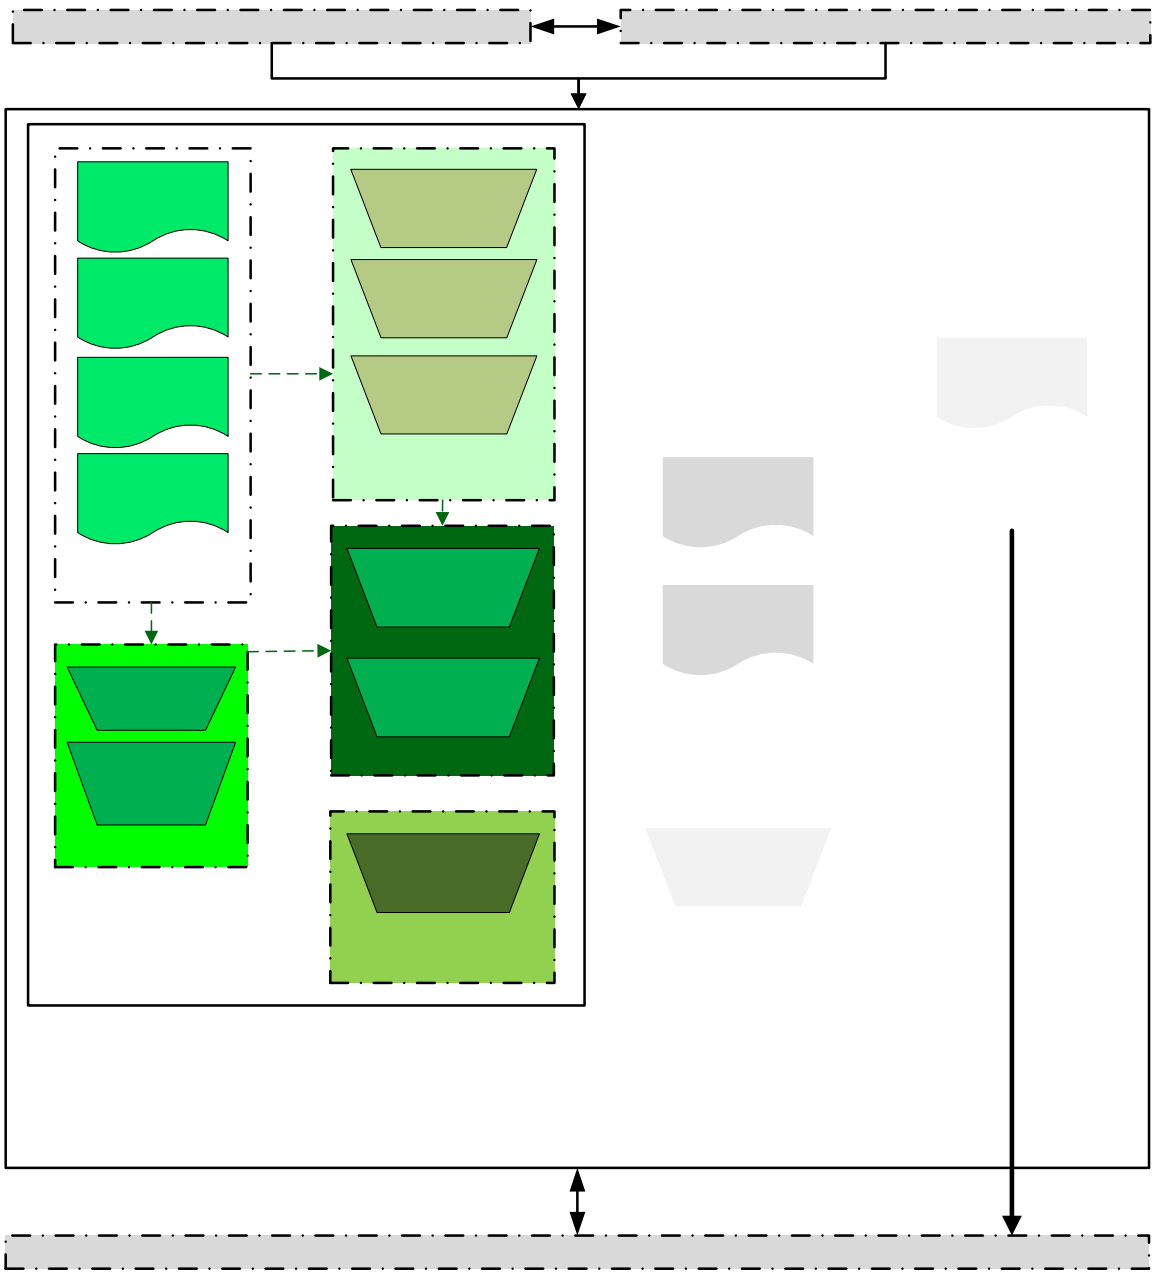

FIGURE 3: LONG-TERM PLANNING PROCESS

D1.2.2 Short-Term Planning Process

The short-term planning process involves the development of discrete projects within each capital investment program. This process involves three components: a study, a draft and an approved project.

The long-term planning process, as explained in Section D1.2.1, identifies and prioritizes the assets and/or issues to be mitigated within each capital investment program, across the DSP planning period. The short-term planning process converts this information into discrete capital projects.

The project development process begins with a study, where these prioritized assets and issues are identified within discrete locations through the use of corresponding enterprise data, decision support tools and load forecasts. Input data used as part of the study to identify these discrete assets will vary depending on the investment program's trigger and secondary drivers.

For example, should an investment program be driven by Failure Risk, decision-support systems such as the Feeder Investment Model (FIM), Asset Condition Assessment (ACA) and enterprise systems such as Ellipse (ERP) would be utilized to identify the prioritized assets that are exceeding their economic end-of-life criteria, are in poor/very poor condition and/or are past their useful lives, respectively. For an investment program that is driven by capacity constraints, decision-support systems such as load forecasting processes would be applied to identify specific investment opportunities. These decision-support systems are each discussed in further detail in Section D3.1.2.1.

Once an investment opportunity is identified, a project draft is produced, in which existing assets are confirmed and new assets to be installed are identified as per a high-level design. These projects then go through a project finalization process where they are validated for content (estimate, description, and justification). Ultimately, this project development process is applied to produce a series of projects within a given capital investment program up to the capital investment spending levels established for that program through the long-term planning process. The project finalization process will also result in further refinement to the capital investment spending levels, as project-level estimates are produced.

As illustrated in Figure 4, some of these projects involve assets to be replaced or issues to be resolved that are of the most urgent nature. These urgent projects will be assigned to the first year of the Capital Expenditure Plan, and therefore, all projects within the same year have equal

priority relative to each other. Projects contained in the later years of the Capital Expenditure Plan will involve assets of lesser priority relative to those projects in the first year of the plan.

Finalized projects will be scheduled for execution within the given year, and the associated capital investment spending levels will be finalized for that given year through the development of detailed designs, estimates and schedules as per this process. Discrete details of the finalized projects (e.g. assets to be replaced, assets to be installed) are used to as inputs to the BCE process as part of long-term planning.

This two-stage process for cost estimation – i.e. high-level estimates used for planning purposes, followed by detailed estimates used for execution purposes – is essential for the efficient planning and execution of Toronto Hydro's large work program.

A planning engineer prepares a high-level estimate to reflect the costs associated with the technical requirements of a specific project, as opposed to the operational realities of executing the work. These requirements can include, for example, the amount of load to be converted, the number of customers to be transferred, the size of cables to be replaced, the capacity requirements, etc. This estimation approach is used for the initial screening of projects and avoids the significant cost involved to produce a detailed estimate for a project that may not go forward.

/C

A designer then prepares a detailed estimate based on the particular features and field conditions for a specific project. A number of factors may cause the cost of a specific project to deviate from the average cost assumptions used for the initial estimate, and these factors are accounted for in the detailed estimate. (Additional factors, such as season, use of overtime labour, system loading, and real-time switching options may also affect actual costs versus detailed estimate costs.)

Over a large number of projects, and through the rigorous application of structured project management techniques, the positive and negative cost variances of individual projects may cancel out such that in aggregate the initial estimates form a reliable indication of the total cost of the projects in the specific program.

The scheduling and execution of projects exists outside of the AM Process as part of the Capital Expenditure Plan. For the 2015-2019 Distribution System Plan, this approach is further detailed in Section E2.3. Capital projects have been produced and scheduled for 2015, and can be found within their respective capital investment programs that are detailed in Sections E5 through to E8 of the 2015-2019 Distribution Systems Plan.

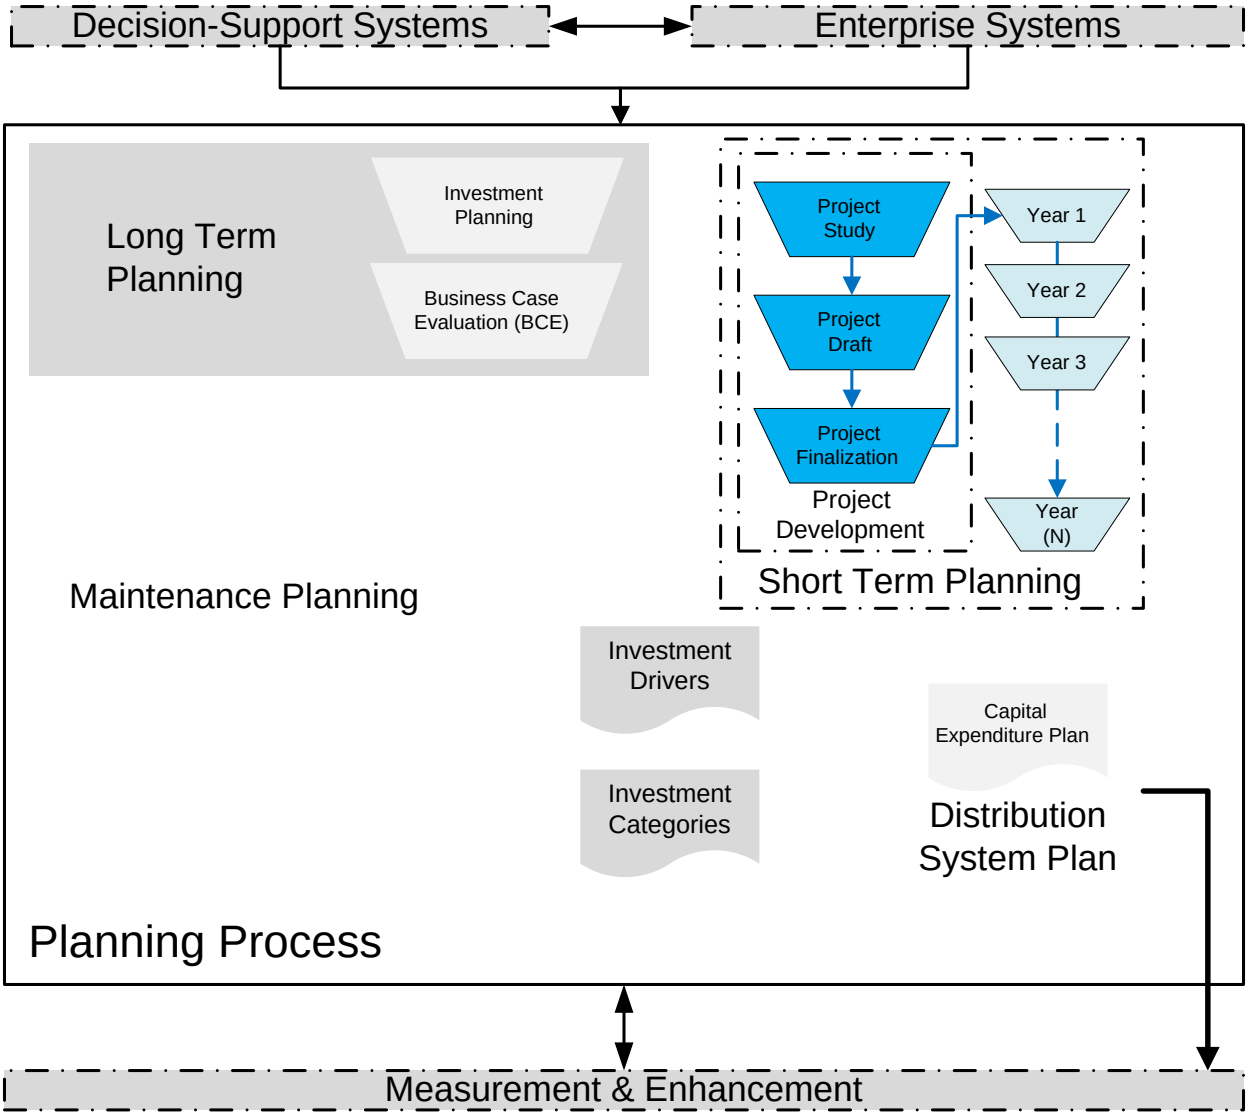

FIGURE 4: SHORT-TERM PLANNING PROCESS

D1.2.3 Maintenance Planning Process

Toronto Hydro's maintenance planning process is designed to assess the condition and extend the life of distribution assets, and maintain their reliability through the development of maintenance programs. Maintenance programs are designed to extract the maximum value from the assets. Maintenance programs complement the produced capital investment programs by allowing Toronto Hydro to sustain the intended operating condition of its asset and preserve operability. Equipment condition is also critical to the safe operation of distribution assets and

directly affects Toronto Hydro employees and the public. Finally, equipment maintenance is essential to help minimize the environmental impact of assets.

As seen in Figure 5, the maintenance programs fall into four categories. High level summaries of these categories are discussed below with more details provided in Section D3.2:

- Preventive Maintenance: Typically involves cyclical inspection and maintenance tasks, which emphasize assessing asset condition and preserving asset performance over the expected life of the asset, and maintaining public and employee safety.

- Predictive Maintenance: Involves testing or auditing equipment for a predetermined condition (or conditions) to anticipate failures, then undertaking the maintenance tasks necessary to prevent those failures.

- Corrective Maintenance: Involves repairing or replacing equipment after a deficiency has been reported, such as actions taken after Emergency Maintenance has restored power. Corrective Maintenance actions may also result from deficiencies discovered during the execution of Preventive or Predictive Maintenance tasks or other planned work.

- Emergency Maintenance: Is the urgent repair or replacement of equipment when the equipment fails, causing a power disruption to Toronto Hydro customers.

Also illustrated in Figure 5, the Maintenance Planning and Long-Term Planning processes intersect at the following points:

- Capital investment programs are developed with knowledge of cross-referencing maintenance programs, to help ensure that program spending is necessary above and beyond the life extension benefits that the maintenance programs offer

- Maintenance programs account for changes associated with capital investment programs, such as new asset classes being introduced or existing asset classes being eliminated.

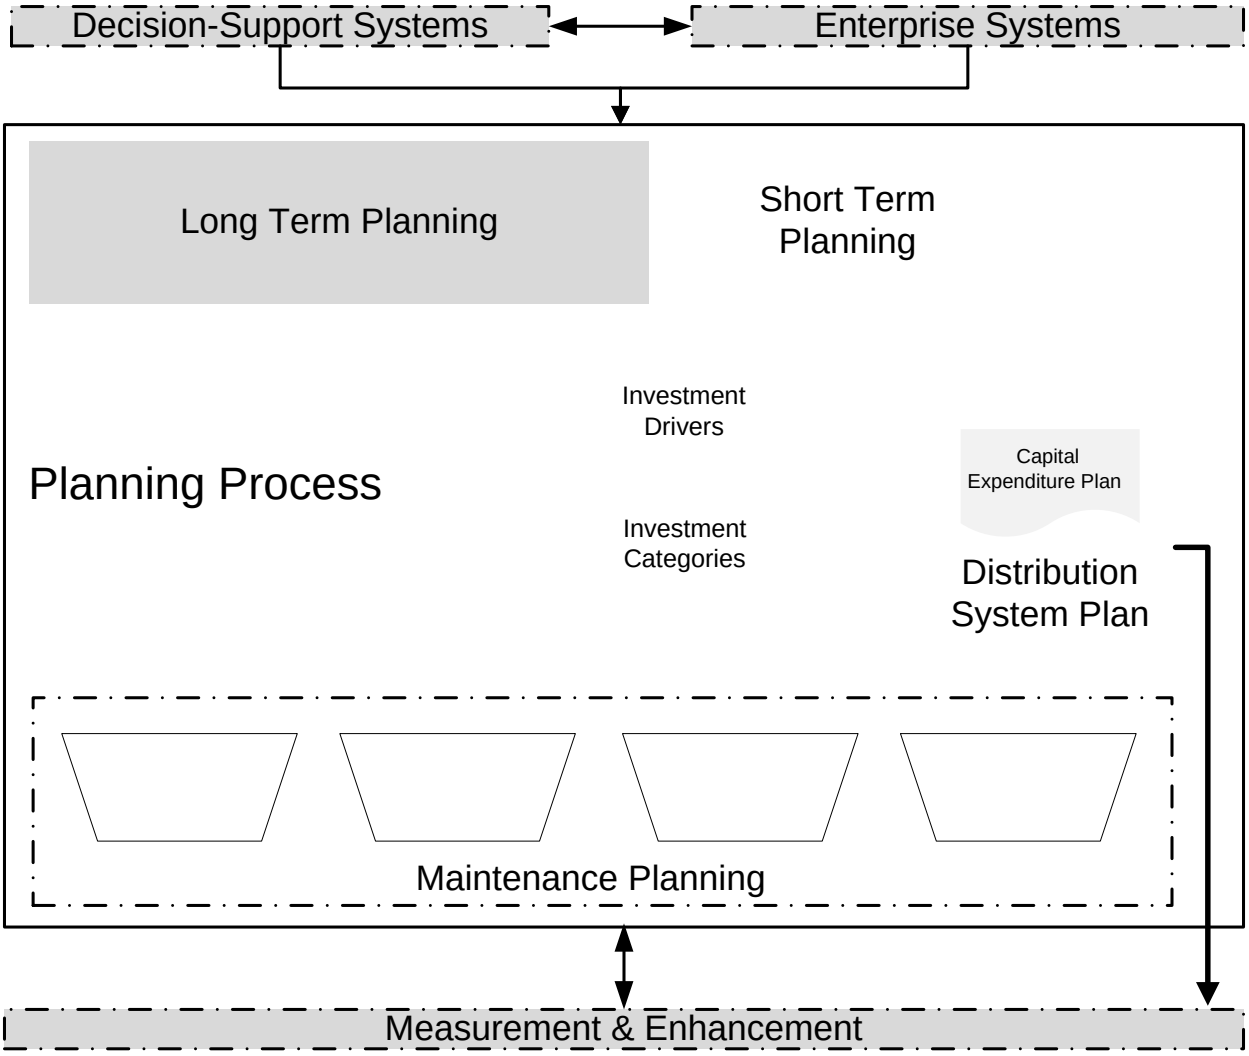

FIGURE 5: MAINTENANCE PLANNING PROCESS

D1.2.4 Measurement & Enhancement

Toronto Hydro's long-term, short-term and maintenance planning processes, discussed in Sections D1.2.1, D1.2.2 and D1.2.3 respectively are executed to produce the Capital Expenditure Plan as part of the Distribution System Plan. As illustrated in Figure 6, this Capital Expenditure Plan is monitored and measured over its execution period, such that continuous improvements can be made. Metrics that Toronto Hydro has adopted in order to measure and monitor continuous improvement during execution of the 2015-2019 Capital Expenditure Plan are further described in Section C.

In addition, Toronto Hydro also expects to execute data quality and decision support system enhancement processes over the course of the Capital Expenditure Plan execution period. These enhancements would ultimately flow back into the long-term planning functions, and influence the outputs of short-term and maintenance planning functions. Improvements and enhancements would also be integrated into future Distribution System Plans.

Section A3 highlights recent improvements and enhancements that have been implemented with respect to data quality, decision support systems and capital expenditure monitoring and measurement as part of the development of this 2015-2019 Distribution System Plan.

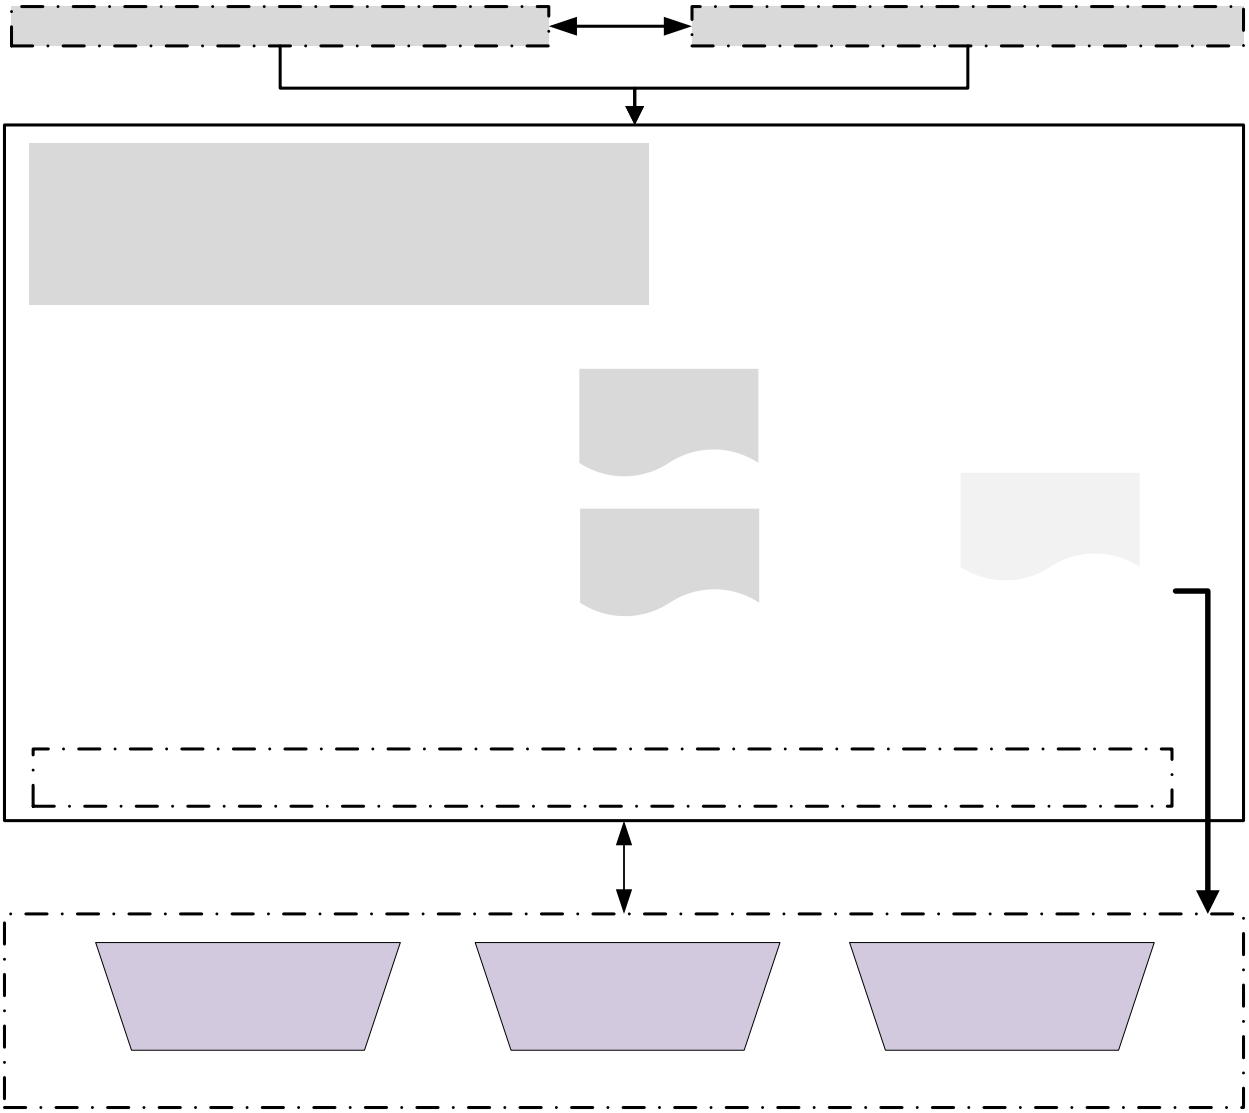

FIGURE 6: MEASUREMENT AND ENHANCEMENT PROCESS

D2 OVERVIEW OF ASSETS MANAGED

D2.1 Distribution Service Area

Toronto Hydro is the second largest municipal electrical distribution utility in North America, serving the City of Toronto – Canada's largest city. The city is bounded by Lake Ontario to the South, Steeles Ave to the North, Mississauga (mainly Highway 427) to the West, and Scarborough/Pickering Townline to the East. Toronto is made up of two distinct customer demographic areas: an urban center in downtown Toronto, and a suburban area around downtown Toronto, which is colloquially referred to as the Horseshoe area. The following sections provide details and insight into the characteristics of the City of Toronto, including the city's customer and load growth attributes, its climate and weather, and its economic profile.

A description of the asset demographics, configuration and the asset condition assessment (ACA) of Toronto Hydro's distribution system follows in section D2.2. For details on Toronto Hydro's ACA program, refer to section D3.1.2.1.

D2.1.1 Customer and Load Growth

Toronto Hydro's distribution system supplies over 730,000 customers with a peak load of 5,362 MVA record in the summer of 2013. Toronto has been experiencing slow and steady population and customer growth, with some minor acceleration in the past few years.

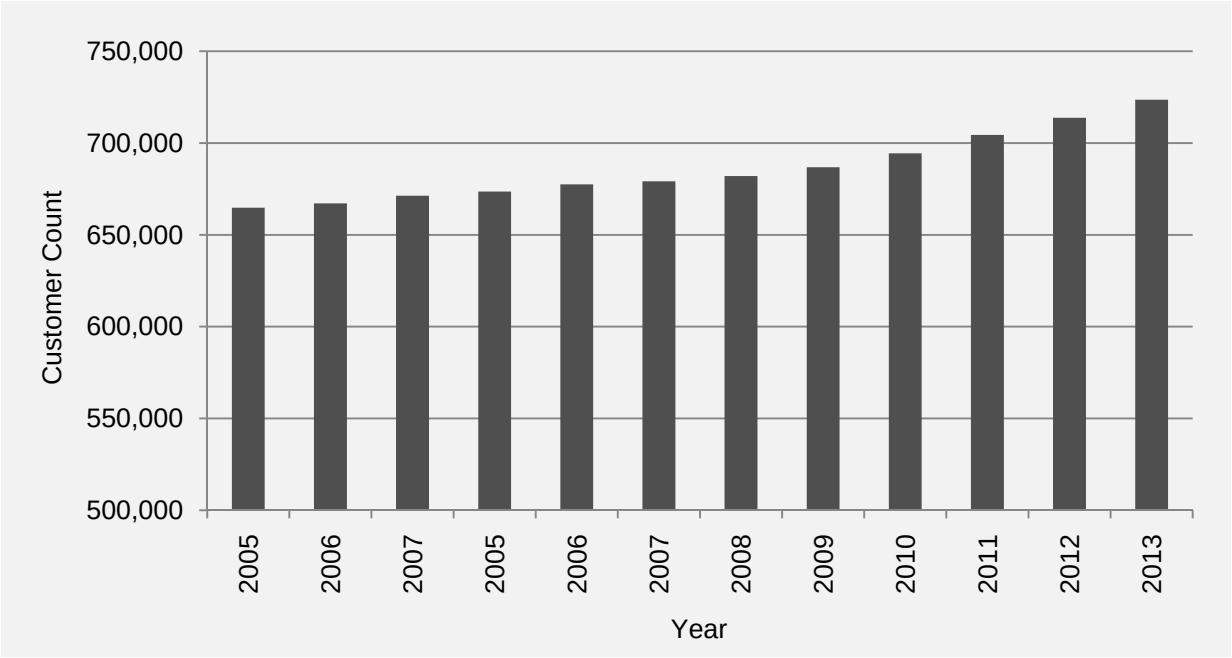

FIGURE 1: HISTORICAL TORONTO HYDRO CUSTOMER COUNTS

Overall system load growth has also been slow and steady. However. growth is highly concentrated due to the high number of large condominium developments. As such, some parts of Toronto are experiencing large increases in demand.

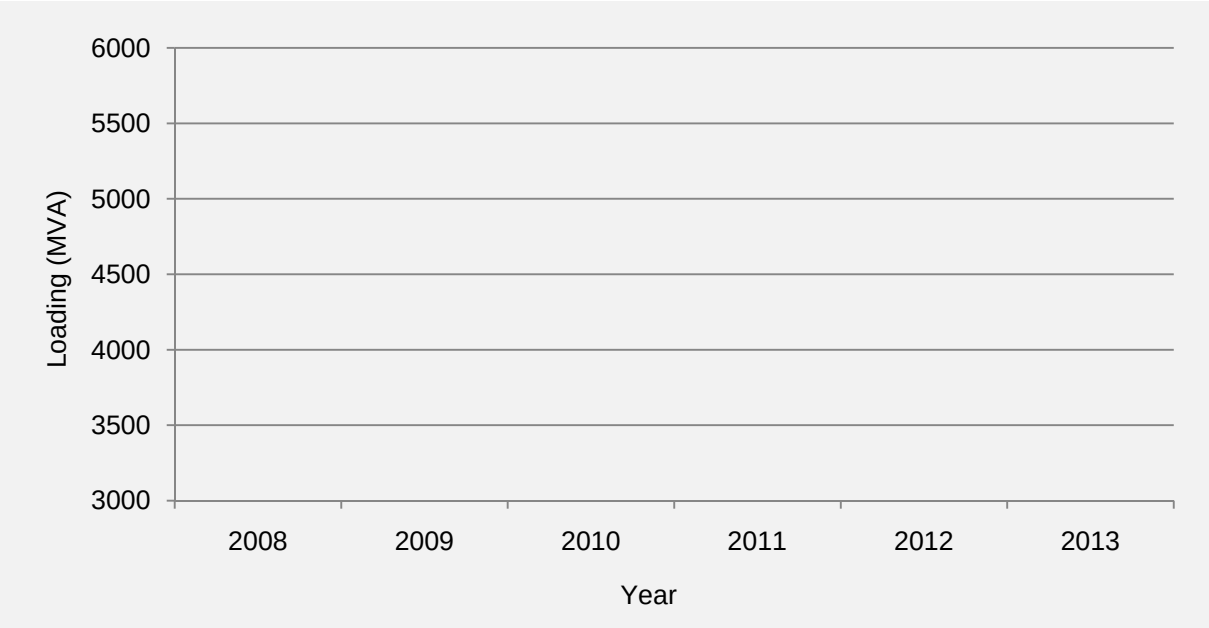

FIGURE 2: HISTORICAL TORONTO HYDRO SYSTEM PEAK LOADING

Per Figures 3 and 4, Toronto had more high rise buildings under construction than any other North American city for four years in a row. This concentrated growth occurs mainly in the downtown area, but also along major transit corridors such as Yonge Street and Sheppard Avenue. The growth is pushing connected distribution and stations equipment to capacity. Infrastructure renewal and upgrades are required to allow Toronto Hydro to continue to supply power to these customers. These investments are also necessary to maintain performance in these areas at the same level as in the rest of the system.

FIGURE 3: TORONTO ECONOMIC UPDATE JANUARY 2014 - NUMBER OF HIGH RISE BUILDINGS UNDER CONSTRUCTION

FIGURE 4: TORONTO ECONOMIC UPDATE JANUARY 2012 - NUMBER OF HIGH RISE BUILDINGS UNDER CONSTRUCTION

D2.1.2 Climate and Weather

Toronto experiences extreme weather at both ends of the spectrum. During hot summers, temperatures can reach up to the mid-30s degrees Celsius, while cold winter temperatures can drop to the negative-20s degrees Celsius.

Toronto also experiences a wide range of other adverse weather conditions at various times during the year. High winds, freezing rain and heavy snowfall are rare, but some of these adverse weather conditions can be extreme and have the potential to cause major outages.

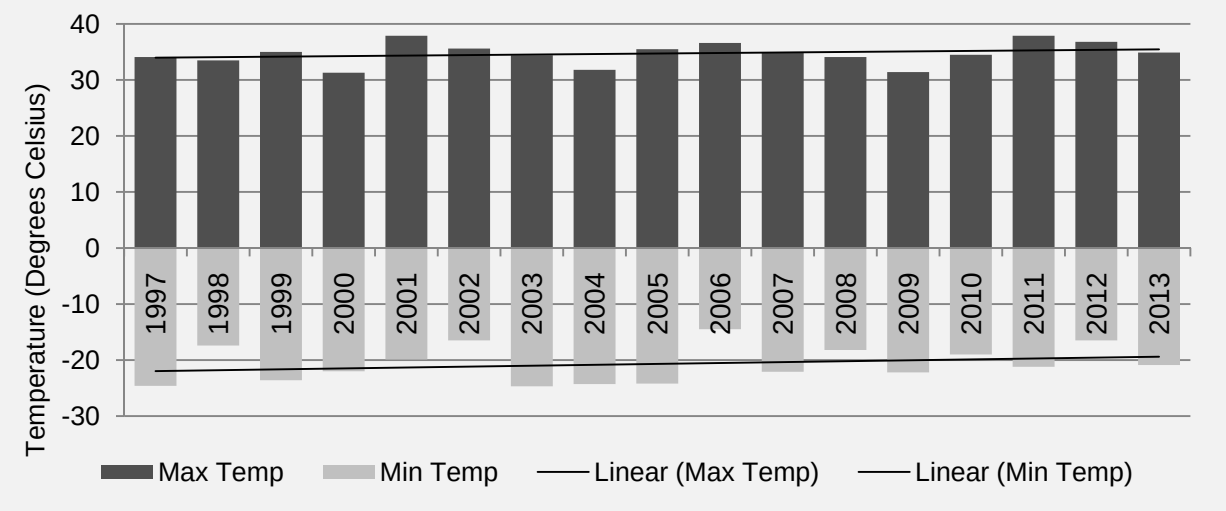

FIGURE 5: HISTORICAL MIN AND MAX TEMPERATURES IN TORONTO (1997-2013) (SOURCE: ENVIRONMENT CANADA)

On July 8, 2013, Toronto saw heavy rainfall and flash flooding which caused a loss of supply due to Hydro One Networks Inc. (HONI) transmission equipment failure. As a result, over half of Toronto Hydro's customers experienced a service outage for more than a day. A freezing rain ice storm on December 21, 2013 caused an outage to nearly half of Toronto Hydro's customers, some of whom were without power for over a week.

FIGURE 6: AFTERMATH OF DECEMBER 2013 ICE STORM SHOWING THE FREEZING RAIN DAMAGE

In order to provide reliable service to its customers in the face of these challenges and major weather events, Toronto Hydro must plan and design around these circumstances. Toronto Hydro does this in several ways, such as replacing assets that are past their useful life, changing the system configuration, or introducing new technologies into the system. Some measures that Toronto Hydro has already put in place include: building new stations with measures to prevent against flooding; converting rear lot infrastructure which is difficult to access for repairs, especially in adverse conditions; and implementing Feeder Automation to help restore customers more quickly. Furthermore, climate adaptation studies are being performed by Toronto Hydro to see what else can be done to the system to mitigate the potential damaging effects of climate change on our system.

D2.1.3 Economic Profile

The City of Toronto is Canada's economic and financial hub. It is home to the Toronto Stock Exchange, as well as the headquarters of five of the nation's largest banks. Toronto produces

11% of Canada's Gross Domestic Product[1] and its GDP growth has outperformed not only the national average, but also the most developed countries in the world in the past year. Toronto is forecast to continue performing better than the national average and either better than or on par with most developed countries over the next two years.[2]

TABLE 1: ECONOMIC GROWTH OF VARIOUS REGIONS AND COUNTRIES

Region or Country	GDP Growth Rates (Estimated or Projected)		
	2013	2014	2015
Toronto	2.4%	2.9%	3.0%
Canada	1.8%	2.5%	2.5%
United States	1.9%	3.0%	3.2%
Euro Area	-0.4%	0.9%	1.4%

Toronto also has a very diverse industrial and commercial base comprised of 11 key sectors such as business and financial services, education, technology, food, entertainment, and tourism.[3] Toronto Hydro's electrical distribution system plays a vital role in the day-to-day operation of services, businesses and industries, as well as the customers who interact with these operations.

D2.2 Asset Demographics and System Configuration

Toronto Hydro's distribution system consists of a mix of overhead, underground, secondary network and stations infrastructure. To provide the best system design taking into account the varying customer densities and conditions that exist in different neighborhoods, local areas often contain a mix of overhead and underground infrastructure. These systems operate at voltages of 27.6kV, 13.8kV, or 4.16kV, and distribute power with approximately 60,600 distribution transformers, 16,000 primary switches, 15,000 km of overhead conductors and 11,200 km of underground cables.

At the feeder level, Toronto Hydro uses two configurations: radial or looped. Radial-connected feeders have no inter-feeder distribution tie points. Should a failure event occur anywhere along a

[1] City of Toronto, Business and Economic Development facts, (Toronto: City of Toronto, 2013), online: City of Toronto <http://www.toronto.ca/toronto_facts/business_econdev.htm>. ["Toronto Business and Economic Development Facts"]
[2] Michael H. Williams, Economic Dashboard – Annual Summary, 2014, (Staff Report) (Toronto: City of Toronto, 2014).
[3] Toronto Business and Economic Development Facts

feeder, the entire feeder and the customers on that feeder would experience an outage until the failure is resolved. Looped-connected feeders have inter-feeder distribution tie points. Should an asset failure occur at either the distribution or station levels, power system controllers can perform sectionalizing and restore parts of the system by either remotely controlling Supervisory Control and Data Acquisition (SCADA) enabled switches, or directing field crews to perform manual switching on the switches that are strategically positioned along the feeder trunk circuits. This allows load to be restored using available capacity in adjacent feeders and or stations. In general, feeders in the Horseshoe area have inter-feeder tie points, while feeders in the central core do not.

Toronto Hydro continues to manage its aging infrastructure and is in the process of renewing its assets to prevent system performance degradation. Approximately 26% of Toronto Hydro's assets are at the end of useful life and an additional 7% expected to reach end of useful life by the end of the decade.

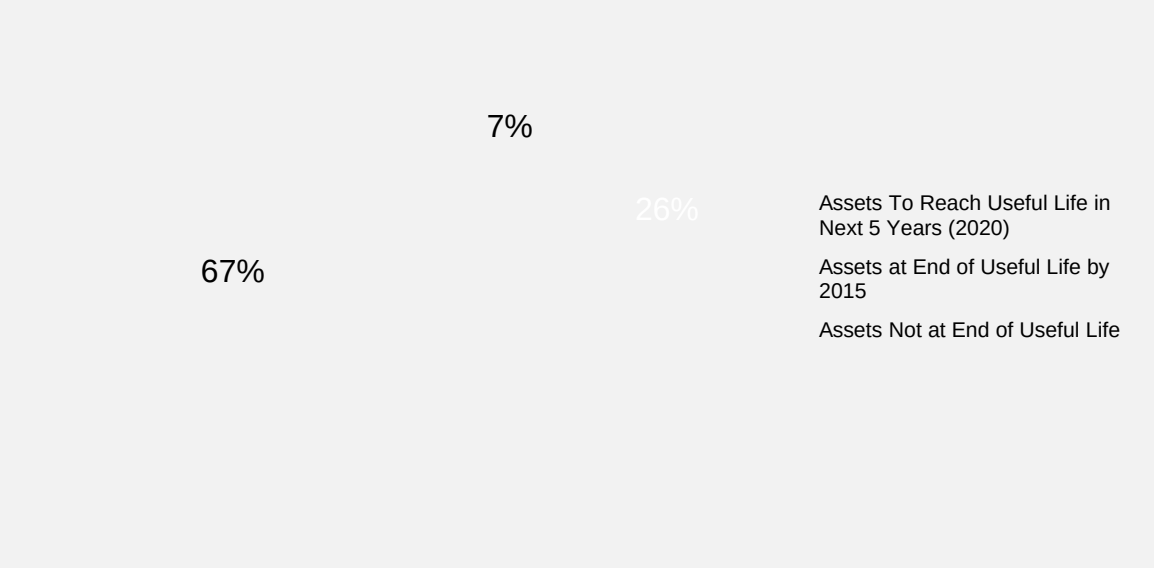

FIGURE 7: ASSETS PAST USEFUL LIFE DEMOGRAPHICS - 2015

Toronto Hydro is not the only utility in Toronto facing this "aging infrastructure" problem. For instance, Toronto Water and Sewage has infrastructure that is over 80 to 100 years old, with 17

per cent of assets past their theoretical service life[4]. Toronto Transit Commission has civil infrastructure that is over 60 years old and that is 20 years past its end of life.[5] The following sections provide a more detailed view of specific portions of Toronto Hydro's electrical distribution system, as well as the associated system challenges.[6]

[6] All asset demographics and asset condition assessment results identified in this section (D2.2) was compiled as of July of 2013. Due to data entry processes, there may be a lag in the records both for asset counts and asset condition demographics.

D2.2.1 Overhead Grid System

The overhead system consists of overhead conductors, overhead transformers, overhead switches and poles. All of these assets are placed above ground in areas where there is sufficient room and free of overhead obstructions such as trees, and tall buildings. This system allows for ease of fault/outage identification as all assets are out in the open and visible to crews. However, this system is prone to foreign interference such as trees, animal or human contact, and weather-related outages caused by conditions such as high winds, or freezing rain.

FIGURE 8: OVERHEAD DISTRIBUTION TRANSFORMER

The majority of the overhead is 27.6kV and 13.8kV, but a subset of the overhead system that is currently being phased out is the 4.16kV overhead Box construction distribution system.

Overall, Toronto Hydro's overhead distribution system consists of approximately 175,000 poles, 8,000 overhead switches, 30,700 overhead transformers, 4,100 circuit km of overhead primary and 10,900 circuit km of overhead secondary conductors. The overhead plant covers approximately 57% of the total distribution system within the City of Toronto. The graphs below show age demographics and asset condition assessment (where available) for overhead distribution assets. Figure 10 shows that there are many assets in the overhead system spanning

all asset classes that are old (40s, 50s and 60+ years old), and deteriorating (asset condition of poor or very poor).

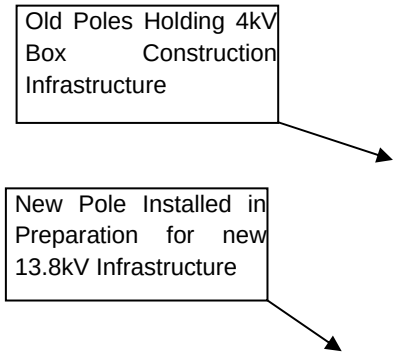

FIGURE 9: POOR CONDITION 4.16KV INFRASTRUCTURE BEING REPLACED WITH NEW 13.8KV OVERHEAD INFRASTRUCTURE

In the overhead system, some of the major challenges facing Toronto Hydro include legacy overhead assets such as porcelain insulators, arrestors and non-standard animal guards, as well as legacy construction types such as rear lot and box construction. These challenges contribute to a poor reliability performance of the system. These assets and construction types are among some of the most problematic issues that must be addressed in the system. Capital investment programs that are planned to target and mitigate challenges within the Overhead Grid System include: Box Construction and Rear Lot Conversion, Overhead Circuit Renewal, Polymer SMD-20 Replacements, Overhead Infrastructure Relocation, Overhead Momentary Reduction, SCADAMATE R1 Renewal, Design and Contingency Enhancements, Feeder Automation, Reactive Capital and Worst Performing Feeder.

Figures 10, 11 and Table 2 provide the age and condition demographics of the major overhead assets.

OH Switch – SCADAMATE	790

D2.2.2 Underground Grid System

The underground system consists of underground cables, underground transformers, underground switches and underground civil infrastructure. All of these assets are placed below grade, at grade, or in building vaults. This system is typically used in areas of higher density where there is not sufficient space to place overhead systems, or in areas where there are a lot of overhead obstructions that would interfere with the electrical distribution infrastructure. The underground system eliminates many non-asset risks present in the overhead system such as foreign interference and weather-related interruptions. However, this system also presents unique non-asset risks, such as flooding and faster deterioration of assets due to moisture build-up. Although this system generally provides better reliability than the overhead system, the causes of outages are more difficult to identify and outage restoration may take longer because the assets are underground and not visible to crews.

FIGURE 12: PAD MOUNTED SWITCH

The main underground system configurations are either radial or looped,. However, as previously mentioned, system types and system configurations are sometimes mixed to provide better reliability or flexibility when repairs are required, as is the case with Underground Residential Distribution (URD). Though URD is not widespread and only appears in limited areas throughout the old Toronto area, the infrastructure still has to be maintained. In URD, primary cables, switches and distribution transformers are placed underground while secondary voltage connections remain overhead. The primary feeders consist of a main-loop, sub-loop and branch circuits. Customers are supplied directly from either the sub-loops or branch circuits, which allows sectionalization within the feeder to minimize interruptions if work is required.

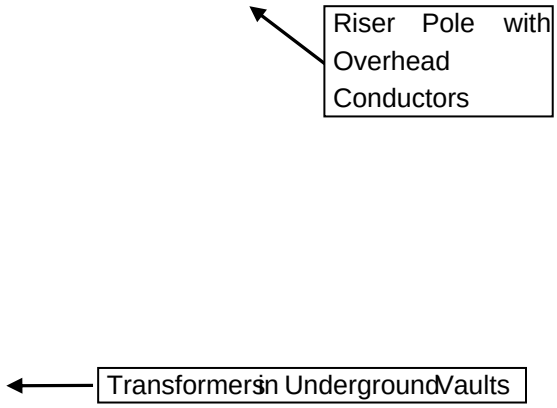

FIGURE 13: TYPICAL LAYOUT OF UNDERGROUND RESIDENTIAL DISTRIBUTION

On Toronto Hydro's underground distribution system, there are approximately 8,000 underground switches, 29,900 underground transformers, 10,900 cable chambers, 5,800 circuit km of underground primary and 5,400 circuit km of underground secondary cables[7]. This underground plant covers approximately 43% of the total distribution system within the City of Toronto. The graph below shows the age demographics of the underground assets. the graph shows that there

[7] Note: Underground asset counts include Secondary Network System asset counts, where applicable, e.g. cables, transformers, etc.

are a number of assets that are old and deteriorating. Although most assets are less than thirty years old, there is still a significant portion that is thirty to sixty years old and require intervention.

In the underground system, some of the major challenges include direct-buried cables, which are rapidly deteriorating and failing, Paper Insulated Lead Covered Cable (PILC), which present a potential health hazard associated with lead material, and Asbestos Insulated Lead Covered Cable, which also presents potential health hazards. Capital investment programs that are planned to target and mitigate challenges within the Overhead Grid System include: Underground Circuit Renewal, PILC Piece-Outs and Leakers, Underground Legacy Infrastructure, Design and Contingency Enhancements, Feeder Automation, Reactive Capital and Worst Performing Feeder.

Figures 14, 15 and Table 3 provide the age and condition demographics respectively of the major underground assets.

D2.2.3 Secondary Network System

The secondary network system, which is predominantly found in the downtown Toronto area, was initially installed in the early-to-mid 1900s to improve reliability for critical loads in the downtown area. As the system evolved, it became one of the major systems that best serves medium sized loads in areas that have high density and small and narrow sidewalks. Such areas do not have any space above grade for distribution infrastructure. The network system consists of interconnected low-voltage secondary cables, which are installed in grid or mesh configuration. These grids are supplied by multiple network units housed in network vaults fed by different feeders, and offer additional redundancies that the typical Overhead and Underground Distribution Systems do not. Should a single primary feeder encounter an outage, network

connected customers will continue to be supplied from the alternate primary circuits which continue to feed into the secondary grid or mesh. Thus, the secondary network system offers greater reliability than either the underground or overhead systems.

The main difference between a network unit and a conventional radially-configured transformer is the addition of a network protector. The network protector prevents power from the secondary network grid from back feeding to the primary side. Should a fault occur on the primary side of the network unit, the network protector will automatically trip. This protects the grid from the fault, and allows the remaining network units to keep the secondary network grid up and running.

Though this system is better at handling normal failure scenarios, in the case of a catastrophic failure such as a vault fire, the secondary network grid that is connected to the vault must be dropped to allow emergency responders to extinguish the fire safely. In such a scenario, all connected customers are interrupted. Because of this catastrophic failure scenario, network equipment must be kept in good condition to prevent vault fires or other failures from occurring. This is one of the reasons Toronto Hydro plans to take a proactive approach to replacing network units at risk of failure.

FIGURE 16: SUBMERSIBLE NETWORK UNIT

In addition to the failure of the electrical assets, the network vaults – the civil portion of the system – are an important component and must be maintained. If the integrity of the vault is compromised, the equipment inside the vault can be damaged, or the vault may become unsafe for crews to enter. Unsafe conditions mean that crews are unable to complete any maintenance or repairs. As can be seen in the asset conditions and age demographics, there are a significant number of both network units and network vaults that are old and deteriorating that require intervention. Fibertop network units in particular is one asset class that Toronto Hydro plans to target specifically due to their poor condition, age and likelihood of causing a vault fire. Figures 17, 18 and Table 4 provide the age and condition demographics respectively of network unit and vault assets.

Capital investment programs that will target and mitigate challenges within the Secondary Network System include: Legacy Network Equipment Renewal, Network Unit Renewal, Network Circuit Reconfiguration, Network Vault Renewal and Reactive Capital.

D2.2.4 Stations

Toronto Hydro's distribution system receives its transmission supply from Hydro One Networks Inc. (HONI) at various voltages of 230kV, 27.6kV or 13.8kV for use in its distribution system at Transformer Stations (TS). In general, Toronto Hydro owns all the medium voltage equipment up to the circuit breaker at the station. However, each station is different and there are different ownership structures for each station's equipment. The following diagram shows the ownership of station equipment and their associated demarcation point.

FIGURE 19: SYSTEM DIAGRAM OF STATION COMPONENTS OWNERSHIP

In some areas, the voltage may be further stepped down to 13.8kV or 4.16kV at Municipal Stations (MS).

Toronto Hydro owns approximately 170 MS and is supplied by 36 TS (some of which are owned by Toronto Hydro, others owned by HONI). Toronto Hydro also owns and operates some of the approximately 270 power transformers, 2,180 circuit breakers, 250 switchgear enclosures and 190 direct-current (DC) battery systems within these stations.

In the Horseshoe area outside of downtown Toronto, feeders generally have inter-feeder tie points to ensure there are multiple restoration options in case of an outage, or if planned work is required to be done. With regards to interruptions due to loss of supply at the station, feeders tied to other feeder of different stations allow customers to be resupplied provided there is available capacity on the tied feeders. On the other hand feeders in the downtown area rely on a radial configuration and do not have inter-feeder tie points. This configuration limits the restoration options for these feeders in case of a loss of supply at the station. To address this reliability issue, Toronto Hydro is planning on implementing inter-feeder tie points for some downtown feeders in its Downtown Contingency program. In addition, Toronto Hydro is proposing and continuing a number of renewal programs for station equipment to ensure that defective stations equipment is replaced prior to failure, which will also help address reliability issues. Capital investment programs that will target and mitigate Stations-related challenges include: Circuit Breaker Renewal, Power Transformer Renewal, Switchgear Renewal, Stations DC Battery System Renewal, Stations Control and Monitoring, Station Building Infrastructure Renewal, Stations Expansion, Stations Ancillary Systems and Downtown Contingency.

Figures 20, 21 and Table 5 provide the age and condition demographics of the station assets.

D2.3 System Utilization

Toronto Hydro completes an annual load forecast of station bus capacity to predict short and long term load growth, to plan for additional capacity to serve customers, to plan for contingency scenarios such as planned work or loss of supply, as well as providing long term plan to meet future load growth. This load forecasting process is further explained in Section D3.1.2.1(v). The

peak utilization should not reach or exceed 100%[8] for extended periods of time to prevent system overloading which may lead to asset failures. This assessment is mainly done at the station bus level as this is where Toronto Hydro must adhere to the Limited Time Ratings set by HONI. It is also where the most data is available to provide an accurate loading forecast, which can help predict any near- and long-term capacity constraints.

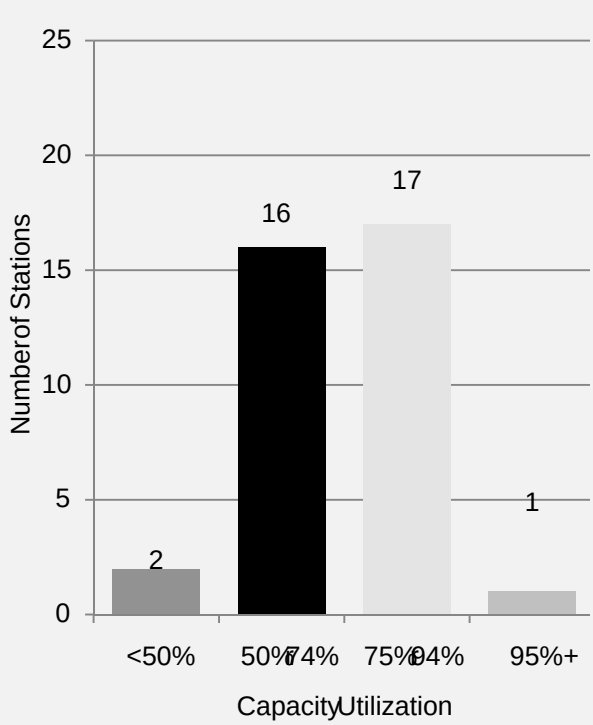

FIGURE 22: FORECASTED STATION LOADING IN 2015

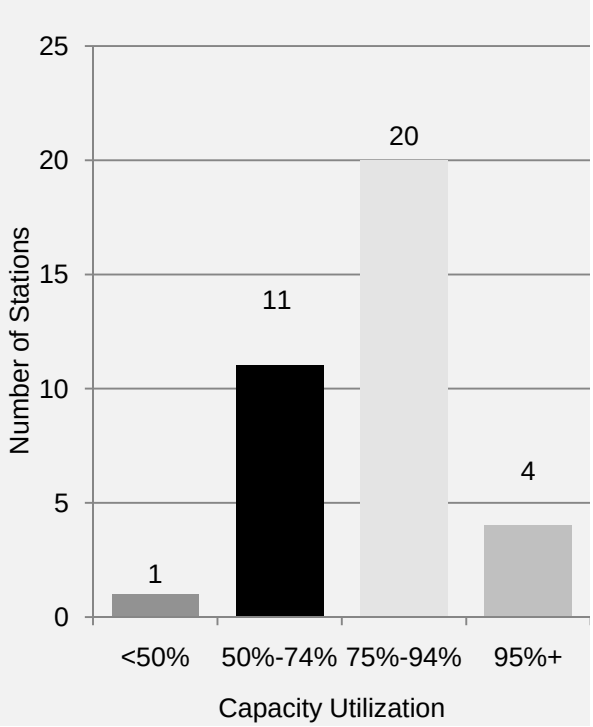

FIGURE 23: FORECASTED STATION LOADING IN 2020

From a station level capacity utilization standpoint, half of Toronto Hydro stations are loaded greater than 75%, with one station that is forecast to be at or near capacity in 2015. Toronto Hydro anticipates that there will be four stations that will be at capacity by the end of the 2020s. It is not prudent to load all assets up to 100% capacity as this would severely limit flexibility to manage abnormal system states (planned or unplanned). In a hypothetical worst case scenario, Toronto Hydro would be unable to transfer load to maintain or replace a failing or failed asset. To

[8] For planning purposes a 95% loading threshold is used for the downtown region, while a 100% bus loading threshold is used for the Horseshoe. This difference in the threshold is due to the fact that there is more load transfer capabilities in the Horseshoe area than the downtown area so more time is required to make plans for downtown capacity constraints, than for Horseshoe capacity constraints. Further details of the load forecasting can be found in section D 3.1.2.1 Decision Support Systems as well as E7.7 Stations Expansion.

mitigate overloading at the stations, engineers analyze the station loading projections as well as available capacity in the area to try to resolve the loading problem. Possible resolutions are to plan load transfers, upgrade existing components, or expand the station.

There are however, a large number of limitations and considerations that must be taken into account in implementing these solutions. They include:

- incompatible system voltages (e.g. 27.6kV vs 13.8kV)
- incompatible system types (radial vs looped, or overhead vs network, etc)
- availability of civil infrastructure
- availability of feeder positions
- environmental/civil barriers (e.g. rivers, highways ravines, etc)
- relative cost of load transfers as opposed to other relief options

Due to all these various considerations, every station must be individually analyzed to determine an appropriate resolution.

On the feeder level, planners typically plan new customer connections or customer load increases by analyzing the area where the additional load requirements are emerging and determining the best solution. Capacity constraints on the feeder level are similar to the capacity constraints at the station level and similar limitations and considerations must be accounted for in the planning process. This process is largely reactive as forecasting feeder loading is difficult because it is difficult to predict where new loads will materialize.

On the asset level, planners are frequently reviewing the system in areas of high capacity utilization or areas of poor reliability to determine what work can be undertaken to improve the system. It is difficult to monitor every asset in the system to ensure it is optimally utilized, however, Toronto Hydro has initiatives in place such as transformer monitors or network automation, which will allow assets to be more closely monitored. These initiatives help prevent overloading which may cause premature equipment failure.

D3 ASSET LIFECYCLE OPTIMIZATION POLICIES & PRACTICES

This section provides further details on Toronto Hydro's Asset Management (AM) policies and practices, which are integrated within the elements of the AM planning process and were first introduced in Section D1. Toronto Hydro strives to optimize its asset lifecycles by balancing the cost associated with the increasing risk of failure as assets age and condition degrades ("risk cost"), against the benefit of delaying the capital spending required for intervention by extending service life for as long as possible. Lifecycle optimization for the assets discussed in Section D2 takes place at the long-term, short-term and maintenance planning levels.

Capital investment practices are influenced at the long-term and short-term planning levels through the use of decision-support systems such as the Feeder Investment Model (FIM), which allow for the optimization of spending at the system investment, program investment, and asset investment levels.

At the long-term planning level, FIM is a key enabler of the risk-based optimization approach, used as part of the Long-Term System Review Process to determine the asset renewal investment timing based upon the economic end-of-life criteria for each asset. It is through this approach that Toronto Hydro plans to eventually achieve a "steady state" at the system-level through the execution of its capital investment plan. As discussed in more detail in Section D3.1.1.2, the steady state represents an optimal balance between required capital investment and aggregate risk costs associated with the existing asset base, such that the total lifecycle cost of the broader asset population is minimized.

Also at the long-term planning level, individual assets are identified and prioritized for replacement through the use of the FIM within capital investment programs and based upon their economic end-of-life criteria as per the Investment Planning process. Using this approach, the FIM balances the costs associated with the increasing risk of failure as assets age and their condition degrades (risk cost) against the benefit of delaying capital spending required for replacement by extending service life for as long as possible. This process is further discussed in Section D3.1.1.3.

At the short-term planning level, the FIM is once again utilized to re-identify prioritized assets for a given capital project as per the Project Development process. This process is further discussed in

Section D3.1.2.2. The FIM is a key enabler of the Business Case Evaluation (BCE) process, which allows the utility to produce a quantified business case for various capital investment programs. This methodology is further discussed in Section D3.3.

Additionally, maintenance investment practices are designed to extract the maximum value from assets through regular inspections, upkeep and repair activities. From these practices, the corresponding outputs are used to produce asset condition results which feed back into enterprise and decision-support systems, which are then used within long-term and short-term planning processes. In this manner, capital and maintenance processes continuously interact with each other.

Interaction points include the fact that capital investment programs are informed through their associated cross-referencing maintenance programs, to ensure that capital investment program spending is above and beyond the life extension benefits produced from the maintenance programs. Maintenance programs also account for changes that are introduced by capital investment programs, including the introduction of new asset classes or elimination of existing asset classes. For instance, the introduction of a new standardized asset class to replace an existing legacy asset class may result in reduction of maintenance costs, thereby introducing cost efficiencies. As such, a balance is ultimately achieved between capital and maintenance investments. Ultimately, maintenance programs are designed to complement the produced capital investment programs by allowing Toronto Hydro to sustain the intended operating condition of its assets and preserve operability.

D3.1 Asset Replacement & Refurbishment Policies

Toronto Hydro's asset replacement and refurbishment policies and practices allow for an optimization and prioritization of spending at the both the asset and system levels.

At the asset level, a proactive risk-based approach is applied to identify the economically optimal intervention time for assets based upon the balance of cost associated with (1) the increasing risk of failure due to asset aging and assets' condition deterioration over time (risk cost), against (2) the benefit of delaying the required spending to mitigate against these risks (capital costs) by extending service life for as long as possible. Maintenance planning further aids in maximizing the service life of assets prior to intervention, such that the maximum asset value is realized.

At the system level, the capital investment approach allows for the eventual achievement of a "steady state", which represents an optimal balance between required system-level capital investment and aggregate risk costs associated with asset failure. Section E2.1 further details the results of the capital investment approach produced for the 2015-2019 Capital Expenditure Plan, which identifies a backlog of investments, mostly comprised of those assets past their economic end-of-life. Achieving backlog mitigation and steady state through a series of stable, moderately paced investments as part of a prudent execution strategy will result in steady and more predictable rates, and the maximization of customer value via the minimization of aggregate asset lifecycle costs.

The asset management practices in the long-term planning process, first defined in Section D1.2.1, allow for the development of capital investment programs and associated investment spending levels, which target prioritized assets and issues at the system level. These practices are further defined in detail in Section D3.1.1.

Similarly, asset management practices contained within the short-term planning process, first defined in Section D1.2.2, allow for the development of discrete projects within each capital investment program. The practice of targeting assets and issues prioritized at the system level through the use of decision-support systems are further defined in detail in Section D3.1.2.

Capital investment spending that is initially established pursuant to long-term planning practices is further refined through the development of projects in Toronto Hydro's short-term planning practices. These spending levels are finalized at the investment program, category and overall levels as part of project scheduling and execution functions which exist outside of the AM

Process. The project scheduling and execution functions that were applied within the 2015-2019 Capital Expenditure Plan are further detailed in Section E2.3.

D3.1.1 Long-Term Asset Management Practices

Long-term asset management practices contained within Toronto Hydro's long-term planning process enable the optimization and prioritization of assets through the development of capital investment programs and associated spending levels. The following sections provide further details into the practices that result in the production of these outputs, including:

- The current-state system analysis (CSA), which provides a foundational set of system and asset data that is used as part of the long-term system review process;
- The long-term system review process, used to evaluate and finalize the capital expenditure approach, execution strategy and expenditure spending levels; and
- The investment planning process, used to produce capital investment programs that target assets prioritized at a system level based upon program drivers.

Further details on each of these practices are provided in the following sections.

D3.1.1.1 Current-State System Analysis

The CSA provides Toronto Hydro with a current-state assessment of the major assets that are currently installed. Key parameters provided from the CSA include:

- Asset registry data (nomenclature, asset class/sub-class, installation type, etc);
- Asset quantity/counts data;
- Age demographics data;
- Condition demographics data;
- Asset-class and system-wide replacement value based upon useful life criteria; and
- Historical reliability data.

The CSA utilizes information from Toronto Hydro's various enterprise systems, including the Geographic Information System (GIS) and Enterprise Resource Planning (ERP) system, coupled with information from AM-specific decision-support systems such as the Interruption Tracking

Information System (ITIS) which stores historical reliability data, and the Health Index (HI) Calculator which stores the generated asset condition assessment (ACA) data. These decision-support systems are further defined and discussed in Section D3.1.2.1. Asset-specific data is retrieved from each of these systems and amalgamated into the CSA.

Through the development of the CSA, Toronto Hydro can quickly establish key information on major assets including age, condition, useful life, and replacement value. This information establishes a foundation that is used in later portions of the long-term and short-term planning processes respectively. Section D2 provides the results from the CSA that was produced as part of the 2015-2019 Distribution System Plan. The CSA ultimately provides the foundation from which the long-term system review process, further explained in Section D3.1.1.2, is executed. Figure 1 illustrates the inputs, contained elements and outputs associated with the CSA.

D3.1.1.2 Long-Term System Review Process

The Long-Term System Review process utilizes the foundational data produced by the CSA in order to produce three deliverables: (i) a proactive capital investment approach that addresses all known system challenges and achieves an optimal balance between required capital investment and risk costs associated with asset failure – also referred to as a "steady state", (ii) an execution strategy that is responsive to customer's price sensitivity while being practical to execute, and (iii) comparison of reliability outcomes for the proactive capital investment approach and execution strategy against a "do nothing"/"run to failure" approach.

Figure 1 illustrates the inputs, deliverables and outputs contained within the long-term system review process.

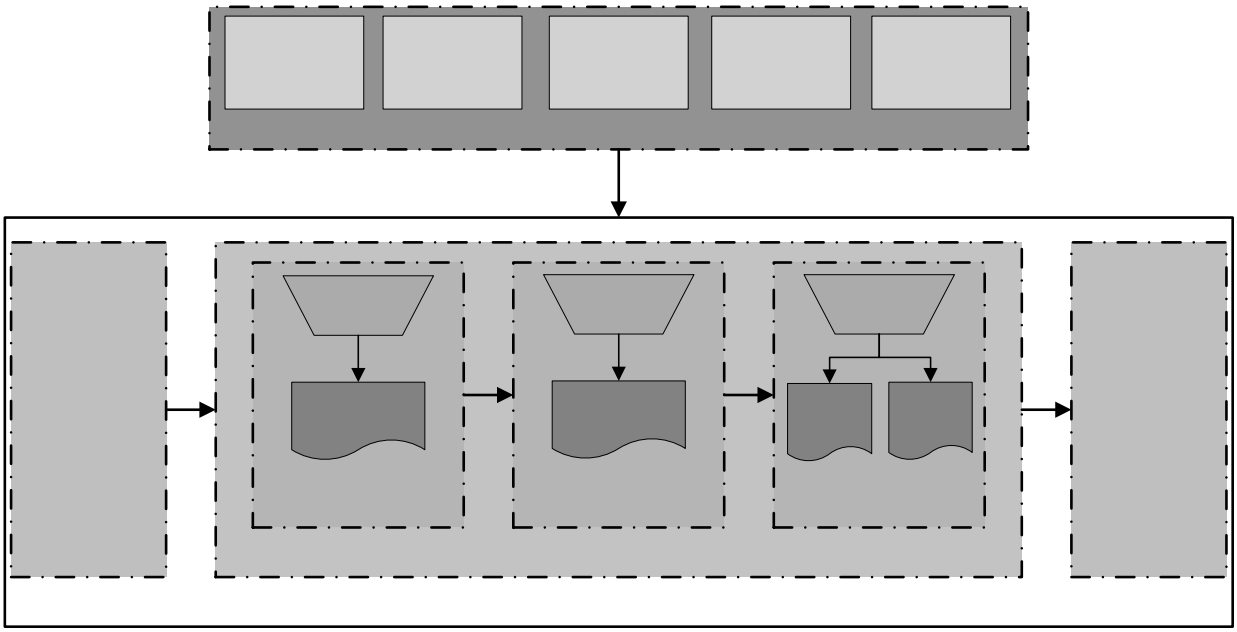

FIGURE 1: LONG TERM SYSTEM REVIEW PROCESS

(i) Derivation of Capital Investment Approach

As part of the first deliverable for the long-term system review process, asset-related information from the CSA is coupled with system-wide information regarding known challenges in order to define the forms of investment that will comprise of the total capital expenditures to take place over the Distribution System Plan (DSP) planning period. These expenditures must lead to the eventual achievement of a steady state, which represents an optimal balance between required system-level capital investment and aggregate risk costs associated with asset failure. In order to achieve a steady state, assets across the distribution system must be evaluated and intervened upon based upon their optimal intervention timing results – also known as the economic end-of-life criteria.

This economic end-of-life calculation is further illustrated in Figure 2, where the increasing annualized risk cost in orange and the decreasing annualized capital cost in green are subtotaled to produce the life-cycle cost in blue – otherwise known as the total operating cost of the new asset in question. Theoretically, the economic end-of-life criteria represents the lowest point of this operating cost across the life-cycle of the asset, illustrated by the orange dot in Figure 2 – otherwise known as the Equivalent Annualized Cost (EAC).

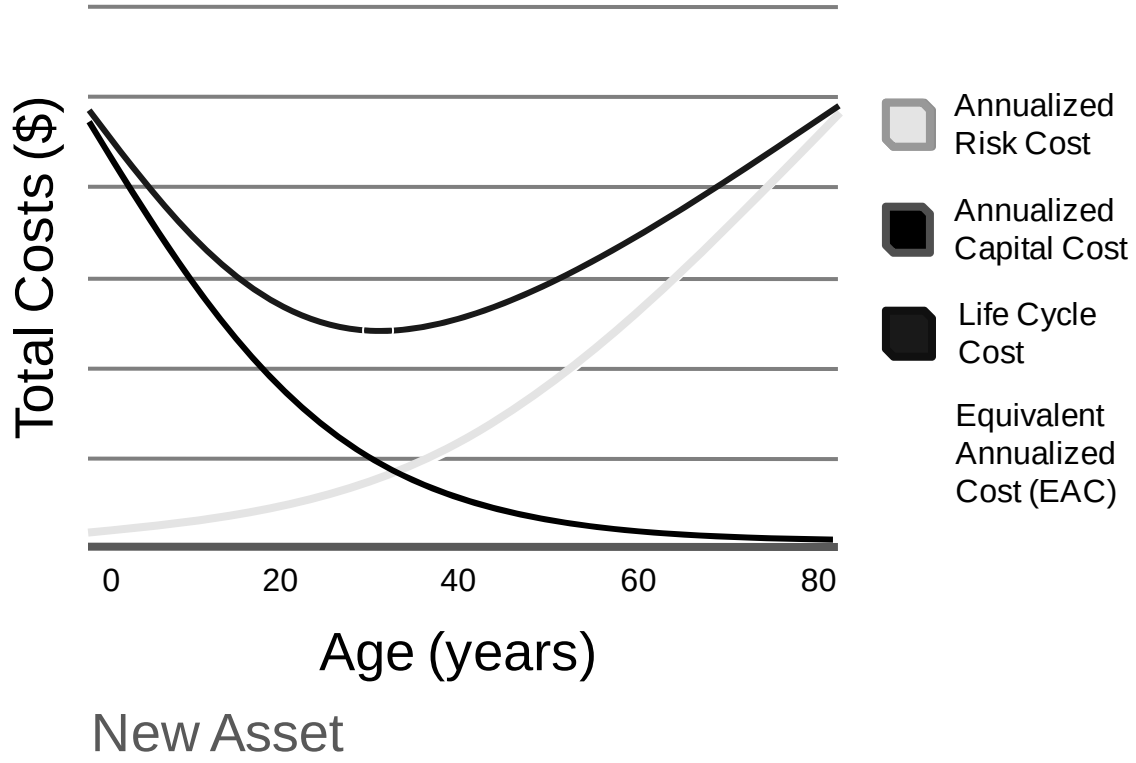

FIGURE 2: LIFE-CYCLE COSTING ANALYSIS

In actual practice, existing assets to be replaced and new assets to be installed possess varying levels of risk. Figure 3 illustrates a practical calculation of an assets' economic end-of-life through the execution of a risk-based optimization approach, enabled via the FIM, whereby the EAC as determined for the new asset is cross-referenced to the existing asset's total costs in order to determine the optimal intervention timing, or economic end-of-life criteria, of the existing asset.

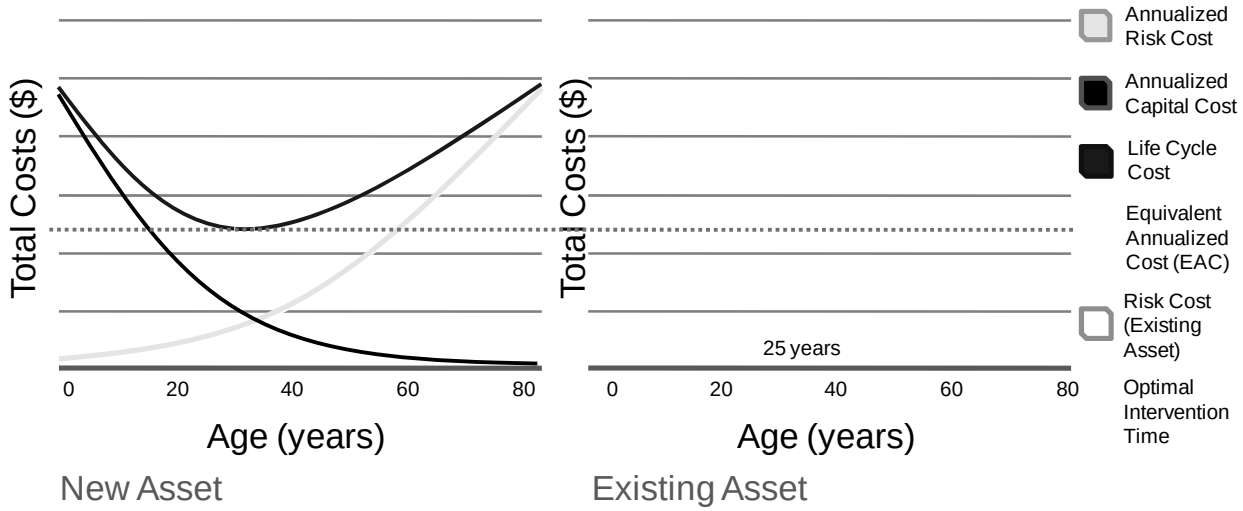

FIGURE 3: LIFE-CYCLE COSTING ANALYSIS (WHERE OPTIMAL INTERVENTION TIME IS A KEY INPUT USED WHEN CALCULATING THE STEADY STATE OF THE DISTRIBUTION SYSTEM AS PER RISK-BASED OPTIMIZATION APPROACH)

By performing this risk-based optimization approach for major distribution assets across the broader population of in-service equipment, such that the timing of asset renewal investments are collectively driven by the respective economic end-of-life results, a capital investment approach is produced that is driven by the system-level objective of achieving steady state, i.e. the condition whereby the total aggregate lifecycle costs of the distribution system is kept at a minimum.

Depending on the forms of investment that are defined within the DSP planning period, varying inputs and information are used to establish the associated capital investment spending levels. As an example, the following forms of investment and associated inputs and information were used as part of the 2015-2019 Capital Expenditure Plan:

- Asset Renewal: Steady state can be achieved through the in-kind replacement of distribution system assets (overhead, underground, secondary network, stations) reaching their economic end-of-life criteria, which is further explained above and illustrated in Figures 2 and 3. A risk-based optimization approach is applied to determine asset renewal investment timing based upon these economic end-of-life results. This approach was applied to those assets evaluated by the FIM, which is further explained in

Section D3.1.2.1(i). For those assets not evaluated by the FIM, asset intervention timing was determined based upon the assets' remaining useful life.

- System-Wide Critical Issues: These are urgent investments relating to safety, capacity and contingency constraints, security-of-supply, operational flexibility and other system-wide issues that go "beyond the asset". These investments were identified with the aid of decision support tools such as ITIS, FIM, ACA and load forecasting coupled with the CSA. These decision-support tools are further detailed in Section D3.1.2.1. Investment spending levels were derived from the costs of the solutions necessary to mitigate these issues.

- Mandatory Operational Investments: These represent the mandatory and necessary day-to-day operational investments associated with metering, customer connections, externally-initiated plant relocations and expansions, information technology, facilities, fleet and capital and maintenance investment support. Investment levels were determined in varying manners depending upon the nature of the activities in question. For example, information technology (IT) investments were derived based upon the IT Asset Management Process which is further detailed in Section D4.

Section E2.1 illustrates how the produced capital investment approach for the 2015-2019 Capital Expenditure Plan contains a backlog of investments for the first year, primarily consisting of assets at or beyond their economic end-of-life or useful life, along with critical issues. Through the elimination of this backlog, the steady state can be achieved, resulting in the mitigation of the corresponding risks. As the execution of this capital investment approach results in this steady state achievement, this balance also creates alignment between the capital expenditure plan and Toronto Hydro's AM objectives.

(ii) Selection of Capital Investment Execution Strategy

The second deliverable as part of the long-term system review process is to evaluate and compare different strategies that can be applied to execute the derived capital investment approach. The selection process will be driven by the need of the strategy to:

- Align to available resources and system constraints such that it can be executed in practice; and

- Result in rate impacts that are responsive to customers' price sensitivities.

The completion of this second deliverable also allows for capital expenditure spending levels to be produced across the DSP filing period at the overall level. These spending levels are further refined through the development of capital investment programs as explained in Section D3.1.1.3, as well as the production of capital projects as part of short-term planning practices further discussed in Section D3.1.2.2. Spending levels are later finalized as part of the project scheduling and execution process, which is explained in Section E2.3.

For the purposes of the 2015-2019 Capital Expenditure Plan, Toronto Hydro selected a "paced" execution strategy that reaches steady state in a gradual manner such that rate impacts remain acceptable and proposed investments align to available resources and system constraints. By pacing the investments in a stable and moderate manner, this ultimately results in smoother rate impacts for customers during the ongoing efforts to reach steady state and beyond. Section E2.1.2 provides further details on this selected strategy.

(iii) Reliability Assessment

The final deliverable as part of the long-term system review process is to compare the reliability outcomes of the proactive capital investment approach and execution strategy against a "do nothing"/"run to failure" approach through the execution of a reliability projection (RP) process, which is further explained in Section D3.1.2.1(iv). The reliability outcomes of the capital investment approach and execution strategy for the 2015-2019 Capital Expenditure Plan is detailed in Section D2.1.3.

D3.1.1.3 Investment Planning

The capital expenditure approach and execution strategy produced by the long-term system review process creates an architecture that can then be populated through the development of capital investment programs as per the Investment Planning process.

Key outputs from the long-term system review process, including the capital expenditure approach and execution strategy, are used within the Investment Planning process in order to produce capital investment programs.

Capital investment programs are produced for each form of investment as established within the long-term system review process. For example, for the 2015-2019 Capital Expenditure Plan, investment programs were developed for: (i) asset renewal; (ii) system-wide critical issues; and (iii) mandatory operational investments.

As per this process, assets and issues are prioritized on a holistic, system-wide basis, for each capital investment program. Prioritization factors vary depending on the drivers associated with the given capital investment program.

For example, asset renewal capital investment programs are typically driven by failure, failure risk, and functional obsolescence trigger drivers. Therefore, prioritization factors such as age, condition, economic end-of-life criteria and historical reliability data are used to identify assets across the system for these capital investment programs.

On the other hand, capital investment programs targeting system-wide critical issues typically have drivers such as safety, capacity constraints, functional obsolescence and system efficiency. For instance, for a safety-driven program all assets of a particular asset type or sub-type may be selected for immediate and equal prioritization due to the potential and in some cases, potentially severe safety risks posed by those assets. For a program driven via capacity constraints, load forecasting processes may be applied in order to prioritize locations across the distribution system with critical load growth concerns.

Capital investment programs that are managing necessary and mandatory day-to-day operational investments are developed based upon their specific scope of activities. For instance, the Metering program, which is described in Section E5.1, contains investments driven by mandated service obligations to customers. The Externally-Initiated Plant Relocation and Expansion program, which is described in Section E5.3, is entirely driven by third-party activities and initiatives.

It is ultimately through this system-wide prioritization process that capital investment spending levels are defined for each individual capital investment program.

As investment programs are developed, inter-relationships between these programs and corresponding maintenance programs are also assessed. For example, if Toronto Hydro plans to replace a sub-standard asset, maintenance activities on this asset type can be phased out. This approach allows Toronto Hydro to maintain assets to utilize an asset's full life-cycle where it is prudent to do so, or replace them, which is expected to achieve maintenance cost savings by reducing maintenance activities. More details about Toronto Hydro's maintenance programs are provided in Section D3.2.

Ultimately, each capital investment program will be assigned to one of the four investment categories (System Access, System Renewal, System Service, General Plant) as defined within

the Ontario Energy Board's (OEB) Chapter 5 Filing Requirements for Electricity Transmission and Distribution Applications.[1] Assignment to a category is dependent on the investment program's trigger driver, and the association of that driver to an investment category as defined in Table 2 of OEB's Chapter 5 documentation.

Once capital investment programs have been established at the long-term planning level, discrete projects are developed within each investment program as per the Project Development process (further explained in Section D3.1.2.2). Following this, a business case evaluation (BCE) will be produced for each capital investment program where it is practicable in order to identify the most cost-effective solution for mitigating the associated challenges and issues to ensure that the program is providing value to customers over its life-cycle. This BCE can only be produced once discrete assets to be intervened upon and/or specific locations where new assets are to be installed have been defined for a capital investment program. For those capital investment programs that are "dynamic" in nature where exact discrete assets cannot be produced or identified, a BCE cannot be practicably produced. For example, a Business Case Evaluation cannot be produced for a capital program such as Customer Connections (Section E5.3) where exact locations cannot be identified for the first year of activities.

The BCE approach is further defined in Section D3.3. Capital investment programs along with their respective BCE results have been provided in Sections E5 through to E8 respectively. Figure 3provides a visualization of the Investment Planning process by which investment programs are created.

As per the Investment Planning process, each produced capital investment program must align to Toronto Hydro's standard design practices and distribution construction standards. All new assets to be installed within each investment program have been reviewed and approved via an equipment approval process to ensure that they are safe and reliable. Standards and regulation adherence information have been provided for each individual investment program declared in Sections E5 through to E8 respectively. An independent review of all Toronto Hydro standards was performed by Power Systems Engineering (PSE) to ensure that these standards fall within typical industry practices and the principles of safety, reliability and efficiency, while applying industry best practices. The PSE report can be found in Appendix B of Section D.

D3.1.2 Short Term Asset Management Practices

Toronto Hydro's applies its short-term asset management process in order to develop discrete capital projects through the use of enterprise data and decision support systems coupled with investment drivers.

The Investment Planning process, as discussed in Section D3.1.1.3, results in the production of capital investment programs, each with holistically prioritized assets and/or issues and associated high-level program spending forecasts. As per short-term asset management policies, these prioritized assets and/or issues are recaptured locally through the use of various inputs, depending on the program driver through the execution of the Project Development process.

Figure 3 provides an overall visualization of the short-term planning process. Section D3.1.2.1 provides further details into the specific decision support systems applied at the local level to produce discrete projects, while Section D3.1.2.2 provides details on the Project Development process.

D3.1.2.1 Decision Support Systems

This section details the various tools that are used to plan system capital investments. The various inputs from the corporate databases discussed in Section D1 are used to assess the risk associated with assets and make system capital investment decisions. A number of tools and processes are utilized for this purpose, including:

- Feeder Investment Model (FIM);
- Asset Condition Assessment (ACA);
- Interruption Tracking Information System (ITIS);
- Reliability Projections (RP); and
- Load Forecasting (LF).

(i) Feeder Investment Model

The FIM is a risk-based analytical model that is used to establish the economic end-of-life for the major asset classes within Toronto Hydro's distribution system. It establishes an optimal time for intervening on a particular asset by balancing the risk associated with asset failure against the capital cost of intervention.

The FIM requires two main inputs to establish a risk analysis of assets: probability of asset failure and the subsequent failure impacts. The probability of asset failure relies on the assets' Hazard Rate Distribution Function (HDF), which represents the conditional probability of an asset failing based on the remaining population that has survived up until that time. The failure impacts, also called the consequence or impact of failure, are quantified by accounting for the direct costs to Toronto Hydro, including materials and labour costs, required to replace an asset, as well as indirect costs.

In addition to the direct costs that are incurred by Toronto Hydro in performing the asset replacement, Customer Interruption Costs (CIC) are also included. CIC values are calculated in two parts: the Event cost and the Duration cost. The Event cost represents the impact due to the occurrence of the outage whereas the Duration cost represents the costs incurred as the length of the outage increases. Toronto Hydro adopted $30 per kVA (peak load) as the Event cost to represent the CIC value due to the initial period of the outage, and $15 per kVA (peak load) per hour to represent the CIC value due to the increasing duration of the outage. These values, which were discussed at length in Toronto Hydro's 2012-2014 rates application, are established through work with consultants as well as the analysis of results from reliability valuation studies. The peak load at the individual asset level is used as a proxy for the number of connected customers as it represents the full load customers may have needed during an outage. In setting these values on a kVA and kVA-hour basis, no distinctions are made between customers by customer class. These values are used to quantify customer interruptions as part of the business case evaluations. As part of on-going enhancements[2] to the Feeder Investment Model, Toronto Hydro is planning to conduct a CIC study to provide more specific breakdown of CIC values within the FIM. Toronto Hydro's proposed spending on this study is outlined in Section E8.8.

The indirect costs account for the full cost of failure to customers and society, such as costs due to physical damage to customer or public property due to an outage, public safety, and environmental clean-up. These represent additional costs that would be incurred in a catastrophic failure of an asset. The total impacts of failure differ from asset to asset because assets operate under varying conditions and loadings.

The product of the probability of failure and the impact cost provides risk quantification for each major asset based on its individual age, condition, typical failure modes, and configuration within

[2] In Toronto Hydro's 2012-2013 rates application, the utility acknowledged that further research could be done to refine the CIC values used by the FIM, examining the types of customers in various areas and the differing effects that an outage may have on them. [EB-2012-0064, Application and Evidence (May 10, 2012).] In its decision, the OEB found that the present limitations of the FIM do not outweigh its usefulness. The OEB also acknowledged that refining the FIM inputs may only come at significant cost. [EB-2012-0064, Decision and Rate Order (April 2, 2013), at page 21.]

the distribution system. In order to determine a life cycle cost, both the estimated risk cost and the replacement cost of an asset are annualized, as shown in Figure 4. The life cycle cost of the asset is then the simple sum of the annualized risk and annualized capital cost. The annualized capital cost is the cost of replacement annualized over its projected life. As shown in Figure 4, the minimum point of the life cycle cost curve, the Equivalent Annualized Cost (EAC) point, defines the life cycle at which the lowest operating cost is incurred and thus the optimal life cycle for a new asset.

By extending the EAC point determined for a new asset to the existing asset within the system (which shares the same configuration), the optimal intervention time (OIT) for that particular asset can be determined, which is detailed in Figure 4.

FIGURE 4: TYPICAL EXAMPLE OF ESTABLISHING THE OPTIMAL INTERVENTION TIME FOR AN EXISTING ASSET

Therefore, by using both the probability of asset failure and the impact to both Toronto Hydro and its customers upon asset failure, the FIM determines a risk cost for a particular asset. Comparing this cost against the capital cost of replacement, the OIT for each asset is established. Thus, the FIM allows Toronto Hydro to evaluate major asset classes within its system and determine a replacement program for each of these asset classes based on a risk mitigation approach.

Further to the direct replacement of an asset, a number of assets have a refurbishment option which involves the replacement of non-standard accessories on overhead assets such as non-standard animal guards or lightning arrestors for overhead transformers and porcelain insulators on poles. The refurbishment option decreases the failure probability of the asset and thus reduces the risk cost of the asset. The FIM considers refurbishment as an option for optimal intervention and weighs the costs of refurbishment against the benefits from the decreased risk achieved by performing the work.

(ii) Asset Condition Assessment (ACA)

Toronto Hydro employs an ACA program to monitor the condition of various key asset classes within its system and produce a health index score to support project planning. The ACA program allows Toronto Hydro to produce a numerical representation of an asset's condition, taking into account key factors that affect its operation, degradation, and lifecycle.

For this rate-setting application, Toronto Hydro asked Kinectrics Inc. to assess the progress that Toronto Hydro has made with its ACA program since Kinectrics' most recent audit in 2012. Toronto Hydro has filed the 2014 Asset Condition Assessment Audit by Kinectrics Inc. as Appendix A to Section D of the DSP.

The basic approach used to develop the health index for each asset class is illustrated in Figure 5.

FIGURE 5: ASSET CONDITION ASSESSMENT PROCESS AS PART OF ACA

The asset classes define the various types of assets within Toronto Hydro's system. The degradation processes and end-of-life criteria are established by subject matter experts based on their understanding of each asset class' causes of failure. The resulting formulation then defines how each condition impacts the health index profile for each asset class. The ACA depends heavily on the inspection of the various assets which is performed as part of the ACA program, thus a health index score can only be produced for asset classes which have sufficient inspection information, examples of asset classes with HI scores are shown in Figure 6 below.

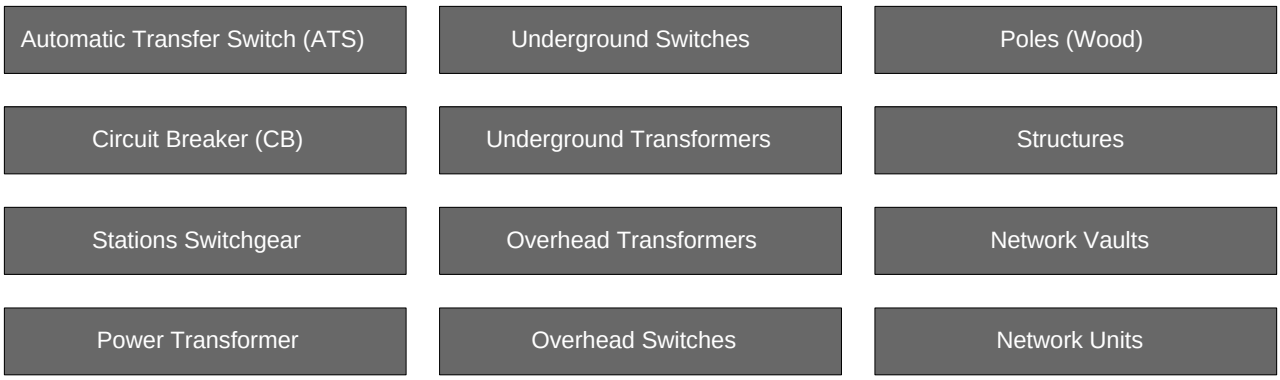

FIGURE 6: EXAMPLES OF ASSET CLASSES EVALUATED IN THE ACA PROGRAM

The resulting health index scoring produced for these asset classes is critical to Toronto Hydro's planning activities. The ACA output is essential in two regards. First, the ACA produces an outlook of the population's condition for each individual asset class within the program. Second, the ACA program highlights trends in the condition of asset classes. These trends can highlight issues that are specific to particular asset classes or subtypes such as manufacturing defects, or design practices. Being aware of these issues and trends allows Toronto Hydro to balance capital investments against continuing maintenance.

(iii) Interruption Tracking In formation System (ITIS)

Toronto Hydro also uses system performance as a key tool in developing capital spending. The state of the distribution system can be understood by analyzing its reliability performance. By continuously analyzing the reliability performance of the circuits within Toronto Hydro's distribution system as well as their substation assets, Toronto Hydro is able to identify areas experiencing reliability issues, which may be caused by asset deterioration or legacy design related issues. The Interruption Tracking Information System (ITIS) is used to store historical outage information. Toronto Hydro utilizes ten major cause codes to classify historical outages within ITIS, including:

- Adverse Environment
- Adverse Weather
- Defective Equipment

- Foreign Interference
- Human Element
- Lightning
- Loss of Supply
- Scheduled Outages
- Tree Contacts
- Unknown

Further, ITIS can provide insight into the number of customers affected by outage events in the system and the duration of each event. This information can then help drive capital investment decisions by identifying assets that are facing continued reliability issues or designs that require a longer to restore. In addition, areas with a high number of outages are then analyzed to determine the root cause of the problem and to identify the most prudent investment decision to alleviate the issues identified.

(iv) Reliability Projections (RP)

In order to conceptualize the impact of investment programs, Toronto Hydro performs an analysis of the historical system reliability and produces a reliability projection based upon:

(a) Asset demographics data produced as part of the CSA;

(b) Historical Reliability performance; and

(c) Planned Programs and their respective impacts to reliability.

The system historical reliability category is broken into individual cause codes, and in some cases such as defective equipment, down to the asset level.

As per the reliability projection process, a Status Quo or “Run to Fail” scenario is produced, in which the progressions of the current system with no proactive intervention is described. The scenario depicts what would happen if technology that exists stays in the system and performs as it does today, with assets naturally reaching an end-of-life point. At the end-of-life point assets begin to fail, leading to worsening reliability. While there are no certain assumptions made about

environment condition changes, the impact of these outages are perceived to increase due to a less robust system as asset degrade.

In addition to the "Run to Fail" approach, Toronto Hydro reviews each of its filed programs for reliability benefits, improved operation flexibility, and asset demographic change. The program level changes are reviewed holistically on a system level, and system impact by sub cause codes is produced. The benefits are then normalized to the full extent of the program level relative to the system.

In general, this conceptual analysis is used by Toronto Hydro to evaluate reliability impact of the proposed capital expenditure plan. It should be noted that this projection does not consider major event days, and the lasting impacts that major weather events can have on asset performance in future years.

(v) Load Forecasting

Toronto Hydro uses a load forecasting process to identify spare capacity at substations or points of constraint within the system. This allows Toronto Hydro to maintain awareness of bus capacity as new connections are made. In order to complete a ten-year load forecast at the substation level, as shown in Figure 7, Toronto Hydro identifies the peak loads (both summer and winter peaks) for each bus that supplies its substations. These peak loads are then normalized based on historical temperatures at which these peaks occurs. This information is then supplemented by historical growth rates based on distinct areas of the system. The areas are distinguished by their distribution system characteristics, demographics, and historical growth. Any information available for customer connections at the time of analysis are included based on the required connection time and the load requested by the customer. However, only 70% of the requested load is applied, because Toronto Hydro has learned from past experience that the load requested is often overstated in the application phase. For larger customers, the load profile is forecasted to grow gradually, based on past observations. The historical growth rates that are calculated are then used to forecast load for future growth.

FIGURE 7: PROCESS TO FORECAST LOAD AT SUBSTATIONS

D3.1.2.2 Project Development

Once capital investment programs are established, as explained in Section D3.1.1.3, the prioritized assets and/or issues identified for each program are intervened upon as part of discrete capital projects. As explained within Section D1.2.2, the project development process can be subdivided into three components: (1) the project study, (2) the project draft and the (3) approved project.

During the study phase, planning engineers analyze discrete portions of the distribution system, such as a neighborhood or street, in order to identify projects that align to the investment program criteria and drivers. Depending on the investment program driver and program type (i.e. core renewal, critical issues or other necessary day-to-day operational investments), enterprise data and decision support systems are applied in order to identify assets at a discrete level such that investment opportunities are identified.

For instance, should a program be driven by Failure Risk, enterprise and decision support systems as discussed in Section D3.1.2.1 will be utilized in order to identify the program-level prioritized assets that align to this driver.

In addition, HI Calculator outputs can be used to identify those assets in very poor and poor condition. The FIM can be used to identify those assets that are nearing, at or beyond economic end-of-life at a particular location. ITIS can be used to cross-reference studied locations against historical reliability events and performance issues. Finally, enterprise systems including the GIS are used to further support the study process, by providing supplementary details such as age, asset type and sub-type information.

For safety or capacity constraint-driven programs resolving critical, system-wide issues, nameplate information or localized data as per the load forecasting process may be used to identify specific investment opportunities.

When an investment opportunity for a project within a particular investment program has been confirmed and verified, a project draft is then produced which confirms the assets to be replaced, and establishes the high-level design for the new assets to be installed. While some projects may involve assets replaced in-kind, other projects may result in non-in-kind interventions, where new assets are installed as per a new configuration. Examples may include the conversion of overhead plant to underground plant in order to minimize non-asset-risk exposure, or the re-configuring of radial circuits to looped circuits and redistribution of load in order to reduce outage duration and impacts accordingly. Ultimately, the high-level forecasts produced via the long-term planning process will be further refined into a capital budget, as more rigorous project estimates are produced.

In tandem with producing the high-level design, the planning engineers also document the scope of work to be performed and produce a high-level cost estimation to execute the project. Efficiency savings are realized by mitigating both the prioritized assets and/or issues along with adjacent assets as a single project, as opposed to replacing these assets individually on a reactive basis. A project study may also be subdivided into multiple project drafts where necessary to allow construction to be executed in manageable pieces that are minimally intrusive to both the general public as well as customers. As part of the project development process, engineers also consider issues such as city road moratoriums, physical restrictions, or particular design related problems that may delay the project or require a redesign.

The project draft then goes through a quality control assessment, where it proceeds into the project finalization stage through the planning supervisor. During this phase, in-field assessments may also take place to verify the accuracy of the data that was used to produce the project.

Ultimately, a series of projects are produced for each investment program, which results in further refinement to the capital investment spending levels for the associated program, since these spending levels are now informed by the discrete project costs. As all of these projects include assets or issues that are of the most urgent nature, these projects will be of equal importance to each other and will be assigned to the first year of the Capital Expenditure Plan. As part of the 2015-2019 Distribution System Plan, capital projects were produced for the 2015 year. These capital projects are detailed in their respective capital investment program sections, located in Sections E5 through to E8.

Once the project finalization is complete, these projects will be scheduled for execution based upon the Project Scheduling and Execution process. Each project is scheduled based upon available resources as well as system constraints such as contingency issues or summer switching restrictions. As part of this process, the detailed project design and estimate are produced which results in the finalization of capital investment spending levels. The applied Project Scheduling and Execution process as part of this 2015-2019 Distribution System Plan is further explained in Section E2.3.

D3.1.2.3 Measurement and Enhancement

Toronto Hydro has developed various metrics to monitor the performance of the DSP through the execution period, which will aid in driving improvements in successive DSP submissions. Section C provides further details on the metrics applied as part of the 2015-2019 Distribution System Plan.

While Toronto Hydro is confident in its Asset Management Process and the rigor underlying its DSP, the utility also adopts the principle of continuous improvement and plans to look for opportunities to enhance its processes. Toronto Hydro sees two central areas where it may be possible to enhance its DSP-related processes: (i) Data Quality Improvement and (ii) Decision Support System Enhancements.

Toronto Hydro plans to review any data gaps or data quality issues identified during the development of the DSP. The utility expects that the feasibility and economic viability of solutions could be considered, in order to attempt to mitigate any data gaps or data quality issues. An optimal solution can then be identified and executed to address the issue in order to improve future planning activities.

Opportunities for improvements are also assessed for the various decision support systems discussed in Section D3.1.2. Based on analyses performed during the development of the DSP, requirements for enhancements may be developed. These improvements could potentially be assessed for feasibility and the enhancements are implemented to the decision support systems over the course of the execution period. Possible enhancements range from how data is handled within a particular system, the user interface, or improved inputs/assumptions within a decision support system.

The results achieved through each of these enhancements allow Toronto Hydro to improve decisions in long term planning, which should lead to continuous improvement in future DSPs.

D3.2 Maintenance Planning Criteria

Toronto Hydro's asset inspection and maintenance program plays an integral role in optimizing the lifecycle of its assets. Inspection and maintenance activities allow Toronto Hydro to monitor the state of assets under operation and undertake actions to keep them operating as designed. Through inspection and maintenance, Toronto Hydro strives to maximize the use of its assets and thereby defer replacement and the associated capital investment where possible and cost-effective.

Asset inspection provides insight into the operating condition of the asset and information regarding premature degradation of assets. The data collected through Toronto Hydro's maintenance and inspection programs allows Toronto Hydro to make key decisions regarding asset renewal, and thus help shape capital investment and maintenance activities. Toronto Hydro's Asset Condition Assessment program, explained in section D3.1.2, is heavily reliant on the information collected through asset inspection and maintenance to determine the condition of the assets. The condition plays a key role in optimizing capital investments. In addition, asset inspection allows Toronto Hydro to identify any safety or environmental risks and initiate the required maintenance activities.

Asset maintenance programs are grouped into four major categories based on their functionality, as shown below:

- Preventive Maintenance
- Predictive Maintenance
- Corrective Maintenance

- Emergency Maintenance

Each of these program types is discussed in more detail in Sections D3.2.1 through to D3.2.4 respectively.

D3.2.1 Preventive Maintenance

This type of maintenance involves inspections and maintenance tasks on a fixed cycle, which emphasizes preserving asset performance over its expected life, and maintaining public and employee safety. Maintenance cycles are defined based on the mean time between failures of a given asset class, and are intended to maintain the asset before it is statistically likely to fail. An example of a preventive maintenance task is the inspection of wooden utility poles, which is carried out on a ten-year cycle. For additional information, please see Exhibit 4A, Tab 2, Schedule 1.

D3.2.2 Predictive Maintenance

This type of maintenance involves the testing and inspection of equipment for predetermined conditions that are indicative of a potential failure, and then undertaking maintenance tasks to prevent those failures. Predictive maintenance is the most effective maintenance approach for those assets that exhibit conditions that can be identified, practically monitored and corrected prior to failure. An example of a predictive maintenance task is Dissolved Gas Analysis of power transformer mineral oil; the presence of dissolved gases and other chemical compounds in the oil indicates failure modes such as overheating, excessive moisture or breakdown of the insulating paper. Corrective maintenance tasks can then be undertaken to correct the deficiencies to avoid equipment failure. For additional information, please see Exhibit 4A, Tab 2, Schedule 2.

D3.2.3 Corrective Maintenance

This type of maintenance involves repairing or replacing equipment after a deficiency has been reported during the execution of preventive or predictive maintenance tasks or other planned work. These tasks typically involve a short planning horizon since a portion of the distribution system is either faulted or isolated, or in a substandard condition thereby putting the system at risk. Since defective equipment is a major contributor to SAIFI and SAIDI, Corrective Maintenance emphasizes restoring assets to an acceptable level of operation, thereby improving system reliability. An example of a corrective maintenance task is Transformer Oil Reclamation; power transformer oil is circulated through filtering devices to eliminate moisture and sludge, the

presence of which would have been identified by the Predictive Maintenance task of Dissolved Gas Analysis.

Corrective Maintenance can also be required as a result of an unplanned system event or emergency. For example, a faulted section of underground cable that had been isolated from the system during an emergency response would be unearthed and replaced as a corrective maintenance action. For additional information, please see Exhibit 4A, Tab 2, Schedule 2.

D3.2.4 Emergency Maintenance

This type of maintenance involves the urgent repair or replacement of equipment that has failed or is in imminent danger of failure, in order to either restore or maintain power. This type of maintenance may also involve an immediate response to a safety or environmental hazard. It emphasizes safe and prompt response to restore service or prevent a service disruption. An example of Emergency Maintenance would be restoration of service to customers that have lost power due to a broken tree branch on the overhead lines. Exhibit 4A, Tab 2, Schedule 2 of the CIR evidence provides further information in this regard.

D3.3 Business Case Evaluation (BCE) Approach

Toronto Hydro uses the FIM to determine optimal intervention timing on an individual asset or the optimal timing for the replacement of a set of assets together. In addition to determining the optimal intervention timing for individual assets, FIM provides a quantification of the estimated risk based benefits of executing a program.

A BCE cannot be produced for capital investment programs which are not “dynamic” in nature (i.e., where discrete assets to be intervened upon and/or specific locations where new assets are to be installed cannot be identified, as explained in Section D3.1.1.3).

There are two types of business case evaluations based on program type that are used to estimate the benefits of a capital investment program:

- Avoided Risk Cost – Capital investment programs with like-for-like renewal of assets
- Cost of Ownership – Capital investment programs with non-in-kind intervention

D3.3.1 Avoided Risk Cost

Like-for-like renewal of assets involves replacing currently installed assets, which are beyond useful life or otherwise require replacement, with new standard equivalent assets. This type of intervention does not necessitate any changes to the configuration of feeders or the distribution system as a whole. Examples include overhead and underground renewals, in which the existing assets are replaced with new standardized assets, with no changes in the overall configuration.

In general, like-for-like renewal of assets is evaluated by estimating the "avoided risk" of performing the work in the first year of the program as opposed to delaying it to the start of the next rate cycle (in the case of this application, 2020). In order to calculate the avoided risk of performing the renewal in first year as opposed to 2020, the various costs and benefits associated with executing the work in a particular year are evaluated.

In essence, the benefit of performing the program is calculated for a set of assets that represent a year's worth of activities in the program. This evaluation is representative of the overall value of performing the work defined within the capital investment program. The avoided risk cost estimation is driven by the economic analyses of one year of individual assets as detailed in Section D3.1.2.1.

When a program analysis is undertaken, assets within the program may be before, at, or beyond their optimal replacement time. Thus, some assets will have sacrificed economic life, which occurs when an asset is replaced before its economic end of life, and others will have incurred excess risk, which occurs when an asset is replaced after its economic end of life. The cumulative sacrificed life and excess risk of the assets involved becomes a cost against the program, which is shown as the red curve in Figure 6. The benefits of the program stem from the savings achieved by performing multiple asset replacements together as opposed to replacing these assets individually. These concurrent intervention benefits include factors such as equipment rentals, transportation of crew and material, excavations, and road moratoriums. The sum of the costs and benefits is the avoided risk cost which captures both the costs and benefits of executing the project immediately rather than waiting to 2020. Note that the program cost is embedded in this analysis and thus the ARC inherently takes into account for the program cost. An example is shown in Figure 8 where the net cost is lower when the project is done in the first year rather than being deferred to 2020.

FIGURE 8: AVOIDED RISK COST AN ALYSIS FOR LIKE-FOR-LIKE PROJECTS

In Figure 8 the area shaded in blue shows the avoided risk cost for a program completed as scheduled in 2015 as opposed to deferring it to 2020. The formula for this calculation is:

Avoided Risk Cost (ARC) = [(PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]

Where:

- NET_COST(First Year of Activity): Represents the estimated net costs in the first year of activities.
- PV(NET_COST(2020)): Represents the present value of the estimated net costs in 2020 for the first year of activities.

The optimal year (blue circle) is the lowest point on the Net Cost curve (blue line). In the optimal year, the Net Cost is calculated as a positive value. This means that the combination of the estimated risk costs and concurrent intervention benefits of the project is lowest in 2015. By

performing the work as scheduled in that year, Toronto Hydro increases the concurrent intervention benefits and lowers the estimated risk costs when compared to the values in 2020.

D3.3.2 Cost of Ownership

Capital investment programs involving non-in-kind interventions are evaluated under a cost of ownership (COO). Capital investment programs with non-in-kind intervention require a change in the overall configuration of the system. There are two major types of non-in-kind interventions. Programs in which existing assets are removed and new assets are installed as part of a new feeder configuration. Examples of this involve work such as the reconfiguration of circuits, the standardization of legacy designs etc. The second type involves the installation of new technology which introduces a benefit to the existing assets, in the form of reduced outage durations and reduced subsequent risks. Examples include the installation of SCADA-technology as well as Feeder Automation in which the existing assets remain intact but the impact of a failure is reduced by the introduction of new technology. The COO calculation is composed of four key factors, including Asset Risk (AR), Non-Asset Risk (NAR), Maintenance Cost (MC), and Additional Quantifiable Benefits (AQB), detailed below.

D3.3.2.1 Asset Risk

In order to establish the Asset Risk, the estimated annualized risk is plotted along with its 'Equivalent Annual Cost' (EAC), as shown in Figure 9. Note that the EAC is the minimum life cycle cost of the asset, including both capital cost as well as future risk as discussed in Section D3.1.2.1. For an existing asset, the AR does not include capital cost since this is a sunk cost that has been already incurred. As such, the asset follows its risk line until it reaches its OIT, at which point it should be replaced and thus, begins to follow the EAC line. The net present value of these costs from the current age onwards, over a 100 year period, represents the AR contribution towards the COO of an asset in a particular design. The COO is represented by the region shaded purple in Figure 9.

FIGURE 9: COST OF OWNERSHIP CALCULATION EXAMPLE FOR AN ASSET

The AR contribution for a program is the sum of all of the individual COO results of the assets within it.

D3.3.2.1 Non-Asset Risk

Non-Asset Risks (NAR) are risks incurred due to any factor that may lead to an outage that is not directly tied to the assets, including animal contact, lightning, adverse weather, and human elements.

These risks are based upon historical failures that were attributed to factors that are considered non-asset related. The information regarding the past failures is derived from 10 years' worth of historical outage data.

Information regarding the number of outages, customer interruptions (CI) and customer hours interrupted (CHI) are captured at the feeder level from this historical outage data. This information is then normalized over the total length of the feeder. This allows for the non-asset risks to be calculated on a per meter basis for a given feeder.

Using this approach, the specific non-asset risks for a particular area of study can then be calculated by multiplying the normalized value times the feeder length in the study area. Toronto Hydro is currently exploring methods to localize historical reliability information to derive more accurate projections. The connected load within the area of study, measured in kVA, is then used

to represent the amount of load that is impacted if an outage were to occur due to non-asset factors, and is subsequently used in calculating the CICs associated with these events.

The Overhead System and the Underground System experience differing outage causes because the non-asset factors that affect an overhead system are different from those that affect an underground system. The applicable non-asset risks for each type of system are used as part of a net present value calculation to produce the final quantified non-asset risks (NAR) associated with the area of study, which represent the NAR contribution to the COO.

D3.3.2.2 Maintenance Cost

Maintenance costs (MC) that are attributed to a particular design also contribute to the overall COO. Therefore, these costs are quantified for both the existing (MC_E) and the new case (MC_N). For example, when a program results in a net reduction in the amount of maintenance required for a system, such as the renewal of an asset to a new standard that requires less maintenance, this change contributes to the difference in the COO, which in turn shown as a benefit of the program.

D3.3.2.3 Additional Quantifiable Benefits

Many programs result in benefits that are not inherently captured in the AR, NAR, or MC values. These are considered to be Additional Quantifiable Benefits (AQB) for a particular program. Some examples of AQBs include operation efficiency savings and the reduction of system losses. Where used for a particular program, AQBs are clearly identified and defined as part of the Business Case Evaluation.

Introduction of AQBs is an enhancement to the business case process as it allows for a broader set of benefits to be considered in the quantified analysis, thereby allowing for a more accurate and robust analysis of the proposed program.

D3.3.2.4 Program Net Present Value and Cost of Ownership

The total cost of ownership for a program is the sum of the net present value of AR, NAR, MC, and AQB for a particular state as shown in Figure 10. The sum of the individual costs of ownership of all assets within the first year of activities of a particular program is used to derive the COO of the program under a particular design or state. The cost of ownership is then determined for both the existing state of the system and the new state that will be established by implementing the proposed program based on the assets for one-year of activities within a capital investment program.

By comparing the COO of a proposed future state based on the first year of activities against the current state for those assets, the benefits of establishing the future state are determined for the capital investment program.

The COO is calculated for each "state" of the assets, existing and proposed as detailed in Figure 10 below.

FIGURE 10: COST OF OWNERSHIP APPROACH FOR BUSINESS CASE EVALUATIONS

As shown in the final line of Figure 10, the Project NPV value equals the difference in the COO between the existing design and new design minus the project cost. If the Project NPV is a positive value, it represents the benefit of carrying out a proposed program.

In summary, where applicable, programs involving like-for-like renewal of assets have an avoided risk cost calculations whereas non-in-kind programs where a business case evaluation can be produced have a cost of ownership approach for the quantification of their respective risk benefits. The quantified business cases for programs are developed using one year worth of program work for the various programs being analyzed. Toronto Hydro utilizes the results of the business case evaluation for each program to assess the benefits of its investments.

D4 INFORMATION TECHNOLOGY ASSET MANAGEMENT METHODOLOGY

Informational technology (IT) is a critical enabler for utility operations. Toronto Hydro relies on IT assets and systems to satisfy its obligations as a distributor, deliver its capital plans and operational programs, and pursue efficiencies and innovation.

The primary objective of Toronto Hydro's IT Asset Management Process is to maximize the value of the IT assets to the utility and ratepayers. IT systems provide optimal value when they deliver expected levels of service in a sustainable manner, and mitigate risks (i.e. impact of failure, cyber security) at optimal costs. This schedule describes the IT asset management principles and IT investment planning methodology that enable Toronto Hydro to achieve this key objective.

IT Asset Management includes the purchase, operation, maintenance, renewal, replacement and disposition of the software and hardware assets. This process is defined by IT Standards, which include:

- requirements for software and hardware assets (e.g., physical, performance, compatibility, security, etc.);
- IT architecture which establishes expected service levels (e.g. performance measurement, reliability requirements, incident/problem management for the assets); and
- lifecycle management schedules for each type of asset.

IT Investment Planning is the process of making the best possible decisions regarding scope and sequencing of asset management and enhancement initiatives. This process is based on well-defined IT standards and up-to-date information about IT assets.

Toronto Hydro's IT Investment Planning Process is divided into two streams: 1) Sustaining Existing Systems, and 2) Enhancement Initiatives. The planning process includes the development of a five-year program of prioritized investments, including a detailed plan for the first year.

D4.1 IT Asset Management

Toronto Hydro developed IT Standards to streamline and optimize IT asset life cycle, define system architecture and to gain operational efficiencies through standardization of IT assets and components. IT Standards are based on information provided by equipment producers (e.g. statistics on mean time to failure), internal historical data of asset failures and industry best practices. Toronto Hydro reviews its IT Standards regularly to ensure that they remain aligned with industry best practices, and relevant for the organization.

As described in more detail below, Toronto Hydro has adopted IT Standards and architecture for both hardware and software assets. Having aligned hardware and software standards enables the implementation of the "Pooled/ Farm-based" environments. A "Pool / Farm" represents a collection of hardware resources which are required to complete desired computing operations that exceed the requirements of a single hardware machine. The implementation of pooled farm based concept provides the following benefits:

- Better management of IT assets, incidents, problems, changes, configurations, security, capacity, and availability of IT assets;
- Enhanced reliability of IT systems;
- Streamlined procurement processes and reduced operating costs;
- Operational efficiencies, such as the rationalization of IT resources;
- Simplified monitoring of the IT assets; and
- Enhanced security.

D4.1.1 IT Hardware Standards

IT Hardware Standards define the management of the physical IT components from acquisition through disposal. Common IT hardware asset management practices include need identification, procurement management, life cycle management, redeployment and disposal management. These practices are applied to the following categories of hardware assets (see Figure 1 below):

(1) Core backend infrastructure assets which are responsible for the computation, storage and communication necessary to support IT systems; and

(2) Endpoint assets which enable end-users to execute, process, complete and review business tasks and operation.

FIGURE 1: IT ASSET MANAGEMENT STRATEGY

IT Hardware Standards and architecture specify what types of hardware assets Toronto Hydro requires to ensure a highly reliable, scalable and manageable platform for business applications, and document the capacity and lifecycle of different assets.

IT hardware must be periodically refreshed to guarantee expected service levels of the systems and to minimize risk of failure impact to the business. Toronto Hydro's IT Hardware Standards seek to define optimal asset replacement timing such that hardware assets operate with the lowest acceptable failure rate at optimal costs. As illustrated in the Figure 2 below, the lifecycle of IT assets generally follows a "bath tub curve" that breaks out into three distinct regions:

FIGURE 2: IT HARDWARE ASSET LIFECYCLE FAILURE RATE OVER TIME

- Decreasing Failure Rate: This is the region of the curve associated with the reducing failure rate over time. This is typical of new IT hardware. The vendor quickly releases service packs, patches and bug fixes that reduce the IT hardware failure rate.
- Constant Failure Rate: As the failure rate decreases it comes to a stage when it stabilizes and it is almost constant. The cost of ownership in this area of the bathtub curve is steady and the considered financially optimal.
- Increasing Failure Rate: As the IT hardware ages beyond useful life, the failure rate starts to increase again. This is attributed to the general operational wear and tear of the asset as well as vendor focus on development of new products, in essence, lack of investment in obsolete products. The system failures and associated maintenance costs start to rise steeply in this portion of the bathtub curve.

Based on the criticality of the infrastructure, industry best practice and vendor specifications, standards define the optimal time to refresh assets before reaching "Increasing Failure Rate" part of lifecycle. This approach minimizes the risk of interruptions to the core processes and technology that the company relies on to execute its capital plans and operational programs in a safe, effective and efficient manner.

D.4.1.2 IT Software Standards

IT Software Standards classify software applications in two categories – Tier 1 and Tier 2 – based on the consideration of the operational criticality of the application, level of complexity, integration with other applications, maintenance costs and number of users.

- Tier 1 applications enable Toronto Hydro's business operations and support company-wide business processes. They are functionally integrated with other applications, and are supported by complex underlying infrastructure such as databases, middleware, storage and network. As a result, Tier 1 applications generally have higher maintenance costs and a large user base. In a disaster scenario, the recovery point objective is less than 4 hours. Examples of Tier 1 applications include the Enterprise Resource Planning System, Inventory Management System and Geo Informational System.
- Tier 2 applications enable specific divisional and departmental processes. These applications have little to no integration with other enterprise applications, and are typically supported by simple infrastructure. In a disaster scenario, the recovery point objective is less than 24 hours. Tier 2 applications generally have lower maintenance costs, and cater to a smaller user base than Tier 1 applications. An example of a Tier 2 application is Hydropedia, a knowledge base system that helps customer service representatives to quickly and accurately address customer questions about Toronto Hydro processes during a phone call.

Regular software upgrades reduce the risk of system failures and cyber security breaches, and align software assets with vendor support cycles. Similar to IT hardware assets, if an application is not upgraded before the vendor support cycle expires, Toronto Hydro may have to procure specialized technical resources to maintain and support the application.

IT Software Standards also seek to maintain the compatibility of software applications and the underlying components (e.g. servers and operating systems) to ensure uninterrupted IT system operations and deliver the desired end user experience and functionality. Because the IT systems and their underlying components are often on different end-of-life and vendor support cycles, maintaining compatibility can be a complex task. Nonetheless, it is a key consideration in mitigating security and failure risks to IT systems from the underlying components.

IT Software Standards take into account average vendor release cycles, as well as the need to minimize incompatibility risks with underlying components. Software asset upgrades could be triggered if the asset reaches its maximum age or number of versions behind latest vendor-released version, or based on compatibility drivers and considerations (e.g. hardware upgrades).

D.4.2 IT Investment Planning

IT Investment planning is the process of developing a five-year program of prioritized investments, including a detailed plan for the first year. Toronto Hydro's IT Investment Planning Process is divided into two streams: Sustaining Existing Systems, and Enhancement Initiatives.

The primary objective of Toronto Hydro's IT investment planning process is to maintain the IT assets that are required to satisfy optimal IT system reliability and availability. This sustainment stream is intended to provide satisfactory levels of service for customers and the utility, and to mitigate IT-related business and operational risks (e.g. non-compliance and failure impact) in a cost efficient manner.

Enhancement initiatives enable Toronto Hydro to leverage technological solutions to optimize or enhance business operations in order to ultimately deliver greater value to customers, and to maximize compliance with new or modified external requirements from entities such as Measurement Canada, the Ontario Energy Board, and the Independent Electricity System Operator.

D.4.2.1 Sustaining Existing Systems

The scope and timing of IT sustainment investments is based on IT Standards and asset specific information that Toronto Hydro stores in its electronic IT assets inventory system. The utility relies on this information to make investment decisions based on structured and up-to-date IT asset information, including: hierarchy of assets and interdependencies; key dates in each asset's lifecycle; vendor, contract and license information; and capacity planning data.

Failure impact or rather IT system criticality is the main consideration that Toronto Hydro takes into account in determining the priority of the investments. Priorities are also influenced by internal program dependencies, asset type complexity, and resource balancing.

In making IT investment planning decisions, Toronto Hydro may also consider additional factors relating to general business growth and associated increased IT requirements, such as process

re-engineering, historic trends of current assets capacity versus utilization by existing information technology systems.

D.4.2.2 Enhancement Initiatives

Further to its commitment to continuous improvement, Toronto Hydro regularly evaluates and considers opportunities to enhance business processes based on new IT solutions.

Prior to investing in new IT systems, Toronto Hydro follows an evaluation process to help ensure that the utility makes well-informed decisions relating to new IT investments. That process includes the following steps:

1. Evaluate: The utility validates the proposed initiative, and works with the relevant business unit(s) to determine the project scope, business requirements, current state business processes, future state business processes, the options to achieve the future state and the preferred approach, costs and benefits.
2. Align: Toronto Hydro reviews the proposed project to help ensure the following:
    - Governance, due-diligence, rationale and accuracy of the project costs and benefits
    - Strategic alignment with Toronto Hydro's objectives (e.g. value for money)
    - Alignment with Toronto Hydro's risk profile (e.g. cyber security)
3. Prioritize: Toronto Hydro prioritizes the project based on a combination of factors, including project dependencies, costs, benefits, strategic alignment and risk assessment.
4. Execute: Project execution typically consists of the following steps:
    - Gathering more detailed user and technical requirements;
    - Mapping the relevant business processes;
    - Developing and/or procuring the application as needed;
    - Provisioning the infrastructure to host the application;
    - Configuring the application(s) to meet the business requirements;
    - Testing the application for compatibility with Toronto Hydro's infrastructure;
    - Engaging users to test that the application meets their business and functional requirements;
    - Training the users about the features and functionality of the application; and
    - Implementing the application across the appropriate utility departments

D.4.3 Five-Year IT Investment Plan

The output of Toronto Hydro's IT Investment Planning process is a five-year IT Investment Plan that, 1) is expected to deliver optimal levels of IT system reliability and availability, 2) complies with the utility's IT Standards and asset management practices, and 3) mitigates risks related to IT assets in a cost efficient manner.

Toronto Hydro's five-year IT Investment Plan for 2015-2019 period includes the following capital investment programs:

TABLE 1: IT INVESTMENT PLAN SUMMARY

Capital Investment Program	Execution Time Frame	Evidence Reference
IT Hardware Refresh Program	2015-2019	Exhibit 2B, E8.04
IT Software Program	2015-2019	Exhibit 2B, E8.05
Enterprise Resource Planning (ERP) Program	2015-2016	Exhibit 2B, E8.06
Voice Radio System Upgrade Program	2015-2016	Exhibit 2B, E8.07

In developing this plan, Toronto Hydro has also considered IT industry best practices, vendors' information, distribution capital program growth and overall business growth as well as historic trends of evolving regulatory requirements. Based on the overall schedule and cost estimates contained in the Five-year IT Investment Plan, the utility develops a detailed plan for the next year (i.e., 2015), which lists, prioritizes, and tracks all the key investment initiatives while in execution.

Toronto Hydro requires flexibility over the five year period to execute its IT capital investment plan. This includes flexibility to manage externally-driven risks, such as the risk that vendors may increase software/ hardware costs over the 2016 to 2019 period or change the release dates for certain applications. Both of these events could affect the cost, timing and pacing of a program in a given year.

In addition, Toronto Hydro requires flexibility because it cannot predict the timing of changes to regulatory requirements from regulatory bodies such as the OEB, Measurement Canada and the IESO. For example, the OEB recently initiated a Policy Review of Electricity and Natural Gas Distributors' Residential Customer Billing Practices and Performance (EB-2014-0198) which could result in a number of significant changes (e.g. the implementation monthly-billing) to the customer billing system.

Furthermore, the technology landscape evolves at a fast pace with new products frequently entering the market. If new technologies that are relevant to Toronto Hydro become available in the 2015 to 2019 period, Toronto Hydro plans to evaluate these new technologies. The five-year Investment Plan could be affected if Toronto Hydro determines that any of these technologies would be beneficial to its operations or would maximize the value of its IT assets.

Subject: Standards Review Study Report

Dear Mr. Turk:

I am pleased to present the enclosed Standards Review Study Report for Toronto-Hydro Electric System Limited. Our report reflects knowledge and responses gained from U H Y L H Z L Q J 7 + (6 / ¶ V documented Standards, in-person interviews, and conference calls that were conducted throughout our review.

Respectively submitted,

Erik S. Sonju
Vice President, Power Delivery Planning and Design
Power System Engineering, Inc.

1 ,QWURGXFWLRQ

1.1 3XUSRVH

Toronto-+\GUR (OHFWULF 6\VWHP)/LPLWHG is the largest municipal electrical distribution company in Canada, serving approximately 719,000 customers in the City of Toronto. THESL is the result of six different utilities that amalgamated on January 1, 1998. This amalgamDWLRQ QHDUO\ WULSOHG 7RURQWR +\GUR¶V FXVWRPHU With any merger or acquisition of different companies, there is always the challenge of integrating standards and practices. Nonetheless, THESL has been progressing toward the implementation of the best standards, practices, and processes KHUHLQ UHIHUHQFHG DV ³6 from the previous six utilities and creating a single comprehensive set that promotes the principles of safety, reliability, and efficiency, while applying industry best practices.

In 2010, THESL re-structured its Standards Department and charged it with the major undertaking of HVWDEOLVKLQJ UHILQLQJ DQG PDLQWDLQLQJ WKH the design, materials, construction, and maintenance of the electric distribution system infrastructure. The department is very near the completion stage of a significant task that involves the review and renovation of all major Standards used by 7+(6/¶V engineering and operations personnel. Before fully deploying the results of their efforts, the department determined that there would be value in hiring an outside independent party to review what has been assembled as a method to ensure that the Standards fall within typical industry practices and promote the previously mentioned principles.

Subsequently, 3RZHU 6\VWHP (QJLQHHULQJ, Inc. was retained by THESL on October 21, 2013 to conduct this independent review, of which the results are summarized within this report. The review consisted of interviews with key individuals in the Standards Department and examination of the various Standards that have and will be deployed across the Company. The IRFXV WKURXJKRXW WKH UHYLHZ SURFHVV ZDV WR DGYRFDWH WKH GHWHUP principles of safety, reliability, and efficiency, as well as follow industry best practices. The review itself was intended to be conducted at a high level, while still being comprehensive enough to acquire a thorough understanding of THESL¶V standards.

1.2 6WXG\ 6FRSH

The scope of this study focuses on the review and evaluation of four major Standards that heavily influence the design, construction, and maintenance of the THESL¶V electric distribution infrastructure. These four Standards, illustrated in Figure 1, include the Standard Design Practices, the Distribution Construction Standards, the Equipment Approval Process, and the Job Planning Process. Each Standard has a specific focus, yet the four Standards complement each other, creating a comprehensive process for all future activities performed by THESL.

Each Standard is further defined and discussed in later sections of this report.

Figure 1 ±THESL Standard Documents

As earlier indicated, the four Standards were reviewed and evaluated on a number of factors.

- The Standard Design Practices (SDP) document was reviewed to determine if design philosophies and guidelines follow industry best practices.
- The Distribution Construction Standards (DCS) were reviewed to determine if installations are optimized in terms of safety, reliability, and efficiency.
- The Equipment Approval Process was reviewed to determine the existence of an orderly process for selecting cost-effective materials that also optimizes safety and reliability.
- The Job Planning Process was reviewed to determine proper overall quality control of the implementation of the previously mentioned Standards.

All Standards were reviewed in comparison to similar electrical distribution utilities in North America that serve highly dense urban areas with a significant amount of underground infrastructure and network systems, as well as an influence of overhead facilities.

1.3 $SSURDFK

Based on the volume and the type of information LQFOXGHG LQ 7+(6/PSE 6WDQGL assembled a team of industry experts. The experts at PSE specialize in electric distribution systems, but lack a thorough understanding of underground civil and structural infrastructure, such as vaults and manholes. As such, PSE subcontracted with LHB, a multi-disciplinary engineering, architecture and planning firm, headquartered in Duluth, MN, to focus on the underground civil and structural related Standards.

The following industry experts participated in this review:

- **Erik S. Sonju** *(PSE Vice President ±Power Delivery Planning & Design)*
  Erik is a licensed professional engineer in 16 U.S. States and has over 15 years of experience with electric utilities, with the majority of those years providing professional engineering consulting services to electric power utilities throughout the United States and Canada. His expertise includes transmission and distribution planning, system protection and sectionalizing, transmission and distribution design, power quality investigations, expert testimony and project management.

- **Darren Westby** *(PSE Manager of Substation Design & Distribution Planning)*
  Darren has over 20 years of experience supporting electric utilities with protection and sectionalizing, system planning, substation design, distribution and transmission line design, power quality investigations, connection of large loads, and project management.

- **Duane E. Craig** *(PSE Senior Engineering Consultant)*
  Duane is a licensed professional engineer in the states of Iowa, Minnesota, and Wisconsin and has over 35 years of experience in the areas of electric utility system planning, overcurrent protection, metering, distribution system design, distribution system operation, distribution generation, electric system interference mitigation, and writing equipment specifications.

- **Michael H. Mezera** *(PSE Manager of Line Design)*
  Mike is a licensed professional engineer in the State of Wisconsin and has over 5 years of experience with transmission and distribution line design including development of line design standards, identification of line corridors, development and review of plan and profile drawings and staking sheets, structure loading calculations, conductor sag and tension tables, and material specifications.

- **Steve Hall** *(PSE Senior Designer)*
  Steve is a licensed designer of engineering systems in the State of Wisconsin and has over 25 years of experience with electric cooperative, municipal, and investor owned utilities. Steve has designed, staked, and overseen construction of distribution and transmission line installations.

- **Michael D. French** *(LHB Senior Civil Project Engineer)*
  Michael is a licensed professional engineer in the states of Michigan, Minnesota, North Dakota and Wisconsin and has over 15 years of experience in planning, permitting, design, construction administration, and project management of civil infrastructure projects. He has provided a broad range of civil engineering services for pulp & paper, electric utility, mining, and manufacturing operations.

- **Alan J. Vorderbruggen** *(LHB Structural Engineer)*
  Alan is a licensed professional engineer in eight U.S. States and has over 25 years of experience in structural and civil engineering design and project management.

He has extensive experience in all structural and civil work associated with electrical substations and transmission lines, including structure design, structure spotting, plan and profile drawings, foundation design, specifications, grading plans and general project management.

Each of the abovementioned reviewers focused on the areas of his particular expertise. The review was conducted at a high level with the intention of putting more focus on those Standards that were rated as having a greater deviation from the industry and a higher level of impact on cost, reliability, or safety.

One aspect of the review considered how the Standards are X Q L T X H W R 7 + (6 / ¶ V V \ V W common with industry-wide practices. For Standards found to be unique, the reviewers identified how greatly they deviated from the industry in terms of impact on capital costs, electric infrastructure reliability, and public and worker safety. While all Standards were reviewed, a greater focus and allocation of time was given to those Standards involving design and construction, as these have a greater influence in the abovementioned areas. Along with this approach, the reviewers explored the differences between infrastructure required for metropolitan downtown areas versus suburban and rural areas, and how this applies to THESL ¶ V Standards collection.

In addition to the review of documented Standards as discussed above, an onsite interview of key personnel in the Standards Department was conducted to gain a general understanding of THESL ¶ Vapproach to Standards development and implementation. Following the onsite interviews, there were two conference calls that focused on addressing specific questions and comments from the reviewers that arose during the evaluation period.

2 *HQHUDO2EVHUYDWLRQV

A number of general observations were obtained during the review process.

First, the Standards Department at THESL consists of professionals who have previous experience with outside entities, which has brought the Department various levels and types of expertise. The Department also consists of professionals who have a long-term relationship and understanding of the downtown Toronto electric distribution system. This blend of outside experience and internal knowledge is personified by a diverse group of professionals with the breadth and depth of knowledge that is needed by WKH WUXVWHHV RI WKH &RPSDQ\¶V

Second, the Department¶V engineers also continue to gain industry knowledge by engaging and participating in various associations, forums and initiatives.

One example of this is THESL¶V participation in the Institute of Electrical and Electronic Engineers (IEEE) and Canadian Standards Association (CSA) working groups. IEEE is FRQVLGHUHG WR EH WKH ZRUOG¶V OHDGLQJ professional association that serves technical professionals globally. IEEE has a Standards Association that offers a library of current standards in the electrical industry. THESL is a subscriber to IEEE Explore, which provides web access to all IEEE standards. The Canadian Standards Association is a non-profit standards organization that develops industry standards across 57 areas of specialization, with electrical standards being one area of expertise. CSA develops, updates, and sells standards through their Standards Store. THESL has a significant library of such CSA Standards. THESL is also currently engaged with CSA industry initiatives and committees, currently serving on the Technical Subcommittee for Transformers and the Technical Subcommittee for Reliability Based Design. By participating in both IEEE and CSA initiatives and activities, THESL is actively and continually exposed to the development of standards both locally and globally.

THESL is also actively involved with the Utilities Standards Forum (USF) as well as an Inter-Utility Forum. The USF is an organization representing approximately 50 Ontario electric distribution companies. Its goal is to collaboratively define standards for its members and reduce duplication of efforts. The USF has developed design standards for electricity distribution that meet the requirements of Ontario Regulation 22/04 under the Electricity Act of 1998. The Inter-Utility Forum is made up of a small group of utilities including Enersouce Hydro Mississauga, Veridian Connections, Peterborough Utilities Group, Horizon Utilities, and London Hydro. 7+(6/¶V LQYROYHPHQW and will continue to be crossKDV to coordinate concepts and ideas with other Ontario-based utilities.

THESL is also a member of the Centre of Energy Advancement through Technological Innovation (CEATI International). CEATI International is a user-driven organization that provides technology solutions and training to electrical utility participants. CEATI International is driven by over 120 organizations, including electric utilities, governmental agencies, and research-based organizations. THESL can benefit from this membership by looking to CEATI International as a research and development aid that will help keep personnel current with new technologies, as well as solidify their understanding of existing technical concepts. Information

gleaned from CEATI , Q W H U Q D W L R Q D O ¶V Work and reports can be applied to new and revised THESL Standards.

Third, THESL has a substantial assembly of documented Standards that is equal to, or exceeds, those that are used by similar large electric distribution utilities in North America. 7 + (6 / ¶ V Distribution Construction Standards (DCS) consist of approximately 1200 individual standards. In addition, 7 + (6 / ¶ V 6 W D Q G D U G ' H V L J Q 3 U D F W L F H V (SDP) Document consists of approximately 140 pages conferring the standard practices to be used by designers.

PSE and LHB reviewed and evaluated approximately 1000 of the 1200 individual standards that make up the DCS. As explained by THESL, the 1000 standards reviewed are intended to be applied to new construction across THESL ¶V system. The remaining 200 standards that were not reviewed are representative sketches of unique installations that are being kept on file for reference. This group of 200 sketches also includes obsolete construction methods, such as box construction, that exist in the field but are no longer applied to new installations. These particular standards are only kept on file for maintenance of existing facilities.

PSE and LHB reviewed and evaluated the SDP document in its entirety.

Finally, thr R X J K W K H U H Y L H Z R I 7 + (6 / ¶ V 6 W D Q G D U G V, D Q G L Q W H U Y with key personnel, it was commonly noted that the Standards Department and associated stakeholders consider the aspects of reliability, cost, and safety when developing, modifying, and carrying out their Standards.

3 6WDQGDUG 'HVLJQ 3UDFWLF

The Standard Design Practices (SDP) document confers 7 + (6 / ¶ V standards as they relate to the design of the electric distribution system.

The SDP document was found by PSE and LHB to be thorough, well documented, and consistent with what is seen in the industry throughout North America as best practices. Only minor comments and questions resulted from the review.

Overall, the standards and specifications contained in the SDP would not be perceived as insufficient or excessive. The SDP address safety and also make accommodations for design and construction considerations that have the goal of managing construction costs, system reliability or otherwise providing construction flexibility.

Generally, civil execution costs are necessarily high simply because the work generally takes place underground, which requires not only excavation of soil, but working around other ground-based infrastructure. The SDP do not appear to make civil construction costs any more significant that they would otherwise be. Certainly there are safety and durability conditions that need to be met, but the requirements set forth in the SDP document do not force the costs to be artificially high compared to typical civil work.

Reliability is the persistence of the system to be able to operate in adverse conditions and under peak demands. 7 + (6 / ¶ V U H V S R Q V L E L O L W \ L V W R H Q V X U H W K D W L W robust and electrically adequate to meet the requirements of its customers who depend on its reliability. The established specifications in the SDP address specific measures to ensure the reliability of both below grade and above grade assets, but in general, once these are constructed (per the specifications) there is little impact on day-to-day electric infrastructure reliability. However, if the infrastructure components are not installed properly, failure could result in impacts to power delivery (if a vault structure were to fail), or a potentially serious safety incident (if conduits were not properly encased in concrete and struck during later excavation work).

With all electric power facilities, the nature of electricity has a component that requires safeguarding from the public and workers. The SDP accomplish this by complying with local codes and best utility practices, ensuring a high level of public and worker safety in the constructed elements. Examples include confirming duct locations during the design stage using test holes or taking into consideration children play areas and traffic exposure in identifying new transformer locations. However, the Standards do not appear to incorporate provisions that are above and beyond generally accepted construction and industry standards with regard to safety.

While every industry has its own unique infrastructure considerations, the items detailed in THESL ¶ V standards are generally common for electric utilities that provide service within dense urban and metropolitan settings. For example, there are specifications that address open trench construction and trenchless/directional drilling construction methods. These apply to power conduits as much as they may apply to sewer or water utility construction within a metropolitan environment. The cast-in-place and precast concrete vaults and chambers also have specific

roles relative to THESL, but are common utility components. THESL also loops the vast majority of feeders and taps, which is both beneficial in terms of reliability and also justifiable due to the close proximity of feeders in a dense load center area. Lastly, there are two separate sections that address duct banks crossing under railroads. Certainly this applies to a power utility in a major metropolitan area, but the requirements for depth of burial and filling void spaces with grout are standards that would be applied in many locations for any type of utility crossing below a set of tracks.

There are a few sections of the SDP that make particular reference to compliance with City of Toronto specifications, which would be a condition unique to THESL. One example of a reference to the City of Toronto is in Section 3.2 of the Standard Design Practices, which addresses General Design Considerations ±Civil. Paragraphs 3.2.1.1, 3.2.1.2, and 3.2.2.1 refer to restrictions and clarifications to be I R X Q G L Q W K H & L W\ Municipal Consent R U R Q W R ¶ V Requirements, specifically for new streets, horizontal and vertical clearances, and excavation and backfill. Another example of a reference to the City of Toronto can be found in Paragraph 4.2.2.1.3, which U H D G V ³' H V L J Q H U V D U H W R U H I H U ± Development O D W H V Infrastructure Policy & Standards (DIPS). ´ The DIPS document is referenced in several other locations as well. There are several other specific references specific to the City of Toronto, similar to the abovementioned sections, but beyond these references, the Standards are fairly common.

The main differences in an electric infrastructure required for a major metropolitan downtown compared to suburban or rural settings include utility installation method (open cutting when space is available compared to trenchless construction in metropolitan areas to minimize surface disturbance and restoration costs), the number of spare conduits to accommodate future needs, setbacks from lot lines, road centerlines (again, a function of suburban or rural areas simply having more space), network systems, multiple overhead circuits, and the need to work around foreign utilities.

Overall, the approximately 140 pages that make up the SDP were found to be what is expected with electric distribution utilities that have similar service areas and environments.

4 'LVWULEXWLRQ &RQVWUXFW

The Distribution Construction Standards (DCS) provide Standards applicable to construction of the THESL electric distribution system.

Similar to the SDP, the DCS were found by PSE and LHB to be thorough, well documented, and consistent with what is seen in the industry throughout North America. Only minor comments and questions resulted from the review.

In general, the DCS follow industry-wide practices that are standard for overhead framing. Standard installation configurations are also used for underground construction. The DCS reference standard materials that are commonly used throughout the industry for both overhead and underground construction.

The DCS were found to be acceptable as shown, subject to several minor suggested modifications that have been discussed with the THESL staff. Overall, the construction assembly configurations would not be perceived as difficult for an installing contractor to understand. The Standards appear to address design and planning considerations, constructability issues, and flexibility to accommodate field conditions. They also provide appropriate consideration to environmental safety (ex. the use of Petro-Plug devices on chamber drains, and the beneficial reuse of concrete transformer pads).

Very few and minor deviations from what may be considered industry-wide standards were noted during the review and evaluation. Of those noted, the deviations were either reasonably justified by THESL due to local conditions and codes, or were undertaken for review and modification by THESL. For example, split bolt connectors were listed in some of the Standards. It was suggested that minimal use of split bolt connectors be considered for overhead tap connection. Because of the design, split bolt connectors are more likely to fail under high electric current loads. THESL indicated that Ampact connectors are normally used and that the split bolt connectors are only used when the situation is such that the Ampact, or perhaps a squeeze-on connector, cannot be utilized.

Although it is generally minor, the most noteworthy deviation from the industry found throughout the DCS is THESL ¶ V exclusive use of Western Cedar poles. Through our experience, Western Cedar poles are generally superior to most other wood pole species; however, it is not uncommon for distribution systems to consist of other wood species of lower cost. During the course of the review, THESL explained that they prefer cedar wood for poles because cedar is generally more uniform in dimension, easier to climb, and lightweight. These beneficial factors, as well as the life longevity of Western Cedar, may very well offset the typically higher cost. Through discussion, THESL agreed that it would be appropriate to perform a comparison review of other wood species such as Northern Red and Southern Yellow Pine to determine if Western Cedar continues to be the best option in terms of cost, safety, and reliability.

Overall, the approximately 1000 standards reviewed that make up the DCS were found to be neither excessive nor delinquent in terms of construction for a distribution system with a focus on reliability, safety, and cost efficiency.

5 (TXLSPHQW $SSURYDO 3URFH

THESL has two approval processes for equipment. One is the approval process for major equipment while the other is for non-major equipment.

Major equipment includes items that: are generally higher in cost on a per unit basis, result in significant cost based on the quantity of units annually installed, have a significant impact on system performance and reliability, or have a significant impact on safety. Examples of major HTXLSPHQW LGHQWLILHG LQ 7+(6/¶V HTXLSPHQW DSSURYDO SU

- Conductors
- Poles
- Insulators
- Breakers and Switches
- Transformers

In addition, non-major equipment includes items that support the operation, but are not directly part of the distribution system, as well as items that have received electrical equipment approval from a recognized certification organization accredited by the Standards Council of Canada. Non-major equipment can also be accepted if it is considered approved by a significant portion of the electric utility industry in North America. THESL refers to these items as Good Utility Practice equipment. Examples of non-PDMRU HTXLSPHQW LGHQWLILHG LQ 7 approval process include:

- Sump Pumps
- SCADA Equipment

,Q ERWK FDWHJRULHV 7+(6/¶V approval process provides a reasonable degree of assurance that products applied to the system are safe and reliable. For instance, items that fall under the major equipment category must adhere to THESL technical specifications. These specifications, that are all reviewed and approved by a THESL professional engineer, include industry standards and qualifying tests amongst other elements. Non-major equipment must either be pre-approved by a recognized certification organization, or have a proven historical record of successful use in the industry. Anything falling short of these qualifiers may only be used on a trial basis and after adequate supporting documentation illustrated that the equipment is suitable for a specific application.

THESL also provides an environment in which employees can submit a request to add or change material to their inventory of approved equipment. This approach is encouraging to see. It allows for maximum input on possible improvements through the type of equipment used on the system, as well as fosters a culture that values input from all personnel which pays dividends by standards being supported and followed. When an employee submits a material change request, a change code is identified. The change codes include: safety, code compliance, assembly feasibility, quality improvement, process improvement, new technology, environment, material issue, labor issue, cost reduction, stock reduction, and harmonization. These codes demonstrate

that THESL is consciously working toward constant improvement under the principles of safety, reliability, and efficiency.

Prior to acceptance of new material, THESL conducts an extensive evaluation process that includes the review by stakeholders representing various functions in the company. Stakeholders involved in this process include representatives from Standards, Supply Chain, Quality & Compliance, and Operations. Material is ranked in a scoring matrix by the level of adherence to THESL technical specifications, price, lead time V P D Q X I D F W X U H U ¶ V I L Q D Q F L D O V terms, ISO 9001 certification, quality control and inspection, reliability and failure rate, ease of installation, size and handling, and durability. This process provides a high degree of certainty that the best products are properly evaluated for selection.

6-RE 3ODQQLQJ 3URFHVV

As with any documented standard, the standard must be followed in order to be effective. The IRXUWK GRFXPHQW WKDW 36(UHYLHZHG LV 7+(6/¶V 6-RE 3ODQQ document, discussions during the on-VLWH LQWHUYLHZV PDGH LW FOHDU WK taken seriously, observed, and verified through quality assurance measures.

As can be expected, this process requires collaboration amongst various departments and personnel from the conception of a job to finalizing its documentation after implementation. There are many facets to the purpose of the process; however, four stand out in terms of the adherence to Standards. These include:

- To endorse the use of only certified construction standards, specifications and approved Standards Design Practices in the assembly of project drawings.
- To ensure that construction is consistent with approved project drawings and that only approved equipment is used.
- To ensure that non-standard construction is certified by a professional engineer.
- To ensure that new construction to the distribution system is inspected and certified prior to putting the distribution system into use in accordance with THESL¶V &RQVWUXFWLRQ 9HULILFDWLRQ 3URJUDP

7KH YDOXH RI WKH DERYH VWDWHG SXUSRVHV LQ 7+(6/¶V -RE quality control when it comes to the implementation of the Standard Design Practices, Distribution Construction Standards, and the use of approved major and non-major equipment. The overall responsibility of adopting the process falls to the corresponding business unit Vice Presidents while the responsibility of implementation and execution falls to the Business Unit Managers and Supervisors, respectively. Being that these levels of responsibilities are clearly stated in THESL¶V -RE 3ODQQLQJ 3URFHVV LOOXVWUDWHV WKH FRPS followed.

Through the interview process, the following was noted:

Designs on the THESL distribution system are completed by certified design technicians who are trained and familiarized with both the Standard Design Practices and Distribution Construction 6WDQGDUGV 7KHVH WHFKQLFLDQV DUH DOVR ZHOO NQRZQ WKURXJKRXW WKH Department provides face-to-face training, as well as training through internally published bulletins that are sent out periodically. THESL has also developed various tools, such as a guying model, that are made available to design technicians that help assure that installations meet standards and are consistent amongst designers. Design technicians are accountable to follow standards, use provided tools (ex. guying tool), and properly document their design for supervisor approval.

E1 SUMMARY

E1.1 Overview of Capital Expenditure Activities

As explained in Section D, Toronto Hydro's AM Planning Process consists of three key stages: Long-Term Planning, Short-Term Planning & Maintenance Planning, which collectively result in the creation and development of capital expenditure plans and associated investment programs.

Toronto Hydro's Long Term Planning processes led to the creation of the 2015-2019 Capital Expenditure Plan (summarized in Section D1.2.1 and explained in detail in Section D3.1.1). This process produced a series of investment approaches and execution strategies (described in detail in Section E2.1). Based upon the selected investment approach and execution strategy, Toronto Hydro generated three forms of capital investment programs, including

(i) "**Core" asset renewal programs**: This area of investment is made of in-kind replacement of assets reaching or exceeding their end-of-life or economic end-of-life criteria.

(ii) **Programs managing system-wide critical issues**: This includes those broader investments of the utmost urgency, designed to target issues that go "beyond the asset", such as load growth and contingency constraints, operational flexibility and accessibility, safety and security of supply issues.

(iii) **Programs that continue to manage necessary day-to-day operational investments**: This includes necessary mandatory day-to-day investments that support the 24/7 operations of Toronto Hydro, including customer-service requests, mandated service obligations, capital and maintenance support.

The utility positioned these investment programs into one of the following four investment categories prescribed by the Ontario Energy Board's (OEB) Chapter 5 *Filing Requirements for Electricity Transmission and Distribution Applications (July 17, 2013)*[1]::

- System Access Investments (Section E5)

[1] Ontario Energy Board, Filing Requirements for Electricity Transmission and Distribution Applications, (Toronto: Ontario Energy Board, 2013). ["OEB Filing Requirements"]

- System Renewal Investments (Section E6)
- System Service Investments (Section E7)
- General Plant Investments (Section E8)

Toronto Hydro categorized each investment program as one of four investment categories, based upon:

- Alignment between program scope and the investment category definition
- Trigger driver associated with this program

Short Term Planning processes (summarized in Section D1.2.2 and explained in detail in Section D3.1.2) were then executed in order to produce discrete projects for the 2015 year for each of the produced investment programs.

E1.2 Expenditure Summary Tables

This section provides breakdowns of the investments contained within Toronto Hydro's Distribution System Plan (DSP) based upon investment categories and drivers.

E1.2.1 Expenditures by Investment Category

Table 1 shows the capital expenditure for the 2015-2019 period for each category. The System Renewal category has the highest spending of around $1.26 billion ($250 million annually) due to Toronto Hydro's continual renewal and replacement of aging distribution assets. The other CAPEX category has the lowest spending of around $147 million ($29 million annually) as it includes costs related to Engineering Capital, Road Cuts, Allowance for Funds Used During Construction (AFUDC), Major Tools and inflation. Section 4.2 provides the details around the spending profiles for all these categories and the major variances within them along with the inter-relationships between each of these elements. In addition, Sections E5-E8 provides the details of the capital programs in these categories.

TABLE 1: CAPITAL INVESTMENT BY CATEGORIES

CATEGORY	Forecasted Spend ($M)						
	Avg.	2015	2016	2017	2018	2019	Total
System Access	$91.29	$86.13	$93.54	$100.93	$90.41	$85.47	**$456.47**
System Renewal	$251.73	$251.74	$234.99	$246.35	$260.08	$265.49	**$1,258.64**
System Service	$66.41	$76.45	$69.60	$62.51	$49.54	$73.95	**$332.05**
General Plant	$58.60	$104.63	$99.44	$28.93	$32.13	$27.88	**$293.01**
Other CAPEX	$29.86	$12.18	$21.22	$28.65	$37.89	$49.37	**$149.31**
Total	**$497.90**	**$531.13**	**$518.79**	**$467.36**	**$470.05**	**$502.16**	**$2,489**

/C

E1.2.2 Expenditures by Investment Drivers

Table 2 shows the capital expenditure for the 2015-2019 period for based on the primary drivers. The three primary drivers with the highest investment are failure risk, functional obsolescence, and customer service requests. The combined investments for these drivers is approximately $1.45 billion due to the System Renewal and System Access programs such as Overhead and Underground Circuit Renewal, Box Construction, Rear Lot Conversion, Customer Connections and Externally Initiated Plant Relocations and Expansion. Conversely, the three primary drivers with the lowest investments are Safety, System Efficiency and Reliability. However, it should be noted, as seen in Table 3, both Safety and Reliability are secondary drivers for 29 and 18 programs respectively.

TABLE 2: CAPITAL INVESTMENT BY PRIMARY DRIVERS

Drivers	Forecasted Spend ($M)						
	Avg.	2015	2016	2017	2018	2019	Total
Customer Service Requests / Third Party Requests	$71.27	$55.31	$71.74	$82.94	$76.58	$69.77	**$356.34**
Mandated Service Obligations	$20.03	$30.82	$21.80	$17.99	$13.83	$15.69	**$100.14**
Functional Obsolescence	$82.81	$80.61	$105.54	$78.31	$75.05	$74.54	**$414.05**
Failure	$33.10	$31.90	$32.71	$33.11	$33.61	$34.18	**$165.51**
Failure Risk	$146.07	$156.91	$130.31	$134.93	$151.42	$156.76	**$730.33**
Safety	$15.11	$16.50	$13.73				**$30.22**
Reliability	$13.07	$10.97	$9.38	$13.83	$13.81	$17.36	**$65.35**
System Efficiency	$12.99	$11.68	$16.20	$11.58	$13.23	$12.24	**$64.93**
Capacity Constraints	$38.39	$43.98	$44.02	$37.10	$22.50	$44.35	**$191.94**
System Maintenance & Capital Investment Support	$44.27	$80.26	$52.14	$28.93	$32.13	$27.88	**$221.35**
Other	$29.86	$12.18	$21.22	$28.65	$37.89	$49.37	**$149.31**
Total	**$497.90**	**$531.13**	**$518.79**	**$467.36**	**$470.05**	**$502.16**	**$2,489.48**

E1.3 Forecasted System Development

Toronto Hydro recognizes that Toronto's development and infrastructure growth will have an impact on the electrical distribution grid. Load growth is experienced in certain areas of the grid which is based on land development such as condominium buildings being constructed. This growth will likely have an impact on Toronto Hydro's peak demand, as is detailed in section E1.3.1. Toronto Hydro's smart grid development is expected to help the utility respond to the increase in load growth and will provide relief to pockets of the distribution grid under heavy demand. Various programs are planned to support aging infrastructure and the increase in load growth, as described in section E1.3.2. In 2015-2019, the forecast system development will accommodate over 625 MW of distributed generation (DG) connections to Toronto Hydro distribution system. The total capacity of Renewable Energy Generation (REG) connections on the Toronto Hydro system is expected to reach 202 MW by the end of 2019 (see section E1.3.3). In order to accommodate the REG projects for the forecasted development period, Toronto Hydro requires the Generation Protection Monitoring and Control program (section E5.5) to be implemented. In short, Toronto Hydro has programs planned to accommodate the growth in its distribution system to provide more benefit to customers and Toronto Hydro.

E1.3.1 Load and Customer Growth

Based on Toronto Hydro's database of pending customer connection requests, Toronto Hydro planners anticipate annual load growth of approximately 4.0% (gross) across the entire service area between 2013 and 2015. Beyond that, based on historical growth rates, Toronto Hydro forecasts annual system wide load growth rate of 1.3% (gross) between 2015 and 2019. Refer to section D3.1.2.1 for more details regarding the bus peak load forecasting process. Toronto Hydro currently serves approximately 733,000 customers. Peak system load in 2013 was 5378 MVA.

A forecast of anticipated distributed generation (DG) connections includes both non-renewable generation sources, such as gas powered generators, and Renewable Energy Generation (REG) sources, such as solar photovoltaic or wind turbines. By the end of 2014, a total of 176.2 MW (nameplate capacity of DG) is expected to be connected to Toronto Hydro's system. This will be comprised of a combination of Feed-In Tariff (FIT) projects, Combined Heat and Power (CHP) resources and other distributed generation. The impact that distributed generation resources have on peak demand is less than the nameplate capacity (as there is no guarantee that it will be operating at 100% rated output coincident with system peak demand). That said, Toronto Hydro expects that distributed generation resources will continue to put downward pressure on future load demand growth at a system level.

Load growth is highly localized based on land development and the economic circumstances of existing customers. The relatively high system load growth of 4% anticipated between 2013 and 2015 is primarily driven by a significant amount of condominium and office tower development, and construction of large, electricity-intensive data centres. A large share of this activity has occurred and continues to occur in the downtown core, and in pockets of the former Cities of Etobicoke and Toronto. Additionally, there are a number of large infrastructure projects under way to construct electrically powered transit within the City of Toronto. These projects, which range in status from "proposed" to "in construction", include the Eglinton LRT, electrification of the Union-Pearson rail link, the Sheppard East LRT project and the Finch West LRT project.

E1.3.2 Smart Grid Development

Toronto Hydro has various programs that enable the development of smart grid technology within its distribution system. Smart grid technology is expected to enhance customer service by, among other things, allowing Toronto Hydro to reduce outage restoration times for customers. In addition, this technology is expected to help Toronto Hydro manage the impacts of aging infrastructure by increasing the responsiveness of the distribution system. A modern distribution system ultimately delivers value to customers by providing reliable and high quality service. Toronto Hydro expects that a smarter grid will help address current challenges by enabling automated responses to outages, reducing outage restoration times, increasing monitoring on system assets, and allowing better visibility and control for customers over their energy usage.

Programs within this filing that contribute to Smart Grid development include, but are not limited to:

- ***Feeder Automation*** - Facilitating faster and less labour intensive system restoration efforts, thus reducing the impact of trunk outages on customers by isolating faulted sections of the feeder. Section E7.3 provides further details on this investment program.

- ***Overhead Momentary Reduction*** - Providing flexibility to the system, fault protection and improving the distribution feeder reliability performance by limiting outage times and containing the outage to a minimal area. Section E7.4 provides further details on this investment program.

- ***Local Demand Response*** - Providing medium-term capacity relief to the Cecil TS by implementing a targeted and localized demand response strategy which primarily leverages new and existing demand response resources to prudently defer distribution system capital investments. Section E7.10 provides further details on this investment program.

- ***Distributed System Communication Infrastructure*** – Providing a reliable telecommunications system that is the backbone of Toronto Hydro's distribution system. Identifying and rectifying gaps in availability, performance, and functionality in the telecommunications backbone caused by the functional obsolescence of the SONET technology at substations and legacy wireless SCADA platforms for infield SCADA. These planned investments are expected to mitigate the loss of SCADA functionality,

which can increase outage duration. Section E6.22 provides further details on this investment program.

- ***Stations Control and Monitoring*** - Replacing aging and obsolete Radio Transmission Units and installing SCADA systems at substations currently without SCADA capabilities. Section E6.16 provides further details on this investment program.

- ***Metering*** - Enabling Toronto Hydro to meet its mandatory service obligations with respect to revenue metering and wholesale metering. Section E5.1 provides further details on this investment program.

- ***Network Unit Renewal*** – Replacing old and obsolete Network Units with new Submersible Network Units, which possess sensors for enhanced load monitoring capabilities. These capabilities allow power system controllers to visibly assess the condition of these assets at the control centre. Section E6.10 provides further details on this investment program.

- ***Overhead Circuit Renewal*** – Replacing existing SCADAMATE switches using the obsolete Motorola radio communication system (DARCOM radio system and MOSCAD terminals) with new switches utilizing standardized communications technology. Section E6.4 provides further details on this investment program.

E1.3.3 Renewable Energy Generation Accommodation

The *Green Energy and Green Economy Act, 2009*,[2] encouraged the use of new energy generation sources, including solar photovoltaic (PV), biogas and wind power generation, to connect to the distribution system as distributed generation (DG). The existing electric grid was designed and constructed to distribute unidirectional power from large and distant generating stations, through the transmission system to its typical distribution loads. The interconnection of renewable energy and DG sources in general introduces a variety of electricity sources dispersed throughout the distribution grid and places new demands on the present infrastructure.

In response to customer requests, Toronto Hydro has completed over 890 DG connections representing over 110 MW to the distribution grid. The connected DG resources in terms of quantities are mostly solar photovoltaic (PV) facilities, along with some cogeneration (combined heat and power), biogas, wind turbines and closed transition generators. The historical approach,

[2] S.O. 2009, C.12. ["GEGEA"]

with large and distant generating stations linked by transmission systems to distribution systems is adapting to accommodate bi-directional flow from DG sources, which are located in close proximity to distribution loads.

Toronto Hydro anticipates over 625MW of DG will connect to the distribution system by the end of 2019. In terms of total capacity of Renewable Energy Generation (REG), the Toronto Hydro system will be able to accommodate 202 MW by the end of 2019. Currently, there are several immediate and long-term challenges from connecting the forecasted DG to the Toronto Hydro system. These issues as discussed in Section E5.5.3 include:

- Short Circuit Capacity Limitations;
- System Thermal Limits; and
- Limited Load Transfer Capabilities.

In order to accommodate the forecasted amount of DG into Toronto Hydro's distribution system, the following solutions have been identified for the 2015 to 2019 period.

- Installation of advanced protection systems at Leslie TS, Wiltshire TS and Basin TS,
- Installation of a bus-tie reactor at Richview TS, and
- Installation of monitor and control equipment at DG sites throughout the distribution system.

E1.4 Regional Planning Considerations

Three regional planning consultations were considered when developing the Distribution System Plan. The Central Toronto Integrated Regional Resource Plan is in-progress. Needs Screening reports were completed for the Metro Toronto Northern Sub-region and Greater Toronto Area (GTA) North Western Sub-regions respectively.

The Central Toronto Integrated Regional Resource Plan is still in progress but the Ontario Power Authority (OPA) has confirmed a long identified issue of capacity shortfalls in the Runnymede TS, Manby TS and Copeland TS areas. Toronto Hydro has been planning remedies for these shortfalls and has discussed and shared alternatives with the OPA and Hydro One Networks Inc. (HONI) as part of the planning effort. The projects contained within the Stations Expansion capital investment program, further detailed in Section E7.9, reflect the regional planning consultations to date for Central Toronto.

HONI's Metro Toronto Northern Sub-region Needs Screening was completed on June 11, 2014 and is attached in Appendix F6.1. The net demand forecast did not identify any station capacity issues within the study period and no further action is recommended at this time. There is no impact to the Distribution System Plan due to the Metro Toronto Northern Sub-region Needs Screening.

The GTA North North-western region Needs Screening was completed on June 27, 2014 and is attached in Appendix F6.2. Transformer stations and transmission facilities in the Sub-region have sufficient capacity to accommodate the expected load over the study period. There is no impact to the Distribution System Plan due to the GTA North Western Sub-region Needs Screening.

E1.5 Customer Connections Capabilities

Toronto Hydro connects customers based on two types of connections: load growth and distributed generation. Each customer connection type has its own existing capabilities and programs to enhance Toronto Hydro's capacity to handle connections.

Load Growth Customers

Toronto Hydro is obligated to connect residential, commercial and industrial customers through the utility's overhead and underground infrastructure. On average, Toronto Hydro receives over 10,000 requests a year. Toronto Hydro anticipates that the number of customer service requests and the size of the customers requesting connection will continue to trend upwards. This upward trend is reflected in the projected spending over the 2015-2019 period, where Toronto Hydro has taken into account the number of new building permit applications and the forecasted development numbers from the city and commercial developers. The slight depression in 2015 is due to the anticipated slowing in construction projects due to the Pan Am Games being hosted in Toronto during the main construction season. In addition to the baseline amounts, a number of major projects with multi-year construction schedules are considered in the spending forecasts. These projects are considered to be extensive customer connections that require planning and work beyond the typical basic connection and that usually have a defined scope of work entering each budget year.

To help enable the city's continued economic success and its ability to serve the growing population, Toronto Hydro is investing in expanding the capacity of its stations and feeders. Connections include typical work associated with providing customer access to the distribution system such as extending underground cable or the installation of an overhead transformer to supply a new service. Toronto Hydro performs expansion work in order to connect customers when required.

For available capacity to be at hand when connecting new customers, Toronto Hydro's ability to do the necessary work is found in the completion of the following programs:

- Customer Connections (section E5.2)
- Load Demand (section E5.4)
- Station Expansion (section E7.9)

- Externally-Initiated Plant Relocation and Expansion (section E5.3)

The Customer Connections program creates benefits from a customer value perspective by fulfilling Toronto Hydro's obligations to provide prompt service to customer service requests, ensuring a reliable distribution system for all customers while connecting new buildings, and efficiently building the system by considering future load growth where applicable. The Load Demand program enhances customer value by increasing Toronto Hydro's ability to promptly address customer service requests, while also adding operational flexibility to improve system efficiency and to accommodate future load requirements. Upgrades found within the Station Expansion program allow Toronto Hydro to address customer connection requirements and loading by addressing system limitation imposed by existing stations equipment. This program will also alleviate system limitations and allow for new load connections to the distribution grid system. Expansion work, within the Externally-Initiated Plant Relocation and Expansion program, is typically needed for larger industrial or commercial connections, or requests in areas of the city that are capacity constrained. Expansion work involves the installation or upgrade of distribution assets such as new circuits or civil infrastructure that is required to accommodate new customer loading. Without this work, the existing distribution system could not accommodate the customer.

Renewable Generation Customers

As of Q2 2014, Toronto Hydro has responded to over 3,000 inquiries from customers and developers through the Feed-in-Tariff Program (FIT) pre-assessments. A wide-range of proponents have submitted project applications, including many schools, housing, large grocery stores and department stores. Toronto Hydro's present rate of inquiry for individual FIT customers is estimated at 7.5 MW per month spread over 50 inquiries. Schools have received over 300 pending offers to connect renewable generation from the Ontario Power Authority (OPA) with over 40 MW of capacity. Distributed Generation (DG) connections are expected to reach over 625 MW of capacity by 2019. These connections represent an additional 450 MW over the five year planning period.

Figure 1 demonstrates the cumulative forecast scenarios for renewable energy and DG connections, and provides a breakdown of renewable generation programs and their contribution to the overall forecast. Table 4 and Figure 1 provide the total DG capacity forecast which includes DG connected, in progress and projected. There is a significant demand and potential to connect renewable energy sources to Toronto Hydro's distribution system. The key responsibility of Toronto Hydro is to offer enabling options to ensure the ability of the DG projects to integrate

with the distribution grid. Toronto Hydro capability to connect new generation customers will be enabled as outlined in the program description of section E5.5.2.

To enable the forecasted connection of DG, Toronto Hydro proposes a Generation Protection, Monitoring and Control (GPMC) program (section E5.5). The objective of this program is to provide uniform access for connecting the projected DG installations across Toronto Hydro's service territory. The work in this program involves the installation of the following protection, monitoring and control equipment for enabling DG facilities:

- Advanced Protection Systems,
- Installation of Bus-Tie Reactor on the Station Bus, and
- Monitor and Control of DG Projects.

The GPMC program (section E5.5) is instrumental in enabling DG connections within Toronto Hydro's distribution system. Adding advanced protection systems and installation of bus tie-reactor enables Toronto Hydro to connect additional DG where distribution constraints presently exist. Furthermore, the real-time monitoring and control system provides the ability to acquire real-time information of DG's connected to Toronto Hydro and facilitates planning and operating a safe and reliable distribution system.

TABLE 4: DG CONNECTION FORECAST BY MW ACCORDING TO PROGRAM TYPE (2015-2019)

Program	Existing (Includes 2014 Planned)	2015	2016	2017	2018	2019	Total (MW)
FIT 1.0 - 2.0	53.9	31.2	0.0	0.0	0.0	0.0	**85.0**
FIT 3.0 - 7.0	0.0	10.7	23.9	25.8	27.7	29.7	**117.8**
CHP	59.6	35.5	28.2	27.3	24.0	104.0	**278.6**
Other DG	62.7	32.9	18.0	8.0	15.0	8.0	**144.6**
Total	**176.2**	**110.3**	**70.1**	**61.1**	**66.7**	**141.7**	**626.0**

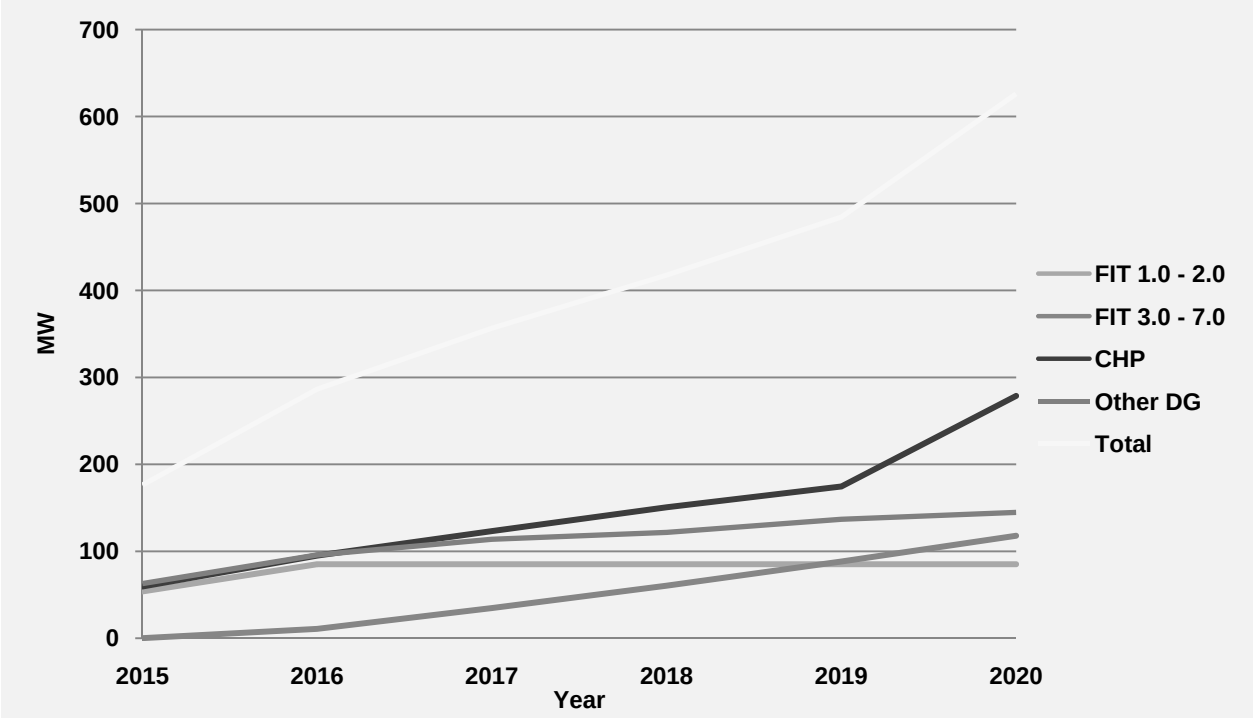

FIGURE 1: GRAPH OF DG CONNECTION FORECAST BY MW ACCORDING TO PROGRAM TYPE (2015-2019)

In accordance with the forecasted grid connected MW, during system peak conditions a projected 185 MW of renewable and clean energy generation will be realized in the next five years, as shown in Table 5.

The peak operation forecast takes into account the effects of DG contribution during system peak conditions. Given the wide range of generation sources and their corresponding capacity, these units typically operate below their maximum rating. Furthermore these distributed energy resources may go off-line due to various factors such as operating, maintenance and other in-service conditions. An operation peak capacity factor was applied for synchronous DG's while accounting for the fact that some DGs may be operating at less than the connected capacity due to various factors such as in-service conditions. A coincident capacity factor was also applied to the solar PV connections to account for solar output given irradiance levels and other factors during system peak conditions. This factor was based on OPA and Toronto Hydro data from simulated and installed connections. For rotating machines, a factor of available DG capacity was estimated to be running to account for maintenance and other contingencies. This five year projection takes into account known and projected renewable and clean energy generation

connections. The projected coincident peak capacity contribution of DG has been estimated at 185 MW.

TABLE 5: DG PEAK OPERATION FORECAST BY MW ACCORDING TO PROGRAM TYPE (2015-2019)

Program	Existing (Includes 2014 Planned)	2015	2016	2017	2018	2019	Total (MW)

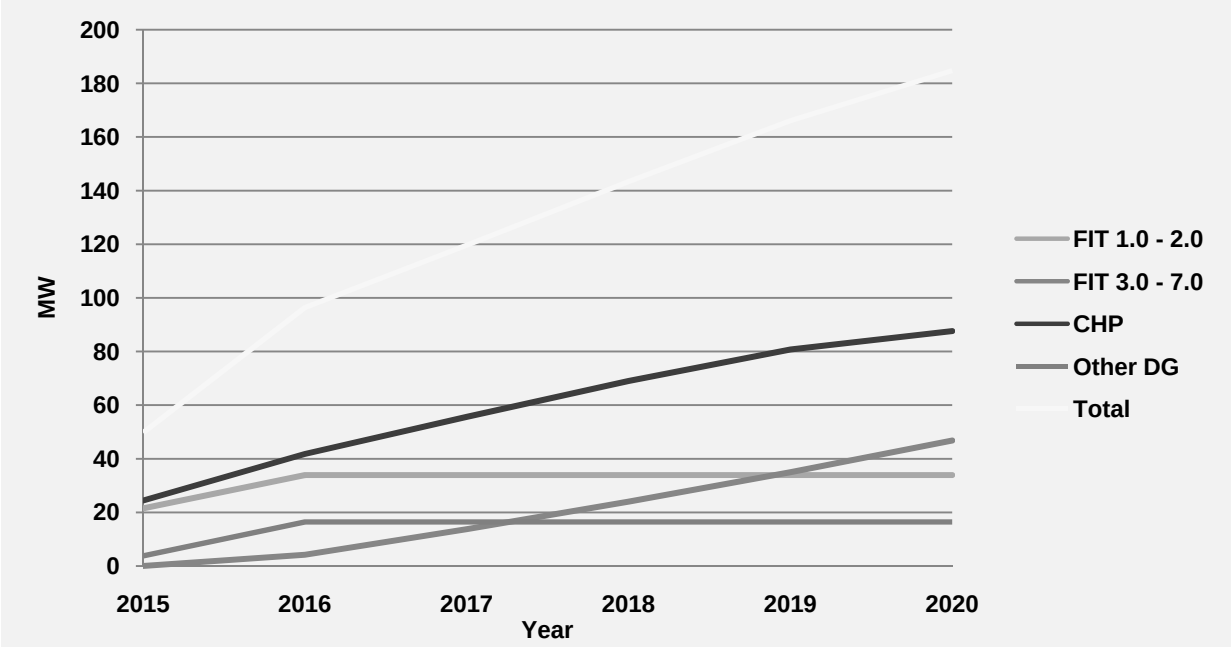

FIGURE 2: GRAPH OF DG CONNECTION FORECAST BY MW ACCORDING TO PROGRAM TYPE (2015-2019)

E1.6 Customer Engagement Activities

In order to better understand customers' preferences and values, Toronto Hydro carried out an extensive consultation on the utility's DSP. As explained in detail in Exhibit 1B, Tab 2, Schedule 7, Toronto Hydro engaged Innovative Research Group Inc. ("Innovative"), a national consultancy with expertise in public opinion research, to design and carry-out a consultation process intended to provide the utility with meaningful information to assist in preparing the DSP.

Toronto Hydro asked Innovative to bring key aspects of the utility's DSP to its most populous rate classes (Residential and General Service < 50 kW) as well as the utility's most populous larger customer market segments (Commercial and Industrial / Manufacturing), and to assess how customers' values and preferences align with the utility's proposed capital work. The consultation also included customers who live in condominiums or other multi-residential buildings. Innovative used a multi-faceted approach to gathering and assessing the needs and preferences of these customers, including the following methods:

1. an online workbook, accessible to any Toronto Hydro customer;
2. randomly recruited focus groups of residential and GS < 50 kW customers, facilitated by Innovative and based on a workbook describing the central pillars of Toronto Hydro's 2015-2019 DSP;
3. consultation with randomly recruited Commercial and Industrial / Manufacturing customers, including a panel discussion with Toronto Hydro staff moderated by Innovative, and focus groups using the same workbook;
4. a statistical telephone survey of 1,206 Toronto Hydro customers from both residential and GS < 50 kW rate classes.

Innovative's final report (available as Appendix B to Exhibit 1B, Tab 2, Schedule 7) documents the process and findings of this consultation in detail. A discussion of how the results of this consultation are reflected in Toronto Hydro's 2015-2019 Distribution System Plan is provided in section E2.4.

Innovative's customer engagement scope did not include Toronto Hydro's very large customers[3]. The utility engages its very large customers with respect to capital work as part of its regular meetings with those customers. During these meetings, Toronto Hydro invited all of its very large customers to submit letters of comment on the utility's ongoing, renewal-focused capital investment plans. Copies of all comment letters received since the utility's last distribution rates application are attached as Appendix A to Exhibit 1B, Tab 2, Schedule 7.

[3] A group including customers whose demand exceeds 5 MW, whose demand exceeds 1 MW and who are served by feeders that have been experiencing a high frequency of outages, and some customers with multiple accounts whose combined demand exceeds 5 MW.

(in green) are subtotalled to produce the life-cycle cost (in blue) – otherwise known as the total operating cost of the new asset in question. Theoretically, the economic end-of-life criteria represents the lowest point of this operating cost across the life-cycle of the asset, illustrated by the orange dot in Figure 1 – otherwise known as the Equivalent Annualized Cost (EAC). However, in actual practice, existing assets to be replaced and new assets to be installed will have different risk profiles. Figure 2 therefore illustrates a pragmatic calculation of the economic end-of-life criteria for a given asset through the execution of a risk-based optimization approach, whereby the EAC as determined for the new asset is applied to the existing asset's risk cost curve in order to calculate the optimal intervention timing, or economic end-of-life criteria, of the existing asset.

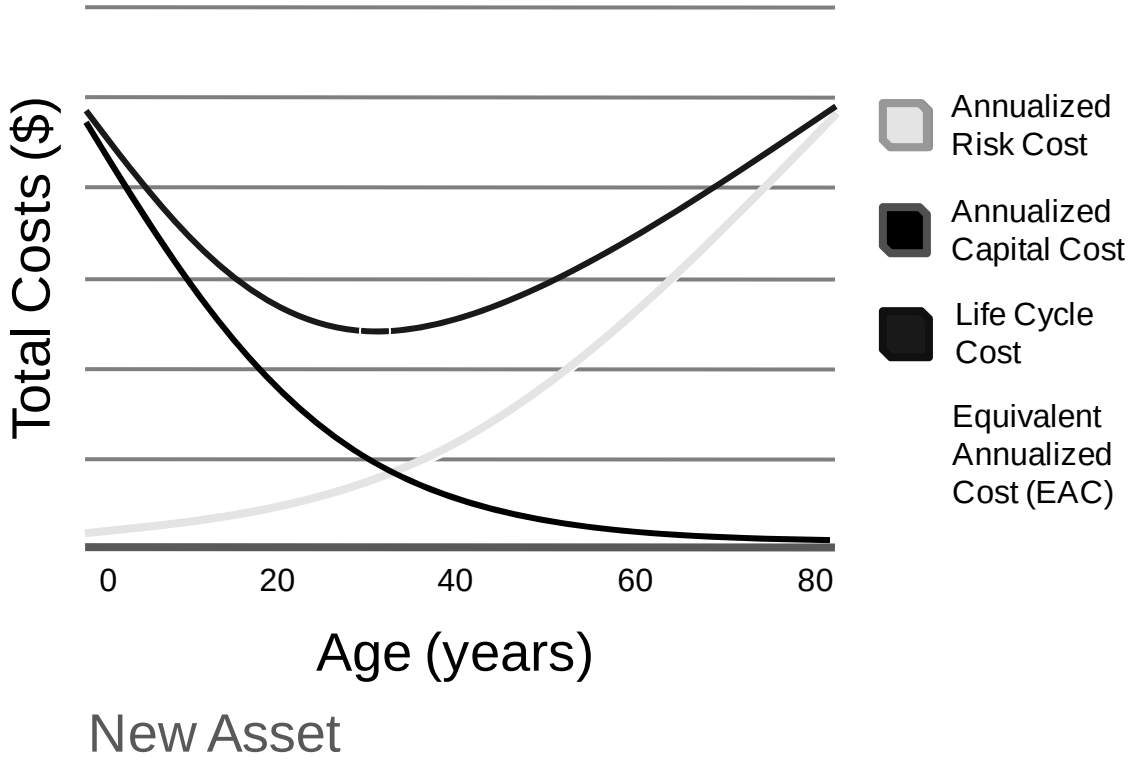

FIGURE 1: LIFE-CYCLE COSTING ANALYSIS (WHERE EAC REPRESENTS THE THEORETICAL STEADY STATE)

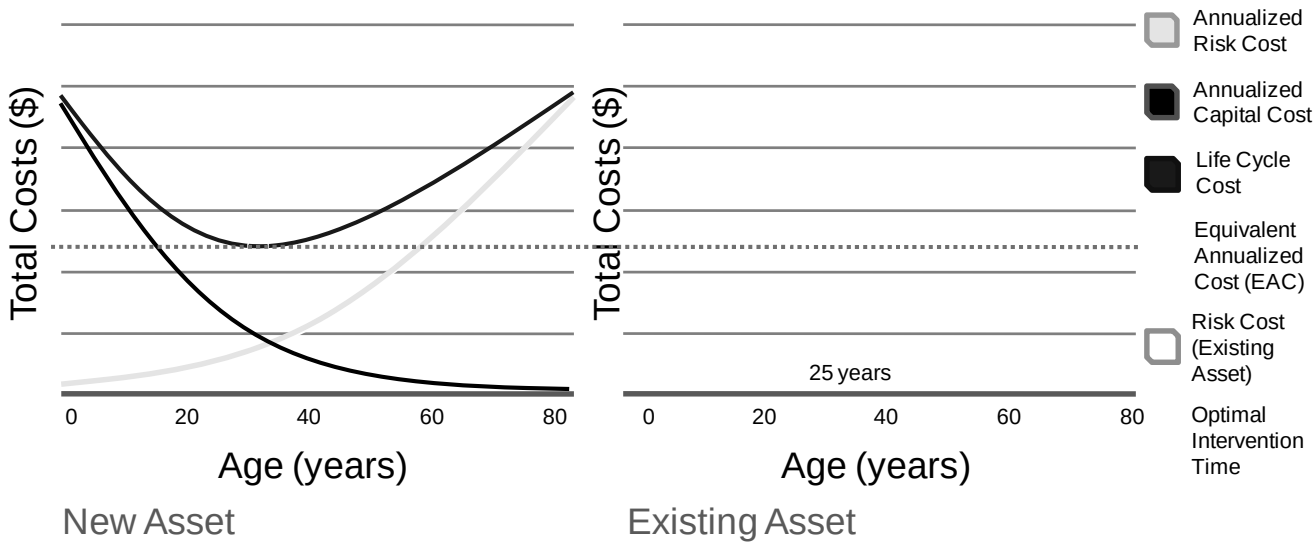

FIGURE 2: LIFE-CYCLE COSTING ANALYSIS (WHERE OPTIMAL INTERVENTION TIME IS A KEY INPUT USED WHEN CALCULATING THE STEADY STATE OF THE DISTRIBUTION SYSTEM AS PER RISK-BASED OPTIMIZATION APPROACH)

By applying this risk-based optimization approach to the broader population of major distribution assets across the system – such that the actual timing of asset renewal investments is, on average, aligned to the economic end-of-life criteria – a capital investment approach can be produced that allows for a optimal steady state to be achieved. Maintaining a steady state investment program is the most prudent approach to system investment, as it ensures that, on average, total life cycle costs of the assets across the system are minimized.

Outputs produced by the long-term system review process include the establishment of overall capital investment levels, which are then populated with capital investment programs as per the Investment Planning process, as defined in Section D3.1.1.3. This Section outlines the results of the long-term system review process as part of this 2015-2019 capital expenditure plan.

The first deliverable in this review process – the derived capital investment approach for the five-year planning horizon from 2015 onwards to 2019 – can be broken down into three areas of investment as illustrated in Figure 3 and further detailed below.

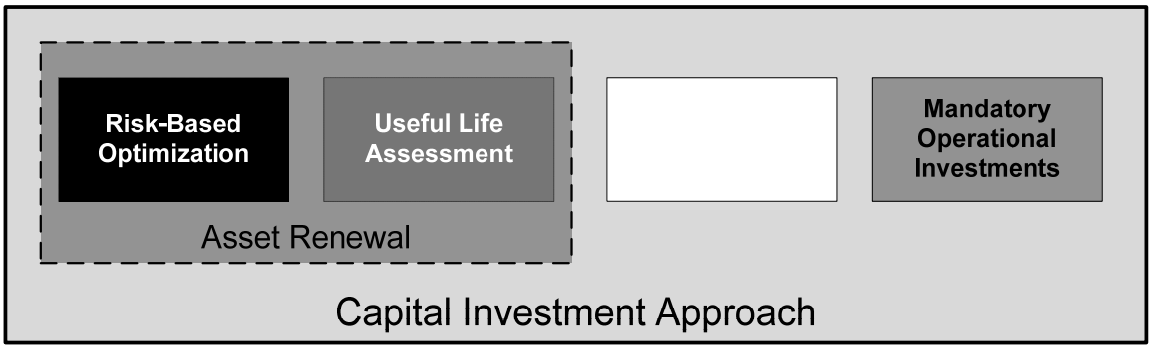

FIGURE 3: CAPITAL INVESTMENT APPROACH (2015-2019)

(a) **Asset Renewal:** To achieve steady state, in-kind replacement must be performed for those assets reaching or exceeding their economic end-of-life criteria. The Feeder Investment Model can be applied as to identify the economic end-of-life criteria and investment timing for all evaluated assets as per a risk-based optimization approach. For those asset classes not evaluated by the FIM, asset investment timing was determined based upon the assets' remaining useful life.

(b) **Critical System-Wide Issues:** This area of investment includes those broader investments of the utmost urgency, designed to target issues that go "beyond the asset", such as load growth, capacity and contingency constraints, operational flexibility and accessibility, safety and security of supply issues.

(c) **Mandatory Operational Investments:** This area of investment includes those necessary and mandatory day-to-day investments that support the 24/7 operations of Toronto Hydro, including customer-service requests, mandated service obligations, capital and maintenance support and non-system physical plant investments associated with Information Technology, Fleet and Facilities.

The spending requirements produced by this capital investment approach, illustrated in Figure 4, reveal a substantial investment backlog of approximately $2.56 billion that would optimally be spent in 2015, followed by approximately $1.55 billion in investment from 2016 through 2019 (in aggregate). The backlog is comprised predominantly of assets that are past their economic end-of-life and end-of-useful life respectively, as well as critical issues that must be urgently addressed. This backlog exposes Toronto Hydro's distribution system to immediate risks. /C

Toronto Hydro's assessment is that the spending requirements reflected are ultimately representative of an economically optimal capital investment approach: execution of these investments would mitigate this backlog and allow for an immediate achievement of steady state. This approach would minimize the operating costs to which customers are exposed when considering capital and risk costs.

However, Toronto Hydro recognizes that executing a capital investment approach of this magnitude in a single year would constitute an unprecedented level of investment, and would result in large step-increases in rates. Moreover, the utility could not reasonably expect to execute this magnitude of investment in a single year considering current system constraints and available resources.

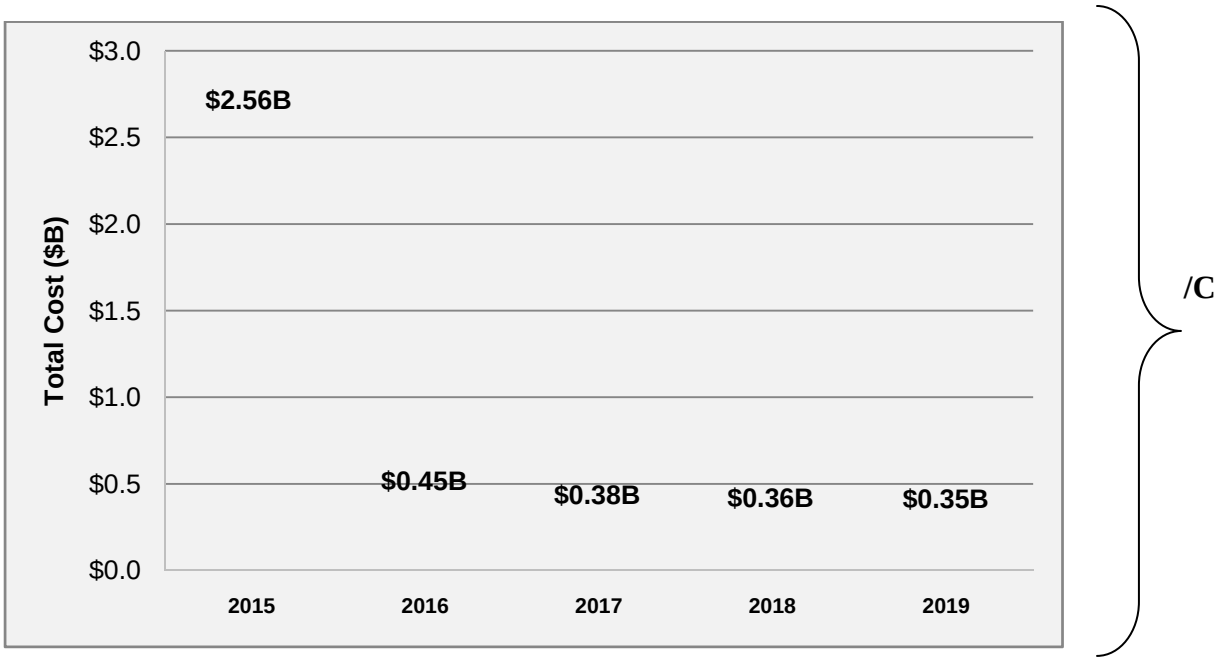

FIGURE 4: ECONOMICALLY OPTIMAL CAPITAL INVESTMENT APPROACH (2015-2019)

Recognizing the infeasibility of completing this work in a single year, Toronto Hydro considered two alternative timelines in which to carry out this work: an "accelerated" strategy as well as the proposed "paced" strategy. The accelerated strategy would allow for the backlog of investments to be managed over the five-year DSP period, such that steady state is achieved by 2019 with a

level of investment of approximately $830 million on average per year, for a total of $4.17 billion over five years.

However, this accelerated strategy would still contain levels of investment that do not align to Toronto Hydro's resources or system constraints, and would result in step-increases in rates for customers.

While Toronto Hydro has determined that the ideal investments in Toronto's distribution system exceed those proposed in this capital expenditure plan, the utility acknowledges customers' price sensitivity and therefore has proposed a more gradually paced 2015-2019 capital expenditure plan intended to arrive at the economically optimal steady state in a gradual manner. The proposed strategy addresses the backlog of investments in a manner that achieves the steady state by 2037. The paced strategy entails a proposed level of investment of $2.49 billion over 2015-2019, or an annual average of just under $500 million. Under this strategy, the backlog of investment remaining after 2019 will continue to be managed between 2020 and 2037, alongside new investments. Such new investments will be planned to manage assets that will reach or exceed their economic end-of-life or useful life criteria, as well as new critical issues that could emerge during this same 2020-2037 period. Toronto Hydro estimates that continuing at this average pace beyond 2020 would result in achievement of steady state by approximately 2037. /C

This gradually paced strategy aligns to Toronto Hydro's resource and system constraints, and is therefore practical to execute. Figure 5 illustrates the required capital investments of both the "accelerated" strategy (on the left) and the "paced" strategy (on the right).

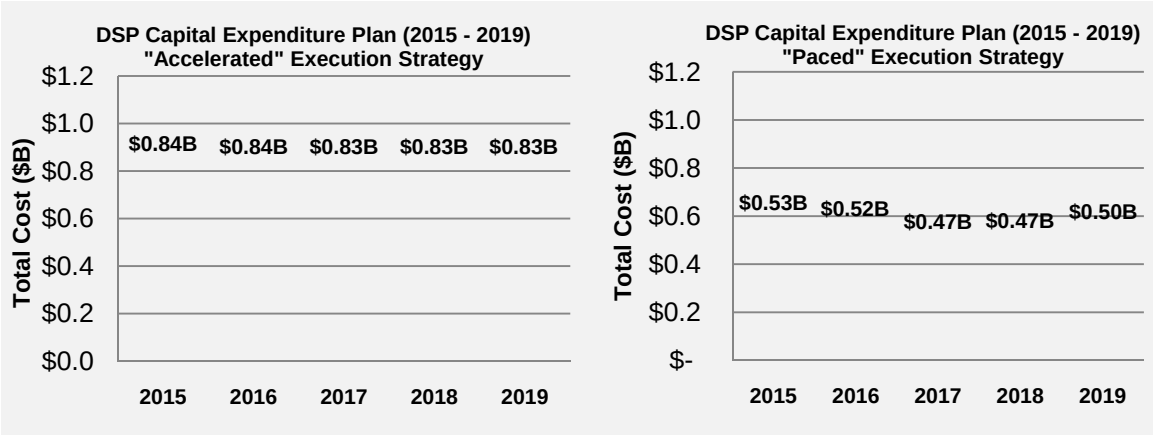

FIGURE 5: ACCELERATED VERSUS PACED CAPITAL INVESTMENT EXECUTION STRATEGIES (2015-2019)

As previously explained, the steady state is the economically optimal condition for the distribution system and ratepayers. By reaching the steady state in the proposed "paced" manner, the fluctuations in capital investment spending, which are driven by uneven depreciation of the asset base and necessitate periods of significantly large multi-year capital investment above historic levels, can be mitigated, leading to more consistent system-wide performance and smoother rate impacts beyond the initial achievement of steady state in 2037. As noted in the results of Toronto Hydro's customer engagement activities (Exhibit 1B, Tab 2, Schedule 7), some focus group and workshop participants, while accepting of the need for significant capital investment above historic levels and the associated bill impacts, felt that the uneven approach to investment over time could have been avoided had Toronto Hydro been building a reserve of capital funds beforehand. While Toronto Hydro is not able to operate a capital reserve fund of this nature, the paced execution strategy described here could, over the long-term, help mitigate the rate increases that can accompany uneven capital investment commitments.

Under the proposed "paced" execution strategy, SAIFI is projected to be reduced from 1.53 outages in 2014) to 1.13 outages in 2019, and SAIDI is projected to be reduced from 1.21 hours in 2014 to 0.97 hours in 2019 respectively. In contrast, should Toronto Hydro not execute this investment approach and instead adopt a run-to-failure approach, SAIFI and SAIDI are forecasted to worsen by another 30%, and 24% respectively over the period from 2015 to 2019. A run-to-failure approach would force Toronto Hydro to manage assets in a reactive manner, exposing customers to associated outages and higher reactive costs associated with the replacement of assets and the restoration of the system.

In summary, Toronto Hydro's distribution system already faces a significant level of risk as evidenced by the backlog of required capital investments. For every year of investment delay, the backlog will increase in size and result in a proportional increase to risk. Toronto Hydro recognizes that the proposed execution strategy carries a greater level of risk due to the longer period of time in which the backlog must be managed. However, this is an execution strategy that will still allow Toronto Hydro to achieve steady state in a manner that is responsive to customer price sensitivity while being immediately executable. This "paced" approach has the benefits of mitigating large fluctuations in system performance over time and helping to smooth future capital investments and corresponding rate impacts. The achievement of steady state allows Toronto Hydro's capital investment approach to align to AM objectives.

E2.1.1 Historic Investment & Demographics

The backlog of required spending as derived within the economically optimal capital investment approach, and illustrated in Figure 4, is the product of historical development, expansion and renewal of Toronto Hydro's system, which has resulted in investment peak periods followed by periods of depreciation and reduced investment.

Much of Toronto Hydro's system was constructed and expanded upon following the Second World War, with investment first peaking in the 1950s and 1960s. This was a period of unprecedented population growth, as illustrated by the blue bars respectively in Figure 6. For the downtown core, this was characterized largely by growth in the commercial, industrial and office sectors. For the former municipalities that make up the "Horseshoe" area around downtown Toronto today, the growth was primarily due to residential development, with associated commercial and retail space. Toronto Hydro's distribution system followed these trends, with intensification in construction of the Secondary Network System and the rapid construction of first overhead equipment, followed by increasing amounts of underground in the Horseshoe, utilizing first-generation direct-buried (DB) cross-linked polyethylene (XLPE) cables.

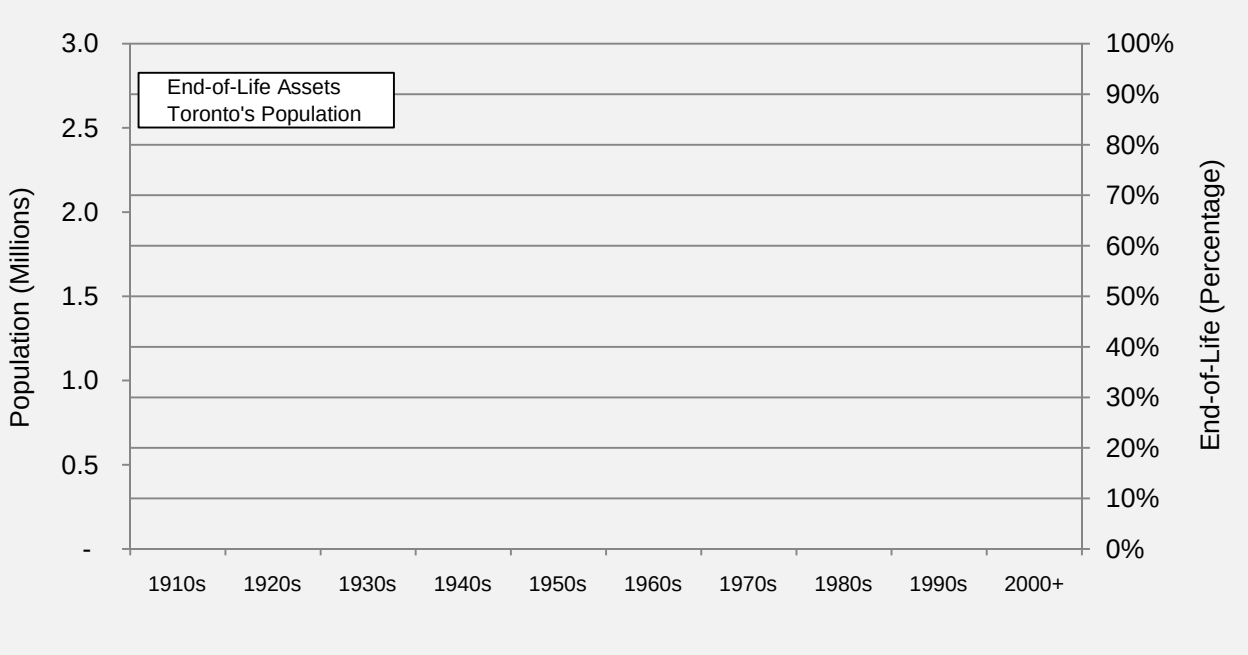

FIGURE 6: TORONTO'S POPULATION AND END-OF-LIFE ASSET DEMOGRAPHICS

This growth period involved the construction of new distribution plant in order to service new customer loads. As such, most of the capital investments involved a commensurate increase in distribution revenues, which enabled Toronto Hydro to finance the capital construction of assets over their lifespan. Eventually, land use reached a saturation point and population growth in both the downtown and Horseshoe areas began to slow down at the end of the 1960s and into the 1970s. While development continued in other areas of the Greater Toronto Area (GTA), the six utilities that would become Toronto Hydro entered into a period of depreciation and reduced spending, during which both revenue growth and capital expenditures slowed. Consequently, the amount of new electricity infrastructure being installed decreased substantially, and rates were kept relatively low.

As the investment peak period results in a large population of assets being installed within a similar time period, future investment peak periods are inevitably required to manage those same populations of assets when they simultaneously reach their economic end-of-life or end-of-useful life criteria respectively, thus producing a pattern of investment peaks followed by periods of reduced spending and depreciation. Toronto Hydro is currently managing its largest investment

peak period to date, which includes infrastructure that has reached or is exceeding its useful life criteria as illustrated by the bars in red in Figure 6.

Figure 7 further illustrates how capital investments necessary to manage this current investment peak period have been on the rise since 2006.

/C

FIGURE 7: HISTORICAL SYSTEM INVESTMENT

From 2012 to 2014, this third peak of investments was managed through a series of OEB-approved Incremental Capital Module (ICM) segments filed as part of Toronto Hydro's 2012-2014 rates application[2]. Many of the DSP programs proposed for 2015-2019 include capital work that is comparable to approved ICM segments, including "core" asset renewal investments for each of the grid systems (overhead, underground, secondary network and stations), the replacement of functionally obsolete infrastructure such as rear lot and box construction, and the replacement of legacy infrastructure currently posing safety issues, including SCADAMATE R1 and Polymer SMD-20 fused switches.

As originally further illustrated in Figure 8 below, approximately 26% of the replacement value Toronto Hydro's asset base will be past its useful life criteria by 2015.

[2] EBr2012r0064.

FIGURE 8: USEFUL LIFE DEMOGRAPHICS – 2015

It is critical that Toronto Hydro is able to manage this backlog as per a capital investment approach and execution strategy that allows for the steady state to be achieved, while also being responsive to customer's price sensitivity and practical to execute when accounting for available resources. The following sections provide further details and breakdowns on the capital investment approach as well as the execution strategies that may be applied in order to eliminate this backlog.

E2.1.2 Capital Investment Approach

The first milestone of the long-term system review process is to derive a proactive capital investment approach. Toronto Hydro's capital investment approach produced as part of the 2015-2019 capital expenditure plan includes three forms of investments:

- Asset renewal investments designed to target those assets nearing, at or beyond their economic end-of-life or end-of-useful life criteria within Toronto Hydro's grid systems (overhead, underground, secondary network, stations).
- System-wide critical issues that are of utmost urgency and go "beyond the asset", introducing challenges associated with safety, operational and capacity constraints, security of supply and load growth.

- Mandatory operational investments that support Toronto Hydro's operations, including Fleet, Facilities, IT, customer-service requests and mandated service obligations, capital and maintenance support.

Toronto Hydro has produced a proactive capital investment approach as part of the 2015-2019 capital expenditure plan that includes details on the challenges being mitigated through the resulting investments, as well as information on the timing of those investments.

E2.1.2.1 Asset Renewal Investments

Asset renewal investments represent in-kind replacements of assets across the four grid systems (overhead, underground, secondary network, stations), that the utility derived for the 2015-2019 period based upon their economic end-of-life criteria as per a risk-based optimization approach rooted in value-based reliability planning, as well as their end-of-useful life criteria based upon the assets' age.

In order for the proactive capital investment approach to achieve a steady state, a risk-based optimization approach was applied through the use of the Feeder Investment Model (FIM) such that the asset renewal investment timing was driven by the economic end-of-life results for each evaluated asset. Once these assets have reached their economic end-of-life criteria, they will be replaced with their standardized equivalents. Economic risks within this approach reflect various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, the costs of emergency repairs and replacement, and the indirect costs associated with asset failures.

Major distribution assets evaluated through the FIM in order to produce these results include overhead and underground distribution transformers and switches, poles, underground primary cables and secondary network units. Section D3.1.2.1 provides further details on the FIM and its inputs.

Figure 9 illustrates the system-wide results of the FIM. Results have been colour-coded based upon their respective economic end-of-life results. Assets that must be addressed immediately have been highlighted in red.

For those assets that Toronto Hydro did not evaluate within the FIM,[3] asset investment timing was then determined based upon the assets' end-of-useful life criteria.

Toronto Hydro employed the use of Hazard Rate Distribution Functions (HDF) in order to forecast the quantity of assets approaching their end of their useful lives and associated costs over a five-year period, from 2015 to 2019. The Hazard Rate methodology is explained in further detail in Section D3.1.1.2.

The collective use of these two approaches allowed Toronto Hydro to derive the asset renewal investment timings and associated spending levels for each of the four major grid systems across the five-year period from 2015-2019, including:

- Overhead circuit renewal investments for poles, overhead pole-top transformers and switches, conductor, poles & associated accessory hardware. The Overhead Circuit Renewal investment program is further defined in Section E6.4.
- Underground circuit renewal investments for underground cables (direct buried and conduit), transformers and switches. The Underground Circuit Renewal investment program is further defined in Section E6.1.
- Secondary network renewal investments for network units, vaults and associated primary & secondary network cables. The Network Vault Renewal investment program is further defined in Section E6.9, while the Network Unit Renewal investment program is further defined in Section E6.10.
- Stations renewal investments for power transformers, circuit breakers, switchgear and DC battery systems. The following stations renewal investment programs target these assets for intervention:
    - Stations Switchgear Renewal (Section E6.13)
    - Stations Power Transformer Renewal (Section E6.14)
    - Stations Circuit Breaker Renewal (Section E6.15)

[3] The risk-based optimization approach that is performed via an FIM evaluation requires for the entire population of assets within a given asset class to be evaluated. Each individual asset within a given asset class must possess mandatory inputs required to produce an economic end of life result. There are certain asset classes that currently cannot be evaluated in this manner, either due to (i) insufficient data, or (ii) lack of a developed FIM evaluation model for that particular asset class.

- Stations DC Battery Renewal (Section E6.19)

It should be noted that those assets that cannot be replaced in-kind (e.g. rear lot and box construction) were treated as critical issues, which are further discussed in Section E2.1.2.2.

FIGURE 9: OPTIMAL INTERVENTION TIMING MAP

E2.1.2.2 Investments to Mitigate System-Wide Critical Issues

Apart from the "core" asset renewal spending, there are also investments that go "beyond the asset", to target critically urgent issues across the distribution system. Examples of system-wide critical issues include:

- Asset infrastructure introducing safety-related issues and challenges (handwells, polymer SMD-20 fused switches, etc.).
- Load growth and capacity constraints
- Security-of-supply risks
- System and downtown contingency issues
- Operational constraints and inflexibilities

Investments required in order to mitigate these issues include:

- Upgrading and re-configuration of existing feeder infrastructure to improve operating flexibility, contingency and restoration capabilities. Associated investment programs include:
  - Contingency Enhancement (Section E7.1)
  - Design Enhancement (Section E7.2)
  - Feeder Automation (Section E7.3)
- Installation of new infrastructure to manage downtown contingency and security-of-supply risks. Associated investment programs include:
  - Downtown Contingency (Section E7.7)
  - Stations Expansion (Section E7.9)
- Standardization of key legacy asset classes and components in order to mitigate functional obsolescence and safety issues along with operational constraints. Associated investment programs include:
  - Customer-Owned Station Protection (Section E7.8)

- Polymer SMD-20 Renewal (Section E7.6)
- Handwell Upgrades (Section E7.5)

- Installation of new technologies designed to reduce outage duration periods, monitor asset performance and provide capacity relief. Associated investment programs include:
  - Energy Storage Systems (Section E7.11)
  - Local Demand Response (Section E7.10)

This category of investment also includes renewal-based investments for functionally obsolete infrastructure that cannot be replaced in-kind, including rear lot and box construction, automatic transfer switches and reverse power breakers, underground legacy infrastructure such as Sachsenwerk switch and fuse units, along with infrastructure installed in inaccessible locations. This infrastructure no longer aligns to Toronto Hydro's current operating practices or procedures, resulting in accessibility and serviceability conflicts, which can result in increased failure risk, reliability and/or safety-related risks.

All critical issues are considered to be of the most urgent nature and therefore are expected to be delivered within the first year of the capital investment approach.

E2.1.2.3 Mandatory Operational Investments

Apart from capital investments to manage "core" asset renewal requirements and mitigate system-wide critical issues, there are also necessary and mandatory investments to support Toronto Hydro's 24/7 operations. This includes:

- Mandated service obligations with respect to Metering investments
- Customer service requests with respect to the connection of new customers and the need to relocation and and/or expand infrastructure in response to third-party requests
- Non-System physical plant investments associated with Information Technology, Fleet and Facilities which form an essential part of Toronto Hydro's operations
- Ongoing capital and maintenance support for asset management systems and standards

The timing of these investments was derived based upon the scope and scale of the associated investment programs and projects.

E2.1.3 Capital Investment Execution Strategy

The capital investment execution strategy represents the second deliverable as part of the long-term system review process. For the 2015-2019 capital expenditure plan, an execution strategy must be derived that allows the derived capital investment approach to be executed in a manner that is responsive to customer's price sensitivity while still being practical to execute.

E2.1.3.1 Pacing: How to Reach the Steady State?

As illustrated in Figure 4, the economically optimal capital investment approach includes a substantial investment peak totaling $2.56 billion in 2015, followed by an additional $1.55 billion of investments from 2016 onwards to 2019. This initial peak is mostly comprised of a backlog of asset renewal and system-wide critical issues that must be mitigated in the first year. /C

The current backlog of assets and the current investment peak period can be effectively ended by executing upon the economically optimal capital investment approach as illustrated in Figure 4. Doing so would result in a steady state achievement by 2016. However, it is clear that the associated expenditures in 2015 would result in large step-increases in customer rates. This investment approach also would not align to Toronto Hydro's available resources and system constraints.

Therefore, Toronto Hydro investigated two execution strategies capable of mitigating this backlog in a manner that would result in capital expenditures that are responsive to customer price sensitivity and are practical to execute:

- The "accelerated" strategy, focused on mitigating the backlog over the five-year DSP period, thus reaching the steady state by 2020. This accelerated strategy provides an improved value for customers through the immediate reduction in risk, thereby allowing the distribution system to spend less time in a sub-optimal (and therefore more expensive) state.

- The "paced" strategy, where steady state is achieved at a more moderate pace beyond the five-year DSP period, resulting in slightly higher aggregate costs, since the distribution system would spend more time in a sub-optimal state, but with more restrained rate increases from 2015 onwards to 2019.

- These two strategies are explained in further detail within the following sections.

(i) "Accelerated" Execution Strategy

The "accelerated" execution strategy is focused on mitigating the backlog of investments within the 5-year DSP period, such that steady state is achieved by 2020.

As illustrated in Figure 10, this strategy requires significant capital investments of approximately $830 million on average per year, with a total five-year investment of $4.17 billion. The advantage of this strategy is that steady state can be achieved in more rapidly, therefore mitigating the risks associated with the backlog within the five-year period. However, it is clear that the rate impacts from this strategy would be substantial for customers. Furthermore, the required investments do not align to Toronto Hydro's available resources and system constraints, and therefore there would likely be execution-related complexities.

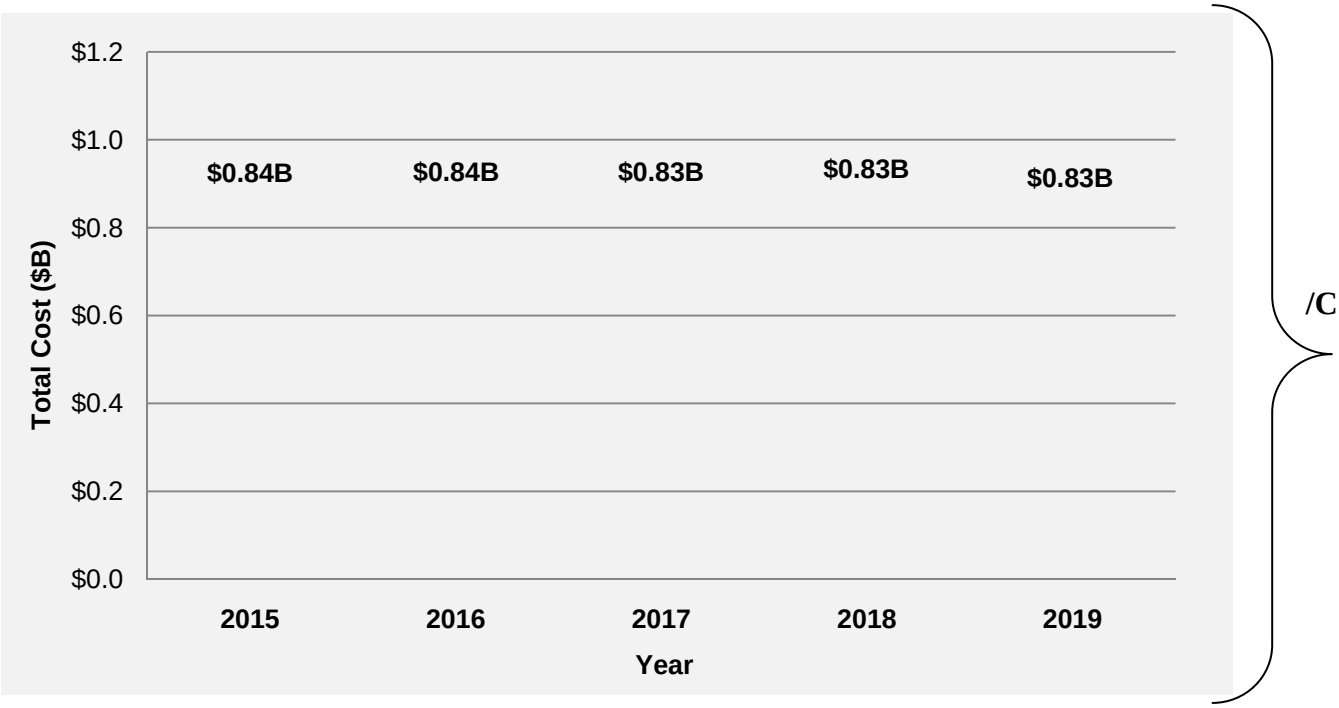

FIGURE 10: CAPITAL INVESTMENT APPROACH AS PER "ACCELERATED" EXECUTION STRATEGY

(ii) Toronto Hydro's Proposed "Paced" Execution Strategy

The "paced" execution strategy, as illustrated in Figure 11, is focused on eliminating the backlog in a manner that remains responsive to customer price sensitivities. This strategy results in a spending requirement of $2.49 billion over the period from 2015-2019, or an average annual investment of just under $500 million. The "paced" execution strategy eliminates the backlog by 2037, thereby allowing for steady state to be achieved. /C

The remaining backlog would necessarily be managed beyond the five-year DSP period. Assuming a similar average annual pace of investment as the 2015-2019 period, this strategy would result in the achievement of steady state by approximately 2037. From 2020 onwards to 2037, not only is the backlog being addressed, but new investments will be made to manage assets reaching their economic end-of-life or useful life criteria or new critical issues that will emerge during this same time period.

As per this strategy, customers are exposed to a greater amount of risk as opposed to the "Accelerated" strategy. However, this strategy still allows for that risk to be eliminated in a reasonable timeframe, with the added benefit of mitigating fluctuations with respect to capital investments and corresponding rate impacts during the 2015-2037 period and beyond. This stabilization of capital investment needs is a product of the steady pace in which investments are being made over this time period. This strategy also aligns to Toronto Hydro's resource allocations and system constraints.

FIGURE 11: CAPITAL INVESTMENT APPROACH AS PER "PACED" EXECUTION STRATEGY (2015-2019)

Toronto Hydro believes that the benefits of reduced rate impacts and execution complexities associated with the "Paced" execution strategy outweigh the benefits of the "Accelerated" execution strategy in terms of reaching the steady state within the five-year period. Based upon these results, Toronto Hydro has selected the "Paced" execution strategy as part of the 2015-2019 capital investment plan. Ultimately, the execution of the capital expenditure plan as per this strategy will result in predictable rates over the five-year DSP term due to the "paced" nature of the investments, and will ultimately allow for steady state achievement by 2037.

Figure 12 illustrates the useful life demographics following the achievement of steady state as per the "paced" execution strategy in 2037. The results illustrate how the replacement value associated with assets past their useful life decrease from 26% as of 2015 to 11% by 2037. Similarly, assets not exceeding their useful lives will increase from 67% as of 2015 to 80% by 2037.

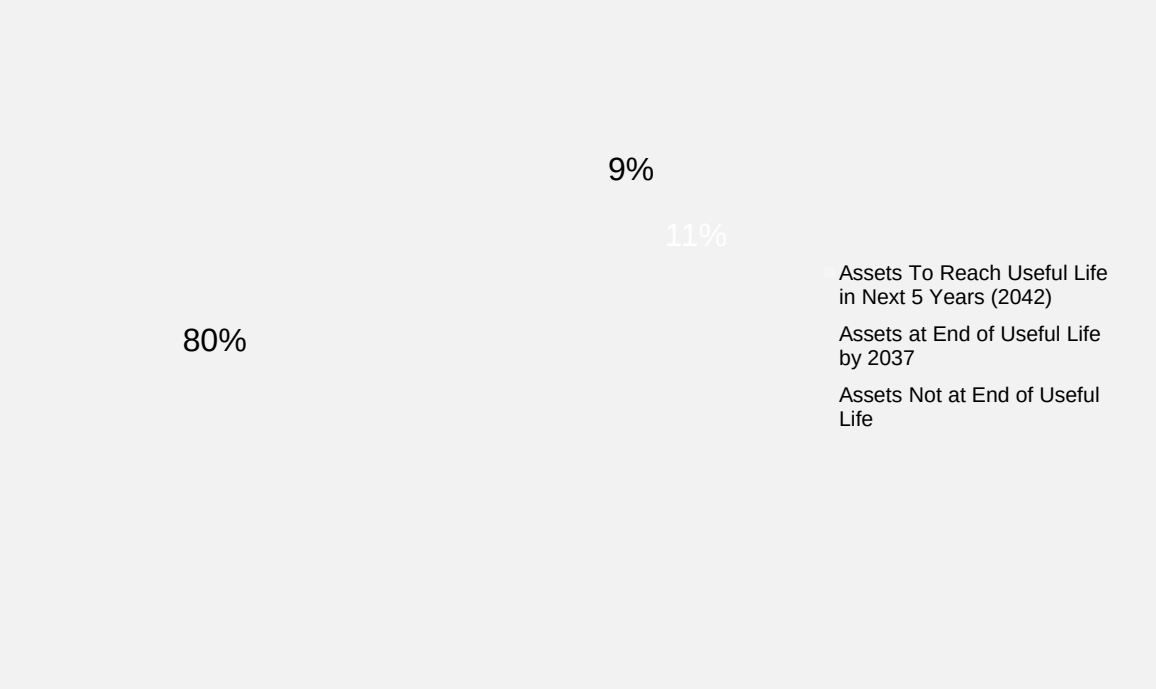

FIGURE 12: USEFUL LIFE DEMOGRAPHICS – 2037

E2.1.3 Reliability Projection

The final deliverable of the long-term system study process is to evaluate and assess the system performance impacts as a result of executing this proactive investment approach as per the "paced" execution strategy, as opposed to the run-to-failure or "do nothing" approach. Figures 13 and 14 respectively illustrate the year-over-year projected reliability comparison between the proactive investment approach and the run-to-failure/status quo approach. This investment program will address the majority of causes, with SAIFI projected to be reduced from 1.53 outages in 2014 to 1.13 outages in 2019, and SAIDI projected to be reduced from 1.21 hours in 2014 to 0.97 hours in 2019 respectively. In contrast, should Toronto Hydro not execute this investment approach and instead adopt a run to failure approach, SAIFI and SAIDI are projected to end the five year CIR period at a value of 1.50 and 1.99 respectively over.

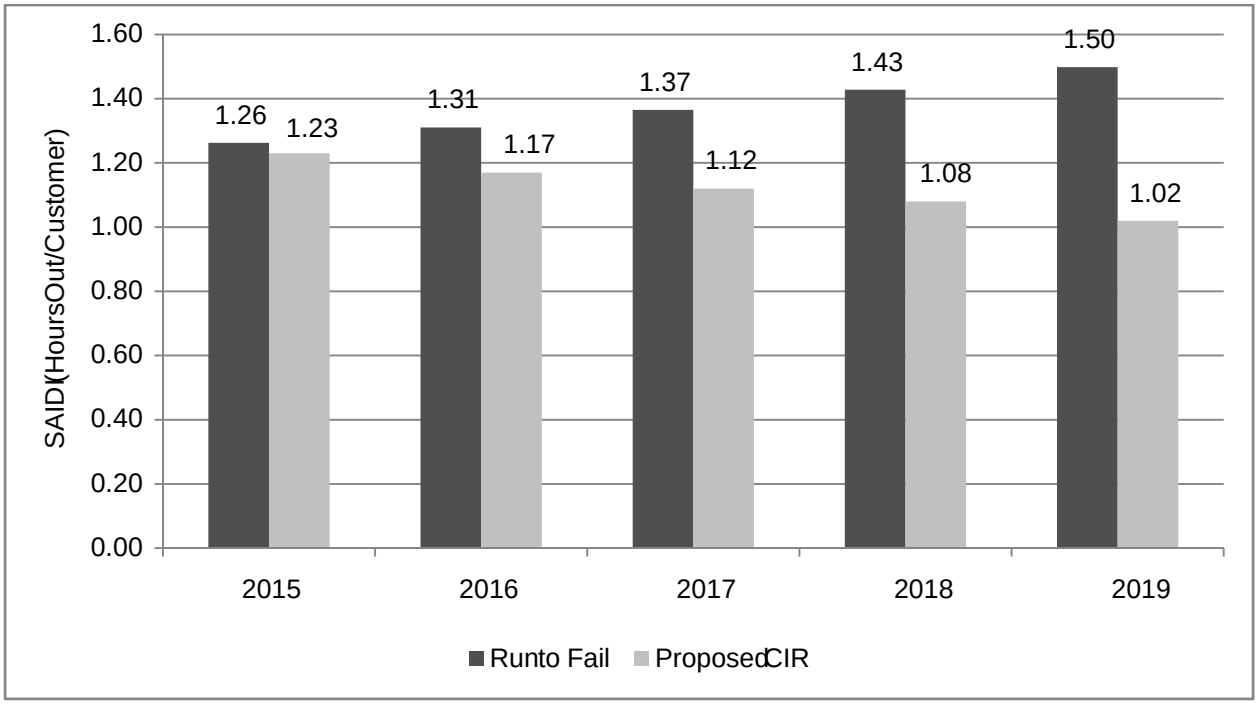

FIGURE 13: FIVE-YEAR SAIDI PROJECTION

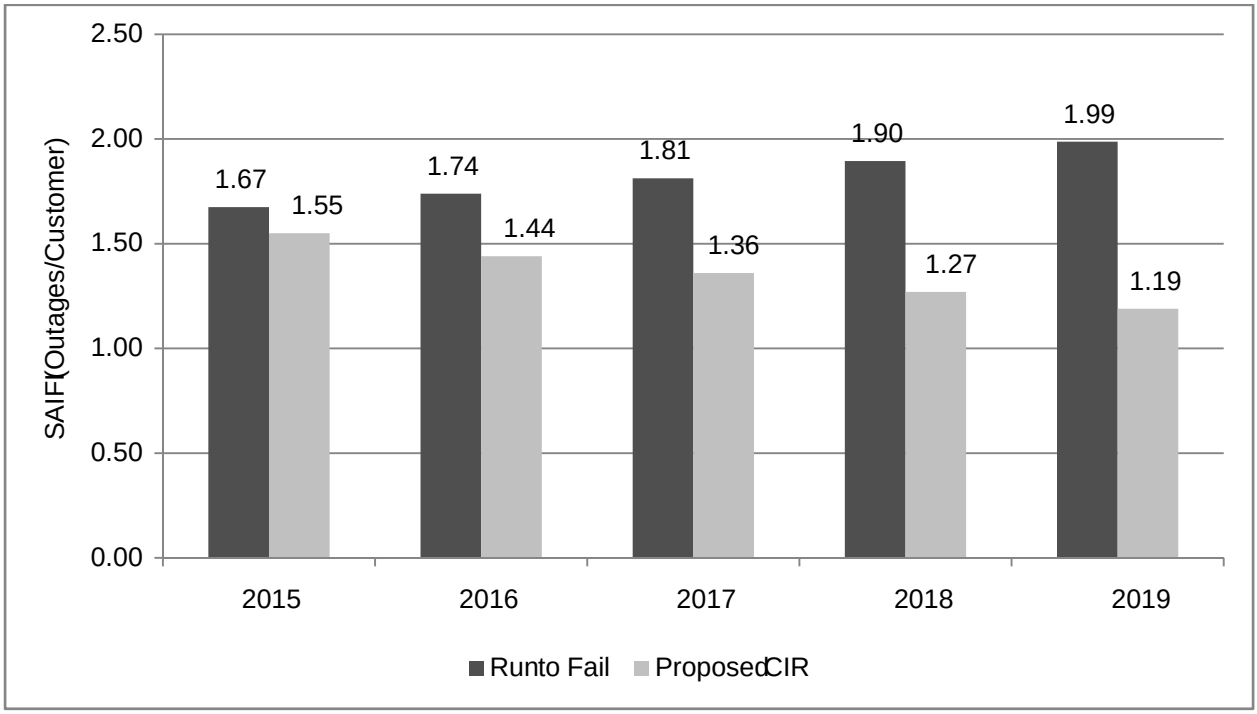

FIGURE 14: FIVE-YEAR SAIFI PROJECTION

It should be noted that this projection does not consider major event days, and the lasting impacts that major weather events can have on asset performance in future years.

The run-to-failure approach assumes that Toronto Hydro will cease all proactive work at a system level and essentially allow assets to fail before replacing them. As per a proactive capital investment approach, Toronto Hydro is able to replace those same assets via a planned outage or series of planned outages, where the customer impacts are minimized and isolated through optimal switching to backup supply feeders. In general, Toronto Hydro will have the new infrastructure in place prior to de-energizing the existing assets to make the transition as seamless as possible.

As per a run-to-failure approach, customers connected downstream from a fuse or connected anywhere on the feeder will be impacted by the resulting asset failure. Asset failures can impact anywhere from ten customers connected to a single transformer, up to 5000 customers connected to a feeder. Once the cause of outage has been established, Toronto Hydro field crews will have to perform fault locating and switching around the identified fault(s), such that the affected location is safely isolated and asset replacement activities can take place. During this time, customers can be adversely affected in their daily routine and are left without power.

Once the impacted asset(s) has/have been replaced, the feeder can be restored to a normal state. However, this approach will eventually lead to possible supplier shortfall or feeders being left in an abnormal state. This “Worst Case Scenario” can lead to entire feeders with no contingency options and leave thousands of customers without power as Toronto Hydro works to replace a single failed asset.

E2.1.4 Capital Investment Program & Project Development

Using the completed outputs from the Long-Term System Review process, including the finalized capital investment approach and execution strategy, Toronto Hydro executed the Investment Planning process as defined in Section D3.1.1.3 in order to produce capital investment programs. These programs align to the three forms of investment considered as part of the Long-Term System Study process, including asset renewal, system-wide critical issues and mandatory operational investments.

As illustrated in Figure 15, these three forms of investments are further integrated into the four investment categories: System Access, System Renewal, System Service & General Plant.

These integrations were performed depending on the nature of the investments coupled with the "trigger" drivers that are associated with each category.

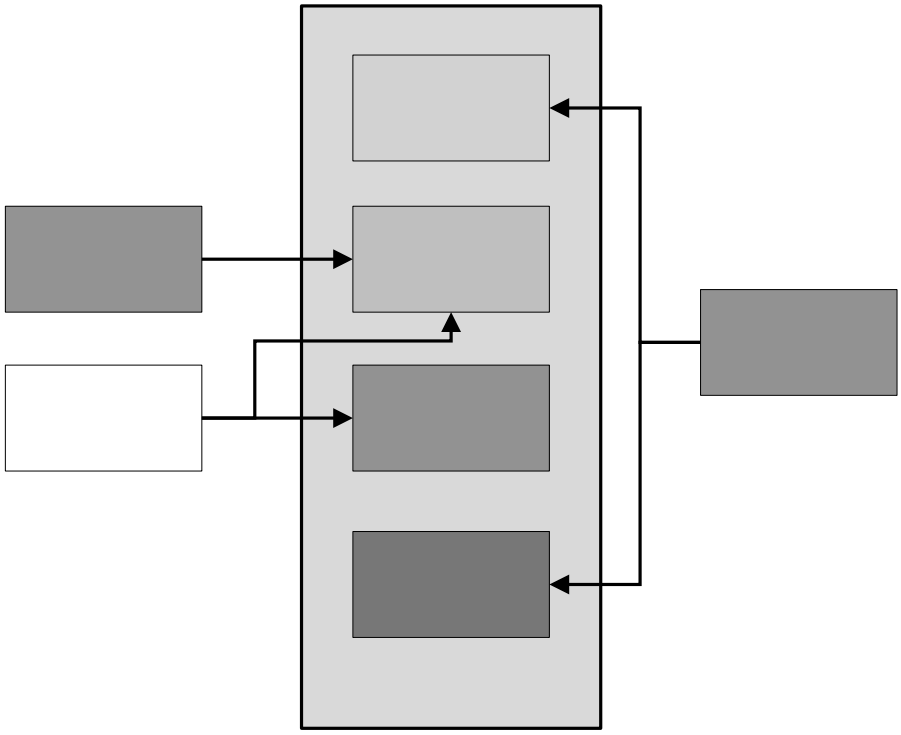

FIGURE 15: MAPPING OF CAPITAL INVESTMENTS TO INVESTMENT CATEGORIES

Asset renewal investments are integrated into the System Renewal investment category. System-wide critical issues are predominantly integrated within the System Service investment category, with the exception of investments targeting functionally obsolete infrastructure such as rear lot and box construction, automatic transfer switches and reverse power breakers, underground legacy infrastructure and infrastructure in inaccessible locations. Those investments have been integrated into the System Renewal category because functional obsolescence is an identified trigger driver within this investment category.

Mandatory operational investments have been integrated into both the System Access or General Plant investment categories, depending on the associated trigger drivers and the corresponding investment category.

As per the process defined in Section D3.1.1.3, capital investment programs and associated spending profiles for the 2015-2019 period have been produced by prioritizing system assets and issues based upon their alignment to their associated program trigger drivers. Sections E5 through to E8 provide further details into the System Access, System Renewal, System Service and General Plant investment categories and drivers respectively.

The project development process, defined in Section D3.1.2.2, has been applied to produce discrete investment projects for the 2015 year. As per this process, prioritized program-level assets and/or issues have been recaptured at the project level through the use of various inputs, including decision-support systems as defined in Section D3.1.2.1, depending on the associated program drivers. As the assets contained and issues to be resolved in these discrete projects have already been prioritized as per the Investment Planning process, all 2015 projects can be considered to have equal priority relative to each other. Projects from 2016 and onwards include a lesser priority of assets for intervention relative to 2015.

Capital investment spending from 2015-2019 has also been further refined as per this process, due to the high-level capital project implementation designs and capital project estimates that have been produced. Investment spending has been finalized for 2015 as per the Project Scheduling & Execution process, which also determines how individual capital investment projects are scheduled and executed within the 2015 year. This process is further detailed in Section E2.3.

Figure 16 provides the final expenditures associated with the 2015-2019 Capital Expenditure Plan, based upon the described capital investment approach and selected execution strategy.

1 **FIGURE 16: CAPITAL INVESTMENT REQUIREMENTS AS PER "PACED" EXECUTION STRATEGY (2015-2019)**

E2.2 Non-Distribution System Alternatives for Capacity Relief

Toronto Hydro does not currently have a policy or procedure for the treatment of non-distribution system alternatives to relieving capacity or operational constraints. "Non-wires" solutions are being examined as part of the Central Toronto Integrated Regional Resource Plan (IRRP) which is underway as described in Section B2.4. Further, "non-wires" solutions to relieving capacity or operational constraints are being proposed as part of the Local Demand Response investment program, described in section E7.10. The outcome of the Central Toronto IRRP and of the Local Demand Response investment program will contribute towards any future policy and procedure for the treatment of non-distribution system alternatives for capacity relief.

E2.3 Project Scheduling and Execution

Capital investment projects declared within the 2015-2019 Capital Expenditure Plan go through a scheduling and execution analysis process. When deciding upon project scheduling, projects are divided by execution groups comprised of internal and external contractors. These execution groups consist of field crews with different skill sets, geographical regions (east, west, and centre) and work types (planned, reactive, and customers' plans). The construction schedules for these execution groups are updated on a regular basis and rebasing of the plan line is performed typically on a quarterly basis or as needed, depending on the number of changes that have taken place since the forecast was issued. There are several factors that impact project scheduling (i.e. determining the sequencing order of projects as well as start and finish times). These factors include:

(1) Project scope and Requirements : The nature of the project (e.g., asset classes being replaced, project locations, impacted feeders, etc.) can have an impact on its scheduling (e.g., certain assets, such as large stations assets, can take time to be delivered to site, and certain project locations or feeders can create different execution complexities).

(2) Project Scope Changes : Changes in the project scope due to unforeseen field conditions can impact its scheduling during the course of the year.

(3) External Constraints : External constraints come from agencies whose planed timelines Toronto Hydro may have limited visibility into, but that Toronto Hydro must consider when scheduling work. These external groups include Metrolinx, TTC, Pan-Am Games, City of Toronto, HONI, and other utilities.

(4) Permitting and Moratoriums : Project schedules will be interdependent on road moratoriums during the course of the year alongside the receipt of permits from the City of Toronto to execute the projects. The permitting process can take months for the City to perform, which must be factored into the final scheduling.

(5) Customer Engagement and Contribution : Project scheduling must account for the necessary time to engage with affected customers and communities. Additional lead time may be necessary to account for changes to a project design if customer/community consensus cannot be reached.

(6) Project Coordination : In several cases, there are identified interdependencies between one project and another, which may result in specific scheduling requirements (i.e. in series or parallel). For example, civil duct work would be done sequentially as a Phase 1 to installing and energizing electrical cable into the duct as Phase 2. In addition, work often requires coordination with other projects in the area so as to minimize outages to customers. Similarly, projects often require coordination of work with HONI or third-party agencies such as TTC or Metrolinx.

(7) System Requirements : System requirements consider feeder availability. For example, the downtown area can be limited by seasonal restrictions, such as summer switching restrictions due to high system loading.

(8) Seasonal Requirements : Seasonal requirements result in some projects being executed at certain times of the year, forcing other projects with more flexible requirements to be scheduled at differing times. These requirements include avoiding trucks on soft soil in spring and fall, and avoiding pole installations or civil work when the ground is frozen in winter.

(9) Resource Availability : Resource availability considers labour constraints, including both internal labour and external contract labour. It also looks at optimal use of critical trades. Critical trades are those not commonly found and include resources such as Certified Power Cable Persons who work on lead cable and the downtown network system.

(10) Reactive Work : Activities where failed assets are being replaced as part of restoration activities may have scheduling impacts on existing proactive projects, particularly if assets within a project happen to fail prior to their scheduled execution. Such failures may result in changes to the scope of the project.

In general, project scheduling and execution must be dynamic in order to manage and account for all of these key elements, while maintaining deployment of resources.

Please see Exhibit 1B, Tab 2, Schedule 4, Appendix A for a detailed description of the complexities in carrying out a large-scale construction project or program in Toronto's dense urban environment.

As per this process, the capital investment plan for 2015 has been based upon Toronto Hydro's current work plan schedule as it stands during the preparation of this evidence.

E2.4 Customer Needs, Preferences and Priorities

As explained in Section E1.6, Toronto Hydro engaged Innovative Research Group ("Innovative") to design and carry-out a consultation process intended to provide the utility with meaningful information to assist in preparing the DSP. The consultation process included randomly recruited, workbook led focus groups, an online workbook accessible to all customers, facilitator led workshops with commercial and industrial users, and finally a statistical telephone survey. Innovative's final detailed report on the process and findings of this consultation is available in Appendix B to Exhibit 1B, Tab 2, Schedule 7.

These findings have provided valuable insight into the needs and preferences of Toronto Hydro's customers and their perception of the utility's priorities. A summary of how key findings are reflected in the DSP follows. The information discussed in the following sections is largely based on results of the final telephone survey, which was administered for the residential and General Service (GS) < 50 kW customer classes. The telephone survey gave Toronto Hydro a detailed view of the preferences of its most populous customer classes. The results of the GS > 50 kW Commercial and Industrial / Manufacturing workshops ("mid-market GS workshops") are referenced below as well, as this was the primary method by which Innovative engaged these larger customer segments.

E2.4.1 Overall Acceptance of Capital Plan

The telephone survey was designed to simulate the experience of customers who had participated in the earlier online workbook and workbook-led consultation sessions. Customers were educated on the state of the system, system challenges and the key aspects of Toronto Hydro's proposed DSP. They were invited to reflect on their personal experience with the system, and were asked to make "value judgments on trade-offs between system reliability and bill

impacts."[4] Customers were presented with forecasted bill impacts for the average user in their rate class based on the investments proposed in the DSP for the 2015-2019 period and forecasted operating expenditures (OPEX).

In general, residential and General Service (GS) < 50 kW customers accept the proposed rate increases associated with the DSP and planned OPEX amounts for 2015-2019.

- 58% of residential customers accept the proposed rate increases.[5]
- 48% of GS < 50 kW customers accept the proposed rate increases.[6]

For the mid-market GS workshops, 36 of 41 participants accepted the proposed rate increases.[7]

While the rate of acceptance of the plan is strong, Toronto Hydro notes that the majority of acceptance is from individuals who chose the "I don't like the rate increase, but I think it is necessary to maintain the grid to a reasonable standard" response. Toronto Hydro's proposed capital execution strategy is inherently sensitive to this difficult balance between current system needs and the level of tolerance for price increases. As explained above in Section E2.1, Toronto Hydro has developed a "paced" capital execution strategy that has been deliberately restrained in order to align with expectations regarding acceptable price increases. (The estimated bill impacts presented to customers in the telephone survey were based on this "paced" strategy.) Ultimately, Toronto Hydro interprets these survey results as validation that the proposed strategy strikes an acceptable balance, and reflecting that the majority of customers accept the need for the proposed level of investment in the DSP.

Customers who most enthusiastically accept the rate increases in both the residential and GS < 50 kW classes cite the avoidance of a future infrastructure crisis, the desire for better service, and the reasonableness of the forecasted price increases as reasons for their responses,[8] all three of which align to Toronto Hydro's asset management policies and chosen objectives as described in Section D of the DSP. Customers who are more reluctant in their acceptance share similar views, but also feel that the rate increases are necessary.

[8] Ibid., pp. 147-148

E2.4.2 System Challenges & Priorities

(i) System Reliability

The following survey results describe the recent reliability performance of the system as experienced by the bulk of Toronto Hydro's customers.

- Over half of all customers in both the residential and GS < 50 kW classes have experienced outages during extreme weather events in the last twelve months.[10]
- Not including extreme weather, about half of all customers in these classes have experienced other power outages in the last twelve months.[11]
- 64% of GS < 50 kW customers report direct costs to their businesses as a result of outages.[12]
- Most participants in the mid-market GS workshops had experienced power service interruptions at their businesses in the previous twelve months. Both commercial and industrial customers experienced revenue and productivity losses due to these outages.[13]

As discussed in Sections D and E, Toronto Hydro's asset management policy with respect to system performance is focused primarily on risk-based decision making, where inferred customer interruption costs (CICs) are quantified as one of several risk costs associated with operating aging assets beyond their useful lives. The utility's chosen pace of system renewal is based largely on the objective of balancing these risks against the capital costs of asset replacement so that the total cost of operating the system is minimized over time. While Toronto Hydro does not set specific reliability targets as part of this process, it does project and track the reliability outcomes of its plan and considers adjustments to the prioritization of projects within and across programs if reliability outcomes are tracking below forecasts.

Customer expectations with respect to future reliability performance were captured through the telephone survey. Customers were informed of the current system average outage frequency (i.e. "the average Toronto Hydro customer experiences between one and two power outages per

[10] Ibid., p. 123
[11] Ibid.
[12] Ibid.
[13] Ibid., p. 84

year"[14]) and duration (i.e. "the average Toronto Hydro customer is without power for one to one-and-a-half hours per year"[15]) statistics, excluding extreme weather, and were asked about their preferences with respect to these benchmarks and their own experience.

- 70% of residential customers think Toronto Hydro should spend what is needed to reduce or maintain the frequency of interruptions.[16]
- 67% of GS < 50 kW customers think Toronto Hydro should spend what is needed to reduce or maintain the frequency of interruptions.[17]
- 74% of residential customers think Toronto Hydro should spend what is needed to either reduce or maintain the length of power outages.[18]
- 67% of GS < 50 kW customers think Toronto Hydro should spend what is needed to either reduce or maintain the length of power outages.[19]

Of the participants in the mid-market GS workshops, service-based commercial users and larger industrial businesses in the manufacturing sector wanted Toronto Hydro to focus on limiting the duration of power outages, as longer outages can have significant consequences for productivity.[20] Other manufacturing business wanted Toronto Hydro to focus on limiting the frequency of outages, as every interruption forces their production equipment to shut down.[21]

Toronto Hydro's proposed "paced" execution strategy, discussed in Section E2.1 above, is projected to improve both SAIDI and SAIFI over the five year planning horizon. As illustrated in Figures 13 and 14, the investments in this period are expected to reduce SAIFI from 1.53 outages in 2014 to 1.13 outages in 2019, and SAIDI from 1.21 hours in 2014 to 0.97 hours in 2019. While part of this projected reliability improvement is the result of basic like-for-like asset renewal, Toronto Hydro is also anticipating significant reliability benefits from investment in high value-for-money improvements in programs such as Feeder Automation (E7.3), Design Enhancement (E7.2) and Contingency Enhancement (E7.1). These relatively low cost enhancements to the existing system are helping Toronto Hydro to maintain a more moderate pace of renewal while

[14] Ibid., p. 130
[15] Ibid., p. 132
[16] Ibid., p. 128
[17] Ibid., p. 129
[18] Ibid., p. 130
[19] Ibid., p. 131
[20] Ibid., p. 84
[21] Ibid.

delivering desired improvements to reliability performance and restoration efficiency during the 2015-2019 period.

With respect to customers experiencing especially poor reliability service, Toronto Hydro continues to administer a targeted and highly responsive Worst Performing Feeder program (E6.21) to manage the number of feeders experiencing seven or more sustained outages in a 12-month rolling period. The utility is also proposing to initiate an Overhead Momentary Reduction program (E7.4) in the 2015-2019 period to improve service to customers on feeders experiencing an especially high frequency of momentary interruptions.

These investments are expected to benefit both residential and business customers of all sizes. Toronto Hydro is also planning to modify and expand the use of secondary network style configurations for delivering a high standard of reliability service to the increasing number of building developments over 25-stories tall across the City, particularly in the downtown core and financial district. Furthermore, Toronto Hydro's dedicated engagement program for very large users or "key account" customers (discussed in Exhibit 1B, Tab 2, Schedule 7) will continue to identify service reliability needs that can be accommodated within the suite of planned capital programs in the DSP.

(ii) System Investment Priorities

Customers were asked a series of values-based questions regarding their preferences with respect to the investment priorities outlined in Toronto Hydro's proposed DSP.

Investment in Aging Infrastructure

- 60% of residential customers think that Toronto Hydro should spend what it takes to renew the system's aging equipment to lessen the impact of power outages, even if it means higher bills.[22]

- 51% of GS < 50 kW customers think that Toronto Hydro should spend what it takes to renew the system's aging equipment to lessen the impact of power outages, even if it means higher bills.[23]

Most participants in mid-market GS workshops felt that the proposed pace of system renewal is appropriate and was balanced with customer bill impacts.[24]

[22] Ibid., p. 133
[23] Ibid., p. 134

As discussed throughout the DSP, the single most significant driver of Toronto Hydro's capital investment commitments over the 2015-2019 period is the need to renew the backlog of aging and obsolete infrastructure. Toronto Hydro's DSP demonstrates that the proposed amount of System Renewal investment, combined with complimentary or otherwise necessary investments in other investment categories, represents the minimum amount of investment appropriate given the distribution system's current and longer-term needs and the operational needs of the business. The telephone survey results summarized above demonstrate that customer preferences and needs are aligned with this approach, as the majority of customers across the broader customer base acknowledge the need for a sustained renewal program and consider the maintenance or improvement of system performance a priority over the avoidance of price increases. As discussed in Section E2.4.2 above, this prevailing view is seemingly based on the fact that customers consider the costs of the proposed DSP to be reasonable, and that a majority of customers believe that proactive investment is a prudent choice now to avoid future infrastructure challenges.

Investment in New Technology

- 67% of residential customers agree with the view that investments in new technology will increase system reliability, make the local distribution system more efficient and save money in the long run. (19% held the opposing view, that new technologies are a luxury and will cost customers more than they are willing to pay.)[26]

- 61% of GS < 50 kW customers agree with the view that investments in new technology will increase system reliability, make the local distribution system more efficient and save money in the long run. (20% chose the opposing view.)[27]

This survey question was intended to capture customer preferences with respect to System Service investments in programs like Feeder Automation (E7.3) and Energy Storage Systems (E7.11), which Toronto Hydro has included as part of its capital expenditure plan in order to enhance customer value through the mitigation of failure impacts and the targeted enhancement of system performance and efficiency. Customer preferences appear to be in alignment with these objectives.

[24] Ibid., p. 85
[26] Ibid., p. 135
[27] Ibid., p. 136

Investment in Equipment and Tools

- 66% of residential customers agree with the view that Toronto Hydro should be wise with its spending, but that it is also important that staff have the equipment and tools needed to manage the system efficiently and reliably.[28]

- 56% of GS < 50 kW customers agree with the view that Toronto Hydro should be wise with its spending, but that it is also important that staff have the equipment and tools needed to manage the system efficiently and reliably.[29]

This survey question was intended to capture customer preferences with respect to General Plant investments. Most customers recognize the importance of investing in effective and efficient business operations and are comfortable paying for these investments as part of the overall DSP.

(iii) Other Feedback

Innovative also asked telephone survey participants for their reaction to various statements that customers had made in previous phases of the consultation process (e.g., during randomly recruited focus groups). The results of these questions provided additional insight into customer values and preferences with respect to capital investment and other issues.

Of the topics most relevant to Toronto Hydro's mandate, the following received strong agreement (ranging from 57% to 81%) from survey respondents. (The respondent reaction results for all of the following quoted statements can be found on pages 140 and 142 of the Innovative Report, Exhibit 1B, Tab 2, Schedule 7, Appendix B.)

- "A few power outages are fine for me personally, but I worry about the impact this has on more vulnerable people, such as the elderly" (statement for residential class only). Most of the investments in Toronto Hydro's DSP address potential outage causes that could affect service to the elderly, individuals relying on life-support equipment, and those who are otherwise vulnerable. Lengthier outages are likely to have a greater negative impact on vulnerable members of the population. A number of Toronto Hydro's proposed programs for the 2015-2019 period are expected to (i) shorten the length of outages and significantly improve restoration efforts (e.g., Feeder Automation (E7.3); Contingency

[28] Ibid., p. 137
[29] Ibid., p. 138

Enhancement (E7.1)) and (ii) mitigate the reliability risks associated low probability, high impact loss of supply events (e.g., Downtown Contingency).

- "Nobody likes to pay more for electricity, but I think we have an obligation to maintain reliability of our local grid for future generations." As explained above in Section E2.1, Toronto Hydro's proposed capital expenditure plan is designed to deliver long-term value to customers by working toward the objective of substantially clearing the accumulated backlog of end-of-life assets. Toronto Hydro is executing this plan in a "paced" manner intended to limit bill impacts in the short-term while helping to ensure more predictable year-over-year bill impacts and system performance outcomes in the long-term. Part of this strategy involves the expansion of cost-efficient, reliability enhancing technologies like Feeder Automation.

- "We should invest in our electricity system now or we will end up paying more the longer we delay our system renewal." This view also aligns to Toronto Hydro's overarching pacing strategy and the timing and pacing rationale that appears in many of the program business cases. Toronto Hydro has a limited number of skilled resources available at any given time to execute a large capital program. Deferral of the distribution system's renewal needs is likely to result in a growing gap between investment needs and execution capacity, potentially resulting in greater capital costs and deteriorating system performance due to resource constraints.

- "Although waiting until electric equipment breaks down is a good way to get full value out of Toronto Hydro's assets, an important city like Toronto cannot afford the associated service interruptions and should have a higher standard of system reliability" (GS < 50 kW customers were presented with a business-specific variation on this statement). The proposed DSP is projected to deliver system-wide reliability improvements over the course of the plan. A comparison of reliability outcomes for this plan versus the "run-to-failure" approach can be seen in Figures 13 and 14 above. Again, some of the most cost-effect improvements to reliability over this period are expected to come from System Service type investments, such as Feeder Automation and Design Enhancement. Leveraging high-value technologies like Feeder Automation will help maximize the value that residential and business customers derive from the City of Toronto's distribution system.

- "The cost of my electricity bill has a major impact on my finances and requires I do without some other important priorities" (GS < 50 kW were presented with a business-specific variation on this statement). As explained in Section E2.1 above, Toronto Hydro has chosen a "paced" execution strategy for its 2015-2019 capital expenditure plan that considers customer expectations with respect to bill impacts. The suite of programs that constitute this plan were chosen to maximize customer value derived from the system while mitigating the required pace of renewal in the short-term and long-term.

E3 SYSTEM CAPABILITY ASSESSMENT FOR RENEWABLE ENERGY GENERATION

This section provides information on the capability of Toronto Hydro's distribution system to accommodate renewable energy generation (REG) and other distributed generation (DG) connections. This information includes REG applications, their number and capacity, the distribution system's ability to connect, as well as known constraints on the distribution and transmission systems. As well, to obtain the complete picture in terms of cumulative generation connections, overall DG projections are presented.

E3.1 Applications

Toronto Hydro has connected over 890 unique DG connections to the distribution grid since 2009. Figure 1 provides an overview of existing DG connections within Toronto Hydro's distribution system. This represents over 110 MW of generation capacity made up of various types of DG technologies.

FIGURE 1: TORONTO HYDRO DG CONNECTIONS (AS OF MAY 31ST, 2014)

For REG in the "over 10 kW" in size category, there are presently 420 applications representing 53.5 MW of capacity that are in progress for connections within Toronto Hydro's service area. The total REG connections expected as of year-end 2014 and 2015 are 53.9 MW and 85 MW, respectively.

E3.2 Forecasted Connections

In order to determine the number of generation connections in the period covering 2015 to 2019, Toronto Hydro developed a DG connection and capacity forecast. The forecast for 2015 through to 2019 was developed using the historical DG connection rate from 2009 to present. The DG forecasting takes into account historical connection trends with respect to various DG programs, projects presently in progress and Feed-In Tariff (FIT) procurement targets. Forecasting uses a linear approximation to forecast the total generation from 2015 through 2019. The forecast

connection rates of DG and REG are consistent with expectations from the Long-Term Energy Plan and OPA procurement plans.

DG includes both non-renewable generation sources, such as gas powered generators, and REG sources, such as solar photovoltaic or wind turbines. An overview of both DG and REG are important to understand the distribution system impact and integration issues. By the end of 2014, a total of 176.2 MW (nameplate capacity of all DG) is expected to be connected to Toronto Hydro's system. This will be comprised of a combination of FIT projects, Combined Heat and Power (CHP) resources and other distributed generation.

A wide range of proponents have submitted project applications for REG, including many schools, housing, large grocery stores and department stores. Toronto Hydro's present rate of inquiry for individual FIT customers is estimated at 7.5 MW per month spread over 50 inquiries. Schools have received over 300 pending offers to connect renewable generation from the Ontario Power Authority (OPA) with over 40 MW of capacity. The total number and capacity (in MW) of REG connections anticipated over the forecasted five-year period are 972 connections with a corresponding 148.9 MW as shown in Figure 2.

Overall, DG connections are expected to more than triple in total capacity by 2019, reaching over 625 MW as shown in Table 1. This represents an additional 450 MW over the five year planning period on top of the 114 MW of existing DG and 62 MW of DG planned for connection by the end of 2014.

TABLE 1: BREAKDOWN OF DG CONNECTION FORECAST (BY MW) PER PROGRAM TYPE (2015-2019)

Program	Existing (Includes 2014 Planned)	2015	2016	2017	2018	2019	Total (MW)
FIT 1.0 – 2.0	53.9	31.2	0.0	0.0	0.0	0.0	85.0
FIT 3.0 – 7.0	0.0	10.7	23.9	25.8	27.7	29.7	117.8
Combined Heat and Power (CHP)	59.6	35.5	28.2	27.3	24.0	104.0	278.6
Other DG	62.7	32.9	18.0	8.0	15.0	8.0	144.6
Total	176.2	110.3	70.1	61.1	66.7	141.7	626.0

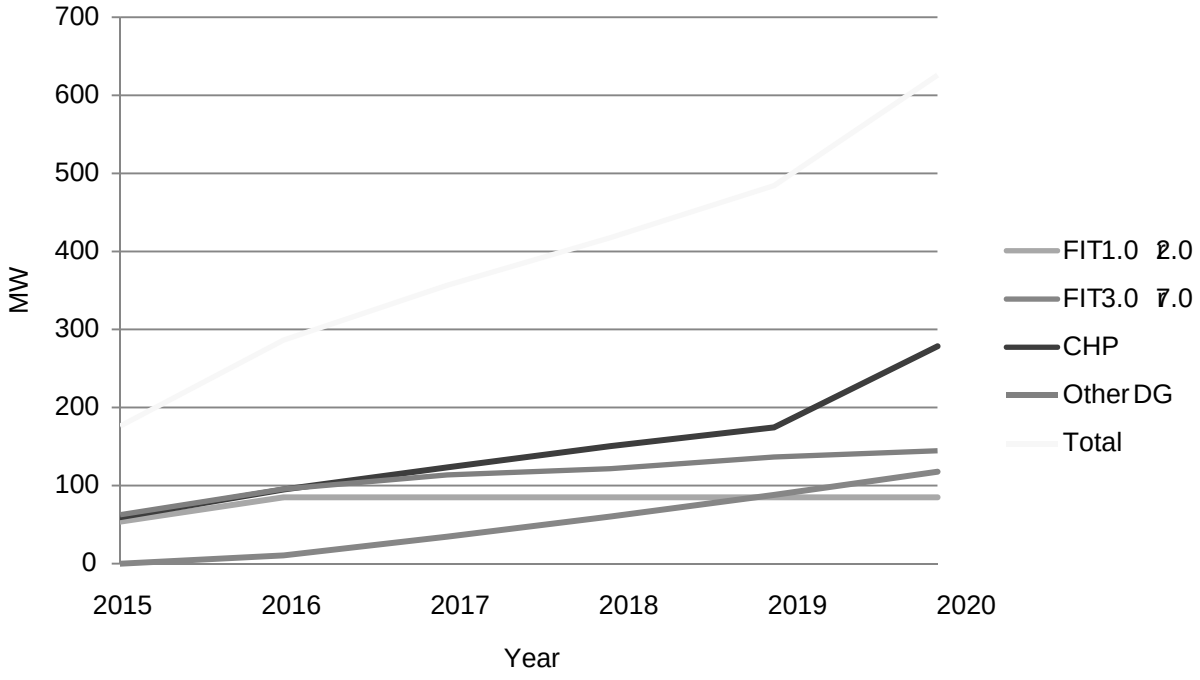

FIGURE 2: GRAPH OF DG CONNECTION FORECAST PER PROGRAM TYPE (2015-2019)

E3.3 Capacity to Connect REG

This section addresses the capacity to connect renewable energy within the service area of Toronto Hydro. Toronto Hydro projects that 626MW of DG will connect to the distribution system by the end of 2019. This capacity will be available for connecting the forecasted DG and REG projects given implementation of the proposed solutions in Section E3.3.3.

E3.3.1 Existing Capacity to Connect

There are several immediate and long-term challenges associated with connecting the forecasted 626 MW of DG to the Toronto Hydro system. As discussed later in section E3.4 Constraints, Toronto Hydro is currently affected by two types of constraints: distribution constraints and transmission constraints. On the distribution level, short circuit capacity is the main constraint that prevents new DG connections to certain stations.

E3.3.2 Existing Constraints to Connect

There are a number of constraints limiting Toronto Hydro's ability to connect DG, including fault current, thermal limits, minimal flows and the ability to transfer loads between feeders in the event of a contingency. The primary constraint at this time is short circuit capacity. At present, the ability to connect new DG is limited by constraints within the Toronto Hydro distribution system and externally in Hydro One Networks Inc.'s (HONI) transmission system.

E3.3.2.1 Transmission Constraints

Presently, transmission constraints pose a DG connection challenge to a significant area within Toronto. The identified transmission constraints at both Manby and Leaside Transformer Stations affect Toronto Hydro's ability to approve requests for DG interconnection. HONI's identified system constraints include the following:

(a) Short circuit capacity constraints per Transmission System Code (TSC) limits;

(b) Thermal Capacity on Station Transformers that limits reverse power flow;

(c) Minimum bus load requirements to limit reverse power flow; and,

(d) Short circuit capacity constraints due to transmission breaker capacity.

As shown in Figure 3, the constrained stations are in the areas of the downtown Toronto 115 kV system and East Scarborough 230 kV system. In 2015, the completion of the planned HONI

capital upgrades on these 115 kV and 230 kV systems is expected to address transmission system short circuit and thermal capacity issues within Toronto Hydro's service area. Toronto Hydro anticipates these constraints will be eliminated as an impediment to the forecasted DG projects in the beginning of 2015.

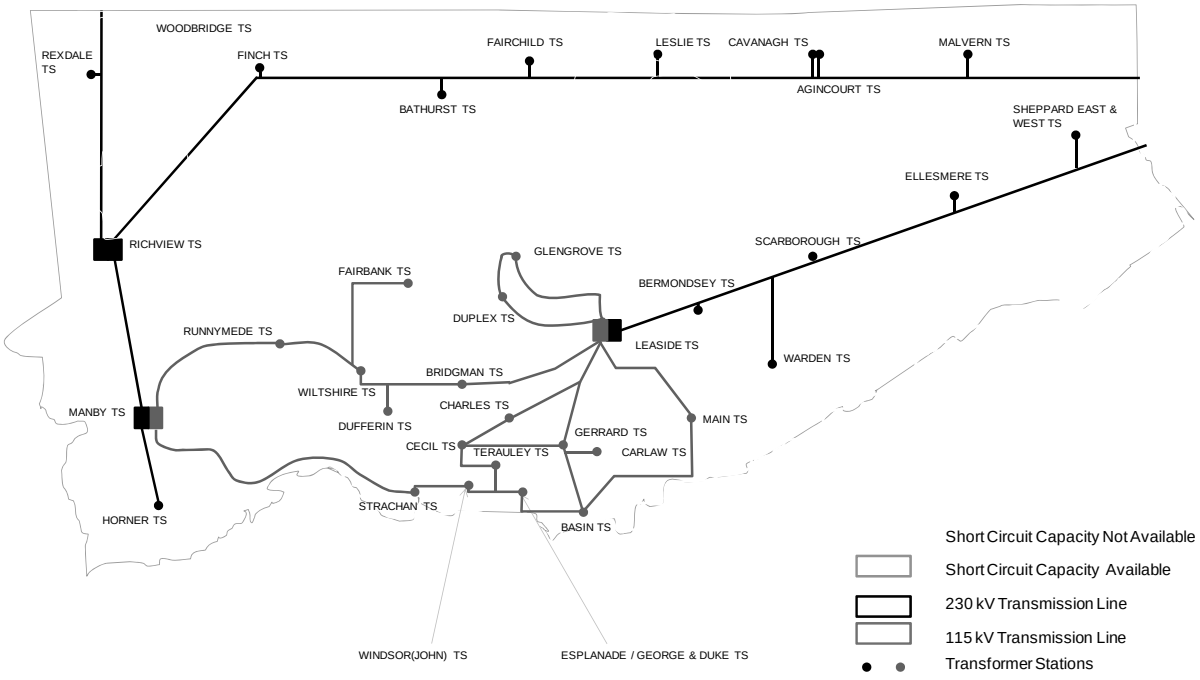

FIGURE 3: SHORT CIRCUIT CONSTRAINTS – PRE-HONI LEASIDE/MANBY/HEARN UPGRADES

E3.3.2.2 Distribution Constraints

The safe and reliable operation of the distribution system prevents Toronto Hydro from connecting DG in situations where short circuit capacity limitations exist. The existing distribution based short circuit capacity constraints are identified as shown in Figure 4. This map displays the areas within Toronto that are presently constrained due to short circuit limits at individual stations. These stations are supplied by HONI transformers and directly connect to Toronto Hydro feeders. The distribution based constraints will remain even after HONI has addressed the transmission constraints at the 230 kV and 115 kV level. As discussed earlier in Section E3.1 (Capacity to Connect), Toronto Hydro proposes advanced high speed protection systems to mitigate the existing short circuit capacity constraints and to satisfy system thermal thresholds, which are

expected to allow the distribution system to accommodate the new REG connections. More detailed information could be found in Sections E5.5.

FIGURE 4: DISTRIBUTION SYSTEM SHORT CIRCUIT CAPACITY CONSTRAINTS MAP

E3.3.3 Planned Solutions to Eliminate Constraints

In order to accommodate the forecasted amount of DG into Toronto Hydro's distribution system, the following solutions have been identified for the 2015 to 2019 period:

(1) Advanced protection systems which are expected to provide the ability to connect additional renewable energy by ensuring system thermal thresholds and short circuit design ratings are satisfied.

(2) A bus-tie reactor that is expected to provide the ability to connect additional DG by lowering the short circuit current on the station bus and distribution system.

(3) Real-time monitoring and control is expected to allow Toronto Hydro to connect the forecasted amount of DG sites, and continue to meet the mandated requirements of the Distribution System Code.

By implementing these solutions, Toronto Hydro expects to be able to provide uniform access across the distribution system, allowing renewable energy generation to connect on a grid-wide basis. In addition, Toronto Hydro forecasts that these investments will permit the utility to connect the forecasted 625MW of DG to the distribution system by the end of 2019. For more detailed information regarding generation protection, monitoring and control, please refer to Section E5.5.

E4 CAPITAL EXPENDITURE SUMMARY

This section summarizes historical and forecasted system capital and system operating and maintenance (O&M) expenditures and their respective drivers for the period 2010 to 2019.

E4.1 Investment Summary (10-Year Comparison)

Table 1 shows the level of spending for the System Access, System Renewal, System Service and General Plant investment categories, as well as the System O&M expenditures, over the historical period from 2010 to 2014, and over the forecasted period from 2015 to 2019. This table aligns with "Table 2 – Capital Expenditure Summary" as specified in Chapter 5 of the Ontario Energy Board's (OEB) *Filing Requirements for Electricity Distribution Rate Applications* (July 17, 2013).

TABLE 1: CAPITAL EXPENDITURE SUMMARY

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
System Access	$44.37	$58.31	$53.15	$86.62	$76.01	$86.13	$93.54	$100.93	$90.41	$85.47
System Renewal	$215.00	$219.25	$157.25	$231.08	$286.37	$251.74	$234.99	$246.35	$260.08	$265.49
System Service	$35.32	$75.63	$38.35	$83.67	$101.34	$76.45	$69.60	$62.51	$49.54	$73.95
General Plant	$55.53	$67.71	$29.28	$33.77	$109.47	$104.63	$99.44	$28.93	$32.13	$27.88
Other CAPEX	$50.36	$24.63	$9.92	$10.52	$12.73	$12.18	$21.22	$28.65	$37.89	$49.37
Total	**$400.58**	**$445.53**	**$287.95**	**$445.66**	**$585.92**	**$531.13**	**$518.79**	**$467.36**	**$470.05**	**$502.16**
System O&M	$114.64	$111.89	$109.03	$119.84	$118.94	$128.76	-	-	-	-

/C

Expenditures within the 2010-2013 historical period are actual expenditures, whereas expenditures for 2014 (i.e. bridge year) are planned expenditures, as the 2014 year has not yet concluded as of this writing.

Section E4.2 provides further details on the capital investments and associated trends for each investment category and the relationship between capital investment and System O&M expenditures.

E4.2 Explanatory Notes on Variances

This section discusses spending profiles for the four capital investment categories and the relationship between capital spending and System O&M expenditures.

E4.2.1 System Access Spending Profile

Toronto Hydro's capital expenditures under the System Access investment category are driven by statutory, regulatory or other obligations that require Toronto Hydro to provide customers with access to the distribution system or to otherwise respond to service requests.

Key investments within the System Access investment category include:

- the connection of new customers and management of those new customer loads through the enablement of load transfer, switching and restoration activities;
- ongoing renewal of metering assets;
- relocation and expansion of plant in response to third party activities; and
- installation of protection and control schemes to manage distributed generation investments (including renewable enabling improvements).

Section E5 provides further details on the nature of this investment category along with full details and justification for the individual capital expenditure programs within. Table 2 outlines the year-over-year spending profile of the System Access investment category from 2010 to 2019.

TABLE 2: SYSTEM ACCESS EXPENDITURES – HISTORICAL & FORECASTED

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
System Access	$44.37	$58.31	$53.15	$86.62	$76.01	$86.13	$93.54	$100.93	$90.41	$85.47

/C

Investments for the System Access investment category were lower in 2010 due to a relatively low level of work executed in the Customer Connections, Metering and Externally-Initiated Plant Relocation & Expansion programs that year. In the subsequent historical years, the total spending in these three programs increased to a peak in 2013 and is anticipated to decrease again in 2014 due to the following:

- The Customer Connections program increased between 2010 and 2013 due to an increasing number of real estate developments. The number of major projects with multi-year construction (e.g., projects related to the Pan Am Games) also increased over this period.

- The amount of work requested by third-party agencies caused an increase in the Externally-Initiated Plant Relocation & Expansion program during the 2010 to 2013 period. In 2013, the scale of projects requested by external parties also increased.

- System Access spending in 2014 is forecasted to be less than in 2013 due to a decrease in Pan Am Games-related Customer Connections work.

- There was also a decrease in the scale of the projects requested by external parties in 2014 compared to 2013.

Toronto Hydro forecasts that expenditures will increase from 2015 onwards to 2017 due to the following factors:

- Continued growth in new developments in Toronto requiring new customer connections.

- Major projects required by agencies such as Metrolinx are forecast to drive increased customer connections.

- Expenditures needed for metering renewal in the Metering program are forecast to significantly increase from the 2014 spend.

- Forecasted expenditures needed for the Load Demand program are forecasted to significantly increase.

- The addition of the Generation Monitoring, Protection & Control program to Toronto Hydro's capital plan. The first period from 2015 to 2017 is addressing existing distribution system constraints while also keeping pace with future connections. Therefore, spending levels are at their highest in 2015 due to the need to address the most urgent existing constraints.

From 2017 onwards to 2019, the overall spending patterns for System Access investments remain the same, with the exception of the Customer Connections and Generation Monitoring, Protection & Control investment programs:

- From 2017 onwards to 2019, there are forecast spending reductions to Customer Connections due to the impact of the Metrolinx activities, which are heavily influencing the spend profile. Toronto Hydro's involvement in these activities is scheduled to reduce and eventual come to completion during the 2018-2019 timeframe, resulting in decreased spending.

- As all existing distribution system constraints within the Generation Monitoring, Protection & Control program are forecast to be addressed by 2017, the final two years of this program focus on addressing only the new distributed generation (DG) connections, which results in spending reductions.

E4.2.2 System Renewal Spending Profile

Toronto Hydro's capital expenditures in the System Renewal investment category are driven by the need to maintain distribution system asset performance at an acceptable standard. These investments will serve to renew those assets that are nearing, at, or exceeding their useful life criteria, along with assets that are functionally obsolete due to accessibility or serviceability deficiencies.

Key investments within the System Renewal investment category include:

- the ongoing renewal of grid systems assets, including overhead, underground, secondary network and stations assets;

- replacement of functionally obsolete legacy infrastructure with infrastructure that meets current standards;

- replacement of failed assets as per reactive processes; and

- continued management of assets along worst performing feeders.

Section E6 provides further details on the nature of this investment category along with full details and justification for the individual capital expenditure programs within. Table 3 outlines the year-over-year spending profile of the System Renewal investment category from 2010 to 2019.

TABLE 3: SYSTEM RENEWAL EXPENDITURES – HISTORICAL & FORECASTED

	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
System Renewal	$215.00	$219.25	$157.25	$231.08	$286.37	$251.74	$234.99	$246.35	$260.08	$265.49

In 2010, investment in System Renewal activities was concentrated on renewing and replacing Toronto Hydro's aging distribution assets and managing Toronto Hydro's worst performing feeders. With the exception of 2012, Toronto Hydro continuously increased annual renewal investments throughout the historical period. This trend was due to the need to proactively manage, through renewal and replacement, the growing backlog of distribution assets that are at or beyond their useful lives. The decrease in spending in 2012 was due to the immediate ramp-down in renewal/replacement capital work following the OEB's decision in Toronto Hydro's Cost of Service application[1] in January 2012.

The decrease in spending from the peak in 2014 to the investments levels from 2015 to 2019 is the result of several factors, including:

- Increased System Service-related investments from 2015 to 2019 targeting critical issues within the overhead, underground and secondary network systems, thereby offsetting core renewal investments within that same time period in order to maintain a "paced" execution strategy.
- Increased Load Demand investments from 2015 to 2019, thereby offsetting core renewal investments within that same time period in order to maintain a "paced" execution strategy.
- Increased System O&M expenditures in 2015, thereby offsetting overall capital investment expenditures within this same time period.

The combined annual amount of System Renewal and System Service expenditures over this period is a result of Toronto Hydro's efforts to establish a prudent balance between (1) ongoing efforts to manage, and eventually clear, the end-of-life and obsolete asset backlog and (2) high value investments that are expected to improve customer value by addressing critical

[1] EB-2011-0144, Decision with Reasons (January 5, 2012).

performance and safety issues (e.g. Stations Expansion) and by improving system operational efficiency (e.g. Feeder Automation). System Service is further discussed in the following section.

E4.2.3 System Service Spending Profile

Toronto Hydro's capital expenditures under the System Service investment category are driven primarily by the need to resolve critical system-wide issues, including capacity and operational constraints, security-of-supply risks, potential safety risks, system reliability deficiencies and other inefficiencies within the existing grid. Beyond the safety and capacity-driven investments in this category, a number of the programs were selected as cost-effective means of delivering significant customer value (in the form of improved service and service efficiency) during the 2015-2019 period while maintaining a relatively modest pace of System Renewal work.

Key investments within the System Service investment category include:

- re-configuration and re-design of feeders to improve restoration capabilities, tree contact resistance and coordination of protective devices;
- installation of assets and technologies to improve restoration capabilities and system efficiencies and mitigate capacity constraints;
- expansion of station infrastructure to mitigate capacity constraints and security-of-supply risks;
- installation of tie points and upgrading of feeder cable sizes to improve load transfer and contingency management capabilities; and
- replacement of legacy assets that pose potential safety risks to crew workers and the general public.

Section E7 provides further details on the nature of this investment category along with full details and justification for the individual capital expenditure programs within. Table 4 outlines the year-over-year spending profile of the System Service investment category from 2010 to 2019.

TABLE 4: SYSTEM SERVICE EXPENDITURES – HISTORICAL & FORECASTED

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
System Service	$35.32	$75.63	$38.35	$83.67	$101.34	$76.45	$69.60	$62.51	$49.54	$73.95

/C

System Service investments between 2010 and 2014 mainly consisted of investments in the Handwell Upgrades and Stations Expansions programs. There is relatively little historical System Service spending related to the overhead, underground and secondary network systems in the form of re-configuration and re-design of feeders, installation of assets and technologies, and installation of tie points and upgrading of feeder cable sizes. Investments for System Service started off at minimal levels in 2010 due to minimal spending related to Stations Expansions. Most of the 2010 spending was made up of capital expenditures in the Handwell Upgrades program.

System Service investment began to increase in 2011 and, with the exception of 2012, continued increasing through 2014, mainly due to Toronto Hydro's investments in the Stations Expansion program – in particular, Phase 1 of construction of the new Copeland Transformer Station (TS). Fluctuation in spending in the Stations Expansion program is due to the fact that the program consists of a small number of significant projects.

The decrease in spending in 2012 was due to the immediate ramp-down capital investments that year following the OEB's decision in Toronto Hydro's Cost of Service application (EB-2011-0144) in January 2012. This ramp-down had a direct impact on the scheduling, execution and resulting spend levels in 2012 associated with Copeland TS.

From 2015 onwards to 2019, System Service investments transition towards the management of critical issues within the overhead, underground and secondary network systems in the form of re-configuration and re-design of feeders, installation of assets and technologies, installation of tie points and upgrading feeder cable sizes. In this same time period, associated investments for Handwell Upgrades and Stations Expansion continue to decrease, resulting in an overall reduction of System Service investments.

The Handwell Upgrades program is planned for completion in 2015. Accordingly, Toronto Hydro does not forecast further spend for this program in the 2016 to 2019 period. The utility also forecasts a decrease in the Stations Expansion program mainly due to the anticipated completion of the Copeland Transformer Station Phase 1 project in 2016. Phase 2 of the Copeland Transformer Station is forecasted to begin in 2019, hence the increase in spending in that year. ***IC***

E4.2.4 General Plant Spending Profile

Toronto Hydro's capital expenditures under the General Plant investment category represent necessary routine and one-time investments into the backbone assets that support Toronto

Hydro's operational activities, including the execution of the capital and O&M related activities and expenditures discussed herein.

Key investments within the General Plant investment category include:

- routine renewal and upgrade of Information Technology hardware and software;
- replacement of the obsolete Enterprise Resource Planning (ERP) system;
- routine renewal and rehabilitation of fleet vehicles and equipment;
- renewal and rehabilitation of building and facilities components and enhancement of security infrastructure in key locations;
- consolidation of operating centres; and
- support programs for ongoing capital and maintenance activities.

Section E8 provides further details on the nature of this investment category along with full details and justification for the individual capital expenditure programs within. Table 5 outlines the year-over-year spending profile of the General Plant investment category from 2010 to 2019.

TABLE 5: GENERAL PLANT EXPENDITURES – HISTORICAL & FORECASTED

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
General Plant	$55.53	$67.71	$29.28	$33.77	$109.47	$104.63	$99.44	$28.93	$32.13	$27.88

/C

Historical spending in the General Plant category was elevated in 2010 and 2011 due to a number of specific needs in several General Plant programs in those years. For example, 2010 and 2011 saw elevated Fleet and Equipment Services costs due to an ongoing fleet renewal program that was required to accommodate the increasing capital program. The spending level decreased significantly in 2012 in accordance with the timing of the OEB's decision in Toronto Hydro's Cost of Service application (EB-2011-0144) in January 2012, and remained at a comparable level in 2013 due to the stabilization of investment requirements across most General Plant programs during the ICM/IRM period. The sharp increase in 2014 spending is attributed to the initiation of Toronto Hydro's Operating Centres Consolidation Program.

Toronto Hydro forecasts that the spending profile will continue at elevated levels for 2015 and 2016 due to several relatively large, one-time IT and facilities investments, including replacement of the obsolete and no longer vendor supported Enterprise Resource Planning (ERP) system, replacement of the obsolete voice radio system, continued execution of the Operating Centres Consolidation Program, and several major asset replacements related existing facilities (e.g. HVAC renewal at Toronto Hydro's 500 Commissioners location). With the completion of these one-time projects, planned spending from 2017 to 2019 is anticipated to taper off significantly.

E4.2.5 Other Capital Expenditures Spending Profile

Toronto Hydro's capital expenditures under the Other Capital Expenditures investment category include the following elements:

- Engineering capital, which represents labour costs associated with engineers, technologists, design technicians and power system controllers (PSCs) for non-discretionary engineering, design and planning work performed on distribution assets that are put in-service. These labour costs are capitalized although they are not directly attributable to specific distribution system assets or projects.
- Historical road cut repairs, which represents the outstanding costs related to temporary and permanent pavement repair work following the execution of application capital investments dating back as far as 30 months.
- Allowance for funds used during construction (AFUDC), which represents the cost to the utility for funds used for the purposes of construction which are allowable for capitalization as defined within the Accounting Procedures Handbook Section 4102.
- Inflation for future expenditures from 2016 onwards to 2019.
- Other miscellaneous capital expenditures, including major tools and pre-capitalized inventory. Expenditures in 2014 also include rental payments to Hydro One Transmission for use of idle transmission facilities. /C /C

Table 6 outlines the year-over-year spending profile of the Other Capital Expenditures investment category from 2010 to 2019.

[2] Ontario Energy Board, Accounting Procedures Handbook for Electricity Distributors, (Toronto: Ontario Energy Board, 2011) at section 410.

TABLE 6: OTHER CAPITAL EXPENDITURES (CAPEX) – HISTORICAL & FORECASTED

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
Other CAPEX	$50.36	$24.63	$9.92	$10.52	$12.73	$12.18	$21.22	$28.65	$37.89	$49.37

/C

Spending reductions in this category from 2010 to 2011 are largely attributed to reductions in engineering capital spending, as certain overhead costs were deemed to be no longer directly attributable to assets as per the 2011 accounting update, therefore resulting in a reduced amount of engineering capital being eligible for capitalization in 2011. The full details associated with the 2011 accounting update and impacts are further explained and defined within Exhibit Q1, Tab 2, Schedule 1 as part of Toronto Hydro's 2011 cost-of-service EDR application (EB-2010-0142).

Engineering capital expenditures are only included within this investment category between 2010 and 2011, and from 2012 and onwards, these costs are integrated within capital investment programs, which therefore drives further reduction in this category between 2011 and 2012 respectively. Increases in this spending category from 2015 onwards to 2019 are largely the product of spending inflation. Furthermore, the AFUDC rate applied by Toronto Hydro from 2010 onwards to 2014 is based on the OEB prescribed rate, whereas the forecasted expenditures from 2015 and onwards are based on MIFRS and thus include AFUDC calculated based on Toronto Hydro's weighted average cost of debt.

From 2016 onwards to 2019, inflation costs are also included within this category, which result in the year-over-year increases.

E4.2.6 System Operating & Maintenance (O&M) Spending Profile

System Operational and Maintenance (O&M) expenditures represent the following five functional areas:

- Supply Chain Services;
- Control Centre;
- Operations Support;
- Distribution Maintenance Programs; and

- Fleet and Equipment Services.

O&M programs within these areas are outlined in greater detail in Exhibit 4A, Tab 02.

Operational programs that support Toronto Hydro's capital and maintenance programs include:

- Supply Chain Services , which supports the execution of Toronto Hydro's asset management plans and other operating programs that rely on procurement and warehousing activities. The overarching goal of the program is to facilitate timely and cost-effective acquisition of services, materials and equipment at requisite quality, while also maintaining an optimal amount of inventory to support uninterrupted work execution and manage materials handling costs.

- The Control Centre , which allows Toronto Hydro to safely and reliably operate the utility's distribution grid through real-time system control and monitoring activities carried out from a single location. The control room coordinates the necessary system switching and restoration work to mitigate the impact of emergency outages, enables load transfers for capital and maintenance work, and monitors the flow of electricity across Toronto Hydro's distribution plant.

- Operations Support , which provides functions such as program and work management, planning, contractor administration, trades training, and engineering support.

Maintenance programs, which assess the condition and prolong the useful life of Toronto Hydro's assets include:

- Distribution Maintenance Programs , which are designed to maintain asset performance (i.e. reliability) and mitigate risks associated with asset failures. The core philosophy at the heart of many of the programs is Reliability-Centered Maintenance (RCM). RCM defines maintenance tasks for a particular asset class to maximize its reliability based on its function and its criticality to the distribution system, while minimizing costs. Programs are also designed to account for risks and other factors such as the safety of Toronto Hydro's employees and the public, obligations found in environment, health and safety legislation and regulations, equipment performance and failure data, manufacturers' recommendations, and industry best practices. Distribution Maintenance programs are executed under four categories which include:

- Preventive Maintenance: Typically cyclical inspection and maintenance tasks, which emphasize assessing asset condition, preserving performance over the expected life of the asset, and maintaining public and employee safety.

- Predictive Maintenance: Testing or auditing of equipment for a predetermined condition (or conditions) that anticipates failures and enables further maintenance tasks to prevent those failures.

- Corrective Maintenance: Repairing or replacing equipment after a deficiency has been reported. Corrective Maintenance actions typically arise from deficiencies discovered during the execution of Preventive or Predictive Maintenance tasks, or temporary repairs that have been made during Emergency Maintenance to restore power.

- Emergency Maintenance: Responding to unplanned and urgent events that occur on the distribution system including the repair or replacement of equipment that has failed and caused a power disruption to Toronto Hydro customers.

f Fleet and Equipment Services , which oversees procurement, maintenance and disposal of Toronto Hydro vehicles, associated equipment, and employee personal protective gear. It is also responsible for ensuring that certain safety equipment and implements are tested and/or repaired in accordance with the requirements of the Occupational Health and Safety Act, 1990, [3] the Infrastructure Health & Safety Association, and other applicable standards.

The expenditures for System O&M are as follows:

TABLE 7: SYSTEM OPERATION & MAINTENANCE EXPENDITURES – HISTORICAL & FORECASTED ($ MILLIONS)

CATEGORY	Historical Spend ($M)					Forecasted Spend ($M)				
	2010A	2011A	2012A	2013A	2014P	2015	2016	2017	2018	2019
System O&M	$114.64	$111.89	$109.03	$119.84	$118.94	$128.76	-	-	-	-

During the 2010 to 2012 period, System O&M expenditures decreased primarily due to reductions in Operation Support services from 2010 to 2011 and reductions in Corrective Maintenance from 2011 to 2012. In 2013, expenditures increased due to costs associated with Toronto Hydro's

[3] R.S.O. 1990, C.O.1. ["OHSA"]

emergency storm response following the December 21, 2013 ice storm. In 2014, expenditures are forecasted to increase from 2012 spending levels due to additional Operation Support services for Toronto Hydro's capital and maintenance programs. In 2015, expenditures are planned to increase primarily due to increases in Distribution Maintenance programs. The projected budgets from 2016 to 2019 are expected to increase in line with inflation.

The number of assets that are approaching or are beyond their expected useful lives has been and will continue to grow during the 2015 to 2019 period. Aging assets necessitate robust maintenance programs to mitigate a wide variety of potential risks associated with possible asset failures including public and employee safety, environmental, system reliability and financial risks. As a result, Toronto Hydro expects that it will be necessary to sustain an increased level of System O&M expenditures during the 2015 to 2019 period in order to allow Toronto Hydro to detect deteriorating equipment conditions and deficiencies prior to equipment failure.

In addition, Toronto Hydro expects that a sustained increase in expenditures will allow the utility to:

- reduce vegetation management cycles;
- conduct PCB testing at below-grade structures, pad-mounted equipment locations and customer locations;
- expand the usage of modern and new technologies, tools and testing methods such as ultrasonic testing to detect partial discharge (corona), infrared scanning to detect thermal anomalies, oil testing to monitor transformer health, and cable testing to detect degradation of underground cables;
- increase proactive maintenance activities at customer locations and substations; and
- enable Toronto Hydro to maintain assets that were formerly part of the street lighting system in Toronto.

Capital and System O&M programs are interrelated, as ageing and deteriorated assets that are not replaced through capital work will result in deteriorating conditions over time. These conditions must be managed through System O&M work, including inspections, tests, and corrective maintenance to mitigate elevated risks of failure. These activities place upwards pressure on expenditures within certain segments of System O&M programs. The opposite also holds true as increases in capital work can result in reductions in some System O&M work.

Examples of this include capital replacements and enhancements for legacy distribution assets such as fibertop network units, reverse power breakers, and porcelain insulators. Examples also include corrective maintenance expenditures, which during the 2010 to 2013 period, experienced a reduction in part due to increases in planned capital expenditures on ageing and deteriorated assets. For 2014 and 2015, corrective maintenance is expected to rise, however it will remain below the peak levels experienced in 2011.

Although System O&M and capital investments are interrelated, a significant portion of System O&M expenditures are directed to activities that are independent of particular capital expenditure levels, including routine maintenance to preserve asset performance over its expected life; vegetation management to maintain minimum clearance requirements for overhead conductor and equipment; cyclical patrols and inspections undertaken to comply with minimum Distribution System Code requirements; corrective maintenance activities to address deficiencies caused by animal, pest, or tree contacts; and emergency maintenance following severe weather and storm damage. In addition, System O&M programs are necessary to provide the information that is used to plan Toronto Hydro's capital programs such as asset health and condition information. This is particularly important given Toronto Hydro's ageing asset base, which cannot be feasibly replaced through capital work in a short time frame due to a variety of factors such as resource and logistic constraints. The information captured through Toronto Hydro's System O&M programs is necessary to enable the prioritization of assets for capital work and to maximize the likelihood that assets that remain in-service have not surpassed end-of-life.

E4.2.6 Overall Trends

As illustrated in Table 11 above, with the exception of 2012, Toronto Hydro's historical capital expenditures have generally increased over the five-year historical period from 2010 to 2014 in the System Access, System Renewal, and System Service investment categories. This increase in investment was made because of Toronto Hydro's gradually worsening distribution system reliability due to a large number of aging and deteriorating infrastructure assets. Also, an increase in investment was required for the capacity growth seen between 2010 and 2014 and the increase in real estate developments and large infrastructure projects during that period.

General Plant spending was elevated in 2010 and 2011, partly due to the corresponding ramp-up in distribution system capital spending. Routine General Plant investments were stable from 2012-2014, but spending increase sharply in 2014 due to the initiation of the Operating Centres Consolidation Program. Spending in the General Plant category appears front-loaded during the 2015-2019 due to a number of larger, one-time investments required in the early years. ***IC***

Generally, the forecasted capital expenditures for the planning horizon of 2015-2019 reflect the continued long-term need for significant capital commitments in order to deliver safe and reliable service to Toronto Hydro's customers. A large portion of Toronto Hydro's infrastructure is expected to deteriorate and become obsolete between 2015 and 2019. At the same time, Toronto Hydro projects that the number of customers and system capacity will continue to grow over the same period. A corresponding increase in capital expenditures is required in order for Toronto Hydro to provide safe and reliable service in these future years.

flow of electricity because DG sources are located in close proximity to the distribution loads that they serve.

Finally, System Access Investments include investments related to the relocation of existing Toronto Hydro plant in order to accommodate third party requests for facility relocation. Third parties requesting plant relocation are typically public agencies responsible for development of public infrastructure. Distribution expansion activities, where implemented in concert with such relocation work, are also included in this category. Table 1 provides the trigger drivers for capital investments in this category.

TABLE 1: TRIGGER DRIVERS FOR SYSTEM ACCESS CATEGORY

Driver	Description
Customer Service Requests	ƒ The fulfilment of Toronto Hydro's obligation to connect a customer to its service. This includes both traditional demand customers and distributed generation (DG) customers. The obligation to connect holds as long as there are no safety concerns for the public or employees and there is no adverse affect on the reliability of the distribution system. ƒ Expansion or enhancements to the system when a connection cannot be made with existing infrastructure.
Mandated Service Obligations	ƒ Compliance with all legal and regulatory requirements and government directives. ƒ Measurement Canada, the Ontario Energy Board (OEB) and the Independent Electricity System Operator (IESO) impose regulations concerning metering that Toronto Hydro must comply with.
Third Party Requests	ƒ Mandated system modifications for property or infrastructure development by government agencies and other entities.

Table 2 provides a brief description for each investment program within the System Access narrative along with total expenditures for each program from 2015 onwards to 2019. Individual section numbers for each investment program are also provided in this table.

TABLE 2: DESCRIPTIONS OF SYSTEM ACCESS INVESTMENT PROGRAMS

Program Index and Name		Descriptions	Total (5 yrs)
E5.1	**Metering**	Enable Toronto Hydro to meet its mandatory service obligations with respect to revenue metering and wholesale metering. This will be accomplished by testing meters, replacing damaged and obsolete meters, and upgrading the under-capacity and obsolete collector stations. Upgrading Toronto Hydro's Interval Metering MDM software will help customers manage their energy use and costs by providing them with timely access to their data.	**$82 M**
E5.2	**Customer Connections**	Toronto Hydro is obligated to connect new customers or upgrade existing customers to a larger service if requested, as required under the terms of Toronto Hydro's distribution license, the Distribution System Code and the *Electricity Act, 1998*. On average, 10,000 requests for new services, upgrades, and removals are made each year and the amount is expected to increase with current and proposed development.	**$261 M**
E5.3	**Externally-Initiated Plant Relocation & Expansion**	Toronto Hydro is required to modify/relocate its system to accommodate property or infrastructure development (e.g., requests from a road authority to move a pole line). Toronto Hydro works with the external agency in question to accommodate the project, and investigates opportunities for cost-efficient expansion work.	**$20 M**
E5.4	**Load Demand**	With increased load in concentrated areas due to the city's growth, equipment (such as undersized cables) in the system must be upgraded in the short-term to address contingency issues to accommodate this increased demand. The problem is expected to be addressed by transferring loads to stations with available capacity, upgrading undersized equipment and cables, and ensuring civil infrastructure can support increased demand. This will allow Toronto Hydro to continue connecting customers in these areas without harming system reliability, customer value, and operational flexibility.	**$75 M**
E5.5	**Generation Projects Protection and Control**	Toronto Hydro is mandated to make every reasonable effort to connect distributed generation users. This program involves installation of bus-tie reactors at station buses, advanced protection systems, and monitoring and control systems to handle the increasing DG penetration in the City of Toronto, including renewable energy generation (REG) projects.	**$19 M**

/C

/C

The following Sections E5.1 though to E5.5 contain the details and justification for each capital investment program contained within the System Access investment category.

E5.1 Metering

TORONTO HYDRO CREW ASSESSING RESIDENTIAL METER

E5.1.1 Summary

Program Description

There are two components to the Metering Program: Revenue Meter Compliance (RMC) and Wholesale Meter Compliance (WMC). Each of these initiatives is designed to ensure that Toronto Hydro remains in compliance with legal and regulatory requirements.

Revenue metering refers to the meters Toronto Hydro uses to measure each customer's energy use in order to accurately bill its customers using time-sensitive rates. Revenue metering is governed by the Gas and Electricity Inspection Act[1] and associated regulations administered by Measurement Canada. The RMC initiative is needed to maintain and manage metering and data collection systems for lawfully and accurately billing customers. Revenue Meter Compliance includes:

- Revenue Meter Replacement
    - Meter Compliance Sampling and Re-verification

[1] R.S.C. 1985, c. E-4. ["Gas and Electricity Inspection Act"].

- Meter Re-verification for Large User Class

- Interval Metering System Upgrade
- SmartSynch Interval meters Replacement
- Suite Metering System Upgrade
- Suite Meter Installations
- Provincial MDM/R Integration

Wholesale metering refers to the metering of electricity supplied to Toronto Hydro at the HONI transmission network grid supply points. This information provides data for the IESO administered Wholesale Market. The accurate measurement of electricity supply to Toronto Hydro is vital to its operation because the utility depends on the measurements to determine the commodity cost that it passes on to consumers. In addition, Toronto Hydro is obligated to remain in compliance with the IESO Market Rules, which define the meter data transmission requirements from LDCs as Market Participants to IESO.

Wholesale Meter Compliance includes:

- Wholesale Metering and Transformer Replacement

The following is a summary of the anticipated benefits associated with this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	• Testing and re-verifying meters will help to ensure that all customers are billed accurately. • Replacing data collection and processing systems is expected to provide timely access to granular energy use data and allows customers to manage and control their energy costs. • Maintaining the accuracy of Toronto Hydro's Wholesale meters impacts the invoice Toronto Hydro pays to the IESO, and directly impacts all of Toronto Hydro's non-interval greater than 50 KW demand customers.
Reliability	• Installing high-end meters for Toronto Hydro's largest customers will provide Toronto Hydro with ground fault data and power quality monitoring information • The Metering Program is expected to improve the reliability of Toronto Hydro's distribution system by maintaining and improving data collection and communication from smart meters and integrating the data with the utility's Outage Management System (OMS).

Efficiency	ƒ Upgrading the Large User MDM system will allow the daily collection and processing of interval data for 9,500 interval meters that at the present time, are manually read because of limitations of the current system's processing time and capacity. ƒ Installation of remote disconnects and reconnects is expected to reduce demands on labour and vehicles, as Toronto Hydro will be able to perform these activities remotely. ƒ Interval metering MDM Software and hardware upgrades for Large Users will include system functionality that allows for more efficient power outage management by providing information for each metering point on outage and restoration notifications. Improved field dispatch efficiency should be achieved, since power outages can be verified before field crews are dispatched to the customer location, reducing power outage duration (SAIDI).
Other Benefits	ƒ The Metering program is expected to provide environmental and economic benefits. Conservation has a direct impact on Toronto Hydro's carbon footprint and the cornerstone of conservation is offering interval data. Conservation programs require the validation of energy savings. In particular, Large Users rely on the detailed meter data to identify the potential areas for saving, and subsequently to confirm that the reduction in electricity usage has been achieved. Contracts between Energy Services Companies (ESCO) and customers will use the energy data to validate and pay for the conservation targets met. ƒ In terms of economics, Interval Metering MDM system upgrade for Large Users is expected to provide information to facilitate contract obligations, support for DR3 and make data available at five minute intervals for the entire group of qualifying customers. This program is also expected to provide information and processing for OPA's distributed generation programs such as FIT and microFIT data collection and credit generation.

Program Drivers

The trigger and secondary drivers for the Metering Program are listed in the table below.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Mandated Service Obligations	ƒ In order to operate as a LDC, Toronto Hydro needs to comply with all legal and regulatory requirements and government directives related to revenue metering and wholesale metering. o For revenue metering, Toronto Hydro is governed by the Gas and Electricity Inspection Act, as well as provincial legislation as governed by the IESO, SME and OEB. o For wholesale metering, in addition to meeting the above regulations, IESO Market Rules specifications also apply.
Secondary Driver	Reasoning

Failure Risk	***f*** Failed or inaccurate meters tend to not measure or under-measure the electricity consumed by the customers. It is incumbent upon Toronto Hydro to ensure meters are systematically tested and re-verified so that failed meters do not remain in service.

Preferred Alternative

As discussed above, Toronto Hydro is required by law to ensure that electricity usage information is collected accurately for the purposes of billing customers. As such, there are no alternatives to this program.

Timing and Pacing

The timeline for the Metering Program's initiatives and projects is driven by regulatory obligations and compliance requirements with respect to the IESO and the OEB. Planned spending for the period 2015 to 2019 is outlined below.

TABLE C: HISTORICAL AND FORECAST SPENDING

	Historical Spending					Future Spending				
Year	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
CAPEX ($M)	$28.4	$22.1	$12.1	$12.2	$14.0	$24.7	$16.6	$14.7	$11.7	$13.7

/C

E5.1.2 Program Description

There are two components to the Metering Program: Revenue Meter Compliance (RMC) and Wholesale Meter Compliance (WMC). While revenue metering is the basis for how Toronto Hydro bills its customers, wholesale metering is the foundation for the bill that IESO issues to Toronto Hydro for wholesale settlement. Each initiative in the Metering Program includes projects designed to keep Toronto Hydro compliant with legal and regulatory requirements.

Revenue metering refers to the meters Toronto Hydro uses to measure each customer's energy use in order to accurately bill its customers using time-sensitive rates. Residential and low volume Commercial Smart Meters and Suite Meters are billed on Time-Of-Use (TOU) rates while larger C&I customers utilize interval meters and are billed on their HOE at the HOEP market price. Revenue metering is governed by the *Gas and Electricity Inspection Act* and associated regulations administered by Measurement Canada. The RMC initiative includes projects needed to maintain and manage metering and data collection systems so that Toronto Hydro can lawfully and accurately bill its customers.

Wholesale metering refers to the metering of electricity supplied to Toronto Hydro at the HONI transmission network grid supply points. This information provides data for the IESO administered Wholesale Market. Measurement Canada regulations and IESO specifications offer meter compliance requirements. The accurate measurement of electricity supply to Toronto Hydro is vital to its operations because the utility depends on the measurements to determine the commodity cost that it passes on to consumers. In addition, Toronto Hydro is obligated to remain in compliance with the IESO Market Rules, which define the meter data transmission requirements from LDCs as Market Participants to IESO.

The Metering program's primary purpose is to enable Toronto Hydro to meet its mandatory service obligations with respect to revenue metering and wholesale metering. The estimated total capital budget for this program is $81.5 million for the 2015-2019 forecast period. The following subsections explain the various initiatives and projects that constitute Toronto Hydro's planned Metering program. /C

E5.1.2.1 Revenue Meter Replacement

Revenue meter replacement is part of the RMC component of this program and consists of the following initiatives:

- Meter compliance sampling and re-verification;
- Meter re-verification for Large User Class

(i) Meter Compliance Sampling and Re-verification

Measurement Canada has sole jurisdiction with respect to the administration and enforcement of the Weights and Measures Act[2] and the Electricity and Gas Inspection Act. These Acts and related regulations govern Toronto Hydro's ability to bill its customers for electricity usage. The requirements state that all meters must be resealed at specified intervals to ensure that a customer's electricity use is metered accurately. Once a seal expires, the meter cannot legally be used for billing purposes and must either:

(1) have its seal period extended (via compliance sample-testing); or

(2) be replaced (i.e., "re-verified" and resealed).

Toronto Hydro has submitted its 2015-2019 meter sampling and re-verification program to Measurement Canada in order to remain compliant with its regulatory obligations. Under the sampling and re-verification program, Toronto Hydro plans to test approximately 3% of its smart meters. Figure 1 below depicts a typical residential smart meter. Measurement Canada regulations permit LDCs to form sample groups of meters with homogeneous meter characteristics and test randomly selected meters from within each sample group for accuracy. In order to form sample groups, several characteristics are taken into account, including the meter's mechanism for measuring electricity usage, as well as when the meters were manufactured, tested and sealed. The meters forming a sample group must be of the same type and have the same meter characteristics. The seals of meters within a sample group may be extended for an additional eight years depending on the results of the meters tested within that sample group.

[2] R.S.C., 1985, c. W-6. ["Weights and Measures Act"]

FIGURE 1: TYPICAL RESIDENTIAL SMART METER

Meters that do not belong to any sample group must be individually removed for re-verification. These meters are made up of a variety of meter types and rate classes and are typically used for C&I customers that require greater functionality, such as peak demand measurement and short interval energy measurements (i.e., intervals as small as five minutes in length). Meters removed for re-verification that have seals expiring between 2015 and 2019 must be removed and replaced before their seals expire.

In all, Toronto expects to remove 31,571 out of a total of 644,000 meters from the field for sample-testing or re-verification from 2015-2019 (see Tables 2 and 3 below). Not included in these figures are the 635 meters for Large User Class C&I customers and the 8,500 SmartSynch interval meters, which are managed under other initiatives of the Smart Meter program. Taking into account the exclusions, the total estimated cost of the meter compliance sampling and re-verification initiative is $12.14 million. /C

TABLE 1: METERS WITH SEALS EXPIRING IN 2015-2019 FOR SAMPLE-TESTING

Year	Seal-Expiring Meters	Sample Meters
2015	14,527	436
2016	194,000	5,820
2017	214,652	6,440
2018	146,498	4,395
2019	55,563	1,667
Total	**625,240**	**18,758**

TABLE 2: METERS TO BE REMOVED FOR RE-VERIFICATION

Year	Large C&I Meters	Small/Medium C& I Meters	Suite Meters
2015	310	39	219
2016	100	86	45
2017	180	170	1,250
2018	15	16	4,134
2019	30	68	6,152
Total	**635**	**378**	**11,800**

Toronto Hydro undertakes electric service disconnections due to customers' payment delinquency. The installation of remote disconnects is expected to result in fewer on-site field work, which saves labour and vehicle costs, thereby reducing Toronto Hydro's operating expenditures and removing the need to physically attend to a property to cut-off the service.

Based on historical trends (see Table 3 below), 31,350 smart meters with remote disconnect switches are projected to be installed between 2015 and 2019 under the delinquent account program. The total incremental cost for the remote connect disconnect switch function is estimated to be $4.83 million for the delinquent account program, or $967 K, per year. The total savings generated from avoiding service disconnection and reconnection field visits is estimated to be $5.9 million over the life of the installed meters. These meters will only be installed when a visit is required to cut the service off due to non-payment. At the time of the disconnection, a remote connect/disconnect meter will be installed to disconnect the service. The installation of this meter will avoid the second site visit to reconnect the service after payment for the account is made, since this meter is capable of reconnecting the service remotely from Toronto Hydro's offices. /C

TABLE 3: ESTIMATED FIELD COLLECTION DISCONNECTIONS

Year	Number of Disconnects Per Year	Estimated Number of Services that Need Remote Disconnect Meters
2015	7,780	6,150
2016	7,860	6,200
2017	7,940	6,270
2018	8,020	6,340
2019	8,100	6,390
Total	**39.700**	**31,350**

(ii) Meter Re-verification for Large User Class

Out of all meters that will be removed for re-verification between 2015 and 2019 (Table 2), 635 meters serve 530 customers that have average monthly demands over one megawatt (1 MW). As a group, these Large User Class customers represent 0.09% of Toronto Hydro's customers, yet they generate approximately 28% of Toronto Hydro's total yearly revenue. These customers also require more sophisticated information requirements for their meters as compared to other customers. For reasons to be explained in Section 5.1.3, the meters will be replaced with higher accuracy meters that have additional features such as three-phase power measurement, meter diagnostic and power quality functionality, as well as ten channels of five minute intervals to support Ontario Power Authority (OPA) conservation and program initiatives.

The estimated cost for this initiative is $6.02 million between 2015 and 2019, or $1.20 million per year. /C

E5.1.2.2 Interval Metering System Upgrade

The interval metering system upgrade project is another element of the RMC component of the Metering program. Toronto Hydro plans to upgrade the interval metering system, including the meter data management system, in order to comply with regulatory requirements and IESO Market Rules.

Toronto Hydro's existing legacy interval metering and complex billing Advanced Metering Infrastructure (AMI) software and hardware and its related components will be completely replaced with a competitively procured advanced AMI solution. Related components include:

- MV90Xi - for interval meter data collection,
- MVSTAR - for interval meter data management, and
- MVWEB - for interval metered customer data web access and web presentment, which provides customers with the ability to (i) download their data, (ii) graph their usage profiles and (iii) display power factor information and various energy bar graphs, line graphs and daily, weekly and monthly comparisons of their energy use.

While the rationale for this project is provided in Section 5.1.3, it merits mentioning here that the replacement system is expected to serve all C&I customers with average peak demand greater than 50 kW (Table 4) given that the current interval metering system is used for Toronto Hydro's largest customers. The interval metering system upgrade should align Toronto Hydro's operations

with the OEB's Proposed Amendments to the DSC, Board File No. EB-2013-0311[3] to amend section 5.1.3 that requires a distributor to install a Metering Inside the Settlement Time Frame (MIST) meter for any installation greater than 50 kW. In order to qualify as MIST meters, interval data must be collected and validated within the designated settlement period. The interval metering system upgrade will enable Toronto Hydro to perform these activities.

> *"The Board is of the view that, given the current metering and pricing environment, it is appropriate to amend section 5.1.3 of the DSC to require a distributor to install a MIST meter on any installation that is forecast by the distributor to have a monthly average peak demand during a calendar year of over 50 kW."*[4]

The new system has the scalability to process up to one million metering points. It will provide interval metered customers access to their previous day's energy use. Toronto Hydro's expected processing time for its 12,500 total meters (3,000 current interval meters and the additional 9,500 not on the current system due to the exorbitant processing time and capacity limitation – the system is 12 years old and cannot be scaled any further) should be less than five hours in total for the data collection, validation and monthly billing processing, with the ability to scale the processing time further if required.

This project, including software installation, hardware upgrades, system interfaces and training, will take about 18 months to implement between 2015 and 2016. The estimated cost of the project is $5.28 million. /C

TABLE 4: CUSTOMERS SUPPORTED BY INTERVAL METERING SYSTEM

Year	Total Meters Impacted	Total Annual Revenue ($M) Read by System
2015	3,000	$147
2016	12,500	$204

[3] EB-2013-0311, Notice of Amendment to a Code (May 21, 2014).
[4] EB-2013-0311, Notice of Proposal to Amend a Code – Proposed Amendments to the Distribution System Code (January 16, 2014) at page 2.

E5.1.2.3 SmartSynch Interval Meters Replacement

SmartSynch interval meters replacement is another element of the RMC component of the Metering Program. Toronto Hydro plans to upgrade SmartSynch interval meters in response to 2G wireless network obsolescence.

Toronto Hydro uses 8,500 SmartSynch Interval Meters that possess wireless GPRS read capability to retrieve billing information on the 2G wireless network. The interval meters are remotely read and the data is made available for customer access the morning after the billing period. However, Rogers Communications Inc. (Rogers) has announced that it is planning on abandoning its 2G wireless network platform in 2018, rendering Toronto Hydro's 8,500 interval meters using a SmartSynch Rogers GPRS module obsolete. Accordingly, these meters will need to be upgraded prior to 2018 so that Toronto Hydro can maintain wireless communications. Given that the operational cost of using wireless technology is about 25% of the cost of using a standard phone line, it is the preferred option in locations where a GPRS signal can be used. Toronto Hydro is working to create a communication network that will be ready by the first quarter of 2015.

Toronto Hydro expects to take the SmartSynch meters out of service, return them to the manufacturer so that they can be retrofitted with a new SIM card and cellular hardware for the 3G network, tested and re-certified at the same time (extending the seal period) and then re-installed. Toronto Hydro estimates that the total cost of this upgrade is $5.27 million and that it should be completed in 2015. /C

E5.1.2.4 Suite Metering System Upgrade

The suite metering system upgrade is another element of the RMC component of the Metering Program. Toronto Hydro plans to upgrade the suite metering MDM system so that the utility can continue to meet the IESO's functional specifications for an AMI.

While the interval metering system described in Section 5.1.2.2 is used to collect and manage interval data for C&I customers, the suite metering system is used for residential customers in apartment or condominium buildings. These multi-suite residential buildings contain multiple suites that are metered individually, with the meter data being transmitted through the building's electric wiring to a computer. A central AMI system at Toronto Hydro collects and manages the meter data from the computers of these multi-suite residential buildings.

The current Primeread system is used to access the building's centralized computer and collect the hourly energy use data from the Power Line Carrier (PLC) computers in the multi-suite

residential buildings was implemented in 2012 when Toronto was downloading data for approximately 26,000 suite meter billing accounts. In the 2015-2019 period, the number of suite meter accounts requiring download is expected to rise from 26,000 to 93,000 (see Table 5). The 93,000 figure is predominantly based on signed contracts that Toronto Hydro has made with developers for new buildings as well as the introduction of a small number of new suite meters in 2015 and 2016. The number of suite meters requiring download from 2017 to 2019 is based on new condominium sales and Toronto Hydro's historical market share. Both the hardware and software of the Primeread system will need to be upgraded to handle the projected higher volume of meter data.

This project's total estimated cost is $1.42 million and is expected to be completed in 2019.

TABLE 5: GROWTH OF SUITE METERS BILLING ACCOUNTS

Year	Number of Suite Meter Accounts
2012	26,000
2013	34,400
2014	45,000
2015	56,000
2016	64,000
2017	73,000
2018	83,000
2019	93,000

E5.1.2.5 Suite Meter Installations

The suite meter installation initiative is another element of the RMC component of the Metering Program.

Specific meters are needed for condominium suites, which are different from smart meters used in residential houses, such as detached houses or townhouses. These condominium suites require the installation of meters that can upload the meter data to a computer in the building, which in turn can be collected by the suite metering system at Toronto Hydro. The developer, owner, or condominium board has the choice to either use a LDC to provide metering services or a unit sub-metering provider. The Energy Consumer Protection Act[5] also mandates that Toronto Hydro provide these services to developers and existing multi-residential buildings where they

[5] S.O. 2010, c.8. ["ECPA"]

have not chosen a unit sub meter provider. The LDC is defined by the ECPA as the suite meter installation meter service provider of last resort in the event that the condominium cannot secure a meter service provider. The developer may also directly request that Toronto Hydro install suite metering for the condominium suites

Instead of bulk-metering all the residential suites of a condominium building as an equivalent single consumer, suite meters are installed so that the electricity usage of the condominium residential suites can be measured separately for billing. The ECPA requires that residential units in new condominiums be metered individually as further explained in Section 5.1.6.

Based on condominium construction projects already scheduled in Toronto, as well as other projected condominium development as referenced in section 5.1.2.4 above, the estimated numbers of condominium suites from 2015 to 2019 that will require suite meter installation by Toronto Hydro are shown in Table 6. The total capital cost estimate for this initiative is $35.61 million. /C

TABLE 6: PROJECTED SUITE METERS TO BE INSTALLED

Year	Number of Suite Meters	Estimated Cost($M)
2015	12,000	$8.58
2016	8,500	$6.22
2017	9,000	$6.56
2018	9,500	$6.98
2019	10,000	$7.27
Total	**49,000**	**$35.61**

/C

E5.1.2.6 Provincial MDM/R Integration

The provincial Meter Data Management Repository (MDM/R) integration initiative is another element of the RMC component of the Metering Program. The objective of this initiative is to integrate Toronto Hydro's customer care and billing system (CC&B) and smart meter data management system (Operation Data Store or ODS) with the provincial MDM/R operated and maintained by the provincial Smart Metering Entity (SME). The following explain each of these elements:

- The ODS is Toronto Hydro's MDM system and the CC&B is used by Toronto Hydro to bill its customers.

- The Provincial MDM/R is the smart meter data management and database system operated by the SME, which is used to manage the smart meter data from all of the LDCs in the province.
    - The Provincial MDM/R retrieves smart meter data from the LDCs' MDMs, and validates and corrects the meter data through a standard Validation, Estimation and Editing (VEE) process to ensure the validity of the meter data for billing. The validated meter data is then be transmitted to the LDCs for billing their customers.
    - The SME is a business unit granted exclusive authority over smart meter data services in the province as well as the maintenance and operation of the provincial MDM/R.

In order for the smart meter data to be retrieved by the provincial MDM/R from the LDCs' MDM systems, and to later be transmitted back to the LDCs' billing systems for billing the customers, it is necessary for the LDCs' MDM and billing systems to be integrated with, or interfaced to, the provincial MDM/R system. The integration, or interfacing, must be implemented based on the protocols and specifications defined by the SME. Extensive testing is required in performing the integration to ensure the proper transmission of data between the LDC's systems and the provincial MDM/R. Business processes of the LDC also need to be modified to allow proper control and management of the meter data transfer to the provincial MDM/R and the validated data being sent back to the LDC in order to bill customers. Both the system related and the business process changes require careful planning and execution, as well as the close coordination of efforts between the LDC and SME personnel.

This program initiative, at an estimated cost of $8.08 million, should allow Toronto Hydro to plan and implement the integration with the provincial MDM/R over the 2015-2017 period so that it can meet its regulatory obligations. The estimated cost includes the re-configuration of Toronto Hydro's billing system and its Enterprise Service Bus (ESB), which is Toronto Hydro's standard enterprise software architecture for systems integration. It will also include system development and testing, particularly with respect to the validation, estimation and editing (VEE) standards[6] established by the SME. /C

[6] O Reg 393/07, at section 1(1): "validation, estimating and editing services" means those validation, estimating and editing services, as specified by the Smart Metering Entity, that are performed on smart metering data to identify and account for missed or inaccurate smart metering data.

E5.1.2.7 Wholesale Metering and Transformer Replacement

Wholesale metering and transformer replacement is part of the WMC component of the Metering Program. Wholesale metering refers to the meters and instrument transformers installed at the transmission grid supply points that track electricity supplied to an LDC or a major power consumer. When the wholesale electricity market opened on May 1, 2002, responsibility for wholesale metering operations was transferred from HONI to each individual Metered Market Participant (MMP), one of which is Toronto Hydro.

Toronto Hydro plans to replace wholesale meters and instrument transformers so that it can comply with IESO requirements. Existing legacy meters and related meter transformers will be replaced with equipment that meets current Measurement Canada and IESO requirements for wholesale metering. The actual metering upgrade involves deæegistering the existing wholesale revenue metering points, preparing the site for new fullyæompliant IESO wholesale metering installations and carrying out the installation work. Toronto Hydro plans to undertake this project so that it can complete full metering point upgrades at all applicable 223 wholesale metering points by 2021, in accordance with proposals previously approved by IESO.

While the project includes upgrading 223 wholesale meters by 2021, of which 141 are scheduled to be completed by the end of 2014, only 14 metering points are proposed to be worked on between 2015 and 2019. These 14 replacements will predominantly occur at “difficult” sites where switchgear replacements and electrical upgrades are needed to rectify the metering layout. As a result, these replacements, which will need to be coordinated with HONI capital projects, will generate higher costs and will be installed at a slower pace.

The estimated cost of this project upgrade within 2015 to 2019 period is $1.25 million. See Table 7 for all of the wholesale metering points that will be addressed from 2015 to 2019. /C

TABLE 7: WHOLESALE METER REPLACEMENT LOCATIONS

Wholesale Metering and Transformer Replacements Projection 2015-2019		
Year	Metering Points	Location
2015	2	Windsor TS (A5,6,9,10)
2016	2	Wiltshire TS (A5,6)
2017	4	Windsor TS (A3,4,7,8) Strachan TS (A5,6)
2018	4	Duplex TS (A1,2) Carlaw TS (A4,5)
2019	2	Windsor TS (A11,12)
Total	14	

TABLE 8: METER ASSETS TO BE REPLACED

Assets (Units)	2015	2016	2017	2018	2019	Total
Compliance Sampling Program Sample Meters Representing Meter Groups with Seals Expiring in 2015-2019	436	5,820	6,440	4,395	1,667	18,758
Re-verification: C&I Meters with Seal Expiring in 2015-2019	39	86	170	16	68	378
Re-verification: Large User Meters with Seal Expiring in 2015-2019	310	100	180	15	30	635
Re-verification : Suite Meters with Seal Expiring in 2015-2019	219	45	1,250	4,134	6,152	11,800
Smart Synch Interval Meters with Obsolete 2G Wireless Module	8,500					8,500
Wholesale Meters and Instrument Transformers to be Replaced	2	2	4	4	2	14
Installation of Remote disconnect reconnects for delinquent Accounts	6,150	6,200	6,270	6,340	6,390	31,350

The following table summarizes the anticipated benefits of the Metering program.

TABLE 9: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Testing and re-verifying meters will help to ensure that customers are billed accurately. ƒ Replacing data collection and processing systems is expected to provide timely access to granular energy use data and allows customers to manage and control their energy costs. ƒ Maintaining the accuracy of Toronto Hydro's Wholesale meters impacts the invoice Toronto Hydro pays to the IESO, and directly impacts all of Toronto Hydro's non-interval greater than 50 KW demand customers. ƒ Upgrading metering at Large User buildings (over 1 MW) is an important customer service initiative; these customers regard this data as a critical component to the maintenance and management of their electrical plant. Large users are often very sensitive to power quality issues in addition to power outages. As well, public safety may be affected by the reliability of the system for certain customers, such as hospitals and public health facilities. These customers are susceptible to the following power quality issues that are only measured by these higher quality metres: harmonics, over voltage, flicker, voltage dips and supply voltage unbalance. ƒ More detailed information will help customers manage their system and will help Toronto Hydro identify the root cause of issues for more speedy resolution as well as preventive maintenance support. ƒ Upgrading Toronto Hydro's Meter Data Management system will provide energy use information through the web for 9,500 customers that are currently using an antiquated model. These customers will be able to view their hourly energy use daily.
Reliability	ƒ Installing high-end meters for Toronto Hydro's largest customers will provide Toronto Hydro with ground fault data and power quality monitoring information, including harmonic content, over/under voltages, phase failure, etc. This information may be used by both the customers and Toronto Hydro to help analyze and identify power quality and other supply problems, as well as root causes for power outages for which Toronto Hydro can take preventative measures. ƒ The Metering Program is expected to improve the reliability of Toronto Hydro's distribution system by maintaining and improving data collection and communication from smart meters and integrating the data with the utility's Outage Management System (OMS).

Efficiency	ƒ Upgrading the Large User MDM system will allow the daily collection and processing of interval data for 9,500 interval meters that at the present time are manually read because of limitations of the current system's processing time and capacity. ƒ Installation of remote disconnects and reconnects is expected to reduce demands on labour and vehicles, as Toronto Hydro will be able to perform these activities remotely. ƒ Installing meters that can be remotely disconnected when customers move out or are delinquent will help to ensure that all customers pay their fair share. Also, delinquent customers will be reconnected remotely, improving service. ƒ Interval metering MDM Software and hardware upgrades for Large Users will include system functionality that allows for more efficient power outage management by providing information for each metering point on outage and restoration notifications. Improved field dispatch efficiency should result because power outages can be verified before field crews are dispatched to the customer location, reducing power outage duration (SAIDI).
Other Benefits	ƒ The Metering program is expected to provide environmental and economic benefits. Conservation has a direct impact on Toronto Hydro's carbon footprint and the cornerstone of conservation is offering interval data. Conservation programs require the validation of energy savings. In particular, Large Users rely on the detailed meter data to identify the potential areas for saving, and subsequently to confirm that the reduction in electricity usage has been achieved. Contracts between Energy Services Companies (ESCO) and customers will use the energy data to validate and pay for the conservation targets met. ƒ In terms of economics, Interval Metering MDM system upgrade for Large Users is expected to provide information to facilitate contract obligations, support for DR3 and make data available at five minute intervals for the entire group of qualifying customers. This program is also expected to provide information and processing for OPA's distributed generation programs such as FIT and microFIT data collection and credit generation. ƒ Metering data will be used to support Toronto's largest customers, employing thousands of Ontarians. This group consists of auto manufacturers, office towers, entertainment complexes, such as Rogers Centre and Air Canada Centre, hospitals and industrial manufacturing plants with sensitive equipment. Toronto Hydro's ability to troubleshoot and provide a stable, uninterrupted supply may be improved with the data that the utility collects from revenue metering, and is important for these customers to remain competitive in the marketplace by minimizing their operational costs due to power interruptions.

E5.1.3 Why the Program is Needed

Toronto Hydro is obligated to meet various legal and regulatory requirements that pertain to revenue metering and wholesale metering. Accordingly, the Metering Program was designed to enable Toronto Hydro to meet these requirements. For revenue metering, Toronto Hydro's legal and regulatory obligations are prescribed under the Electricity and Gas Inspection Act, and the associated regulations issued and administered by Measurement Canada. The OEB and IESO also publish requirements pertaining to smart meters and meter data management. Similarly, wholesale metering falls under Measurement Canada jurisdiction, and Toronto Hydro must also comply with IESO specifications as well.

E5.1.3.1 Program Drivers

The trigger and secondary drivers for each Metering Program are listed below in Table 10. Metering is a System Access initiative, because all of the listed projects are triggered by regulatory obligations.

TABLE 10: DRIVERS FOR METERING PROGRAM

Trigger Driver	Reasoning
Mandated Service Obligations	ƒ In order to operate as a LDC, Toronto Hydro needs to comply with all legal and regulatory requirements and government directives related to revenue metering and wholesale metering. o For revenue metering, Toronto Hydro is governed by the Gas Electricity Inspection Act, as well as provincial legislation as governed by the IESO, SME and OEB. o For wholesale metering, in addition to meeting the above regulations, IESO Market Rules specifications also apply.
Secondary Driver	**Reasoning**
Failure Risk	ƒ Failed or inaccurate meters tend to not measure or under-measure the electricity consumed by the customers. It is incumbent upon Toronto Hydro to ensure meters are systematically tested and re-verified so that failed meters do not remain in service.

(i) Revenue Meter Replacement

Toronto Hydro is required to meet the obligations set out in Sections 9, 11 and 12 of the Electricity and Gas Inspection Act. These requirements state that all meters must be re-sealed at specific intervals to ensure that a customer's electricity use is metered accurately. Once a seal expires, the meter cannot legally be used for billing purposes and must be resealed or re-verified (replaced). There are three revenue meter replacement initiatives as described in Section 5.1.2:

- Meter compliance sampling and re-verification.
- Systematic meter replacement, and
- Meter re-verification for Large User Class.

Meter compliance sampling and re-verification, remote connect and disconnect meters

For large homogenous batches of meters, Measurement Canada permits a sampling protocol to verify the accuracy of the meters as discussed earlier. Between 2015-2019, some of Toronto Hydro's meters have seals that are due to expire (refer to Tables 2 and 3). If the statistical accuracy results from the sample testing are within acceptable levels, all the meters in the meter group will receive a seal extension. The rules and regulations on the formation and testing of the group and sample size are specified in Measurement Canada's S-S-02 Bulletin Implementation Schedule for the Application of Statistical Sampling Requirements (Appendix A) [7] and Measurement Canada's S-S-06 Bulletin Sampling Plans for the Inspection Lots of Meters in Service (Appendix B)[8].

Certain meters need to be "re-verified". Re-verified meters are tested individually because they do not fit within the sampling program are required by law to be removed for testing and replaced with new meters.

Another element of this initiative is the installation of meters that have remote connect and remote disconnect switches. The installation of these meters should result in significantly reduced reconnection times following a disconnection for unpaid bills when the bills are finally paid, since field personnel will not have to be dispatched to the customer's location to manually reconnect the electrical service. Customers should benefit from a speedy reconnection and Toronto Hydro should benefit from improved operational productivity of not having to dispatch a field crew to perform the reconnection. This initiative is expected to free up service teams, leading to improved responsiveness to other service requests.

Further efficiency and productivity could result if there is recurring payment delinquency, since Toronto Hydro will not have to make additional visits to the meter for service disconnections and

[7] Measurement Canada, S-S-02 Bulletin – Implementation Schedule for the Application of Statistical Requirements (Appendix A) (Markham: Measurement Canada,).
[8] Measurement Canada, S-S-06 Bulletin –Sampling Plans for the Inspection Lots of Meters in Service (Appendix B) (Markham: Measurement Canada, 2010).

reconnections. Toronto Hydro will also be able to disconnect services when customers move out and no one has taken responsibility for the service. Based on historic data, approximately 50% of delinquent accounts on will become repeat offenders over the life of the meter.

Once the seals of a meter group have expired, it is illegal for Toronto Hydro to use the meters in the group to bill its customers. The use of meters with expired seals could result in the incorrect billing of customers due to inaccurate meters. Also, in the event that the meters with expired seals remain in use, Toronto Hydro could face financial penalties. Violations concerning the use of meters that do not comply with seal verification regulations fall under the very serious category and would be fined on a per-meter violation basis.

Meter re-verification – for Large User Class

As indicated in Section 5.1.2, the 635 customers making up the Large User Class represent about 25% of Toronto Hydro's total yearly revenue. These customers are key contributors to Toronto's and Ontario's economy and they typically have loads that are sensitive to power quality, and the implications of service interruptions can be severe. These customers include auto manufacturers, office towers, entertainment complexes that host national and international entertainment and sporting events, hospitals and industrial manufacturing plants with sensitive equipment.

The Large User Class customers require meters with enhanced functionality. Results from a survey of Large Use Class customers indicate that customers that current have online access to their detailed electricity usage use it to analyse their consumption and make use of advanced features such as graphing and downloading energy use information. All of these features will be enhanced with additional functionality that is not provided by the existing standard interval meters. These meters will provide voltage information, harmonics for power quality information and will detect ground fault scenarios and the estimated location of the fault. As well, the meters are equipped with an auxiliary power supply and will continue to communicate and measure energy, provide power outage and meter or service health errors and warnings even when power to the meter is lost.

In addition, customers requested several future enhancements and improvements, including: automation and scheduling of data retrieval, the ability to retrieve data for longer periods, the ability to aggregate loads, additional granularity, benchmarking, enhanced hierarchy, privileges for access (multiple buildings) and access to a larger pool of meters. The new meters will provide all of the above functions providing 10 channels of five minute interval data for additional

granularity and power quality information versus their current meter's capability of four channels of 15 minute data, with no power quality information. These customers qualify for Class A global adjustment or OPA programs such as DR3 whereby actual data is required for their account settlement. The new meters are equipped with auxiliary power backup ensuring that any meter issues (the loss of a phase voltage which can have a drastic affect on the energy measured 33% or 1/3 of the energy) can be identified immediately and error messages sent back to Toronto Hydro's office to resolve. Current meters cannot be able to sense that a problem exists.

Replacing meters currently in use by Large Use Class customers at the time of meter re-verification with meters that have added functionality should be beneficial for Large Use Class customers. In addition, these meters provide three-phase power quality information to Toronto Hydro that can be used to investigate distribution system issues related to power quality, in order to take preventative actions.

(ii) Interval Metering System Upgrade

The interval metering system or MDM system manages large C&I customers' interval meter data so that Toronto Hydro can fulfill its obligations to bill these customers based on spot market pricing under the OEB's Standard Supply Service Code (the Code) for Electricity Distributors. Clause 3.2.2 of the Code states:

> "The commodity price for electricity payable by a non-RPP consumer or an electing spot consumer that has an interval meter or another eligible time-of-use meter that is capable of providing data on at least an hourly basis shall be the spot market price determined in accordance with the Retail Settlement Code, with such adjustment as may be made by the IESO in accordance with the Electricity Act and the regulations."[9]

Existing MDM software is obsolete, as system fixes and upgrades are no longer provided by vendors of the software.

Toronto Hydro currently operates the suite of ITRON legacy MV Systems (MV-90, MV-STAR and MV-WEB) making up Toronto Hydro's Large User Interval MDM, or MDM system. These legacy systems are relied on to collect, validate and manage billing data of more than half of the total revenue billed by Toronto Hydro to its customers. The same older systems are also used for

[9] Ontario Energy Board, Standard Supply Service Code for Electricity Distributors (Toronto: Ontario Energy Board, 2011) at section 3.2.2. ["Standard Supply Service Code"]

retrieving data from Toronto Hydro's wholesale revenue meters at the grid supply points to monitor electricity supply to Toronto Hydro for wholesale settlement reconciliation. Due to system limitations, wholesale settlement reports and validation cannot be automated, which makes this process manual, requiring careful redundancy to avoid the potential for errors that arise from a manual process. The interval metering system upgrade is critical because it will enable Toronto Hydro to continue to meet its regulatory obligations, mitigate the risks of billing its largest customers improperly and reconciling the IESO wholesale settlement amounts correctly. In addition, the new software should improve customer access to their interval data, and to promote billing accuracy, since there will be fewer instances of manual entry errors resulting from manual reads and estimates when meter reads are not obtainable due to limited access. The software upgrade and integration with other Toronto Hydro systems, such as the outage management system (OMS), geographical information system (GIS), CC&B, and Asset Management system, is expected to improve Toronto Hydro's ability to maintain asset life and power outage response, thereby improving SAIDI and SAFI, while also reducing costs by continuously improving the utility's efficiency through technology and data management.

In summary, this project is critical to Toronto Hydro's efforts to mitigate the risk of having an obsolete system handle data collection for billing customers and to improve the monitoring of grid supply points. As well, Toronto Hydro expects to be able to provide better customer service and improve Toronto Hydro operational effectiveness.

(iii) SmartSynch Interval Meters Replacement

Toronto Hydro's regulatory obligations include making daily interval data available for access by 8:00 am the next day for its 8,600 SmartSynch meter customers. Remote meter reading is necessary for these interval meters. These meters currently operate on the 2G wireless networks that are scheduled to be phased out by Rogers in 2018. If SmartSynch meters with the 2G wireless module are left in service past 2018, the meters will not be remotely accessible for interval meter data retrieval. Consequently, Toronto Hydro would not be in compliance with the OEB regulation that requires that customers' billing data be available the day after the billing period. Accordingly, SmartSynch interval meters replacement is required to upgrade the communication module to 3G so that Toronto Hydro can continue to meet its regulatory obligations and bill these customers based on the Hourly Ontario Energy Price spot market price for complex billing.

(iv) Suite Metering System Upgrade

The City of Toronto is experiencing significant condominium development. To continue to meet IESO Smart Meter data regulations, Toronto Hydro requires software upgrades to its current data collection system. As specified in the IESO's functional specifications for an Advanced Metering Infrastructure (AMI), it is required that "All Meter Reads collected during the Daily Read Period shall be received by the AMCC and transferred to the MDM/R no later than 5:00 a.m. local time following the Daily Read Period."[10] In the MDM/R V1.0 Technical Interface Specifications, there is the requirement that "Meter Read data (be) received by the MDM/R by 05:00 EST for the prior Daily Read Period shall be available by 07:10 EST on the day following the Daily Read Period"[11].

Currently, Toronto Hydro's Primeread AMI system retrieves data from the 38,000 suite meter customers to facilitate billing. The Primeread AMI system is one of the few systems that support PLC technology for meter data communication. PLC allows the building wiring for electricity distribution to be used for transferring meter data to a computer located in the building, which is subsequently transmitted to a data collection system at Toronto Hydro. Although the current system was implemented in 2012, anticipated growth in the number of suite meters will necessitate adding additional processing capability in the period from 2015 to 2019, as illustrated in Tables 6 and 7.

Additional capacity is needed for Toronto Hydro to meet its IESO data transmission timeline obligations for TOU billing. The Ontario government mandated TOU billing for all residential and small commercial customers in Ontario and the growth in suite meter installations requires upgrades to existing systems to maintain basic functionality so that Toronto Hydro can meet its responsibilities to the Ontario government and to its customers. Toronto Hydro requires hardware and software upgrades to the PLC AMI to maintain its ability to meet IESO obligations by providing the IESO with hourly data by 5:00 am, ensuring that hourly and TOU data can be posted on a customer-accessible website by 8:00 am local time. As can be seen in Table 11, when the number of suite meters is at 73,000 in 2017, there will not be enough hours to retrieve and process the meter data to meet the IESO specifications with the existing system, given that meter data retrieval can only begin after midnight.

[10] Independent Electricity System Operator, AMI to MDM/R Data Transfer, (Toronto: Independent Electricity System Operator, 2006) at page 16.
[11] Independent Electricity System Operator, Meter Data Management and Repository – MDM/R Technical Interface Specifications, (Toronto: Toronto: Independent Electricity System Operator, 2011) at section 2.11.7.

TABLE 11: SUITE METER DATA PROCESSING HOURS ON EXISTING SYSTEM

Year	Suite Meter Accounts	Processing Time (Hour)
2013	34,400	3
2014	45,000	3.5
2015	56,000	4
2016	64,000	4.5
2017	73,000	5
2018	83,000	6
2019	93,000	7

(v) Suite Meter Installation

When a new condominium is built, the ECPA mandates that individual suites be metered separately. Specifically, the ECPA Subsection 33 (2), Installation of Suite Meters Required, states:

> "such persons or classes of persons as may be prescribed shall, in such circumstances as may be prescribed and subject to such conditions as may be prescribed, have a suite meter installed by a suite meter provider in such properties or classes of properties as may be prescribed and for such consumers or classes of consumers as may be prescribed.".[12]

Toronto Hydro is legally obligated to provide suite meter installation service. While the developer may use its own meter service provider or request that Toronto Hydro directly install suite metering, the ECPA states that the LDC is the meter service provider of last resort in the event that the condominium cannot secure its own meter service provider.

In the Suite Metering Regulations under the EPCA and the Ontario Energy Board Act, 1998, [13] for the purposes of subsection 33(2) of the EPCA with respect to units belonging to a class of units described in "Class of Units" in Table 12, the owner or individual responsible for unit is required to have a suite meter installed for that unit by a suite meter provider retained. Toronto Hydro is legally required to be in compliance with the requirements in providing suite metering when requested by the party concerned.

[12] ECPA, at s. 33(2).
[13] S.O. 1998, c. 15. ["OEB Act"]

TABLE 12: SUITE METERING REQUIRED BY SUITE METERING REGULATIONS

	Class of Units	Circumstances	Conditions
1.	Rental unit in a residential complex	Before completion of construction of the residential complex in which the rental unit is located.	Installation must take place in the rental unit before the rental unit is occupied.
2.	Common elements of a residential complex	Before completion of construction of the residential complex.	Installation must take place before any rental unit in the residential complex is occupied.
3.	Condominium unit in a condominium building	Before completion of construction of the condominium building in which the condominium unit is located.	Installation must take place in the condominium unit before the condominium unit is occupied.
4.	Common elements of a condominium building.	Before completion of construction of the condominium building.	Installation must take place before any condominium unit in the condominium building is occupied.
5.	Member unit of a non-profit housing co-operative building	Before completion of construction of the non-profit housing co-operative building.	Installation must take place in the member unit before the member unit is occupied.
6.	Common elements of a non-profit housing co-operative building	Before completion of construction of the non-profit housing co-operative building.	Installation must take place before any member unit in the non-profit housing co-operative building is occupied.

(vi) Provincial MDM/R Integration

The Government of Ontario granted the SME exclusive authority over smart meter data services in the province, as well as the maintenance and operation of the Provincial MDM/R.[14] In order for the SME to exercise such exclusive authority, Toronto Hydro must integrate its billing system and ODS, along with the business processes and practices, with the provincial MDM/R. Toronto Hydro has a statutory obligation to do so, pursuant to s. 53.15 of the Electricity Act, 1998[15]. In addition, it has a license obligation under s. 5.3.13 of the OEB's DSC to comply with the VEE processes set out by the SME. Collectively, these distinct provincial obligations under the OEB require Toronto Hydro to integrate its customer billing system with the MDM/R system operated by the SME. Toronto Hydro currently utilizes an in-house ODS that has the functionality to VEE interval data from its smart meters, and then frame and process the data for Time of Use billing as well as web presentment.

[14] Ontario Regulation 393/07, Smart Metering Entity, at section 5.
[15] S.O. 1998, c. 15. ["Electricity Act"]

(vii) Wholesale Metering and Transformer Replacement

The metering upgrades are required so that Toronto Hydro remains in compliance with the requirements and criteria set forth in the Market Manuals (MDP_PRO_0022)[16] and the Market Rules (MDP_RUL_0002_06[17] and 19 MDP_RUL_0002_06A[18], which define the metering requirements that Toronto Hydro must meet to continue operating as a distributor of electricity and as a MMP. More specifically, Toronto Hydro must replace its legacy transformers with modern instrument transformers that have an approved accuracy class as specified in the MDP_PRO_0022 and MDP_RUL_0002_06 and 19 MDP_RUL_0002_06A. In addition, Toronto Hydro is responsible to ensure that every meter and instrument transformer used for settlement purposes has been approved for this use by Measurement Canada.

To maintain its status as a MMP, Toronto Hydro has committed to a long-term plan with the IESO to complete full meter upgrades at all applicable delivery points. This plan was initiated by a letter submitted to the IESO on August 11, 2009, and approved by the IESO on November 27, 2009. In addition, HONI has committed additional resources for the period of 2015 to 2019 to achieve the upgrade of meters for the sites noted.

The rules related to wholesale metering were developed to ensure a high degree of accuracy, which is of significant importance due to the large volume of electricity being delivered through these meters. The requirements are set out in detail in Chapter 6 of the Market Rules titled Wholesale Metering Compliance Requirements.[19] Many of Toronto Hydro's legacy installations will require investments in order to meet these requirements. In addition, many existing legacy transformers used for wholesale metering require the proposed investments in order to meet American National Standards Institute (ANSI) 0.3% accuracy class required by Section 1.7 of Market Rules- Chapter 6 Wholesale Metering - Appendices. Furthermore, due to requirements imposed by Measurement Canada as detailed in the Electricity and Gas Inspection Act, Toronto Hydro must upgrade some of its legacy wholesale meter installations to increase accuracy by ensuring that a separate meter is installed at each delivery point.

[16] Independent Electricity System Operator, Market Manual 2: Market Administration – Part 2.6: Treatment of Compliance Issues (Toronto: Independent Electricity System Operator, 2012).
[17] Independent Electricity System Operator, Market Rules – Chapter 6 Wholesale Metering (Toronto: Independent Electricity System Operator, 2013).
[18] Independent Electricity System Operator, Market Rules – Chapter 6 Wholesale Metering – Appendices (Toronto: Independent Electricity System Operator, 2012.) ["Market Rules- Chapter 6 Wholesale Metering – Appendices"]
[19] For instance, Section 2 sets out the metering installation requirements. Section 3 of Chapter 6 sets out the obligation to participate in the real-time administered IESO market as a metered market participant. Section 4 sets out the meter installation standards for both main and alternate meters. In addition, the Chapter 6 Appendices set forth the obligations of metered market participants and metering service providers in respect of metering. Finally, Market Manual 2: Market Administration Part 2.6 MDP_PRO_0022: Treatment of Compliance Issues, provides the steps required for the treatment of compliance issues by both Market Participants and the IESO.

It should be noted that, in addition to ensuring that Toronto Hydro remains in compliance with the regulations, this project will also improve the accuracy of billing information for every customer within Toronto Hydro's jurisdiction.

E5.1.4 Timing & Pacing of the Program

The timeline for the Metering Program's initiatives and projects is primarily driven by regulatory obligations and compliance requirements with respect to the IESO and the OEB. Planned spending for the period 2015 to 2019 is outlined in Table 13.

TABLE 13: PROPOSED SPENDING FOR METERING PROGRAM

	Historical Spending					Future Spending				
Year	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
CAPEX ($M)	$28.4	$22.1	$12.1	$12.2	$14.0	$24.7	$16.6	$14.7	$11.7	$13.7

/C

Please note that during the period 2010-2013, Toronto Hydro did not sample test residential and small C&I meters, as conventional meters were all re-verified under the Smart Meter Conversion project impacting the historical metering program spending. Toronto Hydro converted approximately 71,000 meters to smart meters in 2010 and 2011.

There are three programs expected to commence in 2015 that are one-time programs (not included in any of the historical spending years). The one-time programs include:

- Interval metering MDM software and hardware system upgrades,
- SmartSynch Interval Meters Replacement, and
- IESO MDM/R integration project.

In addition to these one-time program costs, the number of new suite meter installations is expected to be 12,000 units in 2015 based on current contracts, which is 30% higher than the average future expected number of new suite meters (9,250 units per year) from 2016-2019 and 33% higher than the historical average of 9,012 units. The higher number of suite meters increases the investment for this program in 2015 by approximately $2 million. In total, one-time programs and higher suite meter installations represent $12.9 million of the $24.7 million forecasted investment in 2015. /C

In general, there are several factors contributing to the year over year variances in investment. The most significant factors are the following:

(1) Smart Meter installations – In years 2010, 2011 and 2012, Toronto Hydro needed to access conventional meters with expiring seal periods, which required certain customers to be disconnected so that Toronto Hydro could obtain access to change meters. Some of these meters also had asbestos backer-boards that led to higher meter replacement costs. Historical spending between 2010 and 2011 is proportional to the conversion of approximately 43,000 conventional meters to smart meters in 2010, compared to approximately 28,000 meters in 2011 when the program was essentially completed. Historical spending further declined in 2012 with only approximately 4,500 conventional meters that were converted to smart meters.

(2) With the conversion of conventional meters, only one reading is needed per billing period to calculate consumption. With smart meters, automated remote readings of 15 or 60 minute interval data for TOU or HOEP are used for billing. This large volume of data requires system upgrades for processing, validating and estimating data. These upgrades are captured in years 2015, 2016 and 2019 and were not captured in the historical spend.

(3) Wholesale Revenue meter changes are to be completed depending on HONI's schedule. The number of wholesale meter points and full metering upgrades can vary drastically each year, causing a variance in spending of $4 to $6 million per year.

(4) Meter system upgrades were not included in past filings.

E5.1.4.1 Ranking & Prioritization

All of the projects in the Metering Program are driven by regulatory compliance requirements. Initiatives that address meters with seals expiring in a program year were given the highest priority in that particular year so that work will be completed before the seals expire. Similarly, if meters in a sampling group fail accuracy testing, the replacement of the sampling group's seals will be given high priority. The remaining projects making up the Metering Program are prioritized based on their relative time criticality. These additional prioritization considerations are further detailed below.

Toronto Hydro plans to install smart meters with remote connect/disconnect switches when a service needs to be disconnected due to bill payment delinquency. This will enable the service to be remotely reconnected, saving the cost of dispatching a field crew to reconnect the service and

reducing the inconvenience to the customers concerned. The meters removed may be reused at other services if there is significant seal life left.

While the upgrade of the interval metering system is not mandated to be completed in a specific year, the initiative should be carried out as soon as possible given that the system is obsolete and is relied on to support billing for $2.23 million of annual revenue. System replacement is therefore scheduled for 2015 and will continue into 2016.

8,500 SmartSynch meters use Rogers' GPRS or 2G network to wireless communicate to Toronto Hydro's back-end data collection systems. As previously mentioned, Rogers has advised Toronto Hydro that this network is being phased out by 2018. The life expectancy of SmartSynch meters is 15 years. Meters will be scheduled to be replaced to ensure that the years in-service, as well as the second seal period will equal the expected 15 year life expectancy of the meters.

Given the projected number of suite meters that will be in use going forward, towards the end of the 2015-2019 period, the existing suite metering system, Primeread, will not be able to collect and process meter data in time for it to be accessible to customers as per regulatory requirements. The need for a system upgrade is dependent on the projected growth in the number of suites requiring suite metering. This growth projection will be closely monitored and the upgrade of the system is scheduled for 2019.

The installation of suite meters is driven by the timing of the condominium construction development projects. Toronto Hydro will need to have the resources available, whether internal or by contract with a qualified service provider, to meet the suite meter installation requirements as requested.

The provincial MDM/R integration initiative is planned for 2015 to 2017. The extended implementation period is necessary to allow all required testing to be performed, both for the system changes and for the changes to business processes. MDM and billing will both be impacted by the MDM/R integration, and both are critical business functions of Toronto Hydro.

Toronto Hydro has committed to a long-term plan with the IESO to complete full meter upgrades at all applicable delivery points by 2021. The timing of the work will be dependent on HONI's schedule, as their resources are required in connection with the work to be completed by Toronto Hydro. The schedule for 2015 to 2019 as shown in Table 8 has been determined with HONI's input, but the precise timing of which work is completed within a given year will ultimately be determined in collaboratively with HONI.

E5.1.5 Program Execution

The projects within the Metering Program will either replace meters or upgrade systems that support metering. Meters to be addressed are distributed across the City of Toronto. In certain instances, meters in certain locations are of similar age since they were installed at a similar time during Toronto Hydro's Smart Meter mass deployment. See Figure 2 below.

Toronto Hydro's Smart Meter deployment began with east crews working from the east border moving west to the city core and west crews starting from the west border moving east to the city core in 2006. Once the east and west regions were completed, Toronto Hydro moved from the north end and moved south. The City of Toronto core was left until the very end. Toronto Hydro's sampling program will work along the same principle since the first seal expiring meters will be located in the east and west regions.

FIGURE 2: MAP OF STRATEGIC DEPLOYMENT STRATEGY BY GEOGRAPHICAL LOCATION AND YEAR.

Work planning will take advantage of geographical concentration wherever possible.

Based on regulatory compliance requirements and the urgency to address the risks associated with system obsolescence, Toronto Hydro expects to execute the initiatives and projects within

the Metering program according to the timeline provided in Table 14. The specifics for each project related to the project scope, work planning and execution are described in Section 5.1.8.

TABLE 14: METERING PROGRAM PROJECTS & SCHEDULE

Project Name	Start Date	In-service Date
Revenue Meter Replacement		
Compliance Sampling and Reverification	Jan 2015	Dec 2019
Large User C&I Reverification with Enhanced Meter Functionality	Jan 2015	Dec 2019
Interval Metering System Upgrade	Jan 2015	Jul 2016
SmartSynch Interval Meters Upgrade	Jan 2015	Dec 2017
Suite Metering System Upgrade	Jan 2019	Dec 2019
Suite Meter Installations	Jan 2015	Dec 2019
Provincial MDM/R Integration	Jan 2015	Sep 2017
Wholesale Metering Equipment Replacement	Jan 2015	Dec 2019

(i) Revenue Meter Replacement

There are three initiatives under revenue meter replacement:

- Meter Compliance Sampling and Re-verification,
- Meter Compliance Sampling Program, and
- Meter Re-verification for Large User Class.

Each initiative is an ongoing operation, and will be planned and executed as follows.

Meter Compliance Sampling and Re-verification

At the beginning of each year within the 2015 to 2019 timeframe, Toronto Hydro plans to create a detailed plan for the sampling and re-verification program for the meters expiring that year. The plan is expected to include all of the work for the entire year with geographical locations for all meters, addresses, customer contact information meter type and service type.

Meter Compliance Sampling Program

Within the compliance sampling program, meter groups that are due for sample testing are identified. To allow an efficient sampling program, meters will be selected by geographical area.

Figure 3 is a map used to form meter groups (also referred to as Meter Test Groups) of homogeneous meters, based on the Geo Code areas. For the year 2015, three Meter Test Groups have been created from which sample meters will be selected using the random number generator and sample selection algorithms from the Toronto Hydro CC&B system. These test groups are only for R1S-single phase, with meter seal year 2006 (expiring 2016). Sample size is determined by Measurement Canada S-S-06, Sampling Plans for the Inspection of Isolated Lots of Meters in Service, Annex C, Table 2, Limiting Quality 3.15.

An example of three Meter Test Groups that have been created for meters with seals expiring in 2016 are shown in Table 15 below.

TABLE 15: EXAMPLE OF THREE METER TEST GROUPS

Meter Group Number	Meter Group Population	Sample Size
9101	14,825	315
9102	15,497	315
9103	16,834	315

From each meter group, the specified random number generator is used to create a sample list. Field activity orders are issued for Toronto Hydro field crews to remove the meters and return them to Toronto Hydro's Accredited Service Provider for compliance sample-testing. Test results are forwarded to Toronto Hydro for record updating and action based on the test results. A pass will result in an update to the meter records only. If meters pass the accuracy tests, the level of the accuracy will determine the seal extension period. For smart meters with a ten-year initial seal period that receive a passing grade, the seals will be extended for eight years. If the sample meters fail the statistical accuracy test, Measurement Canada allows for a second sample of randomly selected meters to be tested. If the second sample passes, the seals for all of the remaining meters will be extended for a period less than eight years depending on the overall statistical accuracy results. If the second sample of meters also fails, the meters in the entire meter group will have to be replaced before the end of the seal expiry year.

Work within the 2015 to 2019 timeframe will be planned and executed as outlined above. Table 2 shows the number of sample meters to be tested during the five years.

FIGURE 3: GEOGRAPHICAL AREA OF THE THREE SAMPLE TEST GROUPS

Revenue meters that do not belong in the compliance sampling program must be removed from service and tested (re-verified) by the accredited meter shop service provider before the seal period expires. Meters with seal periods expiring in the 2015 to 2019 period are identified and printed out in a re-verification list at the beginning of each year for the meters with seals expiring in that year. Field activity work orders are issued from the CC&B system for the field crews to replace the meters. Field work is organized based on the geographical locations of these meters for efficiency purposes.

Meter Re-verification – for Large User Class

Meter removal/installation work for the large C&I customers over 1 MW requires special arrangements with the customers in order to minimize negative impacts to their business operations. Toronto Hydro plans to prepare a list of meters with seals expiring in a given year that are due for re-verification. The Meter Department will then coordinate with the customers concerned to schedule access to their utility room for the metering work. Every effort will be made to accommodate the customers' needs when scheduling work.

Table 2 shows the number of meters expected to be replaced within the 2015 to 2019 period.

(ii) Interval Metering System Upgrade

The interval metering system upgrade is scheduled to begin in January 2015 and be completed by July 2016. The extended project timeline is necessary due to the complexity of the system and business requirements involved. This system is required to aggregate multiple metering points each meter may have a different configuration which needs to be accounted for and managed by the system. For example, each meter within an aggregation calculation may have a specific loss factor, various interval lengths (five minute, 15 minute and 60 minute intervals), various interval channels (some meters have two channels while other meters have as many as 10 channels of interval data) into a summed hourly interval value for each measurement.

Toronto Hydro plans on forming an implementation team at the beginning of 2015 with a Meter Department staff member, who is familiar with the interval metering data collection and data management requirements, serving as team lead. The team will include a representative from Billing, and an Information Technology Systems Consultant, who will enlist other Information Technology resources as and when necessary.

The implementation team will prepare a document that will specify in detail the required functions and technical capabilities of the system for a RFP, and will then work with Procurement to select a suitable vendor through the RFP process. The selected vendor's proposal will include a detailed system implementation plan acceptable to Toronto Hydro. It is vital that the implementation plan include a parallel run stage to ensure the new system performs satisfactorily before the old system is decommissioned.

(iii) SmartSynch Interval Meters Replacement

The 8,500 SmartSynch meters will be upgraded by 2018 through planned staging. This will involve obtaining 100 new SmartSynch meters with a 3G module that will be purchased at the beginning of 2015 to start the staging process. The first 100 SmartSynch meters in the field will be replaced with the new SmartSynch meters. The obsolete 2G SmartSynch meters are returned to the meter shop where they will have their 2G module replaced with a 3G module. These upgraded meters are then used to replace the next 100 2G SmartSynch meters in the field. By recycling batches of 100 meters at a time and upgrading their software, Toronto Hydro can use a lower cost retrofit kit versus purchasing 8,500 new meters. This process is repeated until all the 2G SmartSynch meters have been upgraded. The very last 100 3G SmartSynch meters (upgraded 2G from the field) left over in the end will be warehoused for future use, either to meter new customers or to replace the defective meters in service.

(iv) Suite Metering System Upgrade

Suite metering system upgrades are scheduled to be completed in 2019. Toronto Hydro plans on forming an implementation team at the beginning of 2019 with a Meter Department staff member who is familiar with suite metering data collection and data management requirements serving as team lead. The team will include a representative from Billing, and an Information Technology Systems Consultant, who will enlist other Information Technology resources as and when necessary.

The implementation team will prepare a document that will specify in detail the required functions and technical capabilities of the system for a RFP, and will then work with procurement to select a suitable vendor through the RFP process. The selected vendor's proposal will include a detailed system implementation plan acceptable to Toronto Hydro. It is vital that the implementation plan include a parallel run stage to ensure the new system performs satisfactorily before the old system is decommissioned.

(v) Suite Meter Installation

Toronto Hydro's suite meter installation schedule will be based on the condominium construction schedule submitted by the developers and will be adjusted according to actual construction progress.

(vi) Provincial MDM/R Integration

The Provincial MDM/R integration project is a major undertaking due to its complexity and its potential impact on Toronto Hydro's core business operation. Business-to-Business (B2B) integration of this nature requires changes not just to systems, but also to associated business processes and business practices. Careful planning, implementation and thorough testing at every stage and for all levels will be critical for the success of the integration. Close coordination with the SME throughout the project is also vital.

Since 2013, Toronto Hydro has been working with the SME to plan Toronto Hydro's transition to the provincial MDM/R. In 2013, the two parties undertook a pilot project to explore ways in which they could leverage the existing VEE services and address Toronto Hydro's needs through configuration rather than customization of the MDM/R. Toronto Hydro plans on using the experience and information from this pilot project and the joint workshops that has been

conducted with the SME to assess the gaps in Toronto Hydro's systems to initiate system change design and planning.

Toronto Hydro plans on developing a project plan based on the MDM/R integration technical, business and testing requirements. The SME resource should be engaged from the outset to ensure proper understanding of the SME MDM/R requirements with respect to the interface protocol and specifications. Toronto Hydro plans on holding regular meetings to help ensure that projects progress and to resolve project issues, whether they are system or business process related. Contingency measures will be built into the project plan to ensure billing operation continuity in the event of system problems.

It is critical that test cases be designed to include all situations that can be anticipated, including with respect to data transmission, data processing, meter data uploading and actual billing. Toronto Hydro expects that the implemented solution, including system changes and business process changes, will only be signed off by the business clients after a thorough user acceptance test.

(vii) Wholesale Metering and Transformer Replacement

In order to undertake wholesale metering and transformer replacement successfully, close coordination with HONI is critical since Toronto Hydro personnel will have to work with HONI personnel to carry out the metering equipment upgrade work. At the beginning of each year in the 2015 to 2019 period, Toronto Hydro's Meter Department is expected to meet with HONI to review the work plan and to schedule the resources needed. Toronto Hydro will make every effort to accommodate the resource constraints of HONI.

The actual metering upgrade involves de-registering the existing wholesale revenue metering points, preparing the site for new fully-compliant IESO wholesale metering installations and carrying out the installation work, as indicated in Table 16.

TABLE 16: WHOLESALE METERING REPLACEMENT LOCATIONS

Windsor TS	253 Wellington Street West, Toronto, Ontario
The site is a 115/13.8 kV transformer station supplying local loads. Over multiple years the A5-A6-A9-A10, A3-A4-A7-A8 and A11-A12 feeders, which are in a ring bus configuration, will be subject to a revenue metering upgrade.	
Wiltshire TS (A5,6)	13-19 Wiltshire Avenue, Toronto, Ontario
The site is a 115/13.8 kV transformer station supplying local loads. The A5-A6 is the subject of this revenue metering upgrade.	
Strachan TS (A5,6)	6 Strachan Avenue, Toronto, Ontario,

The switchyard site is a 115/13.8 kV, 60 Hz TS supplying local loads. There are two power transformers (T13 and T15) providing step down transformation from the 115 kV system to the 13.8 kV system.	
Duplex TS (A1,2)	400 Duplex Street, Toronto, Ontario
The site is a 115/13.8 kV transformer station supplying local loads. The A1-A2 is the subject of this revenue metering upgrade.	
Carlaw TS (A4,5)	369 Carlaw Avenue, Toronto, Ontario
The site is a 115/13.8 kV transformer station supplying local loads. The A4-A5 is the subject of this revenue metering upgrade.	

E5.1.5.1 Program Risks

Table 17 illustrates the major program risks that may occur while executing the Metering program.

TABLE 17: PROGRAM RISKS

Initiative/Project	Risk	Impact	Risk Probability	Mitigation
Compliance Sampling Program	Meter group fails sample testing.	Sample sizes would need to be increased or entire sample lot would need replacement. High cost implications.	Low – Meters are relatively new at 10 years old, and accuracy testing in other jurisdictions has been successful.	The risk of sample test failure cannot be reduced. If the initial sample fails, Toronto Hydro will conduct secondary sampling as permitted. If it fails again, Toronto Hydro will schedule the replacement of the meter group concerned within the systematic meter replacement initiative.
Upgrade Smart Synch Interval Meters due to 2G wireless network obsolescence	Conversion kit availability.	Meters would require manual reading if the communication network is unavailable. The cost associated with manual meter reading is high.	Low - vendor is currently already working on a suitable conversion.	Ensure effective and continual communication with vendor to maintain high priority for the project.
Wholesale Metering and Transformer	HONI projects are delayed.	Compliance with IESO Market	Medium – projects are complicated	Work closely with HONI to schedule work and to allocate resources.

Initiative/Project	Risk	Impact	Risk Probability	Mitigation
Replacements		Settlement rules is delayed.	and subject to equipment delays and resource availability.	

E5.1.5.2 External Constraints

The external constraints of the Metering Program are noted below.

- Toronto Hydro will be working closely with HONI resources to carry out the wholesale metering equipment upgrade. HONI resources might be unavailable when required due to other projects that it is working on. To mitigate the risk, Toronto Hydro plans on providing generous advanced notice to HONI and schedule the work accordingly.

- Measurement Canada may change calculation methods related to the metrological parameters, particularly for interval meter data. However, Measurement Canada generally provides sufficient lead time to the LDCs to make the necessary adjustments to their systems.

- Site access to the metering equipment for the Large User Class meter change-out will require coordination with the customers concerned. Toronto Hydro plans on scheduling the work by taking into consideration the customers' business operation if power interruption is needed.

- The provincial MDM/R integration with Toronto Hydro's systems will require IESO's resources, system capacity and performance capability for the large amount of data that will be transferred daily. Integration issues and network interfaces between Toronto Hydro's systems will impact the project timelines and costs. Toronto Hydro plans on working closely with the IESO to mitigate these risks.

E5.1.5.3 Standard & Regulation Adherence

Metering is a fundamental component of the operation of an electric utility and is regulated by federal and provincial regulations, either directly or via regulatory bodies. In addition, metering requires compliance with ANSI standards for communications security. All of Toronto Hydro's meters toned to comply with ANSI standards and have been audited. The Metering Program is

expected to improve meter security encryption for the delivery of data to Toronto Hydro. The Metering program should also enhance customer access and security features for their data. The relevant standards and regulations are identified in Table 18.

TABLE 18: STANDARDS AND REGULATIONS FOR METERING

Revenue Meter Re-verification and Sampling Program	ƒ Weights and Measures Act ƒ Electricity and Gas Inspection Act ƒ Measurement Canada Bulletin S-02 ƒ Measurement Canada's Bulletin S-06
Wholesale Metering and Transformer Replacements	ƒ Meter ANSI standard C12.20 (0.2% accuracy class) ƒ Meter transformers ANSI standard C12.20 (0.3% accuracy class) ƒ IESO Wholesale Revenue Metering Standard IESO Market Rules Chapter 6 Wholesale Metering ƒ IESO Market Rules for the Ontario Electricity Market
Upgrading Smart Synch Interval Meters to 3G Wireless Standard	ƒ Communication standard HSPCA
Remote Disconnect Meters	ƒ Meter ANSI standard C12.20 (0.5% accuracy class)
Upgrade Metering at Large User Buildings (over 1 MW)	ƒ Weights and Measures Act ƒ Electricity and Gas Inspection Act ƒ Measurement Canada Bulletin S-02 ƒ Measurement Canada's Bulletin S-06
Interval Metering, MDM Software and Hardware Upgrade	ƒ Toronto Hydro IT Standards ƒ Sections 3.2.1, 3.2.1A, and 3.2.2 of the Standard Supply Service Code (Appendix C)
Suite Metering, MDM Software and Hardware Upgrade	ƒ Toronto Hydro IT Standards ƒ IESO "Functional Specifications for an advanced Metering Infrastructure" ƒ Sections 3.2.1, 3.2.1A, and 3.2.2 of the Standard Supply Service Code (Appendix C)

E5.1.6 Evaluation of Alternatives

Due to the regulatory obligations for Metering, there are no alternatives other than willfully contravening the rules and governing laws.

E5.1.6.1 Quantification/ Evaluation of Options

(1) Re-verification and Sampling – no alternatives.

(2) IESO Wholesale Settlement – no alternatives.

(3) Large C&I customers AMI – no alternatives.

(4) Suite Meter AMI System Upgrade – no alternatives.

(5) SmartSynch – no alternatives.

(6) Large C&I meters – no alternative.

(7) Remote disconnect – cost of manual R/D based on percent of re-offenders Toronto Hydro standards.

(8) Suite meter installations – no alternative

(9) Provincial MDM/R Integration – no alternative – provincial legislation requires integration with Smart Meter Entity.

(10) Upgrade Smart Synch Interval Meters - reverting to a manual reading process would require immense resources; therefore upgrading the metering to maintain system viability is the only option.

(i) Status Quo

Due to the regulatory obligations surrounding Metering, there are no alternatives to the proposed Metering Program. If Toronto Hydro does not undertake the Metering Program, it may be in violation of the rules governing the operation of an LDC. For example, if the progress of the upgrades does not meet the satisfaction of the IESO, Toronto Hydro may be found to be in breach of the Market Rules.

(ii) Replacement with Standard Equipment

The Replacement with Standard Equipment within the Metering program should allow Toronto Hydro to meet the Mandated Service Obligations and adhere to various regulations as detailed in Status Quo above. This program should also Toronto Hydro to improve the visibility customers have on their electricity use and ensure the accurate billing, providing significant value to the customer. Therefore, this is the preferred alternative.

E5.1.7 2015 Project Details

Table 19 lists all projects that will be partially or completely executed as part of the 2015 work program. In addition to the projects initiated in 2015, Toronto Hydro also forecasts $704 K in carryover costs related to the 2014 wireless collector project, which was originally filed as part of the OEB approved Metering segment in Phase 2 of the utility's 2012-2014 IRM/ICM rate filing. Collectors retrieve hourly data from the utility's 680,000 smart meters and provide an access point to backhaul this data for Time of Use billing. The collectors are also used to process power outage notification, disconnection and reconnection status, meter events and alerts.

Note that the table shows total costs for each project.

TABLE 19: 2015 PROJECTS

Project Number	Project Name	Total Project Cost ($000)	Start Date
30963	Revenue Meter Replacement		
	x Meter Compliance Sampling and Reverification	$12,144	2015
	x Installing Remote Disconnect Meters	$4,833	2015
	x Meter Reverification for Large User Class	$6,019	2015
30965	Interval Metering System Upgrade - MDM Software and Hardware Upgrade for Large Commercial and Industrial Customers	$5,277	2015
30963	SmartSynch Interval Meters Replacement	$5,267	2015
30964	Wholesale Metering and Transformer Replacement	$1,251	2015
31674	Suite Meter Installations	$35,606	2015
31675	Provincial MDM/R Integration	$8,083	2015
31360	Pole Mounted Collector project 2014 carryover[20]	$4,300	2014

/C

/C

[20] Note: $704K of the total $4.3M Pole Mounted Collector project cost is forecasted as carry-over into the 2015 CapEx budget.

E5.2 Customer Connections

TORONTO HYDRO CREW RESPONDING TO AN ELECTRICAL SERVICE REQUEST

E5.2.1 Summary

Program Description

Expenditures in the Customer Connections program account for the system investments and modifications required to provide customers with access to electricity services via Toronto Hydro's distribution lines. The program also includes any additional expansions or enhancements to the system for connections where Toronto Hydro is required to make an Offer to Connect (OTC).

The work executed in this program delivers customer value by serving new customers with timely, cost-efficient and reliable connections to the distribution system. Energizing new residences, businesses and institutions is necessary for the City of Toronto's economic and cultural expansion and development. The following table summarizes the expected benefits of this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Providing connection to the distribution system to residents and businesses ƒ Providing and maintaining reliable and cost efficient service to customers
Reliability	ƒ Reliability to existing customers is maintained or improved through new connections

Safety	ƒ Helps ensure safe connection to the distribution system for all customers, as stated in Toronto Hydro's Conditions of Service.
Efficiency	ƒ Future capital projects and customer expansion are coordinated where possible for cost-efficiencies and to minimize the number of future construction projects.

Program Drivers

The Customer Connections program is driven primarily by the number of customer service requests that Toronto Hydro receives annually. Supporting information such as development and economic forecasts are additional factors that are included in the baseline forecast. According to Economic Indicators data provided by the City of Toronto Economic Development Division, an upward trend in economic growth is reflected in the number of developments being applied for through City zoning applications and building permits. In addition to the baseline amounts, a number of major projects with multi-year construction schedules are considered in the spending forecasts, including the West Don Lands work for the Pan Am Village, the TTC expansion at Leslie and Lakeshore, and several major Metrolinx projects including the Eglinton Light Rail Transit (ELRT) line. The following table is a summary of this program's trigger and secondary drivers.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Customer Service Request	ƒ Obligated to complete new customer connections and/or modifications to existing customer connections. ƒ Required to perform necessary expansions for customer connections or property development in order to provide service.
Secondary Driver	**Reasoning**
Mandated Service Obligations	ƒ As per Conditions of Service and the Distribution System Code, obligated to connect, or make an Offer to Connect to any customer that lies along the distribution system.

Preferred Alternative

As discussed above, Toronto Hydro is obligated to connect customers to its distribution system, where safe to do so, by the Electricity Act, 1998,[2] Distribution System Code and its own Conditions of Service. As such, there are no alternatives to this program.

Timing and Pacing

The proposed timing and pacing of this program is based on several factors. Historical spending amounts and trends inform the baseline forecast for the program, which covers the typical or basic connection work that occurs for customer connections. Development and economic forecasts are additional factors that are included in the baseline forecast to determine projected growth above the baseline in future years, as well as known major projects such as the ELRT.

TABLE C: HISTORICAL AND FORECASTED EXPENDITURES

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Gross ($M)	39.29	58.12	50.11	77.05	65.62	53.90	66.14	77.98	71.73	62.66
Customer Contributions ($M)	(24.05)	(26.93)	(19.11)	(23.62)	(13.48)	(14.60)	(12.36)	(13.09)	(14.83)	(16.10)
Ratio (%)	61.21	46.34	38.14	30.66	20.54	27.09	18.69	16.79	20.67	25.69
Net ($M)	15.25	31.19	31.01	53.43	52.13	39.30	53.78	64.89	56.90	46.56

[2] R.O. 1998, C. 15, Sched. A. ["Electricity Act"]

E5.2.2 Program Description

Toronto Hydro distributes electricity to residential, commercial, and industrial customers via overhead and underground infrastructure. As the owner and operator of this distribution system in the City of Toronto, Toronto Hydro is obligated by section 28 the Electricity Act to connect a building to its distribution system if:

(a) the building lies along any of the lines of the distributor's distribution system; and

(b) the owner, occupant or other person in charge of the building requests the connection in writing.

Expenditures in the Customer Connections program account for the system investments and modifications required to provide customers with access to electricity services via Toronto Hydro's distribution lines. This includes the installation of connection assets such as overhead or underground supply lines from Toronto Hydro overhead service poles or cable chambers, any connections at the customer service mast or meter base, installation of required overhead or padmount transformers, installation and connection of commercial meters, and other basic connection tasks as required by any customer service requests.

The program also includes any additional expansions or enhancements to the system for connections where Toronto Hydro is required to make an Offer to Connect (OTC). Toronto Hydro requires OTCs when the building requesting service cannot be connected to the Toronto Hydro distribution system without an expansion. Expansion work is typically needed for larger industrial or commercial connections, or requests in areas of the city that are capacity constrained. Expansion work involves the installation or upgrade of distribution assets such as new circuits or civil infrastructure that is required to accommodate new customer loading. Without this work, the existing distribution system could not accommodate the customer.

In total, Toronto Hydro forecasts $261 million in net capital expenditures from 2015 to 2019, with an additional $70 million of capital contributions from customers requesting connection. Figure 1 shows the locations of all proposed and approved building development projects in Toronto Hydro's service area as of December 2013. These projects are in various stages of completion, ranging from the pre-construction/zoning approval stage, to under construction, to complete. As illustrated, there are new developments across the Toronto Hydro distribution system, and the investments made through the Customer Connection program will impact Toronto Hydro's entire service area.

FIGURE 1: DEVELOPMENTS IN PLANNING OR CONSTRUCTION STAGE IN TORONTO HYDRO SERVICE AREA

The following table summarizes the expected benefits of the Customer Connections program.

TABLE 1: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Providing connection to the distribution system to residents and businesses ƒ Furthering the economic and cultural expansion of the City of Toronto ƒ Providing and maintaining reliable and cost efficient service to customers
Reliability	ƒ Reliability to existing customers is maintained or improved through new connections
Safety	ƒ Ensures safe connection to the distribution system for all customers, as stated in Toronto Hydro's COS.
Efficiency	ƒ Future capital projects and customer expansion are coordinated where possible for cost-efficiencies and to minimize the number of future construction projects.

The work executed in this program delivers customer value by serving new customers while maintaining reliable and cost efficient service to existing customers. With timely, cost-efficient and reliable connections to the distribution system, residents and businesses are able to maintain a high standard of living and can generate income and value for the City of Toronto. Energizing

new residences, businesses and institutions is necessary for the City of Toronto's economic and cultural expansion and development.

E5.2.3 Why the Program is Needed

As explained previously, Toronto Hydro is obligated to connect new customers in its service area. Upon receipt of a customer service request and after consultation with the customer, Toronto Hydro will make every reasonable effort to connect the customer or, if necessary, issue an OTC to the customer.

In any given year, Toronto Hydro receives over 10,000 connection requests. As highlighted in Figure 1, many development projects are forecasted for the City of Toronto, the majority of which will require new or upgraded service connections. As has been well documented in the media, Toronto led North America in the number of high rise buildings under construction over 2012 and 2013, as shown in Figure 2. As of November 2013, Toronto ranked ahead of major North American cities such as New York and Mexico in high rise construction according to data from construction and commercial real estate firm Emporis.

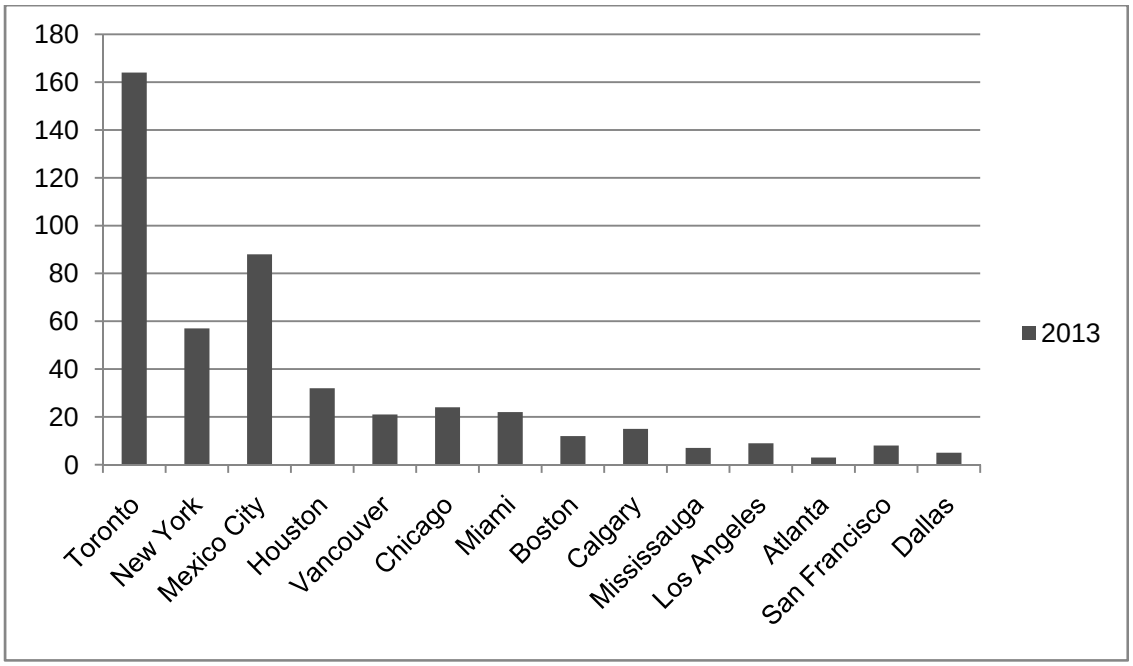

FIGURE 2: HIGH RISE BUILDINGS UNDER CONSTRUCTION AS OF NOV 2013 [7]

[7] Emporis, New High-Rises, online: Emporis<http://www.emporis.com/continent/northamerica>.

In addition to the large number of current developments, economic forecasts indicate that Toronto's economy will experience growth over the 2015-2019 period. According to The Conference Board of Canada, the City of Toronto's Gross Domestic Product (GDP) is forecasted to grow by 3.3% in 2015, 2.9% in 2016 and 2.4% in 2017.

E5.2.3.1 Program Drivers

Table 2 presents the trigger and secondary drivers for the Customer Connections program. The program is a System Access initiative because the trigger driver is customer service requests.

TABLE 2: PROGRAM DRIVERS

Trigger Driver	Reasoning
Customer Service Request	ƒ Obligated to complete new customer connections and/or modifications to existing customer connections. ƒ Required to perform necessary expansions for customer connections or property development in order to provide service. ƒ Maintain service obligations to provide reliable and efficient connection to the distribution system, thereby delivering customer value.
Secondary Driver	**Reasoning**
Mandated Service Obligations	ƒ As per Conditions of Service and the Distribution System Code, obligated to connect, or make an Offer to Connect to any customer that lies along the distribution system.

E5.2.4 Timing & Pacing of the Program

Expenditures in the Customer Connections program are driven primarily by the number of customer service requests that Toronto Hydro receives annually. Toronto Hydro is required to make every reasonable effort to consult and work with the customer within the mandated timelines set out in the Electricity Act and the utility's own Conditions of Service (COS) . The COS require that Toronto Hydro respond to a customer's written request for connection within 15 calendar days of receipt and make an OTC, if required, within 60 calendar days of receipt of the written request, unless other necessary information is required from the customer before the offer can be made. Table 3 shows the historical and future spending for the Customer Connections program.

TABLE 3: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Gross ($M)	39.29	58.12	50.11	77.05	65.62	53.90	66.14	77.98	71.73	62.66
Customer Contributions ($M)	(24.05)	(26.93)	(19.11)	(23.62)	(13.48)	(14.60)	(12.36)	(13.09)	(14.83)	(16.10)
Ratio (%)	61.21	46.34	38.14	30.66	20.54	27.09	18.69	16.79	20.67	25.69
Net ($M)	15.25	31.19	31.01	53.43	52.13	39.30	53.78	64.89	56.90	46.56

The proposed timing and pacing of this program is based on several factors. Historical spending amounts and trends inform the baseline forecast for the program. These baseline amounts cover the typical or basic connection work that occurs for customer connections, such as the activities described in Section E5.2., which include installing a padmount transformer or connecting commercial meters.

Development and economic forecasts are additional factors that are included in the baseline forecast. According to Economic Indicators data provided by the City of Toronto Economic Development Division, retail sales data has shown year over year increases since 2010[8]. This upward trend in economic growth is also reflected in the number of developments being proposed and applied for through City zoning applications and building permits. The same Economic Indicators data referenced earlier shows that the total number of building permits each year has been increasing since 2011, and according to the January 10, 2014, Economic Development Committee Dashboard Report for the City of Toronto, the total value of building permits issued in November 2013 increased by over 120% as compared to the same month in 2012[9]. Given this data and using a similar growth trend, Toronto Hydro anticipates that the number of customer service requests and the size of the customers requesting connection will continue to trend upwards. This is reflected in the projected spending over the 2015-2019 period where Toronto Hydro has taken into account the number of new building permit applications and the forecasted development numbers from the city and commercial developers. The slight depression in 2015 is due to the anticipated slowing in construction projects as a result of the Pan Am Games being hosted in Toronto during the main construction season.

[8] City of Toronto Economic Development and Culture, Economic Indicators Database, online: City of Toronto <www1.toronto.ca/City%20Of%20Toronto/Information%20&%20Technology/Open%20Data/Data%20Sets/Assets/Files/economic_indicators_database.xlsx>.
[9] City of Toronto Economic Development and Culture, Economic Dashboard Report, (Toronto: City of Toronto, 2014) at page 5.

In addition to the baseline amounts, a number of major projects with multi-year construction schedules are considered in the spending forecasts. These projects are considered to be extensive customer connections that require planning and work beyond the typical basic connection and typically have a defined scope of work entering each budget year. Examples include the West Don Lands work for the Pan Am Village, the TTC expansion at Leslie and Lakeshore or several major Metrolinx projects which are described in more detail below. These major projects will typically require an OTC to be signed with expansion work needed to connect the customer.

The higher number of large customer service requests has also required Toronto Hydro to issue an increasing number of OTCs to address situations where the requested service cannot be provided without completing expansion work. Expansion work can have a significant impact on the pacing of the program because it typically requires a substantial amount of resources to plan and construct the infrastructure necessary to connect a large customer. The resulting expansion projects are usually large scale and complex, and thus require weeks or months to complete.

As mentioned above, Metrolinx's light rail transit projects are examples of the sort of large scale customer service requests that will have a substantial impact on the timing and pacing of the Customer Connections program during the planning horizon. Specifically, the Eglinton Light Rail Transit (ELRT) line requires several connection points to the Toronto Hydro system. Approximately 30 new LRT stations are proposed for this line, with a total demand of approximately 90 MVA. Connecting this many stations with such a large load will require significant expansion work over the 2015-2019 time frame and is the primary basis for the substantial net spend in 2017 and 2018. Current timelines and schedules for the ELRT project require the majority of expansion and connection work to be executed in 2017 and 2018 as Metrolinx underground tunneling work is scheduled to be complete in the summer of 2017. Following the completion of the ELRT work, Toronto Hydro anticipates a return to 2014 levels of spending in 2019.

Typically, large customer requests, such as the Metrolinx work described above, not only have a significant impact on Toronto Hydro's capital work program, but also on its capital expenditures. Capital contributions from customers with large connected load are minimal because the forecasted revenues used in the Economic Evaluation are often equal to or greater than the projected expansion and connection costs needed to serve them. As a result, these projects typically produce a positive Net Present Value. The result of the increasing number of these large

requests in recent years and in that projected for the future is a lower ratio of customer contributions to gross capital expenditures.

E5.2.4.1 Ranking & Prioritization

Toronto Hydro ranks and prioritizes jobs in the Customer Connections program in accordance with the schedules and timelines of individual customers and service requests. For customers requiring basic connection, prioritization is on a first come, first served basis, taking into account the in-service date requested by the customer. This prioritization applies where Toronto Hydro has sufficient physical electricity supply, such as overhead or underground lines, to make the connection as well as adequate capacity on the relevant distribution feeder cable and station bus. If either of physical supply or capacity are lacking, the connection will occur once the situation is remedied.

For connections that cannot be completed without an expansion, prioritization of the work is determined in accordance with the timelines and requirements stated in the OTC.

E5.2.5 Program Execution

The Customer Offers group manages the work required under the Customer Connections program for Toronto Hydro. As outlined in Section 2 of the Conditions of Service, the customer or customer representative is required to consult with Toronto Hydro concerning the availability of supply, the supply voltage, service location, metering, and any other details necessary to establish service.

The customer or its authorized representative is required to apply for new or upgraded electricity services and temporary power services in writing. The customer also is required to provide Toronto Hydro with sufficient lead-time to ensure the timely provision of electricity supply to the building or the availability of adequate capacity for additional loads to be connected to the system.

During the consultation and design phase of a customer's request, if it is determined that the connection requires expansion and a subsequent OTC, Toronto Hydro attempts to realize potential cost-efficiencies by grouping other needed investments with the connection project. Primary considerations include future investment plans and forecasted load growth for the project area.

If Toronto Hydro anticipates that load growth will require additional infrastructure upgrades beyond what is required under the expansion work in the OTC, engineers or planners will include the additional distribution work, which can range from installing larger circuits to rebuilding cable chambers, as a part of the project. This coordinated approach is more cost-efficient than returning and performing additional upgrades in the same area at a later date.

An example of this approach to gaining efficiencies can be found along Toronto's Waterfront, where the required civil work to connect new condominiums and developments was augmented to include the additional infrastructure necessary to accommodate the Waterfront's future demands and system requirements.

If during the design and consultation phase of reviewing the customer request Toronto Hydro determines that connection to the distribution system would cause unsafe conditions to the public, workers, or the system, Toronto Hydro reserves the right to deny the request. This is highlighted in Section 2.1.3 of Toronto Hydro's COS:

"…Toronto Hydro is not obligated to connect a Customer within its service area if the connection would result in any of the following...

- Adverse affect on the reliability or safety of Toronto Hydro's distribution system
- Public safety reasons or imposition of an unsafe work situation beyond normal risks inherent in the operation of Toronto Hydro's distribution system

To abide by the section and ensure safe connection to the system, a load analysis is performed for each customer request. This analysis ensures that the requested connection would not overload any Toronto Hydro assets above their rated capacity. Operating assets over rated capacity increases their risk of failure, and could also create potential safety risks. For large connections, this analysis also includes protection and coordination studies to ensure the proper protection is in place so that if a fault occurs, it is cleared in timely manner so that the fault ceases to be fed, which could cause damage to equipment and create potential safety risks.

In addition, while customer connections projects are not intended to result in improved system performance, as part of the connection process, the load analysis also ensures that the load being added not negatively affect reliability. Toronto Hydro provides new customers with connections that are designed to deliver, at a minimum, the level of reliability currently experienced by the customers currently being fed by that feeder or station. If a connection could potentially worsen the reliability of the feeder or station, expansion work is undertaken to increase

capacity or transfer load so that the current level of reliability is maintained. As described previously, this expansion work is charged to the customer through the OTC process.

Once design and consultation with the customer is complete, the resulting work is to be carried out by Toronto Hydro resources unless otherwise stated or agreed upon in the OTC. This work includes the installation of connection assets, such as overhead or underground service lines from Toronto Hydro overhead service poles or cable chambers, any connections at the customer service mast or meter base, installation of required overhead or padmount transformers, installation and connection of commercial meters. Customer charges or allowances associated with the work are pursuant to the OEB's Distribution System Code and Toronto Hydro's COS. One set of charges or allowances are Basic Connection Fees. As contained in Revision 13 of the COS, Toronto Hydro's Basic Connection Fees include:

TABLE 4: BASIC CONNECTION FEES (AS OF MAY 1, 2014)

Customer Class	Basic Connection Fee
Class 1 - Residential	$1,396
Class 2 – General Service (<50kW)	$1.396
Class 3A/3B/3C – General Service (50 kW – 999kW)	$1,396
Class 4 & 5 – General Service (1000kW and Up)	$1,396
Unmetered – Overhead Supply (excluding street lighting)	$446 or $1,011
Street Lighting	$533 or $574

These fees are reviewed annually and updated with notice to customers when Toronto Hydro's COS is revised.

E5.2.5.1 Program Risks

The following are risks to program completion that Toronto Hydro considers when planning and executing the Customer Connections program.

(i) Capacity Upgrade Requirements

Due to the increasing quantity and size of customer service requests, Toronto Hydro anticipates that many future connections will require expansion work to deal with capacity constraints. This could include the installation of new feeders, which would require the preparation of existing feeder positions on the switchgear and possibly even the installation of new assets such as breakers at the station switchgear. These types of upgrades have long lead times that could cause Toronto Hydro to fail to meet the customer's required timelines for connection.

This issue is being addressed through long term forecasting, which includes analysis of city area and development plans in order to plan for the expected increase in demand. Toronto Hydro's load forecast then in turn drives the proactive upgrade or installation of new station assets as required.

(ii) Customer Timelines and Requirements

Due to the nature of the work in the Customer Connections program, customer consultation and involvement is often required. Customer timelines and requirements can therefore present a risk to the project timeline. Changing requirements or increase/decrease in service demand as well as delays in the signing of OTCs can impact the schedule and timeliness of completion.

The Customer Offers group attempts to identify and mitigate these risks during the design and consultation phase with the customer and by adhering to the guidelines in Toronto Hydro's COS to respond to a customer's written request for connection within 15 calendar days of receipt of the written request and will make an OTC if required within 60 calendar days of receipt of the written request.

E5.2.5.2 Standard & Regulation Adherence

Toronto Hydro's COS describes the operating practices and connection policies to connect to the distribution system as required by Section 2.4 of the Distribution System Code. The COS also indicates how Toronto Hydro complies with its obligations under section 28 of the Electricity Act.

E5.2.6 Evaluation of Alternatives

As discussed above, Toronto Hydro is obligated to connect customers to its distribution system, where safe to do so, by the Electricity Act, Distribution System Code and its own COS. As such, there are no alternatives to this program.

E5.3 Externally-Initiated Plant Relocation and Expansion

WORKS AT TORONTO'S UNION STATION

E5.3.1 Summary

Program Description

Expenditures in the Externally Initiated Plant Relocation and Expansion program account for the relocation of Toronto Hydro's assets to accommodate construction by governmental and other agencies.

In general, when relocations are required, Toronto Hydro replaces the existing facilities on a like-for-like basis. This approach is, in most instances, the preferable alternative because it represents the minimum investment that allows Toronto Hydro to continue providing safe and reliable electricity distribution service. However, sometimes the nature of the project is such that like-for-like replacement is not the most efficient or desirable option. In some instances there is an opportunity for Toronto Hydro to maximize construction efficiencies and increase the existing capacity at the same time a relocation project is completed. This often offers a more prudent and cost-effective solution for ratepayers than conducting this expansion work later.

The following table summarizes the expected benefits of this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Opportunistic expansion work reduces the frequency and duration of construction disruptions for local area residents over time
Efficiency	ƒ Reduction in capital costs during the installation of infrastructure through cost sharing agreements, as well as shared construction efforts between Toronto Hydro and other organizations.
Reliability	ƒ Externally initiated relocation and expansion projects are not driven by reliability. However, where Toronto Hydro relocates or expands existing infrastructure, the new infrastructure is installed at current standards, which typically increases reliability.
Safety	ƒ Facilities the establishment of safe work sites that do not have high voltage electrical infrastructure on them. This minimizes safety risks to third parties who request the relocation work.
Other	ƒ Coordination with sponsor agencies provides a benefit to the economic well being of the City. This benefit is realized by Toronto Hydro relocating infrastructure, allowing sponsor agencies to complete their capital work plans, including transit expansions, bridge rehabilitations, and external utility upgrades.

Program Drivers

The following table summarizes the trigger driver for this program.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Customer Service Requests	ƒ Projects are driven by operational decisions of third parties that are beyond Toronto Hydro's control. ƒ Responding to such requests is part of Toronto Hydro's mandated service obligations, including those set out in the Distribution System Code and the Public Service Works on Highways Act, 1990, which requires Toronto Hydro to work with road authorities to complete relocations when requested ƒ Construction work carried out by third parties can provide an opportunity to expand the distribution system in a manner that minimizes disruption to customers and is more cost-effective for ratepayers.

Preferred Alternative

As discussed above, responding to these requests is part of Toronto Hydro's mandated service obligations. As such, there are no alternatives to executing this work.

Timing and Pacing

The timing and pacing of Externally Initiated Plant Relocation and Expansion is primarily determined by the project timelines set by sponsor agencies. Due to the uncertain nature of this work, some projects are delivered on short-notice. Toronto Hydro's projected spending in this program is based on historical expenditures and known or anticipated capital plans from other agencies.

TABLE C: HISTORICAL AND PROJECTED SPENDING FOR RELOCATION PROJECTS

	Historical Spending ($ Millions)					Future Spending ($ Millions)				
Year	2010[1]	2011[2]	2012	2013	2014	2015	2016	2017	2018	2019
Total Project Cost	3.3	7.8	10.7	19.6	12.2	22.3	43.6	52.6	42.8	43.3
Customer Contribution	2.6	2.8	0.9	1.1	3.4	8.7	23.5	24.1	15.0	14.5
Toronto Hydro Costs	0.7	5.0	9.8	18.6	8.8	13.6	20.1	28.5	27.8	28.8

Spending in this program is largely outside of Toronto Hydro's control. Due to the often high cost and significant volatility around the externally-initiated projects, Toronto Hydro has only included a portion the forecast program costs in its funding requirements. Although the utility forecasts that this program will cost approximately $119 million between 2015 and 2019, it has included only one-sixth of this amount (approximately $20 million) in its revenue requirement, or approximately $4.0 million of net Toronto Hydro costs per year. This sub-forecast amount represents a base level of spending that will be required over this term.

Toronto Hydro proposes to seek rates funding only for this sub-forecast base amount, with a variance account to record differences from this amount. Since the current projections for costs over the 2015-19 period are significantly higher than the amount included in Toronto Hydro's

[1] Prior to 2012, relocation projects were grouped together with Capital Projects, and were not tracked as a separate set of projects. The data only reflects the costs of projects within the capital work plan that Toronto Hydro could confirm were relocation projects, and as such, the actual numbers are expected to be higher.
[2] See footnote 1.

funding requirements, the utility is requesting the establishment of a variance account to capture annual differences from this base amount. Further details on the request for this account are in Exhibit 9, Tab 1, Schedule 1. The utility's expectation is that this approach will allow it to fund necessary, non-discretionary work while, at the same time, holding ratepayers harmless from the potential that a material amount of the forecast third party work does not materialize, due to the unpredictable nature, costs, and timing of such projects.

E5.3.2 Program Description

Construction projects initiated by the agencies includes work to maintain, upgrade, expand and improve existing public infrastructure such as roads, bridges, highways, and rail crossings. Among the entities initiating this work are Waterfront Toronto, the City of Toronto, the Ontario Ministry of Transportation, and Metrolinx (GO Transit). Legislation such as the Public Service Works on Highways Act, 1990,[4] mandates that Toronto Hydro work with public entities to facilitate their projects in a timely manner to promote the maintenance and improvement of public infrastructure.

When requested to relocate its infrastructure, Toronto Hydro works with the agencies initiating the work to find an efficient solution to accommodate the project in question. In general, when relocations are required, Toronto Hydro replaces the existing facilities on a like-for-like basis. This approach is in most instances, the preferable alternative because it represents the minimum investment that allows Toronto Hydro to continue providing safe and reliable electricity distribution service. However, sometimes the nature of the project is such that like-for-like replacement is not the most efficient or desirable option. In some instances there is an opportunity for Toronto Hydro to maximize construction efficiencies and increase the existing capacity at the same time a relocation project is completed. In these cases, Toronto Hydro reviews the relocation in conjunction with its future plans before, and works with the sponsor agency to complete system expansion work in conjunction with the required relocation. When Toronto Hydro increases the capacity of its infrastructure during an externally initiated project, this is known as expansion for the purposes of this narrative.

Broadly speaking, the projects within this program can be divided into requests from road authorities, which are governed by the Public Service Works on Highways Act, and those that are not governed by the Act.

(i) Requests from Road Authorities

The Public Service Works on Highways Act defines the obligations of utilities (Operating Corporations, such as Toronto Hydro) with facilities in road allowances and those that have responsibility to operate and maintain road allowances (Road Authority) during the course of construction. When a Road Authority has a project within the road right of way, the Act obligates a utility, such as Toronto Hydro, to relocate these facilities in cooperation with the Road Authority.

[4] R.S.O. 1990, C. P-49. ["Public Service Works on Highways Act"]

Within the City of Toronto, a Road Authority includes the City of Toronto or the Ontario Ministry of Transportation. A typical relocation project for a Road Authority could involve relocation of Toronto Hydro infrastructure due to a City-initiated modification in the road alignment. The new road alignments often require Toronto Hydro poles to be relocated to enable the road realignment.

The Public Service Works on Highways Act provides a mechanism for negotiating the apportionment of labour costs of relocations required by Road Authorities as between the Road Authority and the Operating Corporation. The Act includes a default provision that labour costs must be apportioned equally between the Road Authority and the Operating Corporation, while all other costs of the work shall be borne by the Operating Corporation (i.e. Toronto Hydro). Finally, the Act provides for a mechanism to appeal unfair or unjust cost allocations to the Ontario Municipal Board for a final determination. Road Authorities are also responsible to governmental and regulatory bodies, and thus are also aiming to minimize costs. As such, projects are typically completed with the default provision for labour and equipment costs. Consistent with past experience, Toronto Hydro estimates that it will be able to recover approximately 30% of the total job costs associated with projects from a Road Authority.

For projects that are initiated by a Road Authority, but are not explicitly covered under the Act, such as streetscape improvement projects, Toronto Hydro negotiates cost sharing agreements with the Road Authority on a case by case basis.

(ii) Requests from Other Agencies

Projects initiated by an organization other than a Road Authority are not covered under the Public Service Works on Highways Act. The Act requires Toronto Hydro to work with Road Authorities to complete relocations when requested on public road allowances, and although not mandated to complete relocations for other agencies, should deal with requests in a fair and reasonable manner. The sponsor agency typically funds 100% of the relocation costs of projects where distribution assets are located on the public road right of way, while Toronto Hydro is responsible for the entirety of any expansion work conducted in concert with the relocation. An example of this type of project is the Metrolinx Light Rail Transit (LRT) expansion. This project includes significant work already underway along Eglinton Avenue for the Eglinton LRT, as well as proposed works for the Finch LRT, Sheppard LRT and Scarborough Rapid Transit replacement. The locations of the Metrolinx LRT projects are shown in Figure 1. In total there are over 60 kilometers of light rail planned throughout the City of Toronto to be completed by 2020. The

Eglinton Crosstown line is the only LRT line currently under design, and is expected to run 19 kilometers from Kennedy Station to Jane Street along Eglinton.

Within these corridors, Toronto Hydro is expanding its existing infrastructure in preparation for load growth expected along the LRT lines. The expansions are based on City plans for the area, and projected density increases.

FIGURE 1: MAP OF METROLINX LRT PROJECTS PLANNED FOR COMPLETION BY 2020

Where Toronto Hydro infrastructure is on private property, or right of ways held by other organizations, individual agreements and cost responsibility are typically reviewed on a case by case basis. This was the case with GO Transit's Georgetown South Service Expansion, where Toronto Hydro infrastructure crossed the GO rail right of way. Table 1 outlines various benefits realized through this program.

TABLE 1: PROGRAM BENEFITS

Customer Value	ƒ Opportunistic expansion work reduces the frequency and duration of construction disruptions for local area residents over time
Efficiency	ƒ Reduction in capital costs during the installation of infrastructure through cost sharing agreements, as well as shared construction efforts between Toronto Hydro and other organizations.
Reliability	ƒ Externally initiated relocation and expansion projects are not driven by reliability. However, where Toronto Hydro relocates or expands existing infrastructure, the new infrastructure is installed at current standards, which typically increases reliability.
Safety	ƒ Facilities the establishment of safe work sites that do not have high voltage electrical infrastructure on them. This minimizes safety risks to third parties who request the relocation work.
Other	ƒ Coordination with sponsor agencies provides a benefit to the economic well being of the City. This benefit is realized by Toronto Hydro relocating infrastructure, allowing sponsor agencies to complete their capital work plans, including transit expansions, bridge rehabilitations, and external utility upgrades.

E5.3.3 Why the Program is Needed

Toronto Hydro undertakes the externally initiated relocations and expansions projects solely in response to the capital work initiated by sponsor agencies. Toronto Hydro is required to undertake this work by the applicable legislation and requests from the other agencies. Any expansion work carried out within the program is needed to meet anticipated future load growth, to allow Toronto Hydro to coordinate projects with construction work being carried on by third parties, to minimize disruption for customers, and to realize efficiencies and cost-effective solutions for ratepayers.

E5.3.3.1 Program Drivers

Toronto Hydro's Externally Initiated Plant Relocation and Expansion program is driven by third party requests, requirements under the Public Service Works on Highways Act and other requests from sponsor agencies.

TABLE 2: PROGRAM DRIVERS

Trigger Driver	Reasoning
Third Party Requests	ƒ Projects are driven by operational decisions of third parties that are beyond Toronto Hydro's control. ƒ Responding to such requests is part of Toronto Hydro's mandated service obligations, including those set out in the Distribution System Code and the Public Service Works on Highways Act, which requires Toronto Hydro to work with road authorities to complete relocations when requested ƒ Construction work carried out by third parties can provide an opportunity to expand the distribution system in a manner that minimizes disruption to customers and is more cost-effective for ratepayers.

E5.3.4 Timing & Pacing of the Program

The timing and pacing of Externally Initiated Plant Relocation and Expansion is primarily determined by the project timelines set by sponsor agencies. Toronto Hydro works with sponsor agencies to schedule the work in a manner that meets the requirements of the agencies and the company. Due to the uncertain nature of this work, some projects are delivered on short-notice.

Toronto Hydro's projected spending in this program is based on historical expenditures as well as known or anticipated capital plans from other agencies. Toronto Hydro gathers this information through a number of means, including direct consultation with external agencies, the Toronto Public Utilities Coordinating Committee (TPUCC), project plan publications such as the MTO Southern Highways Program and the Metrolinx Big Move documentation. At this time, the forecast projects, as well as timing for those projects, are based on the most current information available from the sponsor agencies. Toronto Hydro relocation projects are directly related to a capital project from the sponsor agency. Capital plans from sponsor agencies are subject to change based on their business cycles, funding requirements, and changing business demands. Any modification to the sponsor agency's capital plan could impact Toronto Hydro relocation and expansion projects.

The Public Service Works on Highways Act requires Toronto Hydro to work with Road Authorities to complete relocations when requested on public road allowances, and to deal with requests from other agencies in a fair and reasonable manner.

Expansion work is also governed by road work moratoriums that are imposed after road resurfacing is completed. If Toronto Hydro does not complete expansion work in conjunction with capital programs of external agencies, there may not be another opportunity to install required infrastructure in the area for a minimum of five years. The infrastructure requirements are based on predicted growth, future projects, and the reliability of the system.

TABLE 3: HISTORICAL AND PROJECTED SPENDING FOR RELOCATION PROJECTS

	Historical Spending ($ Millions)					Future Spending ($ Millions)				
Year	2010[6]	2011[7]	2012	2013	2014	2015	2016	2017	2018	2019
Total Project Cost	3.3	7.8	10. 7	19.6	12.2	22.3	43.6	52.6	42.8	43.3
Customer Contribution	2.6	2. 8	0.9	1.1	3.4	8.7	23.5	24.1	15.0	14.5
Toronto Hydro Costs	0.7	5.0	9 .8	18.6	8.8	13.6	20.1	28.5	27.8	28.8

[6] Prior to 2012, relocation projects were grouped together with Capital Projects, and were not tracked as a separate set of projects. The data only reflects the costs of projects within the capital work plan that Toronto Hydro could confirm were relocation projects, and as such, the actual numbers are expected to be higher.
[7] See footnote 1.

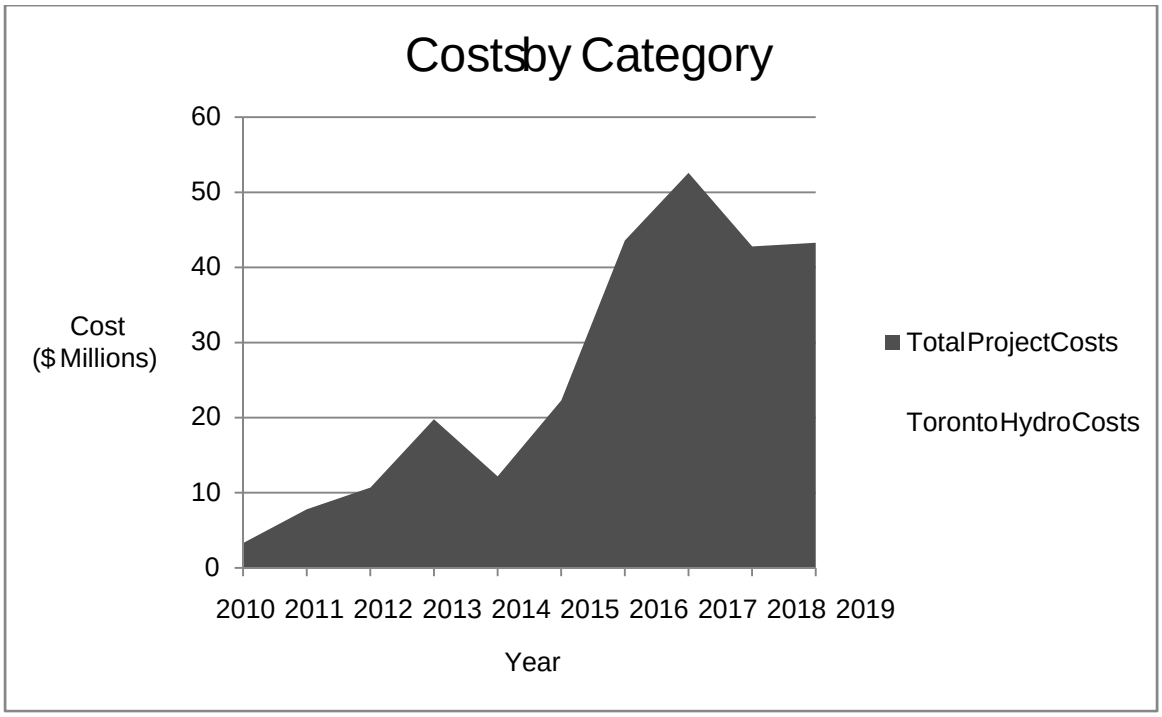

FIGURE 2: HISTORICAL AND PROJECTED SPENDING FOR EXTERNALLY INITIATED RELOCATION AND EXPANSION PROJECTS

Prior to 2012, relocation projects were grouped together with Capital Projects, and were not tracked as a separate set of projects. The data only reflects the costs of projects within the capital work plan that Toronto Hydro could confirm were relocation projects, and as such, the actual numbers are expected to be higher. Since 2012, after Toronto Hydro implemented a new tracking system for relocation projects, a general upward trend of Toronto Hydro costs associated with the externally initiated relocation and expansion program can be seen as a whole.

A large number of City work projects, driven by the Pan Am Games in 2015, had increased the spending required on utility relocations in 2013. These works were focused in 2013 in order to allow the City time to construct the capital projects required for the Pan Am Games in 2014 and early 2015. This is why the number of projects, as well as the overall spending, is predicted to decrease in 2014. While costs are expected to drop in 2014, work associated with the Metrolinx light rail transit projects are expected to significantly increase costs over the 2015-19 period. Design and some construction is expected in 2015, and significant construction investment beginning in 2016, and continuing through construction completion in 2020. Additionally,

electrification of the GO rail service between Pearson airport and Union Station may require significant investments, currently forecast to total $24 million over three years from 2015-2017. These projects, along with other known large projects, are expected to cause the upward trend in relocation and expansion costs to continue. Some of the projects that make a notable contribution to the expected costs are outlined below.

(i) MTO Bridge Rehabilitation Program

The MTO is responsible for the safety and operations of the provincial highways and bridges. This project is driven by the Southern Highways Program of MTO. This program mentions new highway and bridges to be constructed as well as existing highway and bridges to be rehabilitated. Toronto Hydro has identified four locations where there are known conflicts with bridges to be rehabilitated.

(ii) GO Transit Electrification – Union Pearson Express

One of the improvements proposed as part of the Big Move is to electrify the GO Transit network, which will allow the operation of electric motor trains. This is beneficial as these trains are able to run at a higher speed than the current models, and will also mitigate the localized greenhouse gas emissions that result from diesel trains. Although there are long term plans to electrify the entire network, the corridor for the Union Pearson Express will be electrified first, with an estimated construction completion date of 2017. The first 22 km of the line is within the existing GO Transit Rail right-of-way, while a new three km spur is being constructed to connect to the airport. The system that Metrolinx has proposed for the electrification consists of an overhead catenary system that will operate at 25 kV line to ground. Along the portion that is shared with the existing rail corridor, the system will consist of two conductors both at 25 kV at a 180^{o} phase shift, resulting in a line to line voltage of 50 kV, while the three km spur to the airport will only consist of a single conductor at 25 kV line to ground. Figure 3 outlines the route GO Transit plans to follow for the Union Pearson Electrification Project.

At present, Toronto Hydro has identified 24 overhead crossings along the route as conflicts with the proposed overhead catenary system. To mitigate the conflicts, Toronto Hydro's overhead conductors will likely have to be buried under the rail tracks using tunnelling technology. Historically, similar projects have cost between one and two million dollars per crossing. Therefore Toronto Hydro estimates that, if Metrolinx proceeds with the electrification project during 2015-2019, the utility may be required to spend approximately $24 million over that period. However, this project is subject to government direction, and has not been fully approved.

Metrolinx has undertaken preliminary planning milestones, however, technical details are still under review and to be refined by Metrolinx.

FIGURE 3: UNION PEARSON ELECTRIFICATION ROUTE

(iii) Eglinton Light Rail Transit Project

As part of the province-wide push to improve the transportation infrastructure, Metrolinx is constructing a 19km light rail transit (LRT) line along Eglinton Avenue, which will provide the City of Toronto with a second east-west rail transit route. To minimize the impact to vehicular traffic, the central portion of the LRT between Keele Street and Laird Drive will run underground, while the outskirts in the west between Black Creek Drive and Keele Street and in the east between Laird Drive and Kennedy Road will run at-grade. The LRT will be constructed to facilitate connection to other transit systems such as the GO Transit system and the Union Pearson Express at Mount Dennis station, the Spadina Subway at Eglinton West and Allen Road, the Yonge Subway at Yonge-Eglinton Interchange station, and the Bloor-Danforth Line at Kennedy Station. In the future, there is also the possibility that it will connect into an improved Scarborough SRT line. Currently, the construction of the LRT is projected to be completed and in operation by 2020.

A variety of relocations are currently in progress for this project to facilitate the passage of the tunnel boring machines as well as the construction of the station headwalls. The scope of the relocation works, whether overhead, underground, or a combination of both, vary depending on its location. Going forward, the scope of the relocations will likely increase in central Toronto due to the increased road disruption caused by the open cut construction required to build the underground stations. In the areas where the LRT will be at-grade, the relocations required will be to maintain standard overhead clearances between the LRT's catenary system and Toronto Hydro's distribution conductors, as well as underground clearances between the rail tracks and Toronto Hydro's civil infrastructure. In addition to the LRT work, the City of Toronto is expecting significant growth and development to take place along this corridor. To accommodate the proposed development, Toronto Hydro will install additional ducts beyond what is currently required to facilitate the connection of the future development to the distribution network.

(iv) Other Metrolinx Transit Projects

In addition to the Eglinton LRT, Metrolinx is proposing to build two other LRTs along Finch Avenue West and Sheppard Avenue East. The Finch West LRT is proposed to be approximately 11 km in length, and would connect the new Finch West station on the Spadina Subway extension in the east and Humber College, located just east of Highway 27. The Sheppard LRT is expected to be approximately 15 km in length, and would extend from Don Mills station on the Sheppard Subway line in the west, to Morningside Avenue in the east. Both LRTs are proposed to be at-grade on a dedicated right-of-way in the middle of the road. Similar to the Eglinton LRT, the relocations that are required for these LRTs would be to mitigate the conflict with the overhead catenary system for the LRT and Toronto Hydro's overhead distribution lines, as well as to maintain clearances between the LRT rail tracks and Toronto Hydro's underground civil infrastructure. Both LRTs have currently been put on hold, with construction slated to recommence between 2015 and 2017, with completion around 2021.

Figure 4 shows the number and average cost of historical and projected projects. From 2015-2019, the number of projects is expected to increase significantly, as well as the cost per project. This is due largely to the addition of Metrolinx LRT projects. The average number of non-Metrolinx projects per year from 2012-2014 was 34, and it is estimated that this average will continue through 2015-2019. These projects include typical requests seen historically, which include requests from the City of Toronto for road widening, utility installations, the MTO bridge reconstruction program, the Union Pearson Electrification projects. In addition to the typical projects expected to continue through 2015-2019, there is estimated to be an additional 28

Metrolinx projects added per year. The scopes of the Metrolinx projects are typically larger than the standard projects seen in past years, which increases the average cost per project. The additional Metrolinx projects are spread across four LRT lines including Eglinton, Sheppard, Finch, and the Scarborough transit line.

Traditional projects may involve the relocation of a small number of poles, or isolated sections of underground infrastructure, whereas typically Metrolinx projects involve hundreds of meters of infrastructure at a time. This also offers a significant opportunity for Toronto Hydro to install additional infrastructure at this time, given the large areas of improvement. In the case of the Metrolinx LRT projects, the typical station area affect is 100-300 meters. This amount of area allows Toronto Hydro to install sufficient infrastructure to support future growth in the area, including duct runs and cable chambers. This approach often offers a more prudent and cost-effective solution for ratepayers than conducting this expansion work later, including a reduced number of disruptions for local area residents and enhanced benefits from existing road cuts.

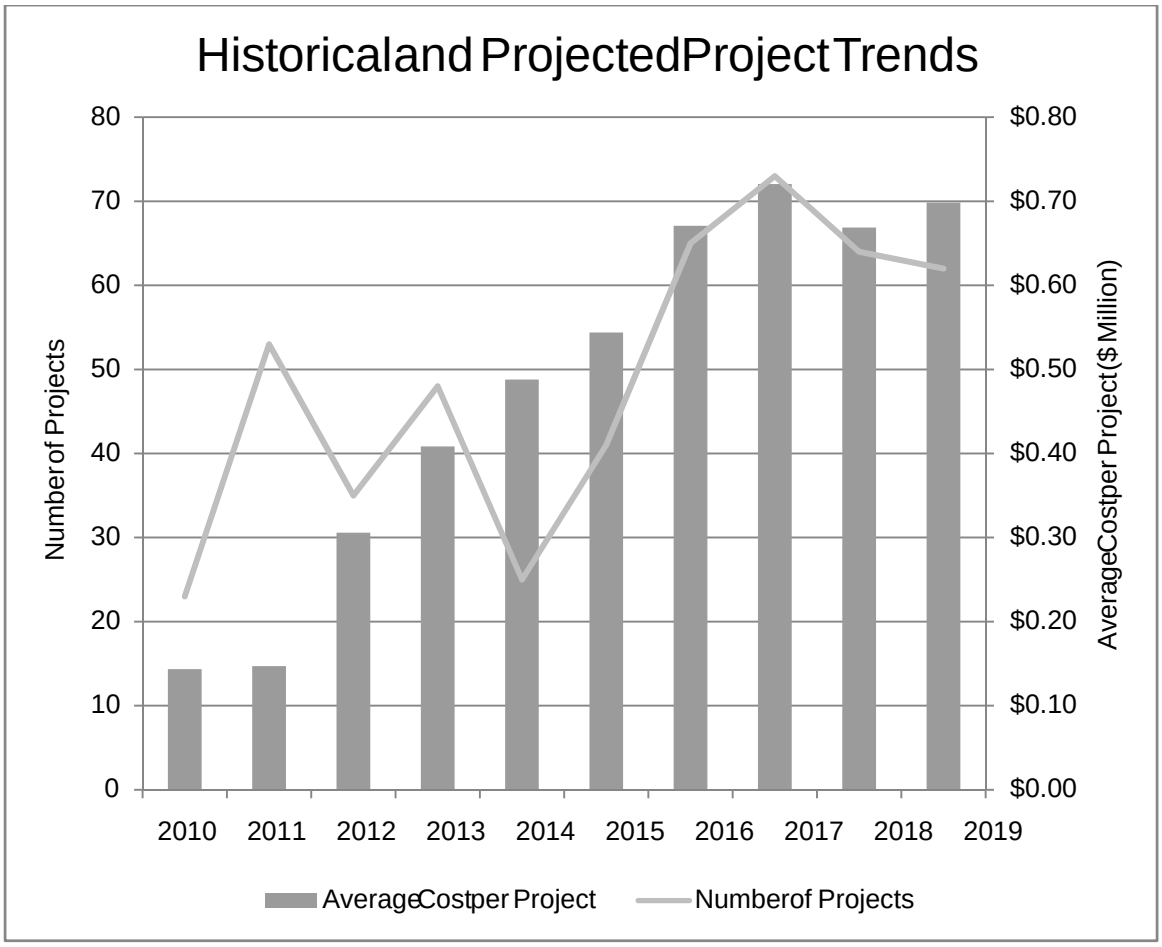

FIGURE 4: HISTORICAL AND PROJECTED PROJECT TRENDS

As noted above, Toronto Hydro has only included a portion of its forecasted costs in its funding requirements. The utility has included approximately $20 million over the five years covered by this application, or approximately $4 million of net Toronto Hydro costs per year. This sub-forecast amount represents a base amount of spending that will be required over this term. As shown in Figure 2 forecasts show that significantly more work is likely to be required over that period.

Toronto Hydro is requesting significant less funding than is forecast to be required. Due to the often high cost and significant volatility around externally-initiated projects and the work's non-discretionary nature, and since the current projections for costs over the 2015-19 period are significantly higher than the amount included in Toronto Hydro's funding requirements, Toronto

Hydro is requesting the establishment of a variance account to capture annual differences from this base amount.

Toronto Hydro's expectation is that this approach will allow it to fund necessary, non-discretionary work while, at the same time, holding ratepayers harmless from the potential that a portion of the forecasted third party work does not materialize, due to the unpredictable nature, costs, and timing of such projects. Please see Exhibit 9, Tab 1, Schedule 1 for further detail regarding the variance account requested for spending in excess of the sub-forecast baseline amount for which Toronto Hydro is seeking rate funding.

E5.3.4.1 Ranking & Prioritization

Externally-Initiated Plant Relocations and Expansions are driven by the schedules and timing of sponsor agencies. Project sequencing is largely dictated by the completion date proposed by the sponsor agency, so Toronto Hydro works with sponsor agencies to coordinate projects in order to increase efficiency. Approximately 75% of externally driven relocation and expansion projects have a requested completion date within 12 months.

E5.3.5 Program Execution

Toronto Hydro completes the majority of the design and construction work for externally-driven relocation and expansion projects using internal resources. For certain projects, typically where detailed work sequencing is required, Toronto Hydro works with sponsor agencies to have Toronto Hydro relocations and expansions completed by approved Toronto Hydro contractors under the agency's general contractor. Toronto Hydro still maintains control of the scope of work and scope changes. An example of this is with Metrolinx for the tunnelling contracts with the Eglinton LRT. Toronto Hydro and Metrolinx entered an agreement to allow Metrolinx to directly engage a Toronto Hydro-approved contractor. Metrolinx was able to dictate the schedule for design and construction, with input and review from Toronto Hydro. Toronto Hydro works closely with sponsor agencies completing the coordinated work on behalf of Toronto Hydro to ensure the scope and costs of the project are controlled. When the project is executed by sponsor agencies, Toronto Hydro has specific control points where review of the scope, cost, design, materials, and construction progress is required.

For all projects, once a project is initiated, coordination takes place between the sponsor agency and Toronto Hydro to determine the scope of relocation work required, a preliminary estimate, and agreed upon cost sharing arrangement. At this point in the process, Toronto Hydro reviews

the system requirements in the area, and determines if any capital upgrades are prudent to install in conjunction with the requested relocation work. The project then proceeds to the Program Management team to arrange for design and construction. Toronto Hydro maintains communication with the sponsor agency throughout the process.

E5.3.5.1 Program Risks

Since the program is based solely on forecast requests from external parties, Toronto Hydro's projected costs are based on historical amounts, ongoing discussions with external agencies, and available information on anticipated large projects. There is a possibility that the forecasted projects will not materialize from the sponsor agency, which would impact the relocation and expansion portfolio within Toronto Hydro. Conversely, projects previously unidentified may be requested, which would add relocation projects required by Toronto Hydro. The proposed variance account will ensure the ratepayers will not be held responsible for any more or less of the relocation work than actually occurs.

E5.3.5.2 External Constraints

The scope, timing and cost of Toronto Hydro's relocation and expansion work are determined in part by the schedule and plans of the sponsor agencies. The sponsor agencies often face their own constraints with respect to execution plans and completion timelines of their projects, requiring Toronto Hydro to work in consideration of these constraints.

E5.3.5.3 Standard & Regulation Adherence

Toronto Hydro complies with the Public Service Works on Highways Act, which requires utilities to work with Road Authorities when there is other work to be completed within the road right of way. All relocated infrastructure must be built to current Toronto Hydro construction standards.

E5.4.6 Evaluation of Alternatives

E5.4.6.1 Quantification/ Evaluation of Options

As indicated previously, Toronto Hydro is obligated to facilitate external agency capital work projects. In general, when relocations are required Toronto Hydro replaces the pre-existing facilities on a like-for-like basis. In most instances this approach constitutes the preferred alternative because it represents the minimum investment on the part of Toronto Hydro to continue providing safe and reliable electricity distribution service.

Sometimes the nature of the project is such that like-for-like replacement is not the most efficient, or otherwise desirable option. In these cases, Toronto Hydro reviews its obligations and options in light of its future plans before it undertakes any plant relocation and/or expansion. As an example, Toronto Hydro has to work with the MTO to facilitate the relocation of existing Toronto Hydro infrastructure off of various bridges throughout the City. Toronto Hydro develops preliminary plans to relocate the existing infrastructure, and then reviews internal plans for upgrades, as well as predicted load growth in the area. To complete the relocation, specialized tunnelling equipment is required to tunnel under the highway. As the equipment is already on site and is being used for the relocation construction, it is more efficient to install additional capacity at this time. Moreover, the analysis indicated that the additional capacity would be required in the area, so it has become prudent to maximize efficiencies and install additional capacity while relocating off of the MTO bridges over Highway 427.

Another example of how expansion and relocations may be combined to maximize efficiencies is the Eglinton LRT project. To accommodate the LRT line on Eglinton, Toronto Hydro reviewed two options. The first option was simply to undertake the relocation necessary to facilitate the Metrolinx project without constructing any additional civil infrastructure to accommodate Toronto Hydro's anticipated demand growth. The second, and preferred, option was to construct civil infrastructure sufficient to accommodate both the relocation and Toronto Hydro's anticipated demand growth and other system requirements. To predict the system capacity that will be required in the future, the Planning teams have been using reports published by the City regarding planned usages for Eglinton Avenue, as well as looking at other examples of similar transit stations and the demand required in those areas. Eglinton Avenue, on average, is currently lacking 25% of the Toronto Hydro infrastructure available, compared to similar areas along transit lines within Toronto.

The second option is the preferable approach for three reasons

(1) The new LRT line will encourage future growth in the LRT corridor, which should in turn increase the electrical load. The existing civil infrastructure is forecast to be insufficient to serve this load growth between 2020 and 2030. It will be less expensive to construct new civil infrastructure to support this load growth simultaneously with relocation work required by the LRT construction.

(2) Toronto Hydro needs to coordinate its expansion work with work of other impacted utilities (i.e., telecommunications, natural gas, sewer, and water in addition to electricity)

to ensure there is sufficient real estate for Toronto Hydro needs. Failure to do so may mean the corridor through the road right of way will be unavailable to Toronto Hydro and sub-optimal alternatives to serve load would be required.

(3) The City of Toronto imposes a five-year moratorium on road cuts in the area once the LRT work is completed, preventing THESL from installing the additional civil infrastructure when required.[9] This could lead to THESL having to install more costly and less optimally located facilities to connect any emerging load.

As noted in section E.5.4.1, the OEB affirmed Toronto Hydro's approach to the execution of prudent work in conjunction with other, non-discretionary work. As a practical matter of cost-effectiveness, it is prudent and cost-effective for the utility to complete other important associated work when carrying out non-discretionary capital projects.[10]

[9] Such moratoriums are part of the Municipal Consent Requirements for the Installation of Plant Within City of Toronto Streets, which states:
To ensure the long-term sustainability of the City's infrastructure, the General Manager enforces a moratorium on all newly improved streets. The moratorium ensures that the integrity of the pavement structure is protected and also serves to minimise the disruptions and inconvenience to the public resulting from repeated construction activity.

E5.4.7 Program Projects

Table 4 illustrates a listing of projected programs for 2015, which are planned for completion as a part of the 2015-2019 Program. Projects carried over from 2014 to 2015 are flagged

TABLE 4: PROGRAM PROJECTS

Project Name	Expansion Potential	Agency	Estimated Project Timelines (Subject to modification by the sponsor agency)	Estimated Project Cost in 2015 ($ Millions)
North West PATH Phase 2 (2014 Carry-over)	Yes	City of Toronto	Q4 2014-Q4 2015	$1.2
427 and Bloor Bridge Rehabilitation	Yes	MTO	Q1 2015 – Q3 2016	$2.2
427 and Burnhamthorpe Bridge Rehabilitation	Yes	MTO	Q1 2015 – Q3 2016	$1.9
427 and Rathburn Bridge Rehabilitation	Yes	MTO	Q1 2015 – Q3 2016	$2.2
Eglinton LRT	Yes	Metrolinx	Q1 2015 – Q4 2019	$4.9
Dupont Subway Station	No	TTC	Q1 2015	$0.4
Six Points Intersection	Yes	City of Toronto	Q2-Q3 2015	$2.2
Union Pearson Express Electrification	Yes	GO Transit / Metrolinx	Q2 2015 – Q4 2017	$4.8
Subtotal of Scoped Projects				$19.8
Additional Projected and Unscoped 2015 Projects		Various	Q1 – Q4 2015	$2.5
Total 2015 Estimated Costs				$22.3

E5.3.7.1 North West PATH Addition Phase 2

This project is initiated by the City of Toronto and is planned to be completed with cost sharing under the Public Service Works on Highways Act. There is opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this relocation project.

The North West PATH is a new underground extension to the City of Toronto underground PATH network from Union Station to Wellington Street via York Street. This expansion will provide additional capacity to accommodate the growing numbers of pedestrians accessing Union Station from the downtown core. The City of Toronto has requested that THESL relocates its

infrastructure that is in conflict with proposed work from the intersection of York Street and Front Street to York Street and Wellington Street. Phase 1 involved relocating the infrastructure at the intersection of Front and York to the area in front of the Royal York Hotel, on York Street. Phase 2 involves the relocation of Toronto Hydro infrastructure along York Street from the area in front of the Royal York Hotel, to the intersection of Wellington Street and York Street. Phase 2 consists of approximately 300 meters of duct and 11 cable chambers. Design of Phase 2 is scheduled by the City to begin in 2014, with construction taking place in 2015. The City project experienced significant delays from the original estimated completion date, which caused delay to the Toronto Hydro relocation work.

E5.3.7.2 Highway 427 and Bl oor Bridge Rehabilitation

This project is initiated by the MTO and is planned to be be completed with cost sharing under the Public Service Works on Highways Act. There is opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this relocation project.

This project is being done due to the rehabilitation of the Bloor Street Bridge over Highway 427. MTO has stated that no utilities are permitted within the bridge structure after rehabilitation, so Toronto Hydro is relocating its assets of the bridge to under Highway 427. To accomplish this, there is a tunnel being constructed under Highway 427, large enough to accommodate sixteen 100mm ducts. The tunnel design should conform to MTO requirements as stipulated within the Guidelines for Foundation Engineering-Tunnelling Specialty for Corridor Encroachment permit Application document. This project consists of approximately 300m of duct and four cable chambers.

E5.3.7.3 Highway 427 and Burnha mthorpe Bridge Rehabilitation

This project is initiated by the MTO and is expected to be completed with cost sharing under the Act. There is opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this relocation project.

This project is being done due to the rehabilitation of the Burnhamthorpe Street Bridge over Highway 427. MTO has stated that no utilities are permitted within the bridge structure after rehabilitation, so THESL is relocating its assets of the bridge to under Highway 427. To accomplish this, there is a tunnel being constructed under Highway 427, large enough to accommodate sixteen 100mm ducts. The tunnel design should conform to MTO requirements as stipulated within the Guidelines for Foundation Engineering-Tunnelling Specialty for Corridor

Encroachment permit Application document. This project consists of approximately 280m of duct and four cable chambers.

E5.3.7.4 Highway 427 and Rathburn Bridge Rehabilitation

This project is initiated by the MTO and is expected to be completed with cost sharing under the Public Service Works on Highways Act. There is opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this relocation project.

This project is being done due to the rehabilitation of the Rathburn Street Bridge over Highway 427. MTO has stated that no utilities are permitted within the bridge structure after rehabilitation, so THESL is relocating its assets of the bridge to under Highway 427. To accomplish this, there is a tunnel being constructed under Highway 427, large enough to accommodate sixteen 100mm ducts. The tunnel design should conform to MTO requirements as stipulated within the Guidelines for Foundation Engineering-Tunnelling Specialty for Corridor Encroachment permit Application document. This project consists of approximately 250m of duct and four cable chambers.

E5.3.7.5 Eglinton LRT

This project is initiated by Metrolinx and will be recoverable from Metrolinx. There is an opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this relocation project.

The Eglinton LRT is a major transit expansion project proposed by Metrolinx as part of their Regional Transportation Plan called the Big Move. The LRT will run between Black Creek Drive in the west to Kennedy Road in the east, with the central portion between Keele Street and Laird Drive being underground and the rest at grade. It will provide a second east-west rail transit route within the City of Toronto, and will connect to other rail transit systems such as the GO Transit system and the Union Pearson Express at Mount Dennis station, the Spadina Subway at Eglinton West and Allen Road, the Yonge Subway at Yonge-Eglinton Interchange station, and the Bloor-Danforth Line at Kennedy Station. To facilitate the construction of the tunnels and headwalls, construction is already underway in various locations along the route. Most of the relocation work required going forward will be to assist the construction of the underground stations and the surface routes. The relocation work required for the underground stations will minimize the conflicts with Toronto Hydro assets within the construction area, while the relocations required for the surface routes will be to maintain standard overhead clearances between the LRT's catenary system and Toronto Hydro's distribution conductors, as well as underground clearances between

the rail tracks and Toronto Hydro's civil infrastructure. During the construction process, additional Toronto Hydro ducts required to accommodate the projected future loads will be installed.

E5.3.7.6 Dupont Subway Station

This project is initiated by the TTC and will be recoverable from the TTC. Toronto Hydro has no requirements to expand its infrastructure in the area in conjunction with this relocation project.

The TTC's Easier Access Initiative proposes to upgrade their subway and SRT stations to be fully accessible by 2025. As part of this program, the TTC will be installing three elevators at Dupont Station on the Bloor-Danforth Line. Two elevators will connect the concourse to track level, while one elevator will connect the concourse to ground level. To facilitate the installation of the elevators, the duct bank feeding the TTC traction power substation will be relocated to avoid the proposed elevator location, and the overhead feeders in the area will be relocated during the construction, and be reinstated to their original alignment upon completion. This project requires coordination between the TTC's General Contractor and Toronto Hydro construction crews to work through the two phases of installing the elevators.

E5.3.7.7 Six Points Intersection

This project is initiated by the City of Toronto and will be recoverable from the City of Toronto as it is an overhead to underground streetscape improvement project. There is opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this streetscape improvement project.

The City of Toronto is planning to redesign the three-way intersection of Bloor Street West, Kipling Avenue, and Dundas Street West to eliminate the multiple overpasses and build an at-grade intersection. In conjunction, a significant amount of land development and streetscape work will be undertaken. The City of Toronto has requested that Toronto Hydro bury its overhead assets along Bloor Street West, as well as to install any underground civil infrastructure required to connect the proposed development to the distribution grid. In addition, the reconstruction of the area will provide Toronto Hydro with the opportunity to expand the distribution system in the area. Toronto Hydro has historically avoided crossing through this intersection due to the complexity of the road configuration, which previously included multiple overpasses. The additional infrastructure will allow Toronto Hydro to have a significant north south duct run through the area for future use.

E5.3.7.8 Union Pearson Electrification

This project is initiated by the GO Transit and the cost sharing agreements for each affected crossing are currently under review. Standard relocation agreements across the GO rail corridor indicate that Toronto Hydro is responsible for all relocation costs. There is opportunity for Toronto Hydro to expand its existing infrastructure in the area in conjunction with this relocation project.

As part of the Big Move, one of the enhancements proposed to the existing GO Transit network is to electrify the tracks, thereby improving the speed of the trains in their fleet and mitigating the local greenhouse gas emissions that results from the use of diesel trains. The infrastructure proposed by Metrolinx consists of an overhead catenary system operating at 25 kV line to ground. In the instances where Toronto Hydro has overhead assets crossing over the rail corridor, the conductors for Toronto Hydro's distribution network and the overhead catenary system will cause a conflict. It is anticipated that 24 crossings will need conflict mitigation by burying the cables underground using tunnelling technology. During this process, the underground crossings can be built such that they can accommodate extra conductors to allow for future system expansion.

E5.4 Load Demand

ACCOMMODATING FOR CITY OF TORONTO'S EXPANDING DOWNTOWN CORE

E5.4.1 Summary

Program Description

The Load Demand program addresses overloads at the bus and feeder level for the 27.6 kV and 13.8 kV systems through load transfers and investing in feeder and equipment upgrades. Through this program, Toronto Hydro plans to make room for new load additions on the distribution system and to alleviate operational constraints that could restrict the utility's ability to execute the most cost-effective system renewal program possible over the five year planning horizon.

Investments in the Load Demand program will deliver customer value by maintaining Toronto Hydro's ability to promptly address customer service requests, while also maintaining operational flexibility and system efficiency. These benefits are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Toronto Hydro is able to connect new customers to the distribution system without extensive delays or adverse impacts to existing customers. ƒ Avoid service quality issues caused by summer peak loads.
Reliability	ƒ Restoration capabilities during outages are maintained with the introduction of spare capacity on existing feeders through load transfers,

	cable upgrades, and equipment upgrades.
Safety	ƒ The risk of failure for overloaded equipment is mitigated. Toronto Hydro workers and members of the public will be less exposed to overloaded infrastructure. ƒ Rebuilding existing civil infrastructure will remove old assets and those in poor condition from pedestrian sidewalks and roadways.
Efficiency	ƒ The additional capacity introduced in this program is expected to give the control room the ability to operate the system with necessary flexibility, especially during the summer peak period. ƒ Currently, operational constraints exist that restrict highly loaded feeders from being removed from service for capital or maintenance work.

Program Drivers

The drivers of this program are summarized in the table below.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Customer Service Requests	ƒ Further load growth due to development in specific areas is expected to limit Toronto Hydro's ability to connect new customers quickly and economically. ƒ Toronto Hydro's obligations per the Distribution System Code Section 3.3.1: "A distributor shall continue to plan and build the distribution system for reasonable forecast load growth. A distributor may perform enhancements to its distribution system for purposes of improving system operating characteristics or for relieving system capacity constraints. "
Secondary Driver	**Reasoning**
Mandated Service Obligations	ƒ Toronto Hydro's system is designed for single contingency conditions. In some cases, equipment is overloaded such that under single contingency, customers cannot be transferred to their standby supplies due to capacity constraints. ƒ Under the Distribution System Code, Toronto Hydro is obligated to connect new customers while not adversely affecting the quality of distribution services received, which is becoming more difficult as the system grows in load without an equal increase in capacity.
Reliability	ƒ A lack of capacity between adjacent feeders can greatly increase the number of customers at risk of facing lengthy interruptions. ƒ Increasing the capacity of the feeder trunk cable can also decrease the likelihood of lengthy outages. ƒ Toronto Hydro's must meet the obligations set out in Section 4.4.1 of the Distribution System Code: "A distributor shall maintain its distribution system in accordance with good utility practice and performance standards to ensure reliability and quality of electricity service, on both a short-term and long-term basis."

System Efficiency	ƒ Restrictions are placed on the system during peak load conditions so that certain feeders cannot be taken out of service. This constrains Toronto Hydro's ability to implement new customer connections and hinders its ability to plan and execute other capital maintenance work in a timely and efficient manner.

Preferred Alternative

The Load Demand program analyzed and evaluated the following options

(1) Maintain the status quo by postponing the upgrades in heavily loaded areas with projected influx of new development.

(2) Add station capacity through expansion of existing stations or construction of new stations in the heavily loaded areas with projected influx of new development.

(3) Upgrade equipment and infrastructure in high load and congested areas of the system and in areas of proposed high load developments with a focus on relieving overloads under first contingency basis.

Option III is preferable as it provides capacity for increased loading in already heavily loaded areas, enables first contingency load transfer in these areas and thereby reduces the risk of widespread, long duration outages for customers.

Evaluating the first year of activities within the Load Demand program produces an estimated net present value (NPV) of $12.25 million. This value accounts for reduction in risk, including the costs of customer interruptions for both asset-related as well as non-asset related interruptions, as well as any additional benefits associated with the program that are realized through the execution of the first year of activities.

Timing and Pacing

The timing and pacing of the Load Demand program is driven by the timing and pattern of development in specific areas of the city, load and customer growth forecasts, as well as known road moratoriums and other external constraints. Deferral of this work could expose the system to operational constraints within the 2015 to 2019 period that could severely impact the reliability of power supply for new and existing customers, and could hinder the ability of Toronto Hydro to efficiently carry-out other planned renewal work during the forecast period.

TABLE C: HISTORICAL AND FORECAST SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.00	0.00	0.29	2.40	1.11	11.96	13.93	14.05	15.70	19.23

The City of Toronto has introduced restrictions, related to the Pan Am Games, on Toronto Hydro that will limit the amount of Load Demand work that it can complete in 2015. Accordingly, in 2015, Toronto Hydro plans to complete the load transfers to Copeland TS in the Windsor TS area. Work at George and Duke MS must also be completed in 2015 in order to avoid a scheduled road moratorium that will prevent work from occurring in the area for a five year period.

In 2016, Toronto Hydro plans to rebuild and expand the civil infrastructure in the Windsor TS area to service the entertainment district customer base. In the next year, planned capacity increases at Carlaw TS will oblige Toronto Hydro to make infrastructure upgrades between Gerrard TS and Carlaw TS. Spending in 2018 and 2019 is dictated by the load transfers required in order to control loading at the bus level for certain stations. The required load transfers must occur in a timely manner to avoid necessary load shedding during the summer peak period.

E5.4.2 Program Description

The Load Demand program addresses overloads at the bus and feeder level. Through this program, Toronto Hydro plans to make room for new load additions on the distribution system and will alleviate operational constraints that could restrict the utility's ability to execute the most cost-effective system renewal program possible over the five year planning horizon. This program impacts the 27.6 kV and 13.8 kV overhead, underground and network systems, and includes the following three activities:

(1) load transfers,

(2) feeder upgrades,

(3) equipment upgrades.

Toronto Hydro plans to spend an estimated $63.14 million on these activities between 2015 and 2019. Each of the activities is explained in detail in the following subsections.

E5.4.2.1 Load Transfers

Toronto Hydro plans to execute targeted load transfer projects on the 27.6 kV overhead and underground systems and the 13.8 kV dual radial distribution system. The load transfer activities in this program focus on transmission stations under pressure from ongoing and anticipated load growth in their respective locales. These load transfers are required to provide load relief and prevent the overloading of existing assets.

FIGURE 1: INCREMENTAL KVA OF PROPOSED LOAD

Figure 1 shows a snapshot of proposed customer loads and illustrates the density of ongoing and future developments anticipated in Toronto. These developments range from new office towers and condominium buildings to commercial sites and data centres. As the figure indicates, the majority of anticipated growth is situated around the downtown core and around major avenues in the former suburbs, i.e. the "Horseshoe" distribution area.

Table 1 below lists the station buses that are addressed by this program in order to provide load relief and prevent the overloading of existing assets in these stations. Forecasts indicate that several buses are trending towards being overloaded in the 2015 to 2019 planning period. While all of the projects under the program are designed to mitigate these load issues, the work to be conducted will depend on the precise circumstances of each station bus and the revised load forecast.

If the required work is not completed, connecting new customers to these stations will likely not be possible. Each new customer request will require load to be transferred to another part of the system; under tight timeline requirements from the customer, non-optimal system configurations may be necessary. These customer connections will likely be more costly and require a longer connection time to complete the work.

TABLE 1: STATION BUSES THAT REQUIRE LOAD TRANSFERS

Station	Bus	Capacity (MVA)	Load Relief Required		
			Year	Projected Load (MVA)	% Loading
BASIN (115KV/13.8KV) TS	A5-6	49	2018	47	96%
BRIDGMAN (115KV/13.8KV) TS	A1-2B	40	2016	38	95%
	A1-2H	66	2020	63	95%
	A7-8H	66	2021	64	97%
CARLAW (115KV/13.8KV) TS	A8-9	41	2015	39	95%
CECIL (115KV/13.8KV) TS	A3-4	47	2019	45	96%
	A5-6	72	2022	68	94%
	A7-8	72	2017	68	94%
CHARLES (115KV/13.8KV) TS	A1-2	45	2020	43	86%
	A3-4	45	2020	43	96%
DUFFERIN (115KV/13.8KV) TS	A5-6	48	2022	46	96%
	A7-8	48	2016	46	96%
ESPLANADE (115KV/13.8KV) TS	A1-2GD	69	2016	66	96%
	A3-4GD	69	2021	66	96%
FAIRBANK (115KV/27.6KV) TS	B & Q	95	2017	96	101%
GERRARD (115KV/13.8KV) TS	A1-2	39	2017	37	95%
HORNER (230KV/27.6KV) TS	B & Y	192	2017	193	101%
LESLIE (230KV/27.6 & 13.8KV) TS	B & Y	101	2015	110	109%
MAIN (115KV/13.8KV) TS	A3-4MN	42	2019	40	95%
MANBY (230KV/27.6KV) TS	Q & Z	63	2017	63	100%
	V & F	112	2019	113	101%
RUNNYMEDE (115KV/27.6KV) TS	B & Y	117	2015	130	111%
SHEPPARD (230KV/27.6KV) TS	B & Y	115	2021	115	100%
STRACHAN (115KV/13.8KV) TS	A1-2	56	2017	53	95%
	A7-8	40	2021	38	95%
TERAULEY (115KV/13.8KV) TS	A3-4	60	2017	57	95%
	A5-6	60	2015	57	95%
WINDSOR (115KV/13.8KV) TS	A13-14	41	2017	39	95%
	A15-16	69	2015	73	106%
	A17-18	49	2016	50	102%

In order to transfer load from one station to another, Toronto Hydro often needs to install and pull new feeders and cable from stations with spare capacity. These stations can either be existing

stations with switchgear that have available capacity and feeder positions, or they can be new stations into which switchgear will be installed in order to create additional capacity. Additional civil infrastructure may also be required to implement a load transfer because existing egress chambers can be congested or require rebuilds. Afterwards, extensive cable pulling and splices are involved to transfer customers from existing feeders to new feeders.

Extending existing feeders is another method of transferring load to feeders with excess capacity. As well, with respect to the Horseshoe distribution area, another alternative that can facilitate the shifting of load is the installation of new switches or the relocation of existing switches.

E5.4.2.2 Feeder Upgrades

Feeder upgrades are another key component of the Load Demand program. In order to meet the growing demand of new customers, Toronto Hydro plans to target portions of feeders within the 27.6 kV distribution system and the 13.8 kV distribution system for upgrades.

(i) 27.6 kV System Feeder Upgrades

The 27.6 kV system is setup as a looped configuration, with feeders tied via switches so that loading can be transferred from one feeder to an adjacent feeder during contingency scenarios (i.e. when a feeder is interrupted). Over time, growth can cause the load to exceed feeder capacity, which constrains system operational effectiveness under both normal and contingency scenarios. In addition, capacity for load transfers is required in order to maintain consistent service during planned maintenance and construction activities. To manage the load growth, Toronto Hydro plans to perform cable upgrades.

Some of Toronto Hydro's feeder trunks contain underground and overhead cables that are smaller than the current standard. These cables can possess less capacity than what station circuit breakers offer. In order to address emerging load capacity requirements, Toronto Hydro plans to upgrade undersized segments of underground cables and overhead conductors and will utilize stranded station circuit breaker capacity in order to provide additional capacity.

(ii) 13.8 kV System Feeder Upgrades

The majority of the underground 13.8 kV system in downtown Toronto is configured as a dual radial scheme. Customers are supplied by two feeders: one that provides their normal supply and the other that operates as standby supply. In some areas that have experienced load growth, customers now have an overloaded standby supply. To address this issue, Toronto Hydro plans

to upgrade primary cables or install new feeders so that load can be transferred to these newly established feeders.

Some 13.8 kV primary feeders may have undersized portions of cable that act as bottlenecks to feeder capacity. Toronto Hydro plans to upgrade undersized trunk cable to the current standard to utilize previously stranded capacity. Figure 2 below depicts non-standard segments of cable along the trunk of feeder A51WR. For underground cable upgrade projects, it is typical that a rebuild or expansion of existing civil plant will be required. The civil plant located downtown is fairly congested and in some cases nearing end-of-life. Replacing cables usually involves installing the new cable prior to removing the existing one. However, existing civil plant may not be able to accommodate additional or upgraded cables in this manner. Therefore, Toronto Hydro also plans to complete upgrades or rebuilds of the existing civil plant to accommodate the cable upgrades.

FIGURE 2: A51WR - EXAMPLE FEEDER - UNDERSIZED CABLE SEGMENTS HIGHLIGHTED

E5.4.2.3 Equipment Upgrades

The network system's transformers are fed from various feeders that are paralleled on the secondary side of the transformer in order to provide a redundant supply to customers. This

configuration helps reduce the risk of customers experiencing momentary interruptions during single contingency events. In order to prevent the overloading of equipment during these events, Toronto Hydro has established that load being supplied by these network vaults should not exceed 50% for two unit vaults, 66% for three unit vaults, etc. This loading requirement ensures that equipment does not get overloaded if one of the primary supply feeders is taken out of service. Overloading is likely to lead to premature deterioration and failure of the network equipment.

Network equipment that is at or over capacity must be upgraded in order to facilitate operating the network system without overloading. Toronto Hydro plans to upgrade network units if they are not already the largest size available. Network equipment comes in three sizes for low voltage distribution (120/208 V) and three sizes for high voltage distribution (240/416 V). For low voltage transformers, the sizes are 500 kVA, 750 kVA and 1,000 kVA, and for high voltage the transformer sizes are 1,000 kVA, 1,500 kVA and 2,000 kVA. An additional benefit of replacing existing overloaded network equipment is the introduction of a more robust submersible design that is capable of operating underwater.

In locations where an upgrade is not possible, an additional transformer may be installed or additional secondary cables will be added between vaults to support highly loaded vaults.

FIGURE 3: 500KVA NETWORK UNIT

E5.4.2.3 Civil Upgrades

Expanding civil infrastructure is an important component of the Load Demand program. As additional customer and loads have been added to Toronto Hydro's system, the civil infrastructure located immediately outside transformer stations has, in certain cases, become progressively more congested. This congestion occasionally limits the ability of planners to optimally allocate and route feeders to supply load. In addition, congestion and a lack of civil infrastructure immediately outside the transformer station can directly impact the ability to fully utilize all capacity on remaining buses.

A similar situation can occur within Toronto Hydro's feeder duct infrastructure as various cables are assigned to new load and routed through available paths. Those paths become congested and as overall loading continues to increase in certain parts of the system, bottlenecks are created. Investing in additional duct bank infrastructure allows Toronto Hydro to reduce the distance between connected loads and supply points, and ensure that all available capacity is made available for allocation in the most optimal way. The following map shows the areas of investment planned for 2015 as a part of this program.

FIGURE 4: MAP

Toronto Hydro anticipates that the investments in the Load Demand program will deliver customer value by increasing Toronto Hydro's ability to promptly address customer service requests, while also adding operational flexibility to improve system efficiency. In addition, the utility expects to realize reliability and safety benefits. These benefits are summarized in the following table.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	x Toronto Hydro is able to connect new customers to the distribution system without extensive delays or adverse impacts to existing customers. x Avoid service quality issues caused by summer peak loads. x The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $24.2 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E5.4.7). x Accounting for capital program costs, the first year's activities deliver a positive NPV of $12.3 million, confirming the economic prudence of the investments (see Section E5.4.7).
Reliability	ƒ Restoration capabilities during outages are maintained with the introduction of spare capacity on existing feeders through load transfers, cable upgrades, and equipment upgrades.
Safety	ƒ The risk of failure for overloaded equipment is mitigated. Toronto Hydro workers and members of the public will be less exposed to overloaded infrastructure. ƒ Rebuilding existing civil infrastructure will remove old assets and those in poor condition from pedestrian sidewalks and roadways.
Efficiency	ƒ The additional capacity introduced in this program will give the control room the ability to operate the system with necessary flexibility, especially during the summer peak period. ƒ Currently, operational constraints exist that restrict highly loaded feeders from being removed from service for capital or maintenance work.

E5.4.3 Why the Program is Needed

The Load Demand program is needed to address customer load growth that is already straining parts of Toronto Hydro's distribution system. Toronto Hydro anticipates that additional development will exacerbate the situation. The existing distribution system was built with a fixed amount of capacity to connect new customers. Surplus capacity on all levels of the system has already been utilized to connect nearby customers; this has led to significant loading of some station buses, feeders, and transformers. In addition, the civil infrastructure that houses electrical

infrastructure is not sufficient to accommodate the additional electrical infrastructure that will be required.

E5.4.3.1 Program Drivers

The drivers of this program are outlined in the chart below and further detailed throughout this section.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Customer Service Requests	ƒ Growth in certain areas of Toronto has led to the distribution system becoming strained. Surplus capacity on all levels of the system has been utilized to connect nearby customers; this has led to the overloading of some station buses, feeders, and transformers. ƒ Further load growth due to development will limit Toronto Hydro's ability to connect new customers quickly and economically. ƒ Toronto Hydro's obligations per the Distribution System Code Section 3.3.1: "A distributor shall continue to plan and build the distribution system for reasonable forecast load growth. A distributor may perform enhancements to its distribution system for purposes of improving system operating characteristics or for relieving system capacity constraints. "
Secondary Driver	**Reasoning**
Mandated Service Obligations	ƒ Toronto Hydro's system is designed for single contingency conditions. In some cases, equipment is loaded such that under single contingency, customers cannot be transferred to their standby supplies due to capacity constraints. ƒ Under the Distribution System Code, Toronto Hydro is obligated to connect new customers while not adversely affecting the quality of distribution services received, which is becoming more difficult as the system grows in load without an equal increase in capacity.
Reliability	ƒ A lack of capacity between adjacent feeders can greatly increase the number of customers at risk of facing lengthy interruptions. ƒ Increasing the capacity of the feeder trunk cable can also decrease the likelihood of lengthy outages. ƒ Toronto Hydro's must meet the obligations set out in Section 4.4.1 of the Distribution System Code: "A distributor shall maintain its distribution system in accordance with good utility practice and performance standards to ensure reliability and quality of electricity service, on both a short-term and long-term basis."
System Efficiency	ƒ Restrictions are placed on the system during peak load conditions so that certain feeders cannot be taken out of service. This constrains Toronto Hydro's ability to implement new customer connections and hinders its ability to plan and execute other capital maintenance work in a timely and efficient manner.

Customer Service Requests

In the last five years, the City of Toronto has experienced robust growth in building developments. City of Toronto data shows that between 2008 and 2012, 1,645 development projects comprised of 148,200 residential units and almost 4.25M m^2 of non-residential Gross Floor Area (GFA) were submitted to the city's Planning Division for review and approval (Table 5). Of the proposed developments, 41% of all residential units and 39% of the non-residential GFA are located in the downtown and central waterfront areas of the City of Toronto, putting significant strain on Toronto Hydro's system.

TABLE 4: PROPOSED DEVELOPMENTS IN THE CITY OF TORONTO (2008 - 2012)

Developments generally move through three stages: submitted (not approved), approved (no permits issued) and permits issued. Of all proposed developments submitted from 2008 to 2012, 47% do not yet have permits issued. Projects without permits represent 79% of all residential units and 60% of all non-residential GFA proposed. The average time that a development takes to reach completion is 4.3 years; therefore, Toronto Hydro expects a large number of the aforementioned developments to be completed between 2015 and 2019. This Load Demand program is required to ensure proper loading on the electrical infrastructure within the system can be maintained during the 2015-2019 period and shortly beyond. The number of proposed projects that are awaiting approval and permits is a clear indication that the City of Toronto will continue to experience construction and development activity going forward, necessitating that Toronto Hydro increase capacity to be able to manage the growth.

(i) Customer Service Requests: Downtown Area

Figure 5 below shows a map of the Entertainment District in the downtown core of the City of Toronto, with the location of Windsor TS and Copeland TS highlighted. Over the last three to four years, many vacant lots have been developed as condominiums. As shown on the map, of the 44 developments listed, 18 are under construction while 21 development projects are proposed or approved. These developments will add significant load onto existing electrical infrastructure that has already seen an addition of 80 developments, or about 100 MVA of load, between Cecil TS and Windsor TS since 2008.

While Toronto Hydro has been able to connect each customer promptly, the development has put a strain on the feeders and station buses from Windsor TS. Some of the activities in the Load Demand program are designed to offload feeders and the station buses at Windsor TS to the soon to be completed Copeland TS so that Windsor TS will be able to continue servicing new customers in the local distribution area.

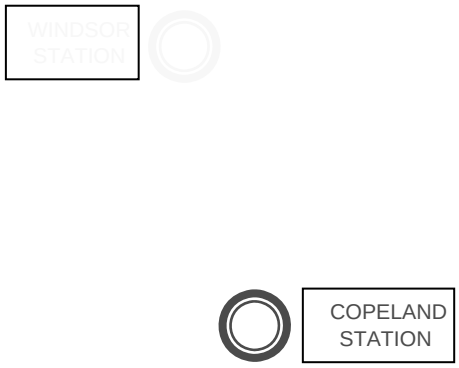

FIGURE 5: MAP OF ENTERTAINMENT DISTRICT, TORONTO (FROM BIA WEBSITE, HTTP://TORONTOED.COM/FILES/DEVELOPMENT_TRACKING_NOV2013.PDF)

As shown in Figure 3, Cecil, Terauley, Windsor and Esplanade are nearing their respective capacities and require load transfers to be able to accommodate the additional load added to the downtown core (of which the Entertainment District is a subset) in recent years. Cecil station is located just north of the area shown in Figure 5, Terauley station is located just east of the area in Figure 5 and Esplanade is located south west of the area in Figure 5.

On a more localized level, customer load growth in certain parts of the downtown core has necessitated the upgrade of secondary network infrastructure. These capacity upgrades will enable the connection of future customers, while also maintaining the reliable operation of the system during contingency events. In Figure 6 there is a comparison of loading on Vault LOC4442 between 1998 and 2012. During this 14-year period, the load grew 24%, or almost 2% annually. This load build-up is not captured in any new customer requests and is attributed to growth in load demand of existing customers over time. As a result, the system in this neighbourhood may have trouble operating under contingency events during the summer peak period. Investments are required to upgrade the equipment in this vault.

1998 Total Load on Network Location 4442: 542kVA	2012 Total Load on Network Location 4442: 714kVA

FIGURE 6: VAULT LOC 4442 (QUEEN ST W AND SOHO ST)

The load on secondary network equipment may be within operating limits during normal operation; however, during single contingency events, loads are shifted, which may result in overloading on network units. In order to prevent accelerated degradation of these assets due to overloading, certain feeders are restricted from being taken out of service. In the above example, the load connected to LOC4442 has risen above 50% loading, which means that Toronto Hydro will likely be unable to take either of the primary feeders out of service for work during peak load periods over the summer months.

(ii) Customer Service Requests: Horseshoe Area

In the Horseshoe distribution area, centers of major development have been planned by the city. As shown in Figures 7 and 8, the major areas of development are Etobicoke Centre, North York Centre, Scarborough Centre and Yonge-Eglinton Centre. 36 proposed projects are located in these four areas of development, which translates into 9% of proposed residential units and 150,000 m^2 of non-residential GFA.

FIGURE 7: MAJOR DEVELOPMENTS MAP - CITY OF TORONTO

FIGURE 8: FOUR MAJOR DEVELOPMENT CENTERS IN THE HORSESHOE

Load growth in these development centers necessitates an upgrade to the electrical infrastructure. Since 2008, Toronto Hydro has received about 60 new requests for these development centres, totalling 80 MVA of new loads added to the existing infrastructure in the area. There is a need to immediately shift load from the existing infrastructure to nearby station and feeders and upgrade existing infrastructure to the latest standards in order to accommodate the continued growth of these areas. Removing the bottlenecks caused by undersized cable on trunk sections will allow Toronto Hydro to maximize the capacity of existing feeders.

Mandated Service Obligations

Utility practices require Toronto Hydro to ensure that its assets are not overloaded (i.e. loaded above rated capacity under normal operating conditions) and that it operates a reliable system that can accommodate future development as per the Distribution System Code. If no action is taken, critical parts of Toronto Hydro's system will be at risk of being overloaded and load

shedding may be required during the summer peak period. The risk of not meeting service obligations is a relatively new risk that is attributable to the rapid influx of new dense load in the downtown core. This trend has caused bus loading to increase to rated capacity and will require offloading in the near term. Operating assets like station switchgear and distribution feeders above their rated capacity over extended periods of time under normal conditions is not an acceptable operating practice for utilities, as doing so could result in a reduction in the useful lives of existing assets, a failure of assets, and/or loss of supply to customers. As such, this program is required to maintain existing reliability and operational flexibility in areas experiencing load growth.

Reliability

The Load Demand program is also required to address the constant overloading of equipment, especially during the summer months, which can lead to the premature failure of undersized primary conductor and cable, impairing system reliability. These undersized legacy assets were installed at least 25 years ago, a period in which the standard trunk cables were smaller than today's and had a lower ampacity rating (i.e. lower current capacity).

The overloading conductors and cables cause their operating temperature to increase. An increase in operating temperate in overhead conductor can reduce the conductor's tensile strength. After a 10% loss of the rated tensile strength, significant sagging occurs, which generally triggers a necessary replacement of the conductor. For underground cables used in the 13.8 kV system (XLPE), conductors will soften as the temperature increases. The cable can deform at high operating temperatures and in areas where the insulation is under mechanical stress (bends in the route). The deformation of the cable can lead to electrical stresses and electrical failures.

The increase of load in the system has led to undersized trunk cable no longer being adequate to supply customers and to backup adjacent feeders. The failure of assets targeted by the Load Demand program could lead to outages that can last over an hour, as crews switch customers to standby supplies until the failure can be isolated and fixed. Failures that require assets to operate as standby supplies can lead to longer outage events. If feeder capacity is constrained, the number of customers able to use these feeders as a standby supply may be limited.

System Efficiency

The Load Demand program is also expected to mitigate current operational constraints that are expected to worsen during peak load periods, impacting system efficiency. In contingency scenarios (i.e. when a feeder is experiencing an interruption), the Toronto Hydro's system is designed to continue operating at or below rated capacity in order to facilitate the transfer of load from feeders under a faulted condition to adjacent feeders, allowing for the restoration of power to affected customers while repairs are conducted. When the load on a faulted feeder exceeds the available rated capacity of adjacent feeders, restoration of power to affected customers is not possible until repairs are completed.

An asset failure occurred on September 10, 2013 that led to the subsequent loss of an entire feeder supplying 4,362 customers from Richview TS. This outage required over 85 minutes of extensive systemic load shifting to restore power to 3,027 customers. 1,335 customers were left stranded without power until repairs were completed 47 minutes later, as there was no available adjacent feeder with capacity.

In addition to being a reliability concern, the operational constraints placed on the system by overloading can impede the efficient and timely execution of planned capital and maintenance work.

E5.4.4 Timing & Pacing of the Program

The timing and pacing of the Load Demand program is dictated by several system pressures and external constraints, including:

(1) the timing and pattern of ongoing and anticipated development in specific areas of the city;

(2) load and customer growth forecasts; and

(3) known road moratoriums and other external constraints on project scheduling in the 2015 to 2019 period.

The spending forecasts presented in Table 6 are based on Toronto Hydro's assessment of how best to prioritize the required load demand work within the 2015 to 2019 period given the aforementioned pressures and constraints. Deferral of this work could expose the system to operational constraints within the 2015 to 2019 period that could severely impact the reliability of

power supply for new and existing customers, and could hinder the ability of Toronto Hydro to efficiently carry-out other planned renewal work during the forecast period.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.00	0.00	0.29	2.40	1.11	11.96	13.93	14.05	15.70	19.23

Investments between 2010 and 2014 alleviated loading problems at Dufferin TS, Strachan TS and Windsor TS. To address loading concerns at Dufferin TS, load was transferred within the station to a lesser loaded bus, and some load was also transferred to Wiltshire TS. Work was completed at Strachan TS to increase the civil capacity to supply new customers, with some of this work expected to continue into 2015 as described in E5.4.7.7. Finally, work was completed at Cecil TS, located just north of the Windsor TS distribution area, in order to accommodate the increased load in the Entertainment District BIA.

Section E5.4.7 provides additional details for projects planned for execution in 2015. These projects are indicative of the type of work that will be planned and executed over the course of the 2016-2019 program. The 2015 projects are generally reflective of the urgent need to free-up capacity in dense areas where additional customer requests are anticipated. For example, a number of projects will aim to move a significant amount of load from the Entertainment District to nearby Copeland TS. These projects are planned to alleviate operational constraints on these feeders during the summer peak period in order to safely and prudently maintain operation of all equipment within rated capacity. Failure to complete these projects in a timely manner could leave Windsor TS buses at full capacity and unable to take on new area customers in the short term. Cost-inefficient projects may be required to connect future new customers in a timely manner, and these projects may result in system configurations that are not optimized for system efficiency and reliability.

The City of Toronto has introduced restrictions, related to the Pan Am Games, on Toronto Hydro that will limit the amount of work that it can complete in 2015. Accordingly, in 2015, Toronto Hydro will complete the load transfers to Copeland TS in the Windsor TS area. Work at George and Duke MS must also be completed in 2015 in order to avoid a scheduled road moratorium that will prevent work from occurring in the area for a five year period.

In 2016, Toronto Hydro plans to rebuild and expand the civil infrastructure in the Windsor TS area to service the entertainment district customer base, as outlined in Section E5.4.3.1(i). In the next year, planned capacity increases at Carlaw TS will oblige Toronto Hydro to make infrastructure upgrades between Gerrard TS and Carlaw TS. The new infrastructure will allow additional cables to be installed and the eventual replacement of the existing cables. Spending in 2018 and 2019 is dictated by the load transfers required in order to control loading at the bus level for certain stations. Each load transfer project is generated from Toronto Hydro's load forecast, which takes into account new customer requests and the timeline of their connection (details of the methodology behind the load forecast can be found in Section D2.3 of the Distribution System Plan). The required load transfers must occur in a timely manner to avoid necessary load shedding during the summer peak period.

E5.4.4.1 Ranking & Prioritization

Toronto Hydro considers several factors when prioritizing projects within the Load Demand program, including:

- Capacity to connect new customers – The primary driver for the program is the need to address areas of the system that are at capacity and that require significant investments in order to connect new customers. The lack of forecasted capacity in the short-term is what ultimately triggers projects within this program.
- Single contingency operation – Currently there are limitations placed on the system to prevent overloading during contingency operations. Projects that introduce additional capacity to allow the operators to remove these limitations will receive a higher priority.
- Reliability – For load transfer projects, sections of cable that require upgrading and that are on feeders with poor reliability or adjacent feeders will be given higher priority in order to improve future outage restoration times.

E5.4.5 Program Execution

The Load Demand program involves a number of load transfers, feeder upgrades and network unit upgrades. The program targets equipment that is overloaded under single contingency and, as a result, it is necessary to conduct most of this work outside of the summer months.

In terms of load transfer work, either new cables are required to be connected to new station feeder positions or existing feeders need to be extended to the desired area. If an existing feeder

is being extended, a feeder outage is required in order to splice together the new feeder. Certain areas may require rebuild or expansion of civil infrastructure in order to accommodate the additional electrical infrastructure.

For feeder upgrade work, new standard cable will be installed prior to de-energizing existing cable. The customers on the feeder will be transferred to standby supplies so that the feeder work can be carried out. Customers will not experience a service interruption; however, the standby supplies will operate under contingency. This work is planned to be carried out outside the summer months to avoid additional stress on existing cables at their peak load. Again, additional or rebuilt civil infrastructure may be required in order to install new cables prior to decommissioning existing cables.

Equipment upgrades require existing equipment to be de-energized prior to the larger capacity equipment being installed. Again to avoid additional strain on existing equipment, completing this work outside of the peak load time during the year would be required.

In order to address loading issues in the Horseshoe distribution area, an interim solution that Toronto Hydro plans to use involves switching load to parts of the system with excess capacity. The operating states of some existing switches will be converted from being “Normally Open” to “Normally Closed” and vice versa in order to shift load between more heavily and lighter loaded feeders. The rearrangements are done to provide alternative paths in the distribution grid to improve the reliability of supply to heavily loaded areas.

Also, in the Horseshoe distribution area, Toronto Hydro plans to construct new feeders from stations with surplus capacity to densely loaded areas; these new feeders will pickup load from existing overloaded feeders. A constraint that may be encountered during the execution of the Horseshoe distribution area load transfer projects is the need to cross major highways, rivers and railways. Toronto Hydro plans to address these issues by creating ducts under highways and railways. Special submarine ducts are being considered for paths across the rivers. Since major load transfers in the Horseshoe distribution adrea are done at 27.6 kV, large areas with primarily 4 kV distribution constraining the desired load transfer paths will be converted to 27.6kV.

Care has been taken to schedule the program’s projects so that they are completed before the next peak demand period (typically taking place in the summer months) in order to avoid rolling blackouts, which could result if multiple feeders are overloaded during such periods.

E5.4.5.1 Proposed Work Plan

The majority of work to be completed in 2015 and 2016 addresses the increased load in downtown Toronto, and specifically in the "Entertainment district". Loads will be transferred to Copeland TS in order to offload Windsor TS and the egress for Windsor TS will be expanded to accommodate the additional capacity added during the Windsor bus replacement.

In 2017, Toronto Hydro plans to upgrade the infrastructure in the Gerrard area to accommodate the replacement of the station bus at Gerrard and the additional cables required for the higher capacity bus. As for 2018 and 2019, details have yet to be confirmed, but Toronto Hydro plans on addressing the need to offload Strachan TS and Esplanade TS.

TABLE 6: 2015-2019 LONG TERM PLAN

Year	Station
2015	Windsor TS to Copeland TS
2015	Esplanade TS to Copeland TS
2015	Terauley TS to Copeland TS
2015	George and Duke Egress
2016	Windsor TS Egress
2016	Fairbank TS
2017	Gerrard/Carlaw TS Egress
2017	Main TS
2017	Manby TS
2018	Dufferin TS
2018	Strachan TS
2019	Leslie TS
2019	Esplanade TS

E5.4.5.2 Program Risks

Several issues can arise that present risks to the Load Demand program. These issues include inaccurate or unforeseen load additions or subtractions, addition of loads or redevelopment of an area with old or a lack of civil infrastructure, road moratoriums and difficulties coordinating with third party utilities.

Inaccurate and incomplete customer data could lead to potential investments made in the wrong areas. This change would require additional investments to ensure infrastructure is then built in the needed areas. The additional infrastructure would require additional planning and construction which would add additional work and costs to the connection of new customers.

In order to complete load transfers, new or existing feeders may need to travel long distances, utilizing several cable chambers and duct banks along the route. Typically this requires a rebuilding or expansion of civil infrastructure. Projects within the Load Demand program may be delayed as a result of this civil infrastructure work since it requires considerable coordination with external parties and other utilities. In addition, city imposed road moratoriums may require Toronto Hydro to create alternate plans before performing infrastructure work.

E5.4.6 Evaluation of Alternatives

Three options were evaluated during the formulation of the Load Demand Program.

E5.4.6.1 Quantification/Evaluation of Options

(i) Status Quo

Maintain the status quo would entail postponing the load transfers, feeder and network upgrades in the heavily loaded areas with projected influx of new development.

Benefits of this option are:

- Deferred capital spending to upgrade assets.

Drawbacks of this option are:

- Increased loading stress to existing electrical infrastructure in heavily loaded areas under first contingency load transfers, which can shorten the operational life time of the electrical infrastructure.
- Rolling blackouts may be required during the summer to ensure that the peak loading remains under the capacity for the system.
- Areas of heavy loading continue to experience increased loading, with the capacity to transfer loads under contingency decreasing.
- Impaired ability to expedite upgrades to relieve heavy loading effectively and efficiently.
- The addition of new high load customers in identified heavily loaded areas may exceed first contingency capacity, making system upgrades increasingly difficult and lengthy.

- The exposure risk to customers in high load areas to lengthy outages due to equipment failures or storms will be higher because contingency load transfers will not be possible due to loads exceeding capacity constraints.

Toronto Hydro does not recommend this option given the drawbacks listed.

(ii) Upgrade Stations Capacity

Under this option, Toronto Hydro would add station capacity through expansion of existing stations or construction of new stations in the heavily loaded areas with projected influx of new development.

Benefits of this option are:

- Builds more capacity into the system.

Drawbacks of this option are:

- Requires a large capital outlay spread over multiple years.
- Requires detailed studies for optimal location, environmental assessments, drawn-out construction times plus additional work for system expansion with new exigent feeders to distribute the newly created surplus around the grid.
- Could take eight to ten years to complete which will be too late based on current load growth forecast. This timeline would expose customers in existing high load growth areas to potential lengthy outages. These outages would result from equipment failures or storms because contingency load transfers would not be possible since loads would be exceeding capacity constraints.
- Does not make use of existing stranded station capacity that could be transferred.

Toronto Hydro determined that this option is not feasible given the drawbacks listed.

(iii) Upgrade Equipment & Infrastructure as per Load Demand Program

The preferred option is to upgrade equipment and infrastructure in high load and congested areas of the system and in areas of proposed high load developments with a focus on relieving overloads under first contingency basis.

Benefits of this option are:

- Provides capacity for increased loading in heavily loaded areas that are already at maximum capacity.
- Enables first contingency load transfers in areas of heavy loading that show trending of load increase, which would otherwise exceed present capacity to transfer loads under contingency.
- Provides capacity to expedite future upgrades and balance system loading.
- By providing adequate contingency load transfer capacity, the program reduces exposure risk and outage durations for customers in identified high load areas resulting from equipment failures or storms.

Drawbacks of this option are:

- Requires capital investment to upgrade existing or install new assets.
- Upgrading of assets can subject customers to the risk of prolonged outages if asset failure occurs when feeders are operated in contingency condition to facilitate construction.

The cost of ownership (COO) and program net benefit (NPV) associated with the Load Demand program is further detailed in Table 9. The cost of ownership is established for both the existing state (COO_E), based on the first year of activities in the program, as well as the new state (COO_N) proposed within this program. The COO of a state reflects the risk of asset failure including both direct and indirect costs, including the costs of customer interruptions, emergency repairs, and asset replacements associated with that design. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Load Demand produces a NPV value of $12.25M, as shown in Table 7 and Table 8.

TABLE 7: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$ 26.83
Non Asset Risk [NAR_E]	$0
Maintenance Cost [MC_E]	$0
Additional Quantifiable Benefits [AQB_E]	$0
Cost of Ownership of Existing Assets [COO_E]	$ 26.83

TABLE 8: LOAD DEMAND BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 2: Conversion to Standardized 13.8kV Feeders (N)	
Asset Risk [AR_N]	$ 2.61
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0
Additional Quantifiable Benefits [AQB_N]	$0
Cost of Ownership of New Assets (Conversion to 13.8kV) [COO_N]	$ 2.61
Option 2: Project Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\Delta COO_1 = (COO_E - COO_N)$]	$ 24.22
Program Cost [PC_1]	$ 11.96
Program Net Benefit [$NPV_1 = (\Delta COO_1 - PC_1)$]	$ 12.25

E5.4.7 2015 Project Details

Table 9 lists all projects that Toronto Hydro plans to partially or completely execute as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015.

TABLE 9: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Project Type (ICM or CIR)
E14011	E14011 Rebuild UG Trunk NT63M12 M8 Brimley - Electrical	$ 0.87 M	CIR
E14026	E14026 Rebuild UG Trunk 502M21-28 Warden - Electrical	$ 0.82 M	CIR

E5.4.7.1 E14011 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: Rebuild UG Trunk NT63M12 M8 Brimley - Electrical

Project Number: E14011

Project Year: 2015

Estimated Cost: $ 865,527

(i) Objective

The objective of this project is to upgrade existing cable to the current standard.

(ii) Scope of Work

TABLE 10: E14011 SCOPE OF WORK DETAILS

District Neighbourhood	BRIMLEY RD & STEELES AVE
Station(s)	AGINCOURT TS
Feeder(s)	63M12, 63M8

Assets (Units)	2015
1000 kcmil TRXLPE CL	3020 M
SF6 PMH 9 Switch	4
SCADAmate Switch	4

(iii) Justification & Benefits

This project will introduce additional capacity for the feeder, allowing it to accommodate more customers. As well, the feeder will be available during contingency situations to backup adjacent feeders.

E5.4.7.2 E14026 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: Rebuild UG Trunk 502M21-28 Warden -Electrical

Project Number: E14026

Project Year: 2015

Estimated Cost: $ 824,147

(i) Objective

The objective of this project is to upgrade existing cable to the current standard.

(ii) Scope of Work

TABLE 12: E14026 SCOPE OF WORK DETAILS

District Neighbourhood	WARDEN AVE & STEELES AVE
Station(s)	CAVANAGH TS

E5.4.7.3 E14442 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: Wallsend OH to UG extension Horgan Plant 47M16 SCNT47M7

Project Number: E14442

Project Year: 2015

Estimated Cost: $ 473,175

(i) Objective

The objective of this project is to transfer existing customers by extending existing feeders into the distribution area.

(ii) Scope of Work

TABLE 14: E14442 SCOPE OF WORK DETAILS

District Neighbourhood	CHEMICAL COURT & MANSE ROAD
Station(s)	SHEPPARD DS

556.5 kcmil ASC	200m

(iii) Justification & Benefits

This project will transfer load from Leaside TS to Bermondsey TS. This project will free up capacity at Leaside TS to connect new/additional customers.

E5.4.7.5 S13462 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: STATION SUPPORT FOR X13470 TO PREPARE STATION CELL

Project Number: X13462

Project Year: 2015

Estimated Cost: $ 80,798

(i) Objective

The objective of this scope is preparing the station cells at Wiltshire TS to accept new feeders that will be used in a project to transfer load from Dufferin TS and decommission a 4dkV transformer at Junction MS.

(ii) Scope of Work

TABLE 18: E14697 SCOPE OF WORK DETAILS

District Neighbourhood	DUFFERIN TS & WILTSHIRE TS
Station(s)	WILTSHIRE TS, JUNCTION MS

E5.4.7.7 X12638 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: Pirandello St Rail Crossing Tunnel

Project Number: X12638

Project Year: 2015

Estimated Cost: $ 981,120

(i) Objective

Construct a new tunnel rail crossing beneath the CN tracks to connect existing civil infrastructure for the west egress at Strachan TS to the existing civil infrastructure at East Liberty St and Pirandello St.

(ii) Scope of Work

TABLE 22: E14697 SCOPE OF WORK DETAILS

District Neighbourhood	LIBERTY VILLAGE
Station(s)	STRACHAN TS
Feeder(s)	N/A

TABLE 23: E14697 ASSETS REPLACED

Assets (Units)	2015
6x4 Duct Bank (m)	200

(iii) Justification & Benefits

The current east egress at Strachan TS leads directly into the south rail crossing along Strachan Ave. This tunnel crossing is extremely deep and the chambers which access the tunnel are old and represent a potential safety risk. In addition, several ducts within the rail crossing have collapsed making cable removal impossible. Under contingency, if the cable could not be removed and new cable cannot be installed there is the risk of an extended outage.

This project entails building a new rail crossing point that would allow for the relocation of all feeders from the unsafe tunnel crossing so that it can be abandoned and/or rebuilt.

E5.4.7.8 X13470 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: LOAD TRANSFER A256DN FROM A5-6DN TO A5-6W

Project Number: X13470

Project Year: 2015

Estimated Cost: $ 577,129

(i) Objective

The objective of this project is to transfer A256DN from A5-6DN bus at Dufferin TS to A5-6W bus at Wiltshire TS in order to reduce load on A5-6DN and maintain loading within firm capacity.

(ii) Scope of Work

TABLE 24: X13470 SCOPE OF WORK DETAILS

District Neighbourhood	DUFFERIN ST & DAVENPORT ST
Station(s)	DUFFERIN TS & WILTSHIRE TS
Feeder(s)	A256DN, A291W

TABLE 25: X13470 ASSETS REPLACED

Assets (Units)	2015
500 KCMIL TRXLPE CABLE	550 M

(iii) Justification & Benefits

Based on 2013 load forecast, loading on A5-6DN will continue to exceed firm capacity in the years to come. This project is necessary in order to contain loading and provide capacity for conversion of 4kV Dupont feeders.

E5.4.7.9 X14683 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: LOAD TRANSFER A273DN, A310DN from DUFFERIN to WILTSHIRE

Project Number: X14683

Project Year: 2015

Estimated Cost: $ 647,804

(i) Objective

The objective of this project is to transfer A273DN and A310DN from A7-8DN bus at Dufferin TS to A5-6W bus at Wiltshire TS in order to reduce load on A7-8DN and maintain loading within firm capacity.

(ii) Scope of Work

TABLE 26: X13470 SCOPE OF WORK DETAILS

District Neighbourhood	WILTSHIRE AVE & DUPONT AVE
Station(s)	DUFFERIN TS & WILTSHIRE TS
Feeder(s)	A273DN, A310DN

Table 27: X13470 Assets Replaced	Assets (Units)	2015
500 KCMIL TRXLPE CABLE		650 M

(iii) Justification & Benefits

Based on 2013 load forecast, loading on A7-8DN will continue to increase and eventually exceed the firm capacity in 2015-2016. This project is necessary in order to contain loading and provide capacity for conversion of 4kV Dupont feeders.

E5.4.7.10 X14697 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: LOC4673 TTC switch replacement w/ Network

Project Number: X14697

Project Year: 2015

Estimated Cost: $ 682,084

(i) Objective

Install new network equipment in LOC 4673 and tie to LOC4691 to relieve capacity constraints in area.

(ii) Scope of Work

TABLE 28: E14697 SCOPE OF WORK DETAILS

District Neighbourhood	RUNNYMEDE-BLOOR & BLOOR-WEST
Station(s)	DUFFERIN TS
Feeder(s)	A33DN, A36DN

TABLE 29: FIGURE 29: E14697 ASSETS REPLACED

Assets (Units)	2015
1000kVA Network Units	2

(iii) Justification & Benefits

During the summer switching restrictions list creation, LOC 4691 was identified as a highly loaded 2-unit vault. Both feeders feeding that vault, A33DN and A36DN, could not be switched out over during the summer period (with a 24 degree restriction) as it would result in an overload of a network unit. LOC 4673, was identified just north of the existing vault as a TTC-style vault that could be converted to a network configuration and be tied to LOC 4691. This would alleviate the overload under contingency issue, allow for summer switching, and provide higher reliability to the existing customer fed via LOC 4673.

E5.4.7.11 X15158 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: Load Transfer A8-9E bus to A6-7E bus Elec Carlaw TS

Project Number: X15158

Project Year: 2015

Estimated Cost: $ 417,732

(i) Objective

The objective of this project is to transfer 3MVA of load from A8-9E bus to A6-7E bus to prevent bus overloading at Carlaw TS A8-9E and to accommodate future load growth. According to the latest load forecast from Capacity Planning, A8-9E bus from Carlaw TS is forecast to reach 100% capacity in the near future.

(ii) Scope of Work

TABLE 30: X15158 SCOPE OF WORK DETAILS

District Neighbourhood	GREENWOOD-CARLAW AVE
Station(s)	CARLAW TS
Feeder(s)	A64E, A31E, A77E, A33E, A78E, A12E, A11E

TABLE 31: X15158 ASSETS REPLACED

Assets (Units)	2015

(iii) Justification & Benefits

This project aims to transfer load from one station bus to another at Carlaw TS.

E5.4.7.12 X15308 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: LOAD TRANSFER ESPLANADE TS TO COPELAND TS

Project Number: X15308

Project Year: 2015

Estimated Cost: $ 2,266,374

(i) Objective

The objective of this project is to transfer five feeders of load from Esplanade TS (A1-2X) to Copeland TS (A3-4CL) bus to accommodate future load growth. According to the latest load forecast from Capacity Planning, A1-2X bus from Esplanade TS is forecast to reach 100% capacity in the near future.

(ii) Scope of Work

TABLE 32: X15308 SCOPE OF WORK DETAILS

District Neighbourhood	YONGE ST & FRONT ST
Station(s)	ESPLANADE TS, COPELAND DS
Feeder(s)	A30X, A31X, A32X, A40X and A41X

(iii) Justification & Benefits

This project aims to transfer load from one station bus to another at Copeland TS. The bus that will be freed up at Esplanade TS will supply new customer loads coming online in the Queens Quay area.

E5.4.7.13 X15320 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: CHARLES FEEDER UPGRADES A52CS, A54CS

Project Number: X15320

Project Year: 2015

Estimated Cost: $ 1,349,649

(i) Objective

The objective of this project is to upgrade and rebuild the civil route for A52CS and A54CS to ensure that the chambers are safe and large enough and have sufficient duct space to accommodate the feeder upgrades.

(ii) Scope of Work

TABLE 34: X15320 SCOPE OF WORK DETAILS

District Neighbourhood	SHERBOURNE & BLOOR STE

(iii) Justification & Benefits

This project allows Toronto Hydro to replace undersized cable.

E5.4.7.14 X15323 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: LOAD TRANSFER TERAULEY TS TO COPELAND TS

Project Number: X15323

Project Year: 2015

Estimated Cost: $ 890,117

(i) Objective

The objective of this project is to transfer 4 feeders from Terauley TS to Copeland TS to accommodate future load growth. According to the latest load forecast from Capacity Planning, Terauley TS is forecast to reach 100% capacity in the near future.

(ii) Scope of Work

TABLE 36: X15323 SCOPE OF WORK DETAILS

District Neighbourhood	BREMNER BLVD & YORK ST
Station(s)	TERAULEY TS, COPELAND DS

TABLE 37: X15320 ASSETS REPLACED

Assets (Units)	2015
500 KCMIL TRXLPE CABLE	500 M

(iii) Justification & Benefits

This project aims to transfer load from one station bus to another at Copeland TS. This load transfer aims to free up capacity at Terauley TS, this gives planners and operators flexibility to connect new customers to Terauley TS and operate the system with less restrictions.

E5.4.7.15 X15436 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: GEORGE AND DUKE CIVIL EGRESS PHASE 1

Project Number: X15436

Project Year: 2015

Estimated Cost: $ 1,255,794

(i) Objective

The objective of this project is to construct new civil infrastructure to improve present and future feeder egress at George and Duke TS.

(ii) Scope of Work

TABLE 38: X15436 SCOPE OF WORK DETAILS

District Neighbourhood	ADELAIDE STE & JARVIS ST
Station(s)	GEORGE AND DUKE TS

Assets (Units)	2015
500 KCMIL TRXLPE CABLE	2,000M
Cable chambers	3
3x5 Duct bank	250M
6x4 Duct bank	50 M

(iii) Justificat ion & Benefits

The new egress would allow for new cable chambers to be constructed for improved and proper cable pulling and racking, ability to install new cable for George and Duke feeders, upgrade and remove old clay tile ducts.

E5.4.7.16 X15583 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: B2DF LOAD TRANSFER

Project Number: X15383

Project Year: 2015

Estimated Cost: $ 56,665

(i) Objective

The objective of this project is to transfer load from B2DF to B11T to accommodate future load growth. A total of 1125kVA will be transferred from B2DF to B11T.

(ii) Scope of Work

TABLE 40: X15583 SCOPE OF WORK DETAILS

District Neighbourhood	MANNING AVE & QUEEN ST W
Station(s)	DAFOE MS & STRACHAN MS
Feeder(s)	B2DF, B11T

TABLE 41: X15583 ASSETS REPLACED

Assets (Units)	2015
Manually Operated Load Interrupting Switch	2 Units

(iii) Justification & Benefits

Current loading on Dafoe MS is projected to exceed firm capacity during the summer peak. This project is necessary in order to contain loading and provide capacity for the addition of new customers in the King West neighbourhood.

E5.4.7.17 X16009 Project Description

Investment Category: System Access

Program: Load Demand

Project Title: LOAD TRANSFER 2 FROM WINDSOR TS TO COPELAND TS

Project Number: X16009

Project Year: 2015

Estimated Cost: $ 402,740

(i) Objective

The objective of this project is to transfer load from Windsor TS to Copeland TS to prevent buses at Windsor TS from overloading.

(ii) Scope of Work

TABLE 42: X15583 SCOPE OF WORK DETAILS

District Neighbourhood	SPADINA AVE & WELLINGTON ST W
Station(s)	WINDSOR TS, COPELAND DS
Feeder(s)	A46WR, A47WR, A19WR, A21WR, A73WR, A79WR

TABLE 43: X15583 ASSETS REPLACED

Assets (Units)	2015
500 KCMIL TRXLPE CABLE	1000 M

(iii) Justification & Benefits

This project aims to transfer load from one station bus to another at Copeland TS. This will help free up capacity at Windsor TS to accommodate the upgrade of A5-6WR bus which will ultimately increase the capacity available at Windsor TS.

E5.5 Generation Protection, Monitoring and Control

DG INSTALLATION AT GROCERY STORE

E5.5.1 Summary

Program Description

The Generation Protection, Monitoring and Control (GPMC) program is required so that Toronto Hydro can continue to fulfill its obligations to connect the growing number of DG projects to the distribution system. This program captures the majority of Toronto Hydro's forecasted "renewable enabling improvements" (as defined in section 3.3.2 of the Distribution System Code (DSC)) for the 2015-2019 forecast period.

DG connections are expected to more than triple in total capacity by 2019, reaching over 625 MW. To (1) alleviate existing connection capacity constraints that currently prevent the expansion of DG in a number of areas and (2) provide Toronto Hydro system controllers with necessary capabilities to monitor and control DG connections, the utility plans to make the following investments over the 2015-2019 period:

(1) install advanced protection systems at three stations with short-circuit capacity constraints;

(2) install a bus-tie reactor at Richview TS to alleviate short-circuit capacity constraints; and

(3) install required monitoring and control systems at all DG facilities.

The anticipated benefits of the GPMC program are as follows:

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Advanced protection systems, upgrades, and monitoring and control will enable the connection of additional DG – including renewable energy generation (REG) – to Toronto Hydro's distribution system.
Reliability	ƒ Advanced protection systems and monitoring and control provide greater reliability for new and existing customers by ensuring that the operation of the distribution system is within allowable limits.
Safety	ƒ Monitoring and control systems help Toronto Hydro avoid backfeed situations by automatically issuing an electronic trip/shutdown command to isolate DG. A backfeed situation can energize a circuit after the utility source has ceased to energize the circuit. This could potentially go undetected by field crews working on the circuit.
Efficiency	ƒ Monitoring and control will provide power system controllers with situational awareness into the operating conditions of all DG connected to the distribution system at the station/bus/feeder when required for planned or emergency load transfers.
Public Policy Responsiveness	ƒ This program aligns to public policy objectives with respect to green energy and the green economy by enabling additional REG connections during the 2015-2019 period and by providing system planning engineers with a level of precision in DG capacity monitoring that is expected to facilitate the maximization of REG and DG penetration at any given time.
Environment	ƒ The program will help realize environmental benefits from connecting renewable DG sources to the grid.

Program Drivers

The GPMC program is driven by OEB guidelines to provide DG access to the distribution system. Forecasted growth in DG connections during the five-year planning horizon stems from the public policy objectives established in the GEGEA regarding the expansion of REG capacity in Ontario.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Mandated Service Obligations	ƒ The DSC obligates Toronto Hydro to make all reasonable efforts to connect a generation facility in a timely manner. ƒ Capacity to connect DG is currently limited, with certain areas of the system currently unable to facilitate any additional DG in 2015 and beyond. ƒ Investments are required to overcome short-circuit capacity constraints and to facilitate integration of DG into the distribution grid with bi-directional flow capability. ƒ Without these investments, Toronto Hydro may not be able to respond to public policy objectives with respect to the expansion of renewable energy generation sources in the province of Ontario.
Secondary Drivers	Reasoning

Drivers	
Safety	ƒ Ensure safe connection and operation of DG. ƒ Provide power system controllers tools to remotely disconnect DG as part of the Work Protection Code procedures to safeguard linepersons from unexpected start-up of generator, preventing backfeed into the local distribution grid area while field crews are present.
Reliability	ƒ Prevent backfeed situations from causing voltage fluctuations and equipment failures. ƒ Monitoring to ensure bi-directional flows are within distribution system design parameters including thermal and short circuit capability. ƒ Provide power system controllers real-time customer generation data to determine load flow and switching procedures during planned and unplanned work. ƒ Integrate real-time customer generation data into distribution planning and generation planning work including the determination of generation to load ratios required to correlate and assess the depth of penetration and system impact.

Preferred Alternative

The GPMC program analyzed and evaluated the following options

(1) Major Asset Upgrades, Monitoring and Control (MAUMC)

(2) Generation Protection, Monitoring and Control (GPMC)

Option II is the preferred option as it is the most cost-effective and timely option for facilitating the continued integration of DG connected to the Toronto Hydro distribution system.

Timing and Pacing

The timing and pacing of the GPMC program is driven by customer requests to connect DG to the distribution system. Toronto Hydro plans to install monitoring and control equipment for existing DG sites between 2015 and 2016, while the remainder will be installed in 2017.

TABLE C: HISTORICAL AND FORECAST SPENDING

/C

E5.5.2 Program Description

The Green Energy and Green Economy Act, 2009 [2] encourages new generation sources, including solar photovoltaic (PV), biogas and wind power generation to connect to the distribution system as distributed generation (DG). DG allows for the generation of electricity from many small decentralized sources located in close proximity to the distribution loads that they serve. This type of generation requires bidirectional flow of electricity. The load and generation levels at the customer point of connection are dynamic and may increase or decrease depending on site conditions. For example, during light load periods, the power from local generation is exported to the distribution grid; during peak load periods, the customer site imports power from the distribution grid. This method of generation contrasts with the traditional approach where large, often distant, generating stations are linked by transmission systems to local distribution systems to supply local loads unidirectionally.

Since the passage of the GEGEA in 2009, Toronto Hydro has made over 890 DG connections with 114 MW of capacity. Figure 1 shows the current distribution of DG connections within Toronto Hydro's distribution system.

FIGURE 1: TORONTO HYDRO DG CONNECTIONS (AS OF MAY 31ST, 2014)

[2] S.O. 2009, C.12. ["GEGEA"]

The GPMC program is required so that Toronto Hydro can continue to fulfill its obligations to connect the growing number of DG projects to the distribution system. This program captures the majority of Toronto Hydro's forecasted "renewable enabling improvements" (as defined in section 3.3.2 of the Distribution System Code (DSC)) and any other necessary DG connection enabling improvements for the 2015-2019 forecast period.

As of June 2014, Toronto Hydro has responded to over 3,000 inquiries from customers and developers through the Feed-in-Tariff Program (FIT) pre-assessments. A wide range of proponents have submitted project applications, including many schools, housing, large grocery stores and department stores. Toronto Hydro's present rate of inquiry for individual FIT customers is estimated at 7.5 MW per month for 50 inquiries. Schools have received over 300 pending offers to connect renewable generation from the Ontario Power Authority (OPA) with over 40 MW of capacity. DG connections are expected to more than triple in total capacity by 2019, reaching over 625 MW. This represents an additional 450 MW over the five year planning period on top of the 114 MW of existing DG and 62 MW of DG planned for connection by the end of 2014.

Toronto Hydro's DG connection forecast is based on historical DG connections from 2009 onwards. It takes into account the historical connection trends with respect to various DG programs, and uses a linear approximation to forecast the anticipated amount of connections and total generation from 2015 through 2019. Please refer to Table 1 and Figure 2 for a year-by-year breakdown of the DG connection forecast.

TABLE 1: BREAKDOWN OF DG CONNECTION FORECAST (BY MW) PER PROGRAM TYPE (2015-2019)

Program	Existing (Includes 2014 Planned)	2015	2016	2017	2018	2019	Total (MW)
FIT 1.0 - 2.0	53.9	31.2	0.0	0.0	0.0	0.0	85.0
FIT 3.0 - 7.0	0.0	10.7	23.9	25.8	27.7	29.7	117.8
Combined Heat and Power (CHP)	59.6	35.5	28.2	27.3	24.0	104.0	278.6
Other DG	62.7	32.9	18.0	8.0	15.0	8.0	144.6
Total	176.2	110.3	70.1	61.1	66.7	141.7	626.0

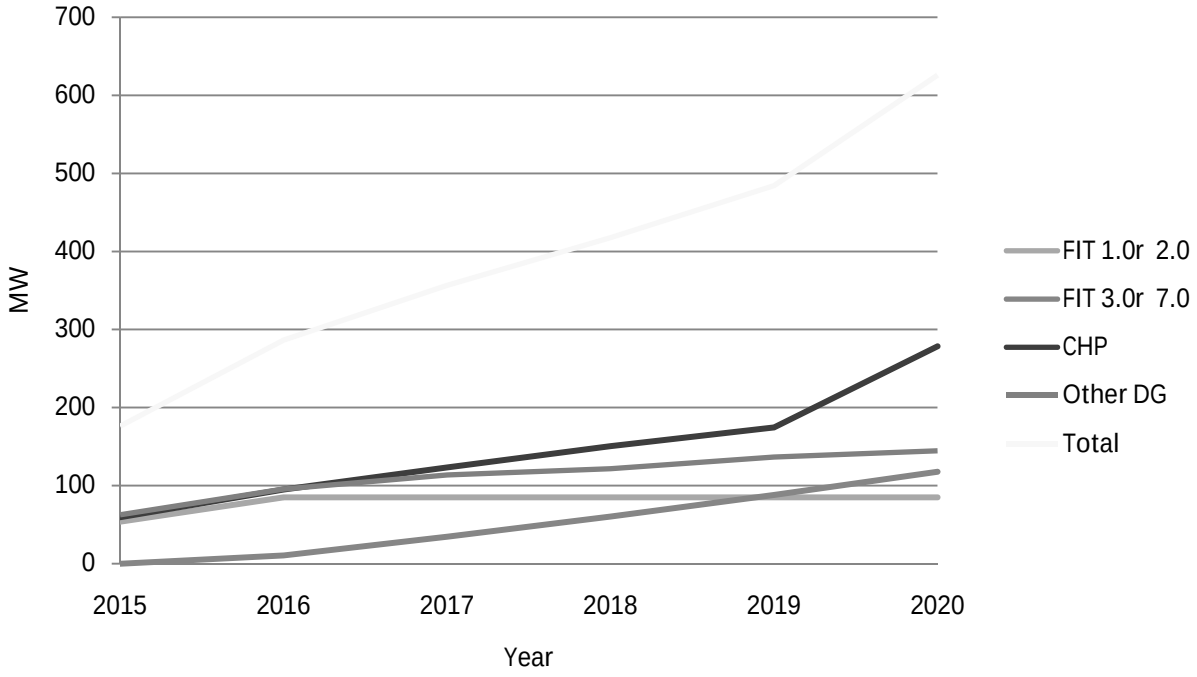

FIGURE 2: GRAPH OF DG CONNECTION FORECAST PER PROGRAM TYPE (2015-2019)

The following protection, monitoring and control equipment is required to facilitate the increasing volume of DG in the Toronto Hydro distribution system:

- advanced protection systems,
- bus-tie reactors installed on the station bus, and
- monitoring and control systems.

Sections E5.5.2.1 to E5.5.2.3 provide detailed information regarding work to be carried out as part of the program. Toronto Hydro forecasts that the selected activities and methods of enabling DG facilities described in detail below will cost an estimated $18.69 million during the 2015 to 2019 period. /C

E5.5.2.1 Advanced Protection Systems

Some of Toronto Hydro's existing and proposed generation customers operate DG projects that connect to the distribution system with an inverter-type interface. These interfaces, which are commonly found on PV generation facilities, can potentially increase short-circuit levels on the

distribution system. Short circuits on power systems require that protection devices such as feeder breakers operate to interrupt current in the order of thousands of amps. Short circuits involve high levels of energy which typically last up to 160 milliseconds. In this transient period, the interaction of DG sources with the grid is quite complex and it is crucial that the various interconnected sources decouple (i.e. disconnect) from the grid within the timeframe of the system designed ratings. If system design fault levels are exceeded, failures and safety hazards can occur. The resulting failures could expose Toronto Hydro equipment to prolonged outages and costly restoration work. A discussion of these safety hazards and the importance of mitigating these risks is provided in Section 5.6.3.1.

In situations where short circuit capacity limitations exist, Toronto Hydro prohibits the connection of DG customers to ensure that unsafe conditions, such as equipment failures, do not arise and to maintain continuity of service to customers. Leslie TS, Wiltshire TS and Basin TS at this time have short circuit constraints on several station buses. To cost-effectively enable the connection of DG at these locations in a timely manner, a high-speed advanced protection scheme must be implemented on buses with short circuit constraints that currently prevent inverter based connections. This technology leverages fibre optic technology with the fast operating time of inverter based devices. Installing this protection system will enable generation customers to connect to the grid where they presently cannot and is expected to mitigate the risks to the distribution system caused by an increasing number of connections.

The advanced protection system uses a high speed communication network with the associated protective equipment to enable the isolation of the generator from the distribution system before the main circuit breakers operate. As a result, the distribution system and customer high voltage equipment is less likely to be damaged during a fault. Inverters inherently have a fast isolation time for inverter gating and are integrated with the communication grid for coordinated isolation (example provide below). Figure 3 below provides an overview of the advanced protection and monitoring scheme. With such a system, the short circuit duration is decreased significantly due to the speed of the electronics as compared to the operating time of mechanical devices.

FIGURE 3: ADVANCED PROTECTION AND MONITORING SCHEME

The microprocessor-based feeder relay protection at the station breakers uses a protocol compliant with National Institute of Standards and Technology (NIST) and Electric Power Research Institute (EPRI) endorsement. The network with self-healing provides a normal and redundant path to feeder customers. All inverter-based generators will cease power production well before the station breaker begins to open, thereby mitigating the short circuit impact. This solution allows the distribution system to operate as designed and well within station-available short circuit capacity limits.

For instance, during a cable fault on the distribution feeder, the transmission supply and all DG sources will feed into the fault. The utility feeder protection will detect the over-current condition and send an open command to the main breaker and simultaneously to all DG sources. The inverter-based DG sources will receive the open command and cease energy production in a short period of time, estimated at 15 milliseconds. The main breaker will open sometime later (in the order of 120 milliseconds). As a result, the DG in-feed will cease much faster than the breaker mechanism, which avoids adverse affects on distribution equipment.

Industry experience indicates that microprocessor-based protection and control devices have a lifecycle of 15-20 years. These devices operate maintenance free for this period of time. Good utility practice requires replacement of this equipment at the end of its lifecycle. Fibre optic cable typically lasts for 25 years, and is also maintenance free unless the cable is cut. In this scenario the entire fibre strand would need to be replaced. Table 2 below outlines the total units of equipment to be installed as part of this portion of the Generation Planning, Monitoring and Control program.

TABLE 2: ADVANCED PROTECTION SYSTEM ASSETS TO BE INSTALLED

Assets (Units)	2015	2016	2017	2018	2019	Total (Units)
Protection and Control Devices(by feeder)	8	7	7	6	3	31
Fibre Optic Interface cable (km)	10	10	10	10	10	50

E5.5.2.2 Bus-Tie Reactor

Richview TS at this time has a short circuit constraint on several feeders. A bus-tie reactor scheme has been proposed to address this limitation.

To facilitate DG connections, bus-tie reactors are installed on the bus to mitigate high fault current levels. Bus-tie reactors lower the short circuit current on the station bus and distribution system by inserting impedance at the bus-tie point. This limits the fault contribution of the two transformer windings in a typical Dual Element Spot Network (DESN) type station arrangement. A reactor of 0.5 ohms could allow up to an additional 15 MW of DG capacity. This method of fault mitigation has been successfully applied by PowerStream and Hydro One Networks Inc. (HONI).

To facilitate Toronto Hydro DG customer connections, exploratory meetings are underway with HONI to install such bus-tie systems. Toronto Hydro plans to work with HONI to install a bus-tie reactor at Richview TS on the BY bus to eliminate the existing fault current constraint. This constraint is generated from the high fault levels at the station due to the low impedance transformers in-service. At present, all proposed connections on the Richview BY bus and any future DG applicants cannot proceed with connection due to the existing constraint. The bus-tie reactor solution will provide relief for this constraint and enable the connection of DG to the system.

A bus-tie reactor has a useful life of 30 years, and requires maintenance every five years. Table 3 below outlines the total units of equipment to be installed as part of this portion of the Generation Planning, Monitoring and Control program.

TABLE 3: BUS TIE REACTOR ASSETS TO BE INSTALLED

Assets (Units)	2015	2016	2017	2018	2019	Total (Units)
Bus Tie Reactor (per station)	0	1	0	0	0	1

E5.5.2.3 Monitoring and Control Systems

Due to the volumes of forecasted DG connections from 2015 through to 2019, Toronto Hydro requires real-time monitoring and control via utility communication networks and the supervisory control and data acquisition (SCADA) system in order to ensure distribution system safety and the adequate management of bi-directional distribution grid flows from DG connections. Real-time monitoring and control is required for existing and future DG sites, 50 kW and above. Toronto Hydro is mandated to connect DG sites to the distribution system, as per Section 6.2.4 of the DSC. With monitoring and control, Toronto Hydro expects to be able to connect the forecasted amount of DG sites to the distribution system while meeting the mandated requirements of the DSC.

Monitoring and control provides situational awareness into the operating conditions of all DG connected to the distribution system, which will give Toronto Hydro the ability to collect data for planning purposes to connect additional DG sites to the distribution system. This will have additional long-term value with respect to planning for future DG connections. Currently, system planning engineers assess the potential to connect a DG site to the distribution system based on estimated thermal loading values. This approach assumes that a DG site will continuously generate 100% of its rated capacity. This inherently limits the number of DG sites that can be connected to the system, because the estimated value assumes that the thermal loading of the DG site is greater than it likely is at any given time. Monitoring and control will provide actual performance data from in-service connections for thermal loading values, which will give Toronto Hydro a more precise view of existing conditions, which in turn will help enable the connection additional DG sites to the distribution system.

Monitoring and control also enables greater real-time visibility into the operating conditions of DG sites located in Toronto Hydro's service territory. Power system controllers need to know the aggregate generation connected to the system during planned or emergency load transfers. A

power system controller must account for all DG during a load transfer, because the increase in generation connected to the alternate feeder may exceed its short circuit capacity. The ability to remotely and automatically disconnect all DG sites on a feeder during planned or emergency load transfers is expected to simplify these operations as it would allow power system controllers to focus on restoration of customers, rather than each individual DG site connected to a feeder.

Toronto Hydro's requirement for monitoring and control is modeled after requirements developed by the Independent Electricity System Operator (IESO). The IESO has developed DG monitoring and control guidelines with a focus on visibility, dispatch and forecasting capabilities for DG sites over 5 MW. At present, the aggregate installed capacity of DG on Toronto Hydro's distribution system is over 110 MW. Because of the volume and capacity of DG sites in Toronto Hydro's service territory, monitoring and control is required to connect additional DG projects and for grid management. This approach to implement monitoring and control is also consistent with the requirements of other LDCs, including PowerStream and Horizon Utilities.

Toronto Hydro's current monitoring and control process allows for the connection of DG sites through a Toronto Hydro communication interface as shown in Figure 4 below. Figures 5 to 7 show customer installations which adhere to the standards developed by Toronto Hydro.

FIGURE 4: MONITORING AND CONTROL INTERFACE TO TORONTO HYDRO SCADA SYSTEM

FIGURE 5: COMMUNICATION GATEWAY INSTALLED AT CUSTOMER DG SITE

FIGURE 6: TORONTO HYDRO COMMUNICATION STANDARD FOR DG CONNECTIONS

FIGURE 7: TORONTO HYDRO COMMUNICATION ANTENNA SETUP AT A CUSTOMER DG SITE

Monitoring and control equipment has a useful life of 15 years and requires maintenance every four years for battery replacement. Table 4 below outlines the total units of equipment to be installed as part of this portion of the Generation Planning, Monitoring and Control program.

TABLE 4: MONITORING AND CONTROL SYSTEM ASSETS TO BE INSTALLED

Assets (Units)	2015	2016	2017	2018	2019	Total (Units)
Monitoring and Control Equipment (per generator)	280	195	201	140	152	968

The GPMC program is instrumental in enabling DG connections within Toronto Hydro's distribution system. This program is fundamentally customer-driven, as the proposed work will allow Toronto Hydro to connect additional customer DG projects to the distribution system, now and in the future.

The planned investments are also critical renewable enabling improvements that Toronto Hydro must carry-out in order to safely and reliably facilitate the continuing proliferation of REG facilities across the City of Toronto. By addressing short-circuit limitations on the system and installing needed monitoring and control capabilities, Toronto Hydro plans to continue to deliver an efficient and timely DG connections program that is responsive to the Ontario Government's public policy goals during the 2015-2019 period and beyond.

Reliability is also expected to be positively affected by the addition of monitoring and control, since these systems give Toronto Hydro visibility into active power generation and system load flows. At this time, the amount of DG penetration has surpassed the one-third level on nineteen feeders; this level of penetration presents the risk of islanding, described further in section 5.5.3.1. Furthermore, a rising number of Toronto Hydro circuits have DG penetration levels in the 25% to 30% range. Toronto Hydro must gain active monitoring and control of DG sites prior to penetration levels growing further.

Power restoration during emergency situations will require DG monitoring and control in addition to the current SCADA telemetry of system/feeder load. For system planning engineers, monitoring and control data provides the means for improving system reliability going forward. Toronto Hydro expects that stations and distribution feeder planning will be increasingly impacted by the depth of DG penetration, and will need to consider DG performance data in order to forecast station load growth as well as new customer connection assessments (for both load and generation proponents).

Figures 8 and 9 demonstrate typical DG installations taking place on the Toronto Hydro distribution system, as enabled by investments in this program.

FIGURE 8: RESIDENTIAL DG INSTALLATION

FIGURE 9: DG INSTALLATION AT A GROCERY STORE

Table 5 provides an overview of the anticipated benefits associated with the GPMC program.

TABLE 5: PROGRAM BENEFITS

Customer Value	ƒ Advanced protection systems, upgrades, and monitoring and control will enable the connection of additional DG to Toronto Hydro's distribution system.
Reliability	ƒ Advanced protection systems and monitoring and control provide greater reliability for new and existing customers by ensuring that the operation of the distribution system is within allowable limits.
Safety	ƒ Monitoring and control systems help Toronto Hydro avoid backfeed situations by automatically issuing an electronic trip/shutdown command to isolate DG. Backfeed results in energizing a circuit after the utility source ceases to energize the circuit.
Efficiency	ƒ Monitoring and control will provide power system controllers with situational awareness into the operating conditions of all DG connected to the distribution system at the station/bus/feeder when required for planned or emergency load transfers.
Public Policy Responsiveness	ƒ This program aligns to public policy objectives with respect to green energy and the green economy by enabling additional REG connections during the 2015-2019 period and by providing system planning engineers with a level of precision in DG capacity monitoring that will facilitate the maximization of REG and DG penetration at any given time.
Environment	ƒ The program will help realize environmental benefits from connecting renewable DG sources to the grid.

E5.5.3 Why the Program is Needed

The GPMC program is required to provide system access to the existing and forecasted levels of DG in Toronto Hydro's distribution system. At the present time, the ability to connect new DG is limited by constraints within the Toronto Hydro system. As DG connection requests increase, Toronto Hydro will face several issues that could inhibit the ability to connect the forecasted DG projects. As per Section 6.2.4 of the DSC, Toronto Hydro is mandated to connect DG to the distribution system:

> "Subject to all applicable laws, a distributor shall make all reasonable efforts in accordance with the provisions of section 6.2 to promptly connect to its distribution system a generation facility which is the subject of an application for connection."

E5.5.3.1 Program Drivers

Toronto Hydro anticipates that the GPMC program will provide additional DG access to the distribution system in accordance with OEB guidelines, DSC requirements, and the legal framework and policies established in the GEGEA. Table 6 presents the trigger and secondary drivers for the program.

TABLE 6: GENERATION PROTECTION, MONITORING AND CONTROL PROGRAM DRIVERS

Trigger Driver	Reasoning
Mandated Service Obligations	ƒ The DSC obligates Toronto Hydro to make all reasonable efforts to connect a generation facility in a timely manner. ƒ Capacity to connect DG is currently limited, with certain areas of the system currently unable to facilitate any additional DG in 2015 and beyond. ƒ Investments are required to overcome short-circuit capacity constraints and to facilitate integration of DG into the distribution grid with bi-directional flow capability. ƒ Without these investments, Toronto Hydro may not be able to respond to public policy objectives with respect to the expansion of renewable energy generation sources in the province of Ontario.
Secondary Drivers	**Reasoning**
Safety	ƒ Ensure safe connection and operation of DG. ƒ Provide power system controllers tools to remotely disconnect DG as part of the Work Protection Code procedures to safeguard linepersons from unexpected start-up of generator, preventing backfeed into the local distribution grid area while field crews are present.
Reliability	ƒ Prevent backfeed situations from causing voltage fluctuations and equipment failures. ƒ Maintain and enhance system reliability by providing monitoring and control. ƒ Monitoring to ensure bi-directional flows are within distribution system design parameters including thermal and short circuit capability. ƒ Provide power system controllers real-time customer generation data to determine load flow and switching procedures during planned and unplanned work. ƒ Integrate real-time customer generation data into distribution planning and generation planning work including the determination of generation to load ratios required to correlate and assess the depth of penetration and system impact.

Toronto Hydro has a dedicated generation planning group that supports connecting DG to the distribution system, which is consistent with the DSC and direction from HONI and the OPA.

Toronto Hydro has identified a number of constraints within its system that have an impact on DG connections and on interconnection-related decisions. The issues that limit Toronto Hydro's ability to connect DG include short-circuit capacity, risk of islanding, thermal limits and the lack of ability to transfer loads between feeders during planned work and emergency situations. Asset failure can occur when distribution equipment exceeds system short circuit levels, equipment thermal ratings and nominal voltage ratings. Asset failures due to distribution system stresses from DG sources can cause transformer equipment failure, surge arrester failure, nuisance outages from sympathetic tripping and other similar effects. Introducing increased levels of bi-directional flows from DG will require protection, monitoring and control to prevent such occurrences during normal operation, planned work and emergency situations.

Short Circuit Capacity Limitations

In situations where short circuit capacity limitations exist, Toronto Hydro prohibits the connection of DG customers to ensure that unsafe conditions do not arise and to maintain continuity of service to customers.

Short-circuit capacity constraints can be both transmission based and distribution based. Transmission based constraints involve the power equipment used for the bulk transfer of electrical energy from large generating plants to transformer stations in an LDC territory. (The transmission system within the City of Toronto operates at 115 kV or 230 kV.) Distribution based constraints involve limitations in the equipment used to distribute electricity to many customers. The distribution system in the City of Toronto operates at a nominal voltage of 27.6 kV or less.) The GPMC program addresses distribution based constraints.

Transmission-Based Constraints

HONI is implementing its own program to relieve transmission based short-circuit capacity constraints encountered by the proliferation of DG. These transmission-based short-circuit constraints currently pose a DG connection challenge to a significant portion of Toronto. Upgrades are underway to alleviate these capacity issues by the end of 2014.

In HONI's 2011 and 2012 transmission revenue requirement filing, transmission constraints at both Manby and Leaside Transformer Stations (TS) were identified,[3] each of which has limited

[3] EB-2010-0002, Application and Evidence (May 19, 2010), at Exhibit A, Tab 11, Schedule 4.

Toronto Hydro's ability to approve requests for DG interconnection. HONI's identified system constraints include the following:

- short circuit capacity constraints per Transmission System Code (TSC) limits;
- thermal capacity on station transformers that limits reverse power flow;
- minimum bus load requirements to limit reverse power flow; and,
- short circuit capacity constraints due to transmission breaker capacity.

The short-circuit capacity and reverse power flow constraints are necessary to ensure the proper operation of both the transmission and distribution systems. These constraints reflect the technical limits of transformer stations and the equipment therein, such as circuit breakers and transformers. Figure 10 illustrates the extent of short-circuit capacity constraints prior to the execution of HONI's planned investments.

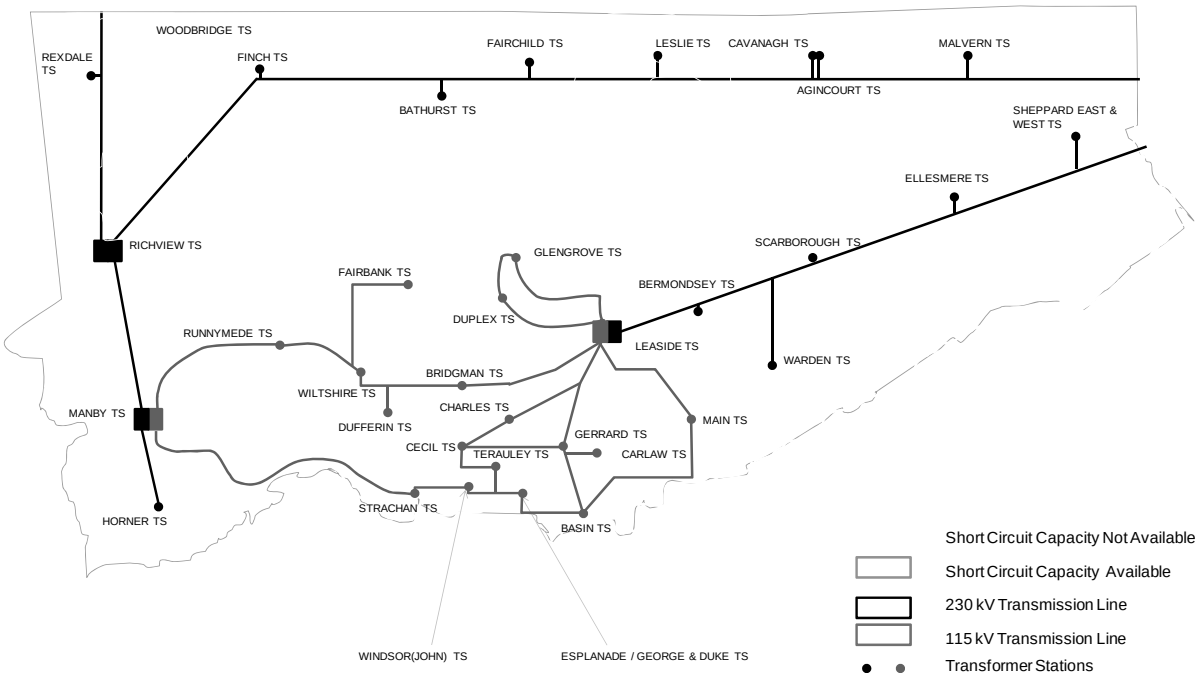

FIGURE 10: SHORT CIRCUIT CONSTRAINTS – PRE-HONI LEASIDE/MANBY/HEARN UPGRADES

Planned HONI upgrades on the downtown Toronto 115 kV transmission system should resolve Leaside TS issues by the end of 2014. Completion of this project along with upgrades to the

Scarborough East 230 kV transmission system should address most of Toronto Hydro's current short circuit and thermal capacity issues. When this work is completed, Toronto Hydro anticipates that it will remove the upper layer of DG connection constraints as imposed by the transmission system.

Distribution Based Constraints

In addition to the transmission based constraints being addressed by HONI, Toronto Hydro must address distribution based short-circuit capacity constraints in specific locations throughout the system. Figure 11 shows areas within Toronto which are presently constrained due to short circuit limits at individual stations. These stations are supplied by HONI transformers and directly connect to Toronto Hydro feeders. The distribution based constraints will remain even after HONI has addressed the transmission constraints at the 230 kV and 115 kV level.

FIGURE 11: DISTRIBUTION SYSTEM SHORT CIRCUIT CAPACITY CONSTRAINTS MAP

The advanced protection system and bus-tie reactor investments proposed within this program will address these short circuit capacity limits, and help ensure that Toronto Hydro has the capacity to connect DG customers.

Downstream distribution system enhancements are necessary to realize the benefits of significant transmission system investments and upgrades presently in the final stages. The transmitter, HONI, has undertaken to replace equipment that alleviates capacity constraints on the transmission system. An additional effort is required by the distributor Toronto Hydro to alleviate capacity constraints on the distribution system.

Anti-Islanding Condition for Distributed Generators

Islanding occurs when a DG source continues to power a portion of the grid even after the main utility supply source has disconnected or is no longer available. This situation must be avoided, as it can interfere with grid protection systems and may potentially be dangerous to Toronto Hydro crews.

The connection of photovoltaic solar inverters and other DG sources must be accomplished in a manner that ensures that unintentional islanding of DG sources cannot take place. Toronto Hydro plans to deploy real-time monitoring and control investments proposed within this program at every DG site to provide the needed ability to address anti-islanding concerns.

One of the anti-islanding measures in the IEEE 1547 Standard for Interconnecting Distributed Resources (DR) with Electric Power Systems, section 4.4.1, requires that "DR aggregate capacity is less than one-third of the minimum load of the Local Electric Power System (EPS)." Some other utilities such as HONI have adopted the one-third rule to ensure unintentional islanding does not occur. With the proliferation of DG in Toronto in recent years, several feeder circuits have already surpassed the generation to minimum load ratio of one-third. A total of nineteen distribution feeders have ratios ranging from 0.34 to 2.86 (refer to Table 7 below). These feeders currently present an increased risk to the distribution system of unintentional islanding conditions.

TABLE 7: FEEDERS WITH GENERATION TO LOAD RATIO GREATER THAN ONE-THIRD

Feeder Name	TS Station Name	TS Bus	TOTAL DG Connected & In Progress (MW)	Minimum Feeder Load (MW)	Generation to Minimum Load Ratio

35-M8	Fairbank	Z	1.32	3.86	0.34
35-M7	Fairbank	Y	1.35	3.98	0.34

DG penetration is growing rapidly, as an additional ten feeders are approaching the one-third limit (as shown in Table 8). These numbers do include the forecasted 626 MW of additional DG capacity anticipated by the year 2019. This four-fold increase in DG penetration will further exacerbate the existing islanding risks. This will adversely affect Toronto Hydro's ability to safely and reliably connect additional DG to the distribution system and could ultimately lead to an increase in declined applications for connections if not addressed by proactive investments into control and monitoring capabilities.

TABLE 8: FEEDERS WITH GENERATION TO LOAD RATIO APPROACHING THE ONE-THIRD REQUIREMENT

Feeder Name	TS Station Name	TS Bus	TOTAL DG Connected & In Progress (MW)	Minimum Feeder Load (MW)	Generation to Minimum Load Ratio

System Thermal Limits and Load Transfer Capability

Protection, monitoring and control upgrades also provide the ability to connect additional DG by ensuring system thermal thresholds are satisfied. Exceeding system thermal limits sacrifices the life of distribution equipment and can cause immediate equipment failure.

For large generation or aggregated generation connections, an important operating condition is the limit of a feeder's continuous load thermal ratings. Feeder planning and operation considers the system impact when the generator is up and running as well as when the units go off-line. These thermal levels come into play with such factors as the variability of various generation sources, system load growth and the occurrence of contingencies. The ability to provide monitoring and control allows Toronto Hydro to monitor and mitigate the thermal levels issue.

Toronto Hydro's existing SCADA system has been configured to allow for the basic monitoring and control of DG sites in Toronto Hydro's distribution system. However, the current backend system was not intended to accommodate the volume of existing and forecasted DG sites. Without system upgrades, Toronto Hydro could lack the necessary situational awareness to safely and efficiently manage DG across the system. To avoid this situation, it is vital to enable the remote monitoring and control of DG sites.

In Toronto Hydro's experience, load displaced by DG has been increasing over the past five years and, as previously discussed, is forecasted to continue increasing at a relative rapid pace. In order to stay abreast of this increase, the GPMC program will provide Toronto Hydro's power system controllers with real-time information concerning DG status and output. Toronto Hydro power system controllers are on duty 24/7 to monitor the distribution system and take immediate corrective actions when emergencies occur. Specifically, they need to have both real-time information on the status and output of DG sites as well as the load connected to any specific distribution feeder.

In case of a distribution system emergency, such as an interruption, occurring on a feeder that has multiple DG sites connected to it, power system controllers need to know the extent of the affected load in order to safely direct the load restoration to the affected customers. Currently, if an emergency occurs on a feeder, power system controllers rely on the feeder loading information provided by the SCADA system to determine the restoration procedure and feeder configuration. With the proliferation of DG, it will likely be necessary to shut down, or transfer, the DG for safety or technical reasons. In addition to the system loads, power system controllers will need to take the aggregate DG capacity into considered in the decision making process for assessing options to restore the interrupted load through other available feeders.

By way of an example, prior to an outage, the net feeder load on a given feeder was 5 MW because the aggregate connected DG was serving 5 MW of the total customer load of 10 MW. The standby feeder requirement for restoring the load in case of an interruption would therefore be 5 MW, as this represents the net load. Following an outage, however, the generation disconnected for a period of time, causing the net load to surge up to 10 MW; the load then settled back down as the generator sources began to reconnect. Identifying spare feeder capacity and restoring a net load of 5 MW can be more readily achieved as compared to the gross load value of 10 MW. The range of power flows will need to be clearly understood and visible to power system controllers to provide the necessary feedback on the state of the system.

The hurdles and pressures that Toronto Hydro faces for integrating DG system wide can be effectively mitigated through monitoring and control. Monitoring and control can alleviate the risks associated with DG for the public and Toronto Hydro field personnel. The Electrical Safety Authority (ESA) Bulletin DSB-07/11, dated August 17th, 2011, outlines a real-world situation where an inverter failed to disconnect and started to back feed into the local distribution system.

> "The Ontario Electrical Safety Code (OESC) rule 84-008 requires a distributed generation system to automatically disconnect electric power production sources when there is a loss of power from the supply authority. In the case of this near miss incident, the solar inverter's "anti-islanding" feature failed to fully disconnect the energy produced from the PV system."

This situation poses a serious potential safety risk to the public, Toronto Hydro workers, and the system in general. If the anti-islanding feature of a DG were to fail, as it did in this situation, the DG would backfeed into the local distribution system, which could potentially pose a safety risk to the public and Toronto Hydro field personnel. Active monitoring and control systems help Toronto

Hydro avoid this situation by automatically issuing an electronic trip/shutdown command when the feeder breaker is opened.

Toronto Hydro takes its responsibility to minimize the level of risk associated with work very seriously. Field personnel wear Personal Protective Equipment (PPE), such as safety gloves, glasses, and boots, but these items represent the last stage of worker protection. In addition to physical disconnection, remote tripping is an additional level of protection for Toronto Hydro field personnel. Automated and remote tripping will add an additional level of protection making it safer to perform work by eliminating the hazard. Refer to Figure 12 outlining the effectiveness of work barriers.

FIGURE 12: EFFECTIVENESS OF WORK BARRIERS

Power system controllers will have the status and state of all DG, either reporting in to the control room or forecasted, and use this information to help the decision making process during planned work and emergency situations.

The real-time monitoring and control investments proposed within this program will be deployed at every DG site to address system thermal limits and load transfer capabilities.

Table 9 provides a summary of the proposed GMPC program and the respective issues addressed. Toronto Hydro anticipates that successful implementation of the GPMC program, in

addition to the successful completion of HONI capacity upgrade investments, will allow for system-wide capacity availability for DG connection, as depicted in Figure 13 below.

TABLE 9: SUMMARY OF GPMC PROGRAM ISSUES ADDRESSED

Technology	Issue(s) Addressed	Result	Location(s)
Advanced Protection System	x Short Circuit Capacity x Anti-Islanding Condition for Distributed Generators x System Thermal Limits and Load Transfer Capability	› Ability to connect inverter based DG within constrained area	x Leslie TS x Basin TS x Wiltshire TS
Bus Tie Reactor	x Short Circuit Capacity	› Ability to connect DG within constrained area	x Richview TS
Monitoring & Control System	x Anti-Islanding Condition for Distributed Generators x System Thermal Limits and Load Transfer Capability	› Ability to connect additional DG in the distribution system	x Distribution system-wide

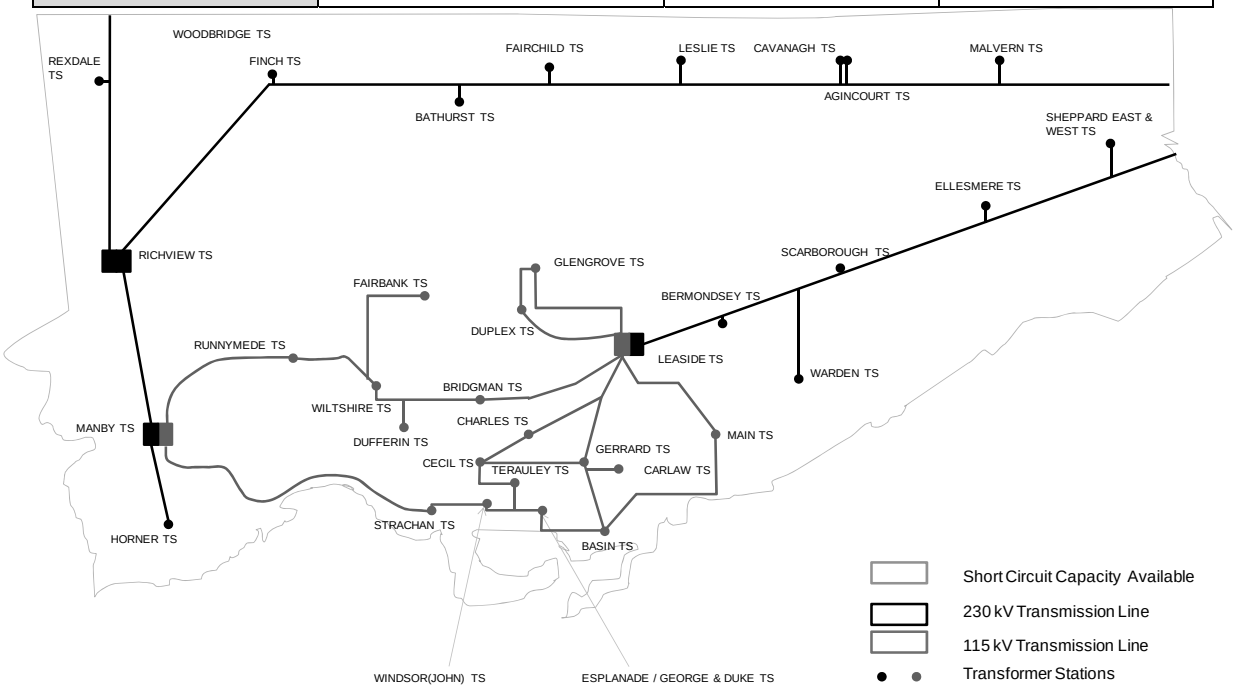

FIGURE 13: DISTRIBUTION SYSTEM AVAILABLE CAPACITY MAP FOR AFTER GPMC PROGRAM

E5.5.4 Timing & Pacing of the Program

The GPMC program is projected to cost $18.69 million over the 2015 to 2019 period. In order to prevent the rejection of DG connections, the installation of advanced protection systems, a bus-tie reactor at Richview TS, and monitoring and control equipment will commence in 2015. As it stands today, Toronto Hydro would not be able to connect customers at Basin TS, Leslie TS, Wiltshire TS, and Richview TS without the advanced protection systems and the bus-tie reactor. In addition, the absence of monitoring and control for DG sites will prevent Toronto Hydro from having real-time situational awareness of the operating conditions of DG sites in the distribution system. This information is vital in ensuring that the forecasted DG connections do not approach or exceed the minimum load, capacity limit, or short circuit constraint. If any portion of the program is delayed or denied, Toronto Hydro's ability to connect customer DG projects could be constrained, which could ultimately lead to an increase in the rejection of DG connections. /C

Toronto Hydro plans to install monitoring and control equipment for existing DG sites from 2015 to 2016 at a rate of 75 units per year. Toronto Hydro plans to install the remaining 73 units in 2017. In parallel, monitoring and control equipment for the new DG sites are planned for installation at a rate of 205,120,128,140 and 152 units per year until 2019 (based on the DG Connections Forecast from Section E5.5.1). Finally, work required for the backend infrastructure necessary to accommodate the remote management of DG sites is planned to be initiated in 2015 and conclude in 2016. Vendor support and maintenance for the backend system is planned to begin in 2016 through to 2019. A yearly breakdown of these costs is provided in Table 10 below. /C

TABLE 10: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**

E5.5.4.1 Ranking & Prioritization

In 2015, Toronto Hydro plans to initiate work involving advance protection systems at Leslie, Basin and Wiltshire TS and a bus tie reactor at Richview TS. These locations have been identified as priorities due to their limited short circuit capacity. Without completing this work, Toronto Hydro will not be able to connect DG sites to these stations. These projects address the immediate need for capacity and short circuit relief to enable the connection of DG sites.

Between 2015 and 2017, Toronto Hydro plans to retrofit 223 existing DG sites that presently do not have monitoring and control. These DG sites have already been commissioned and are active on the distribution system, which allows for immediate scheduling into the work program. As these sites are already operational, it is imperative to have the monitoring and control equipment installed as Toronto Hydro does not have any situational awareness into the operating conditions of these DG sites. The recent proliferation of DG and the rising penetration levels and continues to exacerbate the present situation. The proposed work is planned to be completed at a pace of 75 units per year and will begin with the DG sites that have the largest nameplate value. This is due in part to labour resource availability and the connection of new DG sites. As mentioned in Section E5.5.5.3, Toronto Hydro is dependent on the DG project/site owner to co-ordinate resources for the installation and commissioning of monitoring and control equipment, which complicates work program scheduling. Due to the dependency on DG project/site owners, Toronto Hydro plans to complete the work on an ad-hoc basis. Toronto Hydro expects to connect approximately 745 new DG projects per year from 2015 through 2019 according to the DG connection forecast from Section E5.4.1. /C

E5.5.5 Program Execution

Projects are listed in Section E5.5.8 and outline the work required in order to install advanced protection systems at Leslie, Basin and Wiltshire TS and install the bus-tie reactors at Richview TS. Projects will be created for the installation and commissioning of monitoring and control equipment at DG sites, once the customer/site owner has informed Toronto Hydro that the project is ready for commissioning. Due to the unique nature of each project, the timelines to complete work will vary from site-to-site. This would not apply for sites that require retrofitting for monitoring and control, as they have already been commissioned. Finally, work related to the backend infrastructure necessary to accommodate the remote management of DG sites is planned to occur in parallel with the field work mentioned above.

E5.5.5.1 Proposed Work Plan

Table 11 outlines the entire proposed work plan from 2015 through to 2019.

TABLE 11: 2015-2019 LONG TERM PLAN

Year	Project	Station
2015	Advance Protection System – Basin TS	Basin TS
2015	Advance Protection System – Leslie TS	Leslie TS
2015	Advance Protection System – Wiltshire TS	Wiltshire TS
2015	Bus Tie Reactor - Richview TS	Richview TS

Year	Project	Station
2016 – 18	Advance Protection System – Basin TS	Basin TS
2016 – 17	Advance Protection System – Leslie TS	Leslie TS
2016 - 19	Advance Protection System – Wiltshire TS	Wiltshire TS
2016 - 17	Bus Tie Reactor - Richview TS	Richview TS
2015	Monitoring &Control Retrofit DG Sites – Phase 1	Entire distribution system
2015	Monitoring &Control New DG Sites – Phase 1	Entire distribution system
2016	Monitoring &Control Retrofit DG Sites – Phase 2	Entire distribution system
2016	Monitoring &Control New DG Sites DG – Phase 2	Entire distribution system
2017	Monitoring &Control Retrofit DG Sites – Phase 3	Entire distribution system
2017	Monitoring &Control New DG Sites – Phase 3	Entire distribution system
2018	Monitoring &Control New DG Sites – Phase 4	Entire distribution system
2019	Monitoring &Control New DG Sites – Phase 5	Entire distribution system

E5.5.5.2 Program Risks

The risks associated with the installation and commissioning of bus tie reactors and upgrades to TS protection systems include:

- Limited technical labour resources to install both systems,
- Conflicting timing and inability to coordinate with other capital projects and planned maintenance work of station assets, and
- Transferring existing customer loads to standby feeders.

Advance planning between relevant Toronto Hydro departments will help address issues and constraints related to labour availability and general capacity. Planning this work during off-peak periods will mitigate potential impacts to standby feeders.

E5.5.5.3 External Constraints

Toronto Hydro station upgrades focus on areas with short circuit constrained stations and buses. Resolving the issues will depend on the co-ordination between HONI and Toronto Hydro, to ensure any planned work will not interfere with current or planned capital work initiated by each party. Toronto Hydro must also rely on the DG project/site owner to co-ordinate resources for installation and commissioning activities. Due to the unique nature of every project, the timelines to complete work will vary from site-to-site. To address this variability Toronto Hydro plans to

inform project/site owners, at the beginning of each project, and to provide notice of any work related to commissioning.

E5.5.5.4 Standard & Regulation Adherence

The proposed program will incorporate Toronto Hydro Conditions of Service, Distributed Generation Requirements, and Distribution System Planning Guidelines. These requirements adhere to industry standards such as IEEE 1547 Standard for Interconnecting Distributed Resources with Electric Power Systems, CSA C22.3 No. 9 Interconnection of distributed resources and electricity supply systems and CSA C22.2 No. 257 Interconnecting inverter-based micro-distributed resources to distribution systems.

Integrating customer owned DG in accordance with Toronto Hydro requirements should ensure that system needs are satisfied including protection criteria as well as monitoring and control standards as posted on Toronto Hydro website. The interconnecting DG sources must adhere to Toronto Hydro's standards and regulations to ensure integrity of the distribution grid.

E5.5.5.5 Renewable Energy Generation

As of June 2014, Toronto Hydro's customers have enquired about connecting over 600 MW of inverter-based PV systems and synchronous generation through pre-assessments. As a result of current restrictions, however, applicants may not be approaching Toronto Hydro in areas where project developers know that system constraints preclude connections. Toronto Hydro therefore anticipates that future applications may increase markedly once existing constraints have been addressed and lifted. As such, Toronto Hydro anticipates over 626 MW of distributed generation interconnections on the distribution system.

E5.5.6 Evaluation of Alternatives

E5.5.6.1 Quantification/Evaluation of Options

As mentioned earlier, Toronto Hydro is mandated by Section 6.2.4 of the DSC to connect DG to the distribution system. In order to comply with section 6.2.4, Toronto Hydro evaluated two alternatives for addressing the system constraints that currently limit the utility's ability to connect the growing amount of DG on the system and safely and reliably manage DG connected to the distribution system. These options are explained in detail below.

(i) Major Asset Upgrades, Monitoring and Control (MAUMC)

Rather than execute the GPMC program as described throughout this program narrative, Toronto Hydro could choose to perform major asset upgrades at Leslie, Wiltshire, and Basin TS. Assets to be upgraded include power transformers and switchgear. Monitoring and control equipment would also be installed as part of this option. The work associated with this option would allow for the continued integration, expanded visibility, and automated monitoring and control of DG connected to the Toronto Hydro distribution system beginning in 2017 through 2019 and beyond. The major assets associated with this program have 1-2 year material lead-times, on top of the 1 year required for installation. The entire process may take up to five years. Since Toronto Hydro does not own any of the major assets, it would have to request that HONI perform the upgrades. Because these upgrades would be outside of HONI's planning cycle, Toronto Hydro would have to pay for the upgrades instead of letting HONI replace the assets when required at no cost. This option would help alleviate the issues related to connecting DG to the distribution system, as mentioned in Section E5.5.2; however Toronto Hydro estimates the total cost for this option would be approximately $54.09 million to ratepayers over the 2015 to 2019 period, compared to an estimated $18.69 million for the option outlined in this program narrative. The estimated net present value (NPV_1) of this option is -$47.08 million. /C /C

(ii) Generation Protection, Monitoring and Control (GPMC)

The planned GPMC program would allow for the continued integration, expanded visibility, and monitoring and control of DG connected to the Toronto Hydro distribution system beginning in 2015 through 2019 and beyond. In addition to enabling the integration of DG sites and providing expanded visibility, Toronto Hydro expects that it would have the ability to predict the amount of generation produced by DG connected to the distribution system. This program would help alleviate the issues related to connecting DG to the distribution system, mentioned in Section E5.5.2. The overall cost of this option is $18.69 million over the 2015 to 2019 period.

The cost of ownership of each option is established for both the existing state (COO_E) and the proposed new state (COO_{N2}) based on the planned activities within this program, as shown in Tables 12 to 14. The cost of ownership (COO_{N2}) of a state reflects the risk of asset failure including both direct and indirect costs. These costs include customer interruptions, emergency repairs, and asset replacements associated with a given design. All of these factors combine to form the COO_{N2} for each option. For further details on the COO_{N2} approach, please refer to Section D3.3. The options considered are modeled over a 5-year period due to the fact that both

upgrading the power transformer in option 1 and the installation of bus-tie reactors as part of the proposed program in option 2 will require multiple years for implementation. In addition, the benefits of these options can only be realized once the total work has been completed. As such, the evaluation of the benefits must also be carried over the five year period as opposed to the first year of execution as in the traditional methodology explained in Section D3. When the difference in cost of ownership (ûCOO$_2$) is compared to the associated program costs (PC$_2$), the preferred GPMC program produces an NPV$_2$ of -$18.11 million.

Options (i) and (ii) are the only feasible options for Toronto Hydro to continue accommodating additional DG connections during the 2015-2019 period. When comparing the NPV's of each option, both account for the installation of new assets in order to mitigate the risk of not being able to connect DG customers to our system. Toronto Hydro's inability to connect new DG would violate the DSC's specifications that the utility make a reasonable effort to connect all DG customers and would result in a lack of responsiveness to public policy regarding the expansion of distributed generation in Ontario. Neither of these risks could be translated into a quantifiable metric within this business case exercise, and therefore both options have negative net benefits. In this instance, Toronto Hydro plans to proceed with the least negative option, which is also the most cost-efficient option and the option that will deliver the most value to customers in Toronto and province-wide.

E5.5.7 2015 Projects

Table 15 lists all projects that Toronto Hydro Plans to partially or completely execute as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015.

TABLE 15: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Start Date	
E31556	Basin TS A7A8 Bus	$159,457	2015	/C
E31558	Leslie BY Bus	$212,609	2015	/C
E31559	Wiltshire A3A4 Bus	$382,696	2015	/C
E31560	Richview BY Bus	$31,891	2015	/C
E31561	M&C DG Retrofit – Phase 1	$1,071,548	2015	/C

E5.5.7.1 E31556 Project Description

Investment Category: System Access

Program: Generation Protection, Monitoring & Control

Project Title: Basin TS A7A8 Bus

Project Number: E31556

Project Year: 2015

Estimated Cost: $159,457 /C

(i) Objective

To enable inverter based renewable energy connections to connect onto the distribution grid.

(ii) Project of Work

The scope of work involves the interfacing and commissioning of gateway devices to microprocessor-based feeder protection relays for all station breakers on the Basin TS A7A8 bus. The protection relays will be interconnected through a gateway network system that will interface with the customer DG system. It will serve the purpose of providing transfer trip protection as well as monitoring and control functionality.

TABLE 16: E12345 PROJECT OF WORK DETAILS

District Neighbourhood	CENTRAL & DOWNTOWN TORONTO

TABLE 17: E12345 ASSETS REPLACED

Assets (Units)	2015
Fibre Optic cable	4 km
Gateway Interface	5 units

(iii) Justification & Benefits

With the presently proposed DG connections there will be no further capacity available to connect renewable energy generation. The anticipated benefits include integration of a proposed 10MW biogas plant as well as future opportunities of solar PV connections.

E5.5.7.2 E31558 Project Description

Investment Category: System Access

Program: Generation Protection, Monitoring & Control

Project Title: Leslie BY Bus

Project Number: E31558

Project Year: 2015

Estimated Cost: $212,609 /C

(i) Objective

To enable inverter based renewable energy connections to connect onto the distribution grid.

(ii) Project of Work

The scope of work involves the installation and commissioning of microprocessor-based feeder protection relays at all station breakers on the Leslie TS BY bus. The protection relays will be interconnected through gateway network system that will interface with customer DG systems. It will serve the purpose of providing transfer trip protection as well as monitoring and control functionality.

Feeder Protection Relays	2 units
Fibre Optic cable	5 km
Gateway Interface	2 units

(iii) Justification & Benefits

With future DG connections there will be no further capacity available to connect renewable energy generation. The benefits include integration of solar PV connections.

E5.5.7.3 E31559 Project Description

Investment Category: System Access

Program: Generation Protection, Monitoring & Control

Project Title: Wiltshire A3A4 Bus

Project Number: E31559

Project Year: 2015

Estimated Cost: $382,696

/C

(i) Objective

To enable inverter based renewable energy connections to connect onto the distribution grid.

(ii) Project of Work

The scope of work involves interfacing and commissioning of gateway devices to microprocessor-based feeder protection relays for all station breakers on the Wiltshire TS A3A4 bus. The protection relays will be interconnected through a gateway network system that will interface with the customer DG system. It will serve the purpose of providing transfer trip protection as well as monitoring and control functionality.

TABLE 20: E31559 PROJECT OF WORK DETAILS

District Neighbourhood	CENTRAL & DOWNTOWN TORONTO
Station(s)	WILTSHIRE TS
Feeder(s)	A25W, A26W, A27W, A36W, A37W, A38W, A39W,A42W, A43W

TABLE 21: E31559 ASSETS REPLACED

Assets (Units)	**2015**
Fibre Optic cable	6 km
Gateway Interface	9 units

(iii) Justification & Benefits

With future DG connections there will be no further capacity available to connect renewable energy generation. The benefits include interconnection protection monitoring and control of solar PV connections.

E5.5.7.4 E31560 Project Description

Investment Category: System Access

Program: Generation Protection, Monitoring & Control

Project Title: Richview BY Bus

Project Number: E31560

Project Year: 2015

Estimated Cost: $31,891

/C

(i) Objective

To enable inverter based renewable energy connections to connect onto the distribution grid.

(ii) Project of Work

The scope work involves working with HONI to design and implement and bus-tie reactor suitable to lower the bus fault levels such that DG will be enabled to connect.

TABLE 22: E31560 PROJECT OF WORK DETAILS

District Neighbourhood	UPTOWN TORONTO
Station(s)	RICHVIEW TS BY BUS
Feeder(s)	88M1, 88M3, 88M8

TABLE 23: E31560 ASSETS REPLACED

Assets (Units)	**2015**
Bus Tie Reactor Design	1 unit
Isolation switches	2 units

(iii) Justification & Benefits

With future DG connections there will be no further capacity available to connect renewable energy generation. The benefits include enabling DG interconnections. There have been projects proposed for solar PV interconnection which had to be turned down due to no available short circuit capacity.

E5.5.7.5 E31561 Project Description

Investment Category: System Access

Program: Generation Protection, Monitoring & Control

Project Title: M&C DG Retrofit – Phase 1

Project Number: E31561

Project Year: 2015

Estimated Cost: $1,071,548

/C

(i) Objective

Phase one deals with the retrofit of 75 existing DG sites with monitoring and control equipment.

(ii) Project of Work

The scope of work involves the installation and commissioning of monitoring and control equipment and existing DG sites. The DG site will interface with Toronto Hydro's Control room via a private communication network and existing Toronto Hydro SCADA system. It will serve the purpose of providing monitoring and control functionality.

TABLE 24: E31561 PROJECT OF WORK DETAILS

District Neighbourhood	THROUGHOUT TORONTO HYDRO'S SERVICE TERRITORY
Station(s)	VARIOUS
Feeder(s)	VARIOUS

TABLE 25: E31561 ASSETS REPLACED

Assets (Units)	**2015**
Monitoring and Control Equipment	75

(iii) Justification & Benefits

There are 223 existing DG sites that do not have monitoring and control capabilities. This makes it more difficult for Toronto Hydro to safely and effectively manage the DG connected to the distribution system. In addition, this can prevent Toronto Hydro from connected additional DG to the distribution system. The addition of monitoring and control equipment to existing DG sites will

enable power system controllers to have situational awareness into the operating conditions of DG in the distribution system.

This project represents the first phase deals with the completion of 50 DG sites for 2015.

The System Renewal investment programs detailed within this section serve to target and replace these worst-of-the-worst overhead, underground, secondary network and stations assets. Table 1 describes the primary drivers for capital investments in this category.

TABLE 1: TRIGGER DRIVERS FOR SYSTEM RENEWAL CATEGORY

Driver	Description
Failure Risk	ƒ There is the imminent risk of asset failure due to age or condition deterioration
Functional Obsolescence	ƒ The asset/asset installation is no longer aligned to Toronto Hydro processes and practices such that it can no longer be maintained (e.g., lack of spare parts, lack of accessibility or operational constraints) or utilized as intended in the distribution system
Failure	ƒ Failures have already taken place that Toronto Hydro must reactively respond to as part of capital investment activities.

Table 2 provides a brief description for each investment program within the System Renewal narrative along with total expenditures for each program from 2015 onwards to 2019. Individual section numbers for each investment program are also provided in this table.

TABLE 2: BRIEF DESCRIPTION OF SYSTEM ACCESS INVESTMENT PROGRAMS

Program Index and Name		Brief Description	Total (5 years)
E6.1	Underground Circuit Renewal	Replace end-of-life and obsolete underground assets with new ones on a "like-for-like" basis. The assets include switches, transformers, and cables. Replacing the assets will help improve system reliability and efficiency.	$459 M
E6.2	Paper-Insulated Lead-Covered (PILC) Piece-outs and Leakers	Program will address two issues related to underground PILC cable. PILC cables are aging and a number have developed cracks and pinholes and will either be replaced or repaired. The program will also increase cable length to address unsafe congested areas and allow the cables to be safely and properly routed.	$7 M
E6.3	Underground Legacy Infrastructure	Targets non-standardized equipment that is at or near end-of-life and poses a failure risk. Many of these assets are now obsolete and will be replaced with standardized equipment, helping to improve safety and system reliability.	$27 M

Program Index and Name		Brief Description	Total (5 years)
E6.4	Overhead Circuit Renewal	Focuses on replacing poles, switches, transformers, overhead accessories and street lighting assets that are either aged, in poor condition, or functionally obsolete on a "like-for-life" basis. Toronto Hydro expects the program to mitigate significant sources of outages that negatively impact service reliability to customers and may pose potential safety risks for employees and the general public.	$147 M
E6.5	Overhead Infrastructure Relocation	Provide a modern and efficient configuration to replace feeders that are past end-of-life and functionally obsolete from a design perspective to mitigate the number of system outages. Feeders will be relocated to eliminate difficult-to-access overhead plant, overhead egress plant and overhead plant crossing highways.	$10 M
E6.6	Rear Lot Conversion	This program replaces the existing, end-of-life rear lot distribution service configuration with an underground front lot access system to eliminate challenges in performing maintenance activities and to mitigate the increased risk of long duration outages inherent in the existing plant design. The conversion eliminates operational constraints and reduces the safety and reliability risks associated with this obsolete connection configuration.	$59. M
E6.7	Box Construction Conversion	This program transitions customers from functionally obsolete 4.16 kV box construction feeders to the current standard 13.8 kV or 27.6 kV overhead infrastructure. By eliminating box construction feeders, Toronto Hydro anticipates that the program will reduce safety concerns for crew members dealing with restricted working spaces, improve restoration times and mitigate costs related to load capacity constraint when connecting new customers in the downtown area.	$103 M
E6.8	SCADA-MATE R1 Replacement	This program replaces malfunctioning switches. Moisture has caused internal switch components to corrode. The corrosion poses significant potential safety hazards for the public and Toronto Hydro employees due to misrepresentation of the switch state, preventing core functions of the switch from being used. The new R2 design will improve remote functionality and reliability of the switch, thereby reducing prolonged outages and failure risk for customers.	$13 M

Program Index and Name		Brief Description	Total (5 years)
E6.9	Network Vault Rebuild Program	Rehabilitation of vaults that were identified to be high-risk to protect the assets that are housed within and to eliminate potential safety hazards for crews, pedestrians and emergency response crews in busy downtown areas. Rehabilitation options include decommissioning the vaults, rebuilding the vault roofs, or rebuilding the entire vault.	$45 M
E6.10	Network Unit Renewal Program	Replacement of obsolete and poor condition Network Units that are at risk of failure with new submersible Network Units. Toronto Hydro anticipates that this program is expected to increase service reliability, improve employee safety and reduce environmental concerns by mitigated oil leaks.	$34 M
E6.11	Legacy Network Equipment Replacement (ATS & RPB)	Replacement of automatic transfer switches (ATSs) and reverse power breakers (RPBs) with manual secondary switches, stand alone network protectors (SANPs), or network units. The ATSs and RPBs are no longer supported by their original manufacturer, making it difficult to comply with prudent maintenance practices and policies. These assets are also not submersible by design and are subject to a high risk of equipment failure.	$5 M
E6.12	Network Circuit Reconfiguration	Reconfiguration of the functionally obsolete network system by splitting a large secondary grid into enhanced mini grids. Increasing grid flexibility will enhance its ability to supply new classes of customers, to operate under different contingency events and decrease the necessity to drop the entire network during failure.	$9 M
E6.13	Stations Switchgear Renewal	Replacement of existing switchgears that have become functionally obsolete and that have passed the end of their useful lives. The existing non-arc resistant switchgear at municipal stations and transformer stations will be replaced with type C, arc resistant switchgear with vacuum circuit breakers.	$106 M
E6.14	Stations Power Transformer Renewal	Replacement of power transformers located at municipal stations across the city to mitigate the failure risk of prolonged outages due to assets at the end of their useful lives. This program will directly benefit customers connected to the transformers identified for replacement by reducing outage risk and increasing system reliability in their respective areas.	$12 M

Program Index and Name		Brief Description	Total (5 years)
E6.15	Stations Circuit Breaker Renewal	Replacement of obsolete oil circuit breakers, which are no longer supported by manufacturers, with stand-alone vacuum circuit breakers. Vacuum circuit breakers are cheaper to maintain and are less likely to fail catastrophically.	$9 M
E6.16	Stations Control & Monitoring	This program aims to replace aging and obsolete remote terminal units (RTUs) and install SCADA systems at substations with no SCADA capabilities. Existing RTUs and radio communications networks at Etobicoke MS and downtown Toronto TS will be replaced while modern SCADA systems at Scarborough MS will be installed.	$5 M
E6.17	Stations Ancillary Systems	Replacement of end-of-life and outdated ancillary systems (air compressors, station service power supply systems, fire alarm systems, and fire barriers) that are at risk of failure and functionally obsolete with more reliable modern technologies.	$2 M
E6.18	Stations Buildings	This program focuses primarily on the structural integrity of eleven TS and MS buildings in which electrical stations assets are housed. The program takes a proactive approach to improve existing station buildings to extend their serviceable lives. Toronto Hydro anticipates that this will help ensure uninterrupted service, protect the safety of crews and the public, and ensure the integrity of nearby customer property.	$11 M
E6.19	Stations DC Battery Replacement	Replacement of end-of-life DC batteries and chargers systems with new ones at various stations locations to mitigate battery failure risk and ensure faults are isolated to the local feeder. These batteries are used to provide the necessary power supply to operate the associated circuit breaker assets if the main power supply to the entire station is lost.	$3 M
E6.20	Reactive Capital	Accounts for unplanned, non-discretionary capital expenditures required to repair or replace assets. With proper budgeting and resource allocation, timely reactive work improves safety, reduces the backlog of assets to be maintained, avoids depriving other capital programs of planned resources and reduces strain on the distribution system.	$166 M

Program Index and Name		Brief Description	Total (5 years)
E6.21	Worst Performing Feeder	This program analyses the performance of feeders that are at risk of seven or more outages in a year and determines the root cause of the outage trend. Condition of the equipment will be assessed during feeder patrols and appropriate mitigation work will be performed to alleviate outages caused by design or environmental disturbances. The program improves the reliability of feeders, minimizes power outages for customers experiencing especially poor service, and mitigates the risk of additional asset failures.	$8 M
E6.22	Distribution System Communication Infrastructure	This program renews and improves the telecommunications system by identifying gaps in the communication service platform, updating the obsolete SONET technology and SCADA infrastructure. An updated telecommunication system reduces failure risk an provides safe, efficient and reliable supply of electricity to customers.	$16 M

The following Sections E6.1 though to E6.23 contain the details and justification for each capital investment program within the System Renewal investment category.

E6.1 Underground Circuit Renewal

INSTALLING NEW SUBMERSIBLE BUILDING VAULT SF6-INSULATED SWITCH

E6.1.1 Summary

Program Description

The Underground Circuit Renewal program replaces end-of-life and obsolete assets that contribute to the deterioration of system reliability. The program is a continuation of activities previously described in the OEB approved Underground Infrastructure segment as part of Toronto Hydro's 2012-2014 IRM/ICM rate application.

The Underground Circuit Renewal program replaces three assets types: underground switches, transformers and cables. These assets are primary components of an underground distribution system, and degrade due to age and exposure to harsh field environments. Proactive renewal is needed to ensure that reliability, safety and environmental risks are properly mitigated.

The anticipated benefits of the Underground Circuit Renewal program are as follows:

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Installing newer assets allows for reduced customer disruption in the event of an outage ƒ Improved neighborhood aesthetics depending on the age and condition of existing assets
Reliability	Proactively replacing assets with a high risk of failure is expected to: ƒ Reduce customers interruptions ƒ Mitigate safety risks to employees ƒ Minimize reactive repair costs
Safety	ƒ Minimize safety related issues due to flashovers (seen with pad-mounted and submersible switches and non-switchable submersible transformers). ƒ Minimize the risk associated with dig-ins of direct buried cables and cables in direct buried PVC ducts.
Efficiency	ƒ Improved restoration time by replacing older and unreliable assets with modern equipment capable of remote sensing and operation (i.e. switchgear). ƒ Improved isolation of transformers without affecting power supply to customers on the rest of the distribution system. ƒ Faster cable replacement of underground cables due to the concrete encased duct infrastructure.
Other	ƒ Elimination of routine CO_2 washing used to maintain air insulated pad-mounted switches.

Program Drivers

The trigger and secondary drivers for the Underground Circuit Renewal program are:

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	Various combinations of external factors, including, but not limited to, dirt, salt, dust, moisture and humidity affect: ƒ all switch types, thereby accelerating the degradation to both the enclosure and internal components of the switch which in-turn increases their failure risk as the equipment ages in the field. ƒ all transformers, leading to cumulative corrosion on the enclosure, seals and gaskets resulting in compromised enclosure and oil integrity and inevitable failure of the unit. ƒ insulation integrity of XLPE cables; resulting in failure of underground cables regardless of their method of installation (direct buried or in duct for this particular cable type).
Secondary Drivers	Reasoning

Safety	The main safety concerns with the assets in the program include: ƒ arcing and flashover due to switches and transformers (and the harm it poses to field crews and the public) ƒ dig-ins due to unprotected direct buried cable and cable in direct buried duct. ƒ environmental safety concern includes SF6 gas leakage into the atmosphere due to vintage URD switches.
Functional Obsolescence	The inherent design flaws of the various assets targeted for replacement through this program include: ƒ live-front and open louver design of air-insulated switches (pad-mounted or building vault). ƒ live-front design of non-switchable submersible transformers. ƒ poor quality assurance and manufacturing standards of earlier generations of XLPE cable.

Preferred Alternative

Toronto Hydro evaluated the following options for the assets addressed in this program:

(1) Do nothing and replace on a reactive basis only

(2) Proactively replace these aged assets with new, standard equipment

Option II is the preferred option as it will best mitigate the risks associated with failure of the current, end-of-life assets.

The replacement of underground switches, transformers and cable in the first year of the program will result in an avoided risk cost (ARC) of $102.93 million, as detailed in Table 8. This value represents the avoided cost of executing the first year of activities as scheduled as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the probability of failure of the assets and multiplying this figure by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. Further details on the ARC approach is provided in Section D3.

Timing and Pacing

Table C provides a summary of the five year historical spending in the Underground Circuit Renewal program (or its equivalent) as well as projected spending from 2015 to 2019.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	108.4	90.3	53.8	68.8	108.1	96.0	80.1	84.0	99.7	99.5

Given that a high population of assets will be approaching the end of their useful lives in 2015, Toronto Hydro expects to maintain a level of investment similar to the forecasted 2014 magnitude throughout the 2015-2019 period. Minor fluctuations in the pacing of investment over the forecast period (e.g. the drop in spending in 2016 and 2017) will likely be required to facilitate other high-priority renewal and service investments in the underground system using similar resources. The proposed rate of investment in the Underground Circuit Renewal program will allow Toronto Hydro to prudently and proactively manage the significant backlog of end-of-life and poor condition underground assets, maintaining system reliability performance while enhancing customer value with the installation of more robust and reliable underground construction.

E6.1.2 Program Description

The Underground Circuit Renewal program replaces end-of-life and obsolete assets that contribute to the deterioration of system reliability. The program is a continuation of activities previously described in the OEB approved Underground Infrastructure segment as part of Toronto Hydro's 2012-2014 ICM application[1].

The program consists of three major underground asset classes: switches, transformers and cable. Each asset class is discussed in further detail in this section. These assets are primary components of an underground distribution system, and degrade due to age and exposure to harsh field environments. Over time, equipment will reach a point where failure risk accelerates and proactive renewal is needed to ensure that reliability, safety and environmental risks are properly mitigated. Reliability and environmental risks are discussed further in section E6.1.3.1 and safety risks are discussed further in section E6.1.3.2.

The estimated total capital budget for this program is $459.2 million for the 2015-2019 forecast period.

E6.1.2.1 Replacement of Underground Switches

Figure 1 shows a breakdown of the various types of switches used in Toronto Hydro's underground distribution system.

FIGURE 1: TORONTO HYDRO'S UNDERGROUND SWITCH BREAKDOWN

The switching assets targeted for replacement in this program are:

[1] EB-2012-0064.

- pad-mounted, air-insulated switches (referred to as "pad-mounted" for the remainder of the document),
- submersible oil-insulated switches (referred to as "oil-insulated" for the remainder of the document),
- submersible[2] vintage SF_6-insulated switches used only in the underground residential distribution (URD) system in downtown Toronto (referred to as "vintage URD" for the remainder of the document), and
- building vault, mini-rupter switches (referred to as "mini-rupter" for the remainder of the document).

Pad-mounted switches are prone to premature failure due to the louvers that allow ingress of air borne moisture and contaminants inside the switch cabinet. This is similar to the degradation process that affects mini-rupter switches. Corrosion and oil leakage cause oil-insulated switches to fail, resulting in a potentially catastrophic[3] failure (discussed further E6.1.3.1). As well, vintage URD switches are dated and known to have a gas leakage problem inherent to the former design of the bolted viewing window.

Given the failure risks associated with all switch types; and functional obsolescence of submersible switch types, all switches will be replaced with the new generation of SF_6–insulated switches. The new generation of switches has a stainless steel enclosure to prevent premature rusting and degradation of the cabinet. The unit consists of welded viewing windows that mitigate SF_6 gas leakage into the environment. As well, programmable relays are used instead of fuses for downstream circuit protection. This eliminates the need for on-site switch re-fusing after a fault on the branch circuit. The units also have internal grounding provisions making grounding easier and safer for crews in comparison to the external grounding elbows on the existing switches.

[2] "Submersible switch" will be used as a general term to refer to both oil insulated and vintage URD throughout this document.

[3] The terms 'catastrophic failure', 'fail catastrophically', and related forms, are used throughout the DSP programs presented in this Application. These terms refer to a mode of failure of an electrical distribution component in which incidental damage to other equipment and/or injury to a person occur or could occur, in addition to the loss of the electrical distribution function of the component itself. Arc flashes, fires, falling debris, and structural collapse are examples of catastrophic failure. Catastrophic failure is distinguished from failure by design and simple failure modes in which a component, such as a fuse, performs according to design to interrupt the flow of electricity.

The SF_6-insulated switches replacing the existing submersible (both oil-insulated and vintage URD) and building vault switches typically use a single, top operable switch positioned just below ground level. Due to the switches' construction, the vaults can be dry or subject to flooding. Figure 2 provides an example of the new pad-mounted SF_6-insulated switch that is used in Toronto Hydro's distribution system. Figure 3 provides an example of a typical SF6-insulated switch suitable for either submersible or above ground vaults.

FIGURE 2: NEW PAD-MOUNTED SF6-INSULATED SWITCH

FIGURE 3: NEW SUBMERSIBLE AND/OR BUILDING VAULT SF6-INSULATED SWITCH

It should be noted that the SCADA capability for remote sensing offered by the new SF_6 switches offers increased system efficiency. This improves restoration time in the event of a power failure while saving the cost associated with crews physically operating the switch on site.

Another advantage of pad-mounted SF_6-insulated switches is that it has the same circuit configuration and footprint as the existing pad-mounted units, thereby avoiding additional cable and civil construction work. As well, all external components of the SF_6-insulated switch are sealed. Therefore it is a low-maintenance asset and does not require costly, routine CO_2 washing to remove accumulated contaminants on the switch components which is commonly required for the existing pad-mounted switches.

E6.1.2.2 Replacement of Underground Transformers

Three types of transformers are used in Toronto Hydro's underground distribution system: below-grade submersible, pad-mounted and building vault.

Submersible transformers are installed in underground vaults that experience degradation mainly due to internal and external factors (details of which are discussed in section E6.1.3). Pad-mounted transformers installed outdoors experience degradation primarily due to external factors (i.e., dirt, water and ice). Vault transformers are installed in an indoor environment and experience degradation caused by contaminants trapped inside the building they are housed in (i.e. dust and moisture/humidity). Given the failure risk associated with each of the existing transformers in the field, they will all be replaced with units best suited for their existing applications.

Non-switchable submersible transformers will be replaced with new switchable submersible transformers that allow for isolation of the individual transformer vault without affecting power supply to customers on the rest of the distribution loop. All related transformer ancillary equipment (i.e. elbows and terminations) will be replaced with the non-switchable, submersible transformer to ensure compliance with Toronto Hydro's current transformer installation standard.

Replacing non-switchable submersible transformers with switchable submersible transformers allows for isolation of the individual transformer without affecting power supply to customers on the rest of the distribution loop (discussed in greater detail in E6.1.3).

As well, depending on the age and condition of pad-mounted and building vault transformers, they will be replaced with new transformers of like size, except where loading necessitates a larger size transformer. Where prudent and feasible, all related ancillary (i.e., cable and terminations) and building vault switches (i.e., mini-rupters) will be replaced at the same time. Figure 4 provides an example of the new below-grade submersible, pad-mounted and build vault transformers that will be installed through this program.

FIGURE 4: NEW BELOW-GRADE SWITCHABLE SUBMERSIBLE, PAD-MOUNTED AND BUILDING VAULT TRANSFORMER

E6.1.2.3 Replacement of Underground Cables

Two main types of cables exist in Toronto Hydro's underground distribution system: cross-linked polyethylene (XLPE) and tree-retardant, cross-linked polyethylene (TR-XLPE).

Almost all remaining XLPE cable, either direct buried or in duct has reached and/or passed its useful service life. This cable type was installed in the system before 1990 and was fabricated using dated manufacturing processes (as detailed in section E6.1.3). Due to the failure risk presented by this cable type and its functional obsolescence, Toronto Hydro plans on replacing the remaining XLPE cable in the system with TR-XLPE cables in concrete-encased ducts. This is

a continuation of renewal activities previously described in the OEB approved Underground Infrastructure segment of Toronto Hydro's 2012-2014 rate filing[4].

TR-XLPE cables use improved materials and are fabricated using a triple extruded, dry cure process that reduces impurities and moisture penetration into the cable insulation. The incorporation of a Poly Vinyl Chloride (PVC) or Polyethylene (PE) jacket, metal foil barriers and other water migration controls further reduces moisture penetration into the insulation. As a result, these cables can maintain their original insulation integrity for a longer period of time, improving performance in wet underground operations. As well, new TR-XLPE cables allow for the option of "strand-blocked" conductors. This further mitigates the risk of longitudinal penetration of water along the cable.

Aged XLPE cable either direct buried or in duct will be replaced with new TR-XLPE cable in concrete encased duct. Concrete encased ducts provide physical protection for cables due to ground shifts, vehicular weight, and dig-ins. Once the civil infrastructure for a concrete encased duct bank has been installed, it can last for several decades. This has been demonstrated with the concrete encased duct banks used in downtown Toronto where many are over 60 years. Although cables inevitably age and outages may occur due to faulty equipment or natural causes, having the appropriate civil infrastructure (concrete encased ducts) in place simplifies the cable replacement job. With concrete encased ducts, the entire cable segment between two cable chambers is removed and a new cable pulled through the ducts. The latter advantage means that power may be restored more quickly to customers in case of an unplanned outage and that the cable life cycle is renewed. An example of the problems related to direct buried cables is illustrated in Figure 5. (In this particular case, the customer had to be notified in the middle of the night to move their vehicle so that the faulted cable under their driveway could be repaired and power restored.)

[4] EB-2012-0064, Tab 4, Schedule B1.

FIGURE 5: DISTURBANCE TO CUSTOMER IN THE MIDDLE OF THE NIGHT TO REPAIR CABLES AND RESTORE SERVICE

Figure 6 illustrates the new TR-XLPE cable, concrete encased duct bank and duct bank schematic used by Toronto Hydro for underground distribution purposes. Details regarding how assets were prioritized will be discussed in section E6.1.4.1.

FIGURE 6: NEW TR-XLPE CABLE USED FOR UNDERGROUND DISTRIBUTION

In addition to XLPE cables, conductors between street lighting poles are also approaching the end of their useful service life. Many of these conductors are not only aged but also direct buried and face similar degradation problems seen in direct buried XLPE cables. Since the underground

conductor running between the poles is considered to be a distribution asset, it falls under the responsibility of Toronto Hydro. As such, based on age and historical reliability, these conductors will be replaced as part of this program. The City of Toronto will fund the replacement of all unregulated street lighting poles, luminaries and conductors in the pole, up to the lamp. Therefore, replacement of street lighting poles will be coordinated with the replacement of the conductors between the poles. In doing so, all existing infrastructure is planned to be brought up to Toronto Hydro's standard and placed within concrete encased ducts.

An overview of underground assets to be replaced in 2015 is given in Figure 6. Table 1 provides a snapshot of the assets which will be replaced during the 2015 test year and the four consecutive years which follow (2016-2019). As well, a summary of the program benefits is given in Table 3.

FIGURE 7: OVERVIEW OF UNDERGROUND ASSETS TO BE REPLACED IN 2015

1 **TABLE 1: UNDERGROUND CIRCUIT RENEWAL PROGRAM ASSET REPLACEMENT UNITS**

Assets (Units)	2015	2016	2017	2018	2019	Total
Underground Switches	84	71	74	88	88	405
Underground Transformer	348	291	305	362	361	1,667
Underground Cable (circuit km)	149	125	131	155	155	715

/C

2 **TABLE 2: SUMMARY PROGRAM BENEFITS**

Customer Value	***f*** Installing newer assets allows for reduced customer disruption in the event of an outage (i.e. quicker restoration due to SCADA switches and no digging for cable replacement). *f* Improved neighborhood aesthetics depending on the age and condition of existing assets (i.e. heavily rusted transformers and switches). *f* The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $102 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.1.7).
Reliability	Proactively replacing assets with a high risk of failure will: *f* Reduce customers interruptions *f* Mitigate safety risks to employees *f* Minimize reactive repair costs
Safety	*f* Minimize safety related issues due to flashovers (seen with pad-mounted and submersible switches and non-switchable submersible transformers). *f* Minimize the risk associated with dig-ins of direct buried cables and cables in direct buried PVC ducts.
Efficiency	*f* Improved restoration time by replacing older and unreliable assets with modern equipment capable of remote sensing and operation (i.e. switch). *f* Improved isolation of transformers without affecting power supply to customers on the rest of the distribution system. *f* Faster cable replacement of underground cables due to the concrete encased duct infrastructure.
Other (flashovers, dig-ins)	***f*** Elimination of routine CO_2 washing used to maintain pad-mounted switches. *f* Complete removal of cables in duct when a feeder is abandoned rather than dead-ending the cables and leaving it in the ground where removal of direct buried cables is not economically feasible.

E6.1.3 Why the Program is Needed

Assets addressed in the Underground Circuit Renewal program are aged, in poor condition and/or have inherent design flaws. The program targets three types of assets for proactive intervention: switches, transformers and cables.

E6.1.3.1 Program Drivers

Table 3 summarizes the trigger and secondary drivers for the Underground Circuit Renewal program.

TABLE 3: UNDERGROUND CIRCUIT RENEWAL PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	Various combinations of external factors, including, but not limited to, dirt, salt, dust, moisture and humidity affect: • all switch types, thereby accelerating the degradation to both the enclosure and internal components of the switch which in-turn increases their failure risk as the equipment ages in the field. • all transformers, leading to cumulative corrosion on the enclosure, seals and gaskets resulting in compromised enclosure and oil integrity and inevitable failure of the unit. • insulation integrity of XLPE cables; resulting in failure of underground cables regardless of their method of installation (direct buried or in duct for this particular cable type).
Secondary Drivers	**Reasoning**
Safety	The main safety concerns with the assets in the program include: • arcing and flashover due to switches and transformers (and the harm it poses to field crews and the public) • dig-ins due to unprotected direct buried cable and cable in direct buried duct. • environmental safety concern includes SF6 gas leakage into the atmosphere due to vintage URD switches.
Functional Obsolescence	The inherent design flaws of the various assets targeted for replacement through this program include: • live-front and open louver design of air-insulated switches (pad-mounted or building vault). • live-front design of non-switchable submersible transformers. • poor quality assurance and manufacturing standards of earlier generations of XLPE cable.

It can be seen in Table 3 that the trigger driver for all three asset types targeted for replacement in the Underground Circuit Renewal program is Failure Risk. Among the various external and

internal elements affecting these assets, moisture is the common culprit which accelerates both the aging and degradation process. This leads to catastrophic failures (i.e., arc-flashes, internal short circuits), which are a safety risk to both Toronto Hydro field crews and the public. The reliability and safety risks associated with these assets will be discussed in greater detail in this section. Lastly, functional obsolescence of certain asset types (i.e., oil-insulated switches, non-switchable submersible transformers and XLPE cables) means that standards for replacement are no longer available. Therefore, during an unplanned outage, these items would not be stocked and will need to be replaced with standard equipment. Customers would face unnecessary lengthy outages until a solution can be implemented. The following sub-sections provide more specific details on the drivers to replace these assets. These factors ultimately drive the decision to replace these assets over the 2015 to 2019 period.

(i) Underground Switches

In recent years, Toronto Hydro has had to replace pad-mounted switches well in advance of the end of their useful service lives. As well, there has been an increase in the need to replace oil-insulated switches in the field. This is mainly due to the safety hazard these units pose to field crews and the public once they start to become contaminated and begin to age. Section E6.1.3.2(ii) discusses catastrophic failures which have occurred due to both oil-insulated and pad-mounted switches as well as the impacts these failures have on the system.

Pad-mounted switches are designed to be vented naturally through louvers under the hood of the enclosure. This provides a route for airborne particles, such as dust and road salt, to enter the switching compartments. These contaminants land and accumulate along the barriers separating the different phases of the switches and other components contained within the asset. Scheduled preventive maintenance (i.e., CO_2 washing) is effective in removing the excessive buildup of contaminants; however, it is only effective for a limited time as contaminants will build up again. More importantly, CO_2 washing causes microscopic damage to the coating on the insulator within the switch. Over time, this will result in degradation to the insulation strength of the switch and lead to premature failure. Therefore, although prudent, routine maintenance does not extend the useful service life of the switch. Instead, it perpetuates the potential for catastrophic failure, since the uneven surface is now an ideal platform for partial discharge activity which will inevitably lead to a flashover.

Other sources of contamination include the concrete foundation, upon which the pad-mounted switch rests, where primary cables attach to the fusing and switching compartments. These

cables may be tightly packed within the enclosure, creating an environment with tight clearances and an increased potential for moisture formation. As the ambient temperature changes, the trapped moisture condenses into water, dampening the dirt and other contaminants that are already present on the insulation surface. The surface then becomes conductive and eventually creates a carbonized track between the live terminal and ground. This "tracking" and increased leakage current eventually results in a flashover. A flashover may also result from partial electrical discharge in the air, known as corona, due to contaminants and moisture.

The result of a flashover is a near simultaneous ignition of all combustible material within the compartment. The flashover also releases an ionized gas that travels to other compartments in the enclosure. This ionized gas is conductive and can result in a discharge of electrical energy within the other compartments of the switch. This ultimately results in additional flashovers and combustion that leads to the total failure of the unit.

Toronto Hydro engineers suspect that this breakdown process is affecting pad-mounted switches. This aligns with the increasing frequency of reports by crews of corona activity within this asset type. Figure 8 provides an illustration of how contaminants build up on a typical pad-mounted switch leading to a potential flashover.

FIGURE 8: PENETRATION OF CONTAMINANTS ONTO LIVE-FRONT COMPONENTS OF PAD-MOUNTED SWITCHES

There are two types of submersible switches covered by this program: oil-insulated and vintage URD.

Oil-insulated switches are installed in below grade vaults, exposed to dirt, salt and other contaminants that degrade the physical integrity of the unit. This degradation can cause the non-stainless steel enclosure to corrode, leading to oil leakage and eventually the failure of the oil-insulated switch. Oil-insulated switches can fail catastrophically, resulting in a fire. These units must be replaced to ensure reliability and mitigate potential safety risks to the public, field crews and the environment. An example of a catastrophic oil-insulated switch failure, which took place on April 25, 2013, is discussed in section E6.1.3.2 (ii).

Vintage URD switches were installed in Toronto Hydro's underground residential distribution system in the late 1980s and early 1990s. A large portion of these switches do not have stainless steel enclosures. Therefore, many have been damaged by corrosion from moisture present in the underground vault environment.

Due to the inherent design flaw, which includes bolted viewing windows; these units have higher gas leakage rates and are now exhibiting "low gas" conditions. This has resulted in operational constraints to field crews because switches with low gas cannot be operated due to the safety risk they present (i.e., potential for flashover). This prevents Toronto Hydro from safely executing normal system operations, leading to longer outage times for customers. An incident was documented on October 7, 2006, where a Toronto Hydro protection and control crew member suffered facial burns while performing a routine inspection of an air-insulated pad-mounted switch. While opening a compartment door, debris from the environment initiated a flashover event which resulted in facial burns to the employee. Figure 9 shows an example of existing SF_6-insulated switches used in Toronto Hydro's URD system.

FIGURE 9: EXISTING SUBMERSIBLE VINTAGE URD SWITCH

Mini-rupters are switches typically used in building vaults. Although reliable, they are a type of air-insulated switch, exhibiting safety risks similar to those of pad-mounted switches. A complete discussion of the risks associated with pad-mounted (air-insulated) switches is located earlier in this section. The full extent of the discussion and associated risks and concerns applies to these switches as well.

A snapshot of the ten-year reliability of the underground switches discussed in this program is shown in Figures 10, 11 and 12. In these figures it can be seen that proactive switch replacement has started to result in system improvements beginning around 2009. The total number of failures and customer interruptions pertaining to switches has started to decline. However, the number of switches remaining in the field is aging at a rate faster than replacements can be executed. If Toronto Hydro does not maintain the current renewal pace, the utility expects that the benefits seen in the figure will not be sustained and failure rates will start to increase. Therefore it is important to continue proactive replacement of the remaining switches to help ensure the system reliability is maintained.

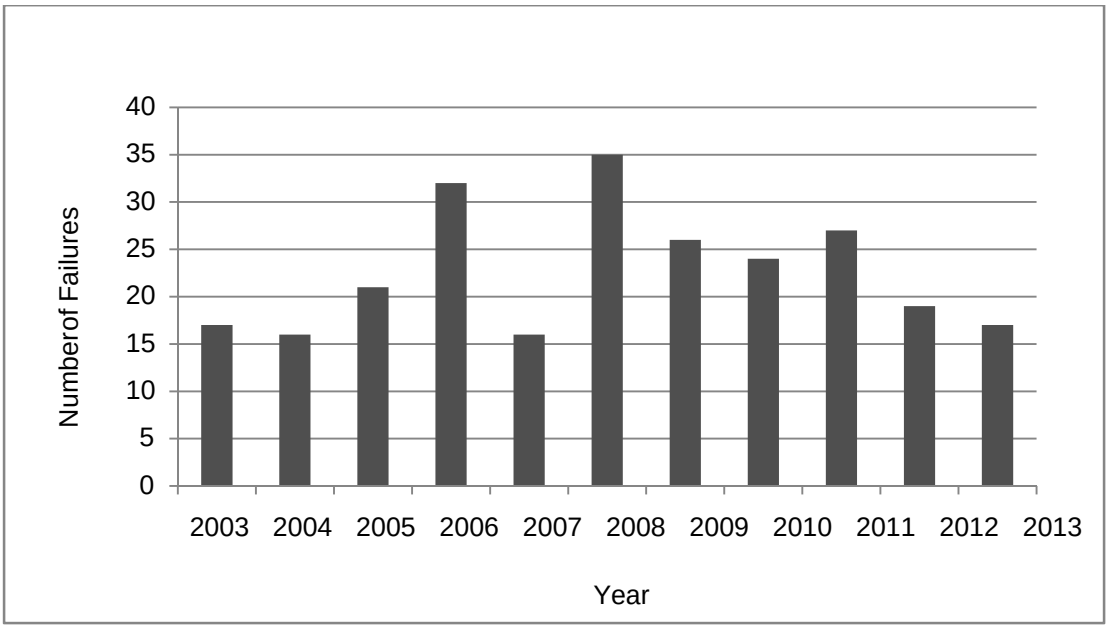

FIGURE 10: TEN-YEAR SNAPSHOT OF OUTAGES DUE TO UNDERGROUND SWITCH FAILURES

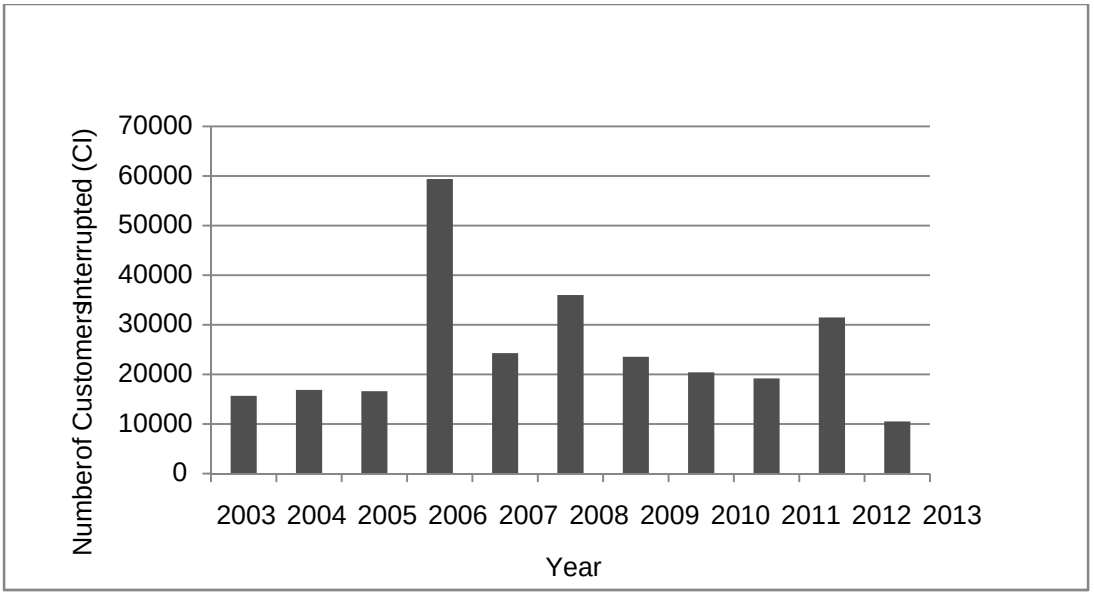

FIGURE 11: TEN-YEAR SNAPSHOT OF TOTAL CUSTOMERS INTERRUPTED (CI) DUE TO UNDERGROUND SWITCHES

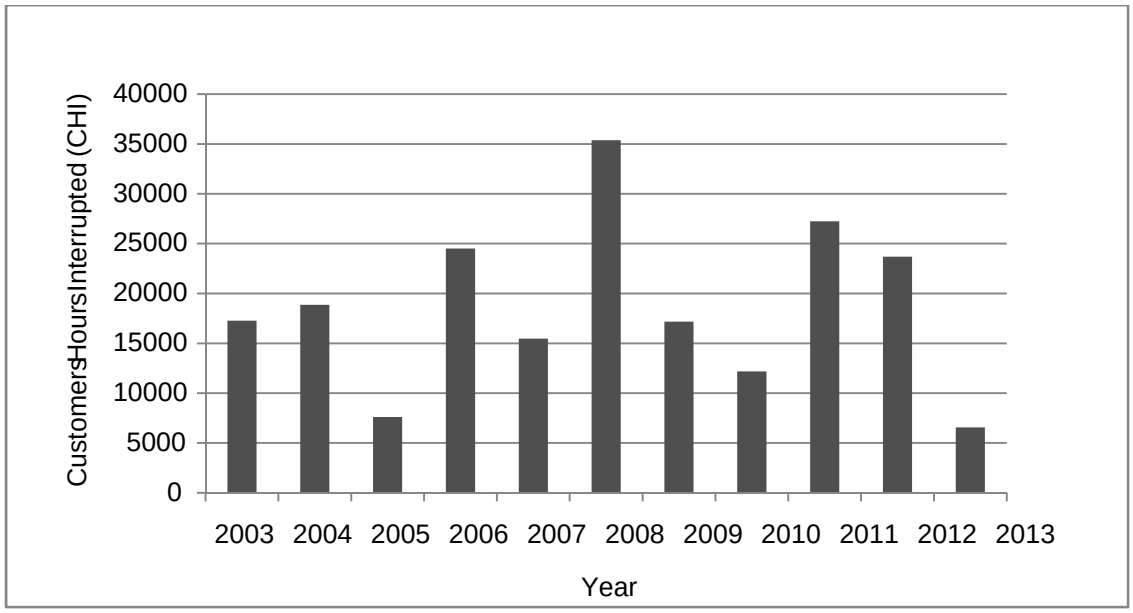

FIGURE 12: TEN-YEAR SNAPSHOT OF CUSTOMER HOURS INTERRUPTED (CHI) DUE TO UNDERGROUND SWITCHES

(ii) Underground Transformer

Transformer degradation is caused by both external and internal elements. Among the various degradation factors (i.e., dirt, aging etc.), moisture is the single most destructive element that affects transformers both externally and internally. External sources of moisture are seasonal precipitation and humidity. Moisture is present internally due to penetration through bushings, aged/poorly fitted gaskets or naturally as a result of the decomposition of the paper insulation (which produces CO_2 and H_2O).

The most destructive effect moisture has on a transformer is the loss of the oil's insulating ability, which may occur either:

- during periods of high load - water can boil off the conductor surfaces and the vapor bubbles can lead to dielectric failures as they rise to the top; or
- during periods of cool down after high load - during cool down, the water molecules combine with the oil vapor molecules, resulting in oxidation.

Once the oil has started to oxidize, it is be able to absorb more water (referred to as "water-saturated-decay-molecule"). This molecule is polar and naturally attracted to areas of high stress (i.e., conducting surfaces), which leads to arcing.

Therefore, external degradation due to moisture leads to corrosion and oil leakage into the environment. The secondary effect of this leakage is a reduction of the oil within the transformer that will cause the paper insulation to dry, and when paired with the heat created within the unit due to loading, will inevitably result in arcing and potentially catastrophic failure of the unit.

Whereas internal degradation due to moisture leads to a reduction in the oils insulation integrity, damage to the paper insulation and arcing along the conducting surfaces within the transformer. Figure 13 illustrates the difference between new and aged paper insulation within a transformer.

In both cases the damage is harmful to the public and field crews. It is imperative to replace aging transformers in the field to ensure safety and system reliability.

Damage due to moisture in aging transformers have been the leading cause in an increase seen in oil spills since 2012. The Environmental Health and Safety department at Toronto Hydro has seen a spike in transformer related oil spills linked directly to aged and corroded transformers. In 2013, there were a total of 107 transformer related oils spills, 25 of which were reportable to government agencies. This represents a 92% increase when compared to 2012 which totaled 15 spills two of which were reportable to government agencies. To date, there have been a total of 13 transformer related oil spills, five of which were reportable to government agencies in 2014. Based on this information, over 80% of the spills are due to aged and corroded transformers.

As well, there is a documented incident of a catastrophic transformer failure which took place on May 17, 2011. Figure 14 is a report published in the Toronto Star of a Toronto Hydro-owned transformer which failed. This was an older style transformer that had started to leak, the oil leakage eventually led to the catastrophic failure of the unit, causing a fire. Figure 15 is a photo taken by a bystander at the time of the incident.

FIGURE 13: MICROSCOPIC SCALE, DIFFERENCE BE TWEEN FIBERS IN NEW AND AGED TRANSFORMER PAPER INSULATION DUE TO MOISTURE DAMAGE

"News/GTA
Agincourt Mall evacuated after fire in transformer

By: Christine Dobby Staff Reporter, Published on Thursday May 17, 2011.

A blown hydro transformer forced the evacuation of the Agincourt Mall at Sheppard Ave. E. and Kennedy Rd. on Thursday.

The mall, which is home to both a Wal-Mart and a No Frills grocery store, was without power after a fire started in a hydro transformer about 15 to 20 feet from the building shortly after 6 p.m., said Toronto police Staff Sgt. Karl Heilimo.

Shoppers were evacuated due to smoke but there were no injuries reported and the power outage was limited to the mall, Heilimo said.

The cause of the fire or when the mall would reopen was not known."

FIGURE 14: TORONTO STAR ARTICLE - AGINCOURT MALL FIRE DUE TO TRANSFORMER FAILURE

FIGURE 15: PHOTO OF AGINCOURT MALL FIRE TAKEN BY BYSTANDER

A snapshot of the 10-year reliability of the underground transformers discussed in this program is shown in Figure 16, and Figure 18. In these figures it can be seen that proactive transformer replacement has started to show system improvements beginning around 2009. The total number of failures and customer interruptions pertaining to transformers has started to decline. However, similar to the switches discussed previously, the number of transformers remaining in the field is aging at a rate faster than replacements can be executed. If Toronto Hydro does not maintain the current renewal pace, it expects that the benefits seen in the figure will not be sustainable and failure rates will start to increase. Therefore it is important to continue proactive replacement of the remaining transformers to ensure the system reliability is maintained.

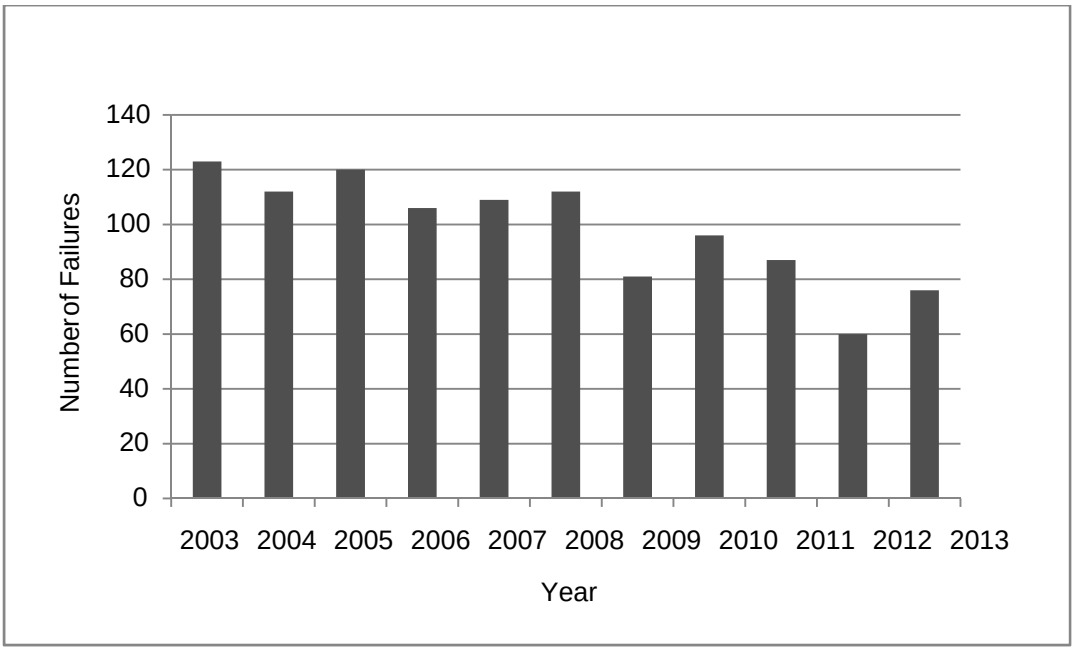

FIGURE 16: TEN-YEAR SNAPSHOT OF OUTAGES DUE TO UNDERGROUND TRANSFORMER FAILURES

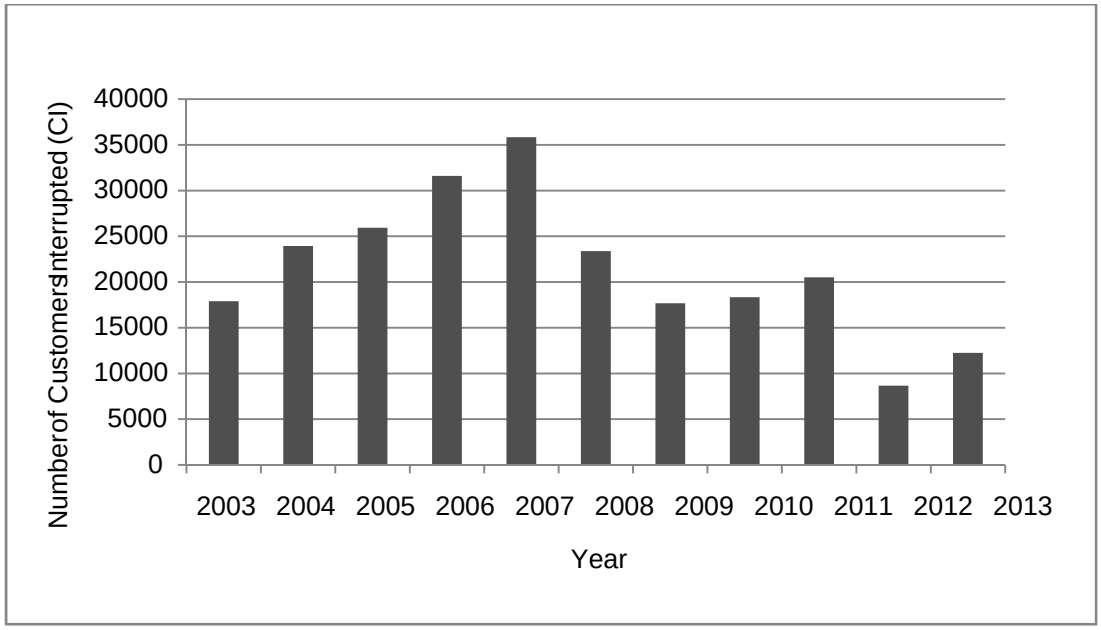

FIGURE 17: TEN-YEAR SNAPSHOT OF TOTAL CUSTOMERS INTERRUPTED (CI) DUE TO UNDERGROUND TRANSFORMERS

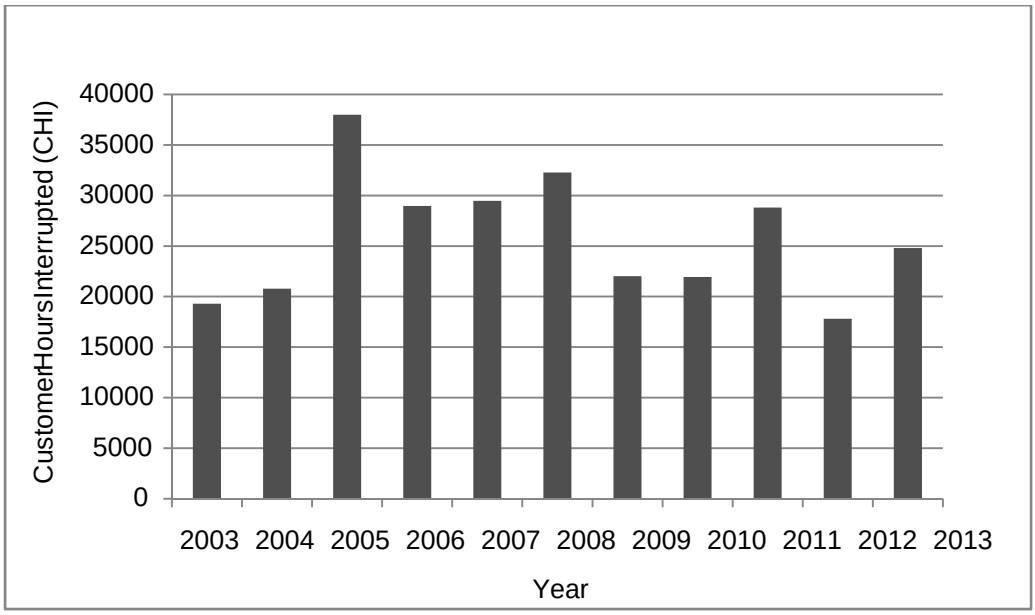

FIGURE 18: TEN-YEAR SNAPSHOT OF CUSTOMER HOURS INTERRUPTED (CHI) DUE TO UNDERGROUND TRANSFORMERS

(iii) Underground Cable

The most significant degradation process for vintage cross-linked polyethylene (XLPE) cable is "water treeing." Water treeing starts with moisture penetration into the cable insulation in the presence of an AC electric field. These trees are microscopic tears within the dielectric. In the early stages of water treeing, the path between the conductor and neutral remains intact. However, over time, continuous seepage of moisture into the insulation combined with electrical stress allows ions from the conductor to start migrating into the microscopic tears. These tears then become carbonized and form electrical trees. Once this final stage of treeing is reached, the cable quickly fails due to internal short circuits that occur between the primary conductor and the neutral shield on the outside of the cable insulation.

Figure 19 depicts the internal short circuit that occurs once electrical trees are formed in the dielectric insulation. Figure 20 provides field and laboratory samples of microscopic voids (bubbles) and damage (water and electrical trees) to the insulation. There is an immediate need to address the issues associated with XLPE type cables which were installed either direct buried or in ducts in an effort to increase system reliability.

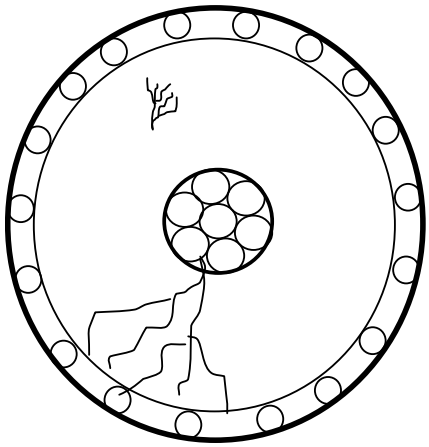

FIGURE 19: SHORT CIRCUIT BETWEEN PRIMARY CONDUCTOR AND NEUTRAL SHIELD DUE TO ELECTRICAL TREEING

FIGURE 20: FIELD AND LABORATORY SAMPLES OF MICROSCOPIC VOIDS (BUBBLES) AND DAMAGE (WATER AND ELECTRICAL TREES) TO EXTRUDED DIELECTRIC INSULATION

Underground street lighting conductors (the conductors running between two poles) provide power to street lights mounted on a pole. Most of these conductors are direct-buried. Constant exposure to moisture and soil contamination has caused deterioration of the conductors' insulation, which leads to eventual failure. Depending on the location of failure, it may cause loss of power to a number of street lights, which can lead to customer complaints and potential public safety risks. Toronto Hydro believes it is prudent to replace the conductors at the same time as the street lighting poles to ensure more reliable service to residents of the City of Toronto.

A snapshot of the ten-year reliability of the underground cables discussed in this program is shown in Figure 21, Figure 22 and Figure 23. In these figures it can be seen that proactive XLPE cable replacement has started to show system improvements since around 2007. The total number of failures and customer interruptions pertaining to XLPE cables has started to decline. However, the XLPE cable remaining in the field is aging at a rate faster than rebuilds can be executed. If Toronto Hydro does not maintain the current renewal pace, it expects that the benefits seen in the figure will not be sustainable and failure rates will start to increase. Therefore it is important to continue proactive replacement of the remaining XLPE cable to ensure the system reliability is maintained.

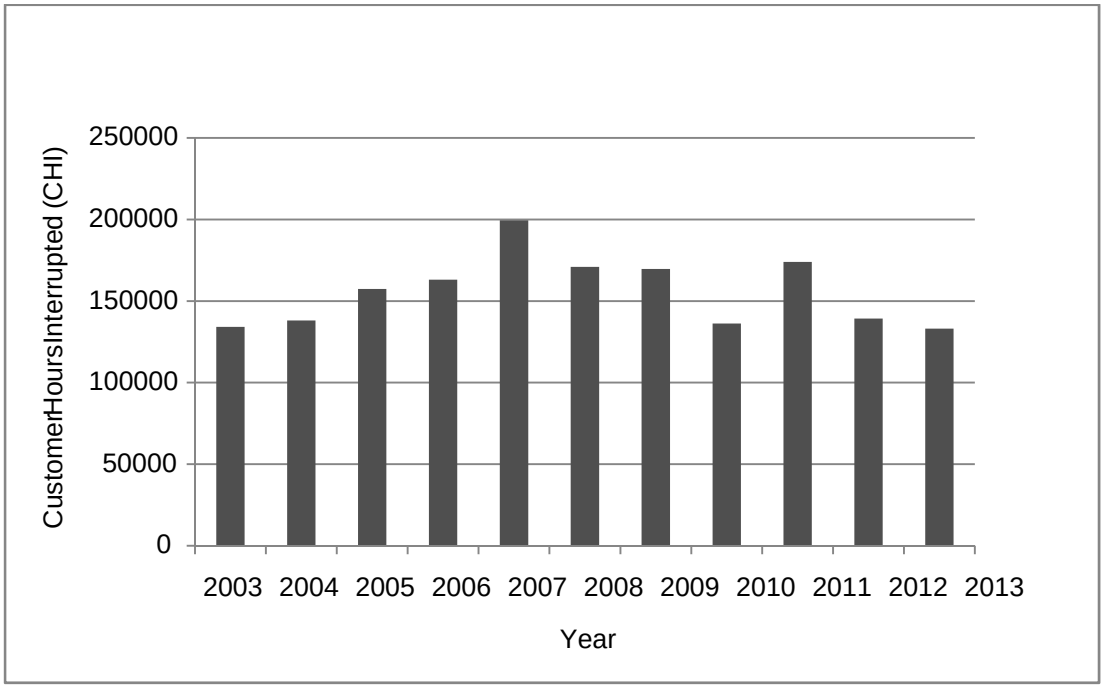

FIGURE 23: TEN-YEAR SNAPSHOT OF CUSTOMER HOURS INTERRUPTED (CHI) DUE TO UNDERGROUND PRIMARY CABLES

E6.1.3.2 Asset Details

In this section, the lifecycle and failure impacts of switchgear, transformers and cables that will be replaced through this program are discussed in greater detail.

(i) Asset Lifecycle

Table 4 provides an overview of the average useful service life of the various assets suggested for replacement through this program. Although the assets have varying useful service lives, based on the discussion in section E6.1.3.1, moisture is the common factor affecting all underground assets. Therefore, the extent of external damage limits the actual service life of assets compared to their expected useful service life.

As described above, moisture corrodes the enclosures of switches and transformers leading to oil leakage and tracking which can result in arc-flashes and potentially catastrophic failures, potentially posing safety risks to the public and field crews (further discussed in E6.1.3.2 (ii)). As well, moisture seeps into the cable insulation and leads to water-treeing which eventually turns to electrical trees that result in internal short circuits leading to cable failures.

TABLE 4: UNDERGROUND ASSET – TYPICAL USEFUL SERVICE LIFE

<table>
<tr><th colspan="2">Switch</th><th colspan="2">Transformer</th><th colspan="2">Cable</th></tr>
<tr><th>Type</th><th>Average Useful Life</th><th>Type</th><th>Average Useful Life</th><th colspan="2">Type</th><th>Average Useful Life</th></tr>
<tr><td rowspan="2">Pad-mounted</td><td rowspan="2">30</td><td rowspan="2">Submersible</td><td rowspan="2">33</td><td rowspan="2">Direct buried</td><td>Jacketed</td><td>40</td></tr>
<tr><td>Un-jacketed</td><td>23</td></tr>
<tr><td>Vintage URD</td><td>40</td><td>Pad-mounted</td><td>35</td><td colspan="2" rowspan="2">Cable in duct (Jacketed/Un-jacketed)</td><td rowspan="2">50</td></tr>
<tr><td>Mini-rupter</td><td>40</td><td>Building vault</td><td>35</td></tr>
</table>

Switches are an essential component of the distribution system. They are used for feeder load switching, isolation and emergency power restoration procedures. The average service life of pad-mounted switches is 30 years while vintage URD and mini-rupter switches are 40 years each. A detailed discussion of the various factors affecting the degradation of switches has been given in section E6.1.3.1 (i).

Transformers are key components used to step voltage down and supply commercial and residential customers with electricity via underground cables. Submersible transformers have an average service life of 33 years while pad-mounted and building vault transformers have an

average useful service life of 35 each. Direct buried cables have an average service life of 23 and 40 years for un-jacketed and jacketed types respectively while ducted cables have an average service life of 50 years.

However, the service life of both transformers and cables are significantly impacted by the presence of moisture in the atmosphere and underground environment into which they are installed. Due to this, they show signs of aging and start to fail sooner than expected. A detailed discussion of the various factors affecting the degradation of transformers and cables has been given in section E6.1.3.1 (ii) and E6.1.3.1 (iii) respectively.

Figure 24 illustrates the remaining life of all assets targeted for replacement through the Underground Circuit Renewal program. From this population of underground assets that are targeted for replacement in this program, 1,349 switches, 7,504 transformers and 692 kilometers of cable are currently operating beyond their useful service lives. This indicates that by 2015, the majority of the underground assets in the program will need to be replaced. However, due to operational constraints and limited resources, it is not prudent or feasible to replace all of these assets at once, and the work has been spread over the 2015-2019 period. Section E6.1.4 provides a detailed discussion on the timing and pacing of the program.

FIGURE 24: REMAINING USEFUL LIFE OF ALL ASSETS ADDRESSED IN THE UNDERGROUND CIRCUIT RENEWAL PROGRAM

(ii) Asset Failure Impacts

The switches, transformers and cable targeted for replacement in the Underground Circuit Renewal program are aged, in poor condition or have inherent design flaws. In this section the failure impacts of these assets to the system will be looked at in further detail.

Failure Causing Secondary/Local Outage

The failure mode that would impact the least number of customers would be an outage that only affected customers downstream of a distribution transformer or on a segment of a feeder. This is referred to as a secondary or localized outage. While the system is designed to handle first contingency, a contingency plan does not always exist at this level due to the relatively small number of customers impacted. As such, restoration requires the equipment to be replaced by some other form of resupply.

The impact of this type of failure varies depending on the type of asset and how it is connected in the circuit. For example, pad-mounted switches are designed to feed up to six single phase distribution (residential) loops. In the event of an unplanned outage, up to 1,200 customers could experience an outage.

Due to functional obsolescence, non-submersible transformers in particular, pose a risk to the system independent of the degradation factors discussed in section E6.3.1. According to Toronto Hydro outage information, 12,242 customer interruptions (CI) in 2013 were due to transformer failures alone. Each customer experienced interruptions lasting an average of two hours (customer hours interrupted or CHI).

The majority of existing submersible transformers in the field are non-switchable. These units have been in the field for many years and, over time, transformer elbows may have seized due to corrosion. This makes it difficult for field crews to operate the elbow to isolate the faulty unit without risking personal injury. As a result, failure of any non-switchable submersible transformer in a loop will require the entire loop to be de-energized to enable safe isolation of the unit by field crews. In the event of an unplanned non-switchable transformer outage, up to 1,200 customers can experience a short term outage while crews isolate the feeder at the switchgear. Once the feeder is isolated, up to 200 customers in the loop of the failed transformer will experience a sustained outage lasting six to eight hours.

Additionally, these transformers do not have a built in current limiting fuse (CLF). In the 1980's, after experiencing a number of submersible transformer failures, Fault Fiter fuses were installed upstream of these units. This fuse is a current-limiting device inside a PMH-4 pad-mounted switch and is installed at the beginning of a loop to protect downstream transformers from excessive high fault current. However, the standard for submersible transformers was recently harmonized so that each new submersible transformer is of a switchable type and contains an internal CLF. When an existing non-switchable submersible transformer in the field fails, it is replaced with a new switchable submersible transformer. Given that the former relied on the CLF of the PMH and the latter has an internal CLF, this leads to what is called 'protection mis-coordination' as shown in Figure 25. This may result in a partially operated Fault Fiter fuse after the internal CLF in a submersible transformer has cleared the fault current. The Fault Fiter fuse may operate prematurely upon re-energization, causing the customers in the loop to experience a secondary outage. This time the PMH will need to be replaced and the secondary outage can result in up to 1200 customers losing power.

FIGURE 25: ILLUSTRATION OF PROTECTION MIS-COORDINATION OF NON-SWITCHABLE AND SWITCHABLE TRANSFORMER IN ONE LOOP

Historical failures due to extreme low gas and direct buried cables related to the secondary/local outage scenario for switches and cables include the following:

- A "low gas" event took place in March 2013; feeders A5L, A10L and A6L were connected to a submersible SF_6 switch which failed catastrophically due to low levels of SF_6 gas. This outage is also described in detail in the Underground Legacy Infrastructure (section E6.4) program in terms of how not having standard replacement parts available impacted the outage duration. In this case, the low gas pressure inside the switches caused an internal fault to ground which resulted in failure of all three incoming feeders. This outage initially affected 70 customers, including many large apartment buildings.

- On April 25, 2013 there was a catastrophic failure related to an oil-insulated switch on feeder 51-M28 which left 421 customers without power. In this case, the external contamination buildup on the unit degraded the physical integrity of the unit. This in turn caused the enclosure to corrode and oil to leak igniting a fire which led to the unit failing catastrophically. The failure caused traffic congestion along Sheppard Ave East (where the unit was located) and potential transformer oil seepage into the environment.

- On August 1, 2013, a failure on feeder A320CE left a total of 3,133 customers without power due to low gas failure of SF_6 switches. Had the switches functioned as intended, only 1,298 customers would have been without power during this event. In this case, the breaker supplying the primary feeder had failed. Once it had been determined that there was no cable damage, the crew needed to close the normally open point on the standby feeder using a 600A submersible SF_6 switch. However, the switch was low on gas and could not be operated. Therefore, the controller had to open the breaker on the standby feeder, causing an outage to all customers normally supplied by the standby feeder. Once the standby feeder was out, the proper switching could occur to isolate the failed feeder; then the controller was able to reclose the breaker on the standby feeder. As a result 1,835 additional customers were affected by the outage.

- As well, a direct buried cable example can be seen in the Bridletowne area. Since 2011, this area has experienced many repetitive outages, five of which were specifically related to direct buried cables. Due to these five outages, 10,484 customers in the Bridletowne area have been without power for a total of 6,524 outage hours over the past three years (2011 to 2013). Figure 26 is a map of the Bridletowne neighborhood. It should be noted that the majority of projects issued for the 2015 rate filing are designed to deal with many of the problems associated with the 502-M22 feeder, including upgrades to Bridletowne circle.

FIGURE 26: MAP OF BRIDLETOWNE FED BY 502-M22

Failure Causing a First Contingency Feeder Outage

A failure mode which would have a severe impact to customers is an outage that takes out an entire primary feeder, referred to as a first contingency feeder outage. The system is designed to handle a first contingency, so while customers on a feeder will still be interrupted by a failure, they can restored before the source of the failure is complete resolved. Outage restoration time will depend on the number of customers on the feeder.

An example of this can be seen with pad-mounted switches connected to the trunk portion of a feeder. Pad-mounted switches are commonly connected to the trunk portion of a feeder for load distribution and feeder switching. When load is transferred from one feeder to another, individual switches are closed or opened so that power can be diverted from one feeder to another. These actions cannot occur when a pad-mounted switch fails, leading to a significant impact on system reliability. According to Toronto Hydro outage information, 10,525 CIs in 2013 were due to switch failures alone. Each customer experienced interruptions lasting an average of 0.63 hours (customer hours interrupted or CHI).

The catastrophic failure of a pad-mounted switch may also present a potential safety risk to the public. As these units are installed on city sidewalks, anyone in the vicinity of the pad-mounted switch could be injured if the switch door or other exposed parts were to dislodge during an explosive failure. An example of a contaminated air-insulated switch that failed can be seen in Figure 27.

FIGURE 27: FAILED AIR-INSULATED PAD-MOUNTED SWITCH (TAKEN NOVEMBER 19, 2008)

Failure Causing a Second/Multiple Contingency Feeder Outage

The failure mode that would have the most severe impact on customers is an outage that takes out multiple primary feeders. This is referred to as a second (or multiple) contingency feeder outage. The system is not designed to handle a multiple contingency, so there may be customers on the interrupted feeders that cannot be restored before the source of the failure is in some way resolved. Outage restoration will depend on the severity of the damage to each feeder.

An example of this can be seen during a cable outage, depending on where the cable has failed. According to Toronto Hydro outage information, 181,577 CIs in 2013 were due to primary cable failures alone. Each customer experienced interruptions lasting an average of 0.73 CHI. Installing new TR-XLPE cable in concrete-encased duct helps to reduce the lengthy repair process associated with repairing/replacing direct buried cable as described in (a) to (g) below and shown in Figures 28 to 30.

Repair Process

Identify the faulted cable segment (50-100m length) based on visual inspection of the interrupted devices

(a) Install fault-locating equipment (thumper) to determine the fault location[5]

(b) Dig a splice-pit in the identified location (see Figure 28)

(c) If the device erred in the location of the fault, repeat thumping and step (c)

(d) Cut and remove the faulted section of cable (see Figure 29)

(e) Install a new section of cable and connect via splices (see Figure 30)

(f) Back-fill pit

FIGURE 28: FIELD PERSONNEL WITHIN A SPLICE- PIT PREPARING TO SPLICE A FAULTED CABLE TO RESTORE SERVICE TO AREA

[5] Thumping itself weakens an already aged, stressed cable due to the repeated short term high voltage (up to 30kV) DC pulses transmitted to locate the fault, http://www.abb.com/cawp/seitp202/003a3146d08e8aedc12578380056f1f3.aspx

FIGURE 29: FIELD PERSONNEL WITHIN SPLICE-PIT, REMOVING FAULTED CABLE SEGMENT

FIGURE 30: FIELD PERSONNEL COMPLETED SPLICING THE CABLE. NOTICE TWO SPLICES REQUIRED FOR EACH FAULTED CABLE SEGMENT

In addition to direct buried cables, Toronto Hydro also has cables in ducts. There are two types of ducts installed in the underground distribution system: direct buried PVC and concrete encased. Ducts minimize many problems associated with direct buried cables, including: replacement of an entire faulted cable segment (rather than splicing); reduced residential disturbance (no trenching/splice pits required for cable repair); and added mechanical protection against dig-ins and environmental contaminants.

Direct buried ducts are installed in two ways: open-trench and micro-tunneling. Open-trench provides some flexibility as to how the ducts are laid and allows for the ducts to be installed flush between two cable chambers or transformer vaults. Micro-tunneling allows for minimal disturbance above ground by avoiding long length trenches. In this case, a clearance is required to set up the micro-tunneling bore head, prohibiting ducts from running flush between cable chambers or transformer vaults. Instead, a portion of the cable on either end must be direct buried. In the event of an unplanned outage on a cable installed in the latter scenario, two splice pits are required to expose the direct buried cable portions before the new cable can be pulled through the ducts. Unplanned repairs in this case are as difficult and intrusive as repairs made to direct buried cables. However, in the case of the former duct installation, cables can be pulled directly from the cable chamber or building vault transformer with minimal disruption to customer property. Thus, where prudent, the direct buried ducts will be replaced with concrete encased ducts as per Toronto Hydro's standard. An example of both types of direct buried duct installation is given in Figure 31.

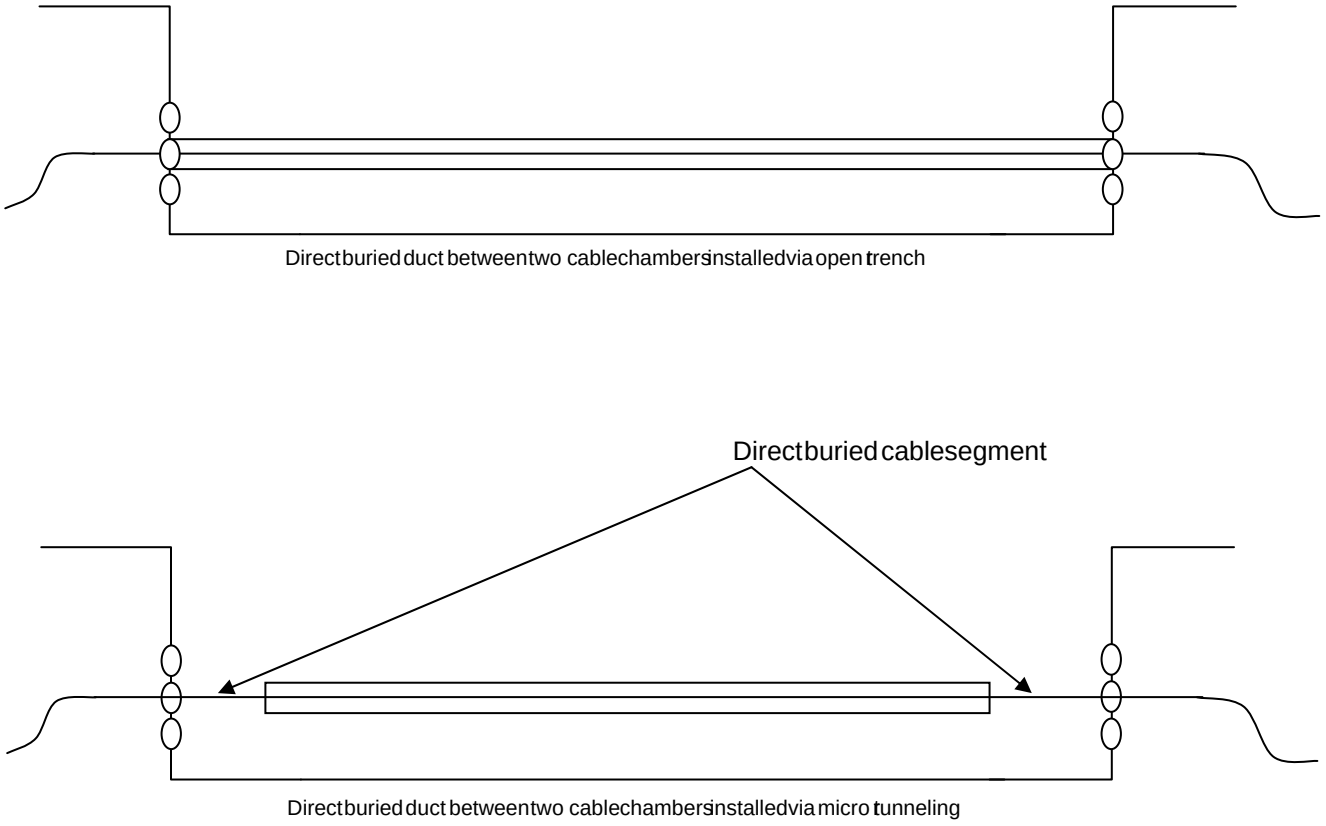

FIGURE 31: OPEN-TRENCH AND MICRO-TUNNEL DIRECT BURIED DUCT CONFIGURATIONS

Failures Causing System Operating Constraints

A final failure mode that would impact customers is a failure causing an operating constraint. This refers to the situation when equipment can no longer be operated as intended. When this occurs, forced feeder outages may be required to operate the system. This impact of the outage varies based on the equipment involved and could affect multiple primary feeders. Most outages incurred due to operating constraints would be momentary outages.

An example of this type of failure on the system can be seen when a vintage URD switch indicates “low-gas” levels. In this case, the switch is considered a failed switch. A detailed discussion of the failure impacts of this type of switch has been given in the Underground Legacy Infrastructure program (section E6.4). A summary of the reliability impact of this failure has been discussed earlier in this section (E6.1.3.2 (ii) – Failures Causing Secondary/Local Outage).

E6.1.4 Timing & Pacing of the Program

Assets planned for replacement in this program are aged, unreliable and in some cases contain critical design flaws. These factors pose failure and safety risks to the system, customers and field crews. This program proposes to proactively replace these assets over the next five years to mitigate system reliability risk as well as to enhance customer and crew safety. Table 5 provides a summary of the five year historical spend on the Underground Circuit Renewal program or its equivalent as well as projected spending from 2015 to 2019.

TABLE 5: SUMMARY OF FIVE YEAR UNDERGROUND RENEWAL PROGRAM SPEND

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	108.4	90.3	53.8	68.8	108.1	96.0	80.1	84.0	99.7	99.5

The drop in spending from 2011 to 2012 was related to the timing of the regulatory decisions with respect to Toronto Hydro's previous Cost of Service filing and the subsequent 2012-2014 ICM filing.

Given that a high population of assets will be approaching the end of their useful lives in 2015, Toronto Hydro expects to maintain a level of investment similar to the forecasted 2014 magnitude throughout the 2015-2019 period. Minor fluctuations in the pacing of investment over the forecast period (e.g. the drop in spending in 2016 and 2017) will likely be required to facilitate other high-priority renewal and service investments in the underground system using similar resources. These types of investments (e.g., Feeder Automation (E7.3), Design Enhancement (E7.2), Underground Legacy Infrastructure (E6.3)) address similar or related underground assets and are expected to deliver complimentary reliability, safety and system efficiency benefits for customers on the underground system.

The proposed rate of investment in the Underground Circuit Renewal program will allow Toronto Hydro to prudently and proactively manage the significant backlog of end-of-life and poor condition underground assets, maintaining system reliability performance while enhancing customer value with the installation of more robust and reliable underground construction. Toronto Hydro expects that a slower pace of investment would increase the backlog of end-of-life underground assets, making it increasingly difficult to efficiently mitigate deteriorating system reliability performance in the future.

E6.1.4.1 Ranking & Prioritization

Switch and transformer replacements are generally prioritized to coordinate with cable replacements. However, switches and transformers that are in need of replacement but are not connected to cable that is in need of replacement will be prioritized by historical feeder reliability, asset condition, the number of customers that would be affected by a failure and the duration of such an outage. This approach is intended to ensure switches and transformers on feeders that suffer the highest number of outages or long outage durations are refreshed as soon as possible.

Cable replacement is prioritized based on factors such as the number of failures experienced by the cable segment as well as the number of underground cable failures experienced by the feeder. Replacement of cable in duct is mainly prioritized based on suggested optimal year of intervention derived from Toronto Hydro's Feeder Investment Model (FIM). A detailed discussion of the FIM model is given in Section D3.

Capital replacement for street lighting assets is prioritized on the basis of the age and condition of the street lighting pole and luminary as well as historical underground conductor failure rate. Replacing conductors supplying power to street lights will be prioritized based on the condition of the pole it is connected to and will be coordinated with the City of Toronto.

E6.1.5 Program Execution

This program consists of three major underground asset classes: switches, transformers and cables. The program proposes to replace:

- Pad-mounted, oil-insulated, vintage URD and mini-rupter switches which are approaching end-of-life with new SF_6-insulated switches.
- Non-switchable, submersible transformers will be replaced with switchable submersible transformers and pad-mounted and building vault transformers with similar units.
- Direct buried XLPE cable and cable in direct buried duct will be replaced with new TR-XLPE cable in concrete encased duct.

Detailed discussions of these assets have been given in Section E6.1.2.

The intent of the underground renewal program is to replace assets that will pose a higher failure risk, are functionally obsolete or pose a safety risk to field crews and the public with newer, standard assets.

It can be seen in section E6.1.3.2 (ii) that the majority of assets considered in this program are due for replacement in 2015. The underground replacement initiative taken since 2007 has produced significant reliability improvements in terms of CIs and CHIs as discussed in section E6.1.3.1. Although it would benefit the distribution system to replace all assets approaching end-of-life in 2015, it is neither practically feasible nor prudent to do so. Therefore, in an effort to maintain the reliability improvements and ensure a prudent approach to asset upgrades, the assets are expected to be replaced from 2015 to 2019. By replacing the assets proposed for the first year of the program, the ARC to the distribution system is $102.93 million.

E6.1.5.1 Proposed Work Plan

The Underground Circuit Renewal projects will primarily be performed on feeders emanating from 27.6 kV transformer stations (TS), because the majority of feeders supplying residential customers in the North York and York area are designed as 27.6 kV underground distribution circuits whereas the circuits supplying Toronto, Scarborough and Etobicoke use 13.8 kV or 4.16 kV overhead distribution. Given that this program addresses underground circuit renewal, the bulk of the work will be along 27.6 kV circuits and, where applicable, underground 13.8 kV and 4.16 kV circuits.

E6.1.5.2 Program Risks

The risks associated with the Underground Circuit Renewal program include, but are not limited to:

- Unforeseen (i.e., emergency) updates and changes to existing road moratoriums by the City of Toronto.
- In this case, Toronto Hydro will monitor the road moratorium list and delay or accelerate individual projects within the 2015 to 2019 program accordingly.
- Unforeseen weather conditions that may affect either the summer heat restriction list (i.e., more feeders added to the list due to extended periods of unanticipated heat/humidity) or construction in the fall/winter (i.e., hurricanes or ice storms).

In this case, depending on the level of the emergency, resources will be limited and as a result, projects may be shifted to the following year. Because of such scenarios, program management has prioritized projects to be High, Medium and Low. In a case where natural events push a project to the following year, low priority projects may be deferred. This will allow major projects to be completed while maintaining system reliability in the event of an emergency.

E6.1.6 Evaluation of Alternatives

E6.1.6.1 Quantification/Evaluation of Options

(i) Status Quo

By maintaining the status quo, all assets that have been discussed in the Underground Circuit Renewal program will remain in the distribution system until eventual failure, at which point the assets will be replaced on a like-for-like basis with similar assets. Doing so is expected to perpetuate the safety and reliability problems discussed in section E6.1.3.

(ii) Replacement with Standard Equipment

All assets that have been discussed will be replaced with newer, standard assets. This will allow the distribution system to benefit from these assets as discussed in section E6.1.2. Table 7 summarizes the existing assets in the field and their proposed replacement options.

TABLE 6: SUMMARY OF EXISTING AND PROPOSED REPLACEMENT ASSETS

Asset Class	Existing Type	Proposed Replacement Asset [6]
Switches	Pad-mounted	SCADA operated, SF_6-insulated switches
	Oil-insulated	
	Vintage URD	
	Mini-rupter	
Transformer	Non-switchable submersible	Switchable, submersible
	Pad-mounted	Pad-mounted
	Building vault	Building vault
Cable	Direct buried XLPE	TR-XLPE cable in new concrete encased duct
	XLPE in direct buried duct	
	End-of-life TR-XLPE in duct [7]	

The replacement of underground switches, transformers and cable in the first year of the program will result in an ARC of $102.93 million, as detailed in Table 8. This value represents the avoided cost of executing the first year of activities as scheduled as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the assets' probability of failure and multiplying this figure by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. Further details on the ARC approach is provided in Section D3.3.

[6] Based on Toronto Hydro's standard design practice
[7] In this case only the end of life "cable" is replaced. The existing duct structure will be re-used.

TABLE 7: AVOIDED RISK COST BUSINESS CASE EVALUATION

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 **[PV(NET_COST(2020)]**	$192.56
Net Cost for the First Year of Activity **[NET_COST(First Year of Activity)]**	$96.00
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$102.93

E6.1.7 2015 Project Details

Table 9 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved Underground Infrastructure segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 8: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	**CIR Projects**
18.6	77.3

IC

Table 10 lists all projects that will be partially or completely executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

The following subsections provide project details for all 2015 projects.

E11628, E11629, E12128 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Morningview UG Rebuild Phases 1 & 2 - Elec and Phase 3 – Civil (47M3)

Project Number: E11628, E11629, E12128

Project Year: 2015

Estimated Cost: $2,525,621.00

(i) Objective

Rebuild the UG distribution system of the Morningview area under consideration. The civil portion of Phase 1 and 2 has been completed. E11628 and E11629 will complete the electrical portion. E12128 will complete the civil portion of Phase 3. All projects appeared in the ICM approved segment.

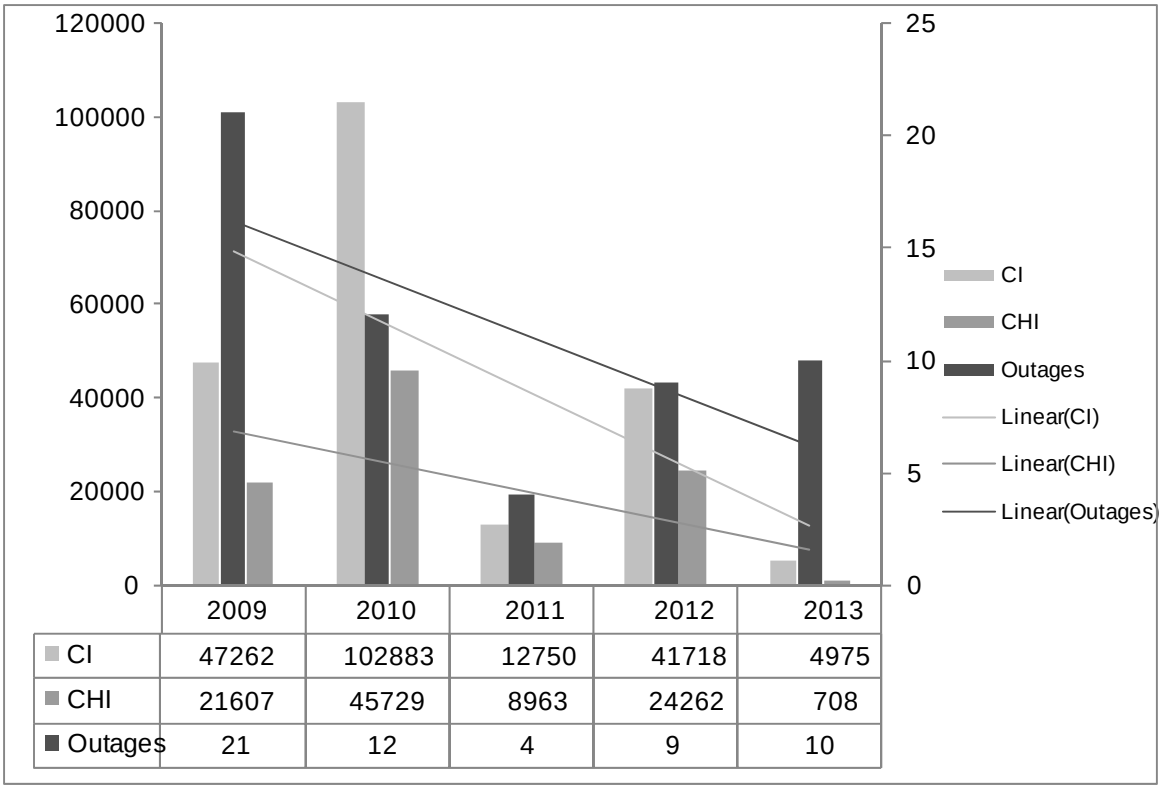
(ii) Scope of Work

TABLE 10: SCOPE OF WORK DETAILS

District Neighborhood	Scarborough Rouge River
Station(s):	Sheppard TS (27.6kV)
Feeder(s):	SCNT47M3

TABLE 11: ASSETS TO BE REPLACED

Assets to be Replaced	
Primary Cable	6,350.28m + 5,568.91m
Underground Transformers	35 + 33
Underground Switchgear	0
Poles	0
Overhead Transformer	0
Overhead Switch	0



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 12: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ Direct buried cable ƒ Installed 1984 (30 years old)
Reliability	ƒ The feeder was the Worst Performing Feeder (WPF) from 2005 to 2012 ƒ Reliability improvements seen due to recent rebuilds, however feeder is still ranks second in the WPF list with 10 sustained outages in 2013 alone
Other (i.e. road moratoriums, etc)	ƒ N/A

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 32.

E11803 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E11803 Rebuild feeder egress H9M32 and M26 Ellesmere-Civil

Project Number: E11803

Project Year: 2015

Estimated Cost: $770,354

(i) Objective

Replace the old and partially direct buried cables for the egress of feeder H9M32 and H9M26 from Ellesmere TS station. E11803 will install the civil infrastructure necessary to complete the project.

(ii) Scope of Work

TABLE 13: SCOPE OF WORK DETAILS

District Neighborhood	Scarborough Centre
Station(s):	Ellesmere TS (27.6kV)
Feeder(s):	SCH-A9M32, SCH-A9M26

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

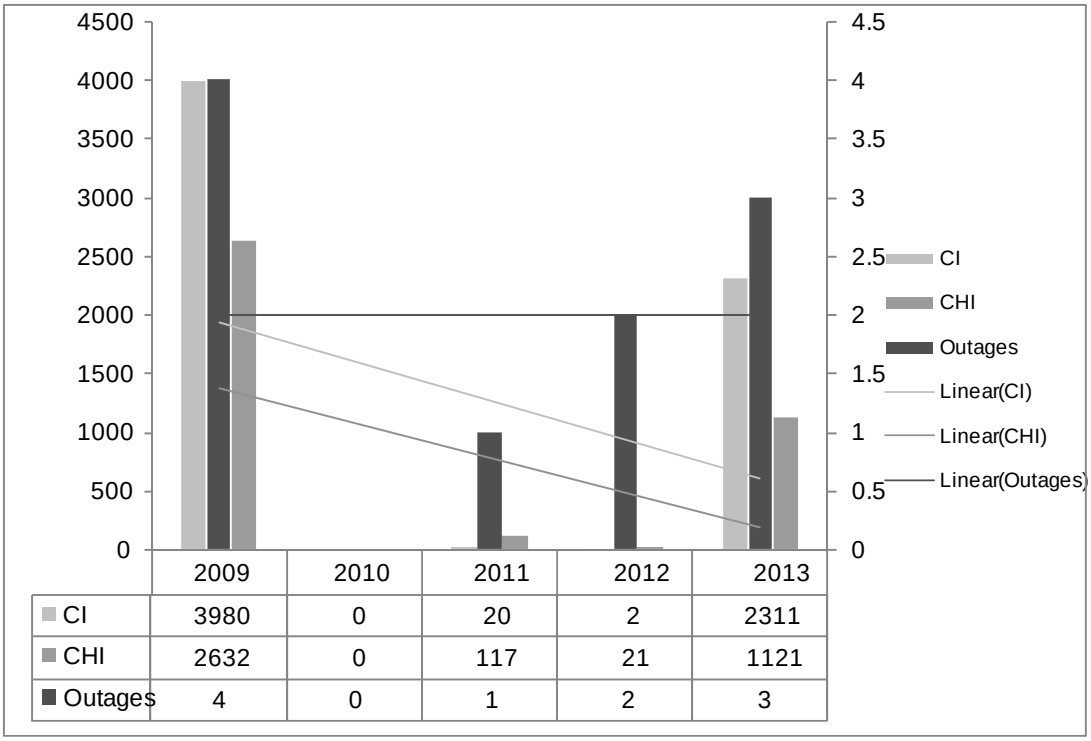

TABLE 14: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ Direct buried cable ƒ Installed 1979 (35 years old)
Reliability	ƒ Increasing number of outages from 2011 to 2013, not including momentary outages
Other (i.e. road	ƒ N/A

Supplemental Details	Description
moratoriums, etc)	

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 33 and 34.

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

E12210 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12210 - Venture Drive UG SCNT47M1 - Elec

Project Number: E12210

Project Year: 2015

Estimated Cost: $1,838,314

(i) Objective

Rebuild a portion of SCNT47M1 out of Sheppard TS to improve reliability and service to customers. The civil portion has been completed. E12210 will complete the electrical portion of the project.

(ii) Scope of Work

TABLE 15: SCOPE OF WORK DETAILS

E12217 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12217 Windfield Bayview Area Rebuild (51M21, NYSS27F1)

Project Number: E12217

Project Year: 2015

Estimated Cost: $172,201

(i) Objective

Rebuild 4.16kV primary distribution system fed by Windfield MS (SS27) by converting to 27.6kV system. Most of the load from this station will be connected to NY51M21. To increase efficiency, this project combines OH and UG work that is needed to complete the conversion. E12217 is ICM approved.

(ii) Scope of Work

TABLE 21: SCOPE OF WORK DETAILS

District Neighborhood	Don Valley West
Station(s):	Windfield MS (4.16kV)
Feeder(s):	NYSS27F1, NYSS27F2, NYSS27F3

E12243 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12243 Durnford-Rylander-Tideswell Rebuild Ph2 Electrical (47M17)

Project Number: E12243

Project Year: 2015

Estimated Cost: $57,400

(i) Objective

Rebuild the old direct-buried and failing primary 3-phase distribution line passing along Durnford Rd, Rylander Blvd, Tideswell Blvd, Vandorf St and Sheppard Ave.

E12243 will complete the electrical portion of the project, which was ICM approved.

(ii) Scope of Work

E12244 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12244 Tallpine Rebuild Phase Electrical (47M17)

Project Number: E12244

Project Year: 2015

Estimated Cost: $688,805

(i) Objective

Rebuild the old direct-buried and failing primary single-phase distributions consisting three lateral loops supplying houses on Vandorf St, Tallpines Ct, John Graham Ct, a section of Sheppard Ave, Raycliff Ct, Shallice Ct, Porthclair Ct, Parsborough Ct, Durnford Rd, Rylander Blvd, Tideswell Blvd, Carlisle Cres and Durnford TH complex.

E12244 will complete the electrical portion of the project, which was ICM approved.

E12267 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12267 Clappis on Rebuild Electrical (47M17)

Project Number: E12267

Project Year: 2015

Estimated Cost: $229,602

(i) Objective

The objective of this project is to rebuild the old and failing primary distribution of Centennial Park II Subdivision (Clappison Blvd.) supplied by feeder NA47M17.

E12267 will complete the electrical portion of the project, which was ICM approved.

(ii) Scope of Work

E12278 Project Description

Investment Category: **System Renewal**

Program: **Underground Circuit Renewal**

Project Title: **E12278 Nashdene-Tiffield UG Rebuild - Elec (NAR26M22)**

Project Number: **E12278**

Project Year: **2015**

Estimated Cost: **$3,628,734**

(i) Objective

Rebuild a portion of NAR26M22 out of Malvern TS to improve reliability and service to this industrial neighborhood. E12278 will complete the electrical portion of the project.

(ii) Scope of Work

TABLE 36: SCOPE OF WORK DETAILS

District Neighborhood	ScarboroughrRouge River

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

E12302 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12302 McNicoll Maybrook SCNAR26M32 UG Rebuild - Civil

Project Number: E12302

Project Year: 2015

Estimated Cost: $1,378,994

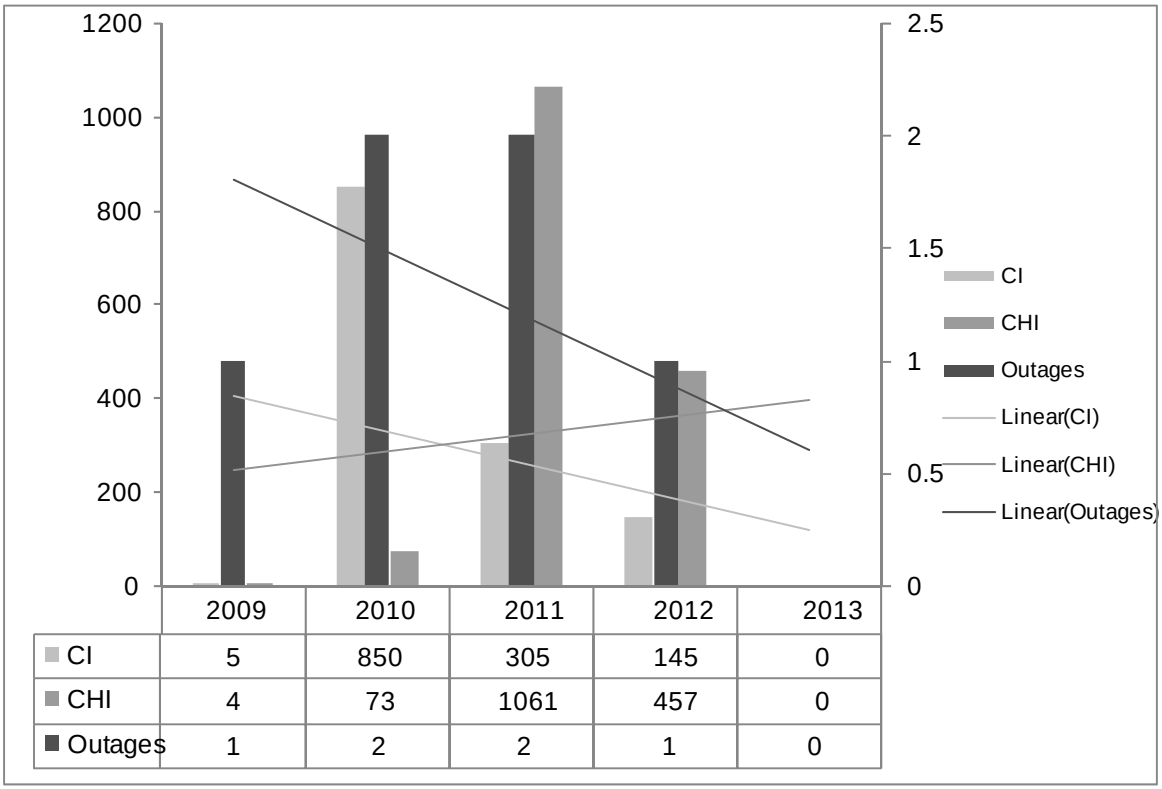
(i) Objective

Rebuild a portion of NAR26M32 out of Malvern TS to improve reliability and service to customers. E12302 will install the civil infrastructure necessary to complete the project.

(ii) Scope of Work

TABLE 38: SCOPE OF WORK DETAILS

District Neighborhood	Scarborough Rouge River
Station(s):	Malvern TS (27.6kV)
Feeder(s):	SCNAR26M32



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 39: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ Direct buried cable ƒ Installed 1979 (35 years old)
Reliability	ƒ Cables in project area experienced 2 recent failures
Other (i.e. road moratoriums, etc)	ƒ N/A

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 46.

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

E12310, E12311 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Scunthorpe Invergordon UG Rebuild Ph A – Civil/Electrical H9M26 SCNAH9M26

Project Number: E12310, E12311

Project Year: 2015

Estimated Cost: $ 2,013,936.00

(i) Objective

Replace the old direct-buried 350kcmil primary cables in the area of Scunthrope Rd and Invergordon Ave supplied by feeder NAH9M26. The distribution will be reconfigured to increase operational flexibility and provide better protection.

E12310 will install the civil infrastructure necessary to complete the project; E12311 will complete the electrical portion of the project.

(ii) Scope of Work

TABLE 40: SCOPE OF WORK DETAILS

District/Neighborhood	Scarborough/Rouge River
Station(s):	Ellesmere TS (27.6kV)

E12331 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E12331 Civil Works for Rebuild of NYSS38F2 off Bunty Lane NYSS38F2

Project Number: E12331

Project Year: 2015

Estimated Cost: $51,856

(i) Objective

Rebuild the aged direct buried 13.8kV infrastructure via voltage conversion to 27.6kV. E12331 will install the civil infrastructure necessary to complete the project.

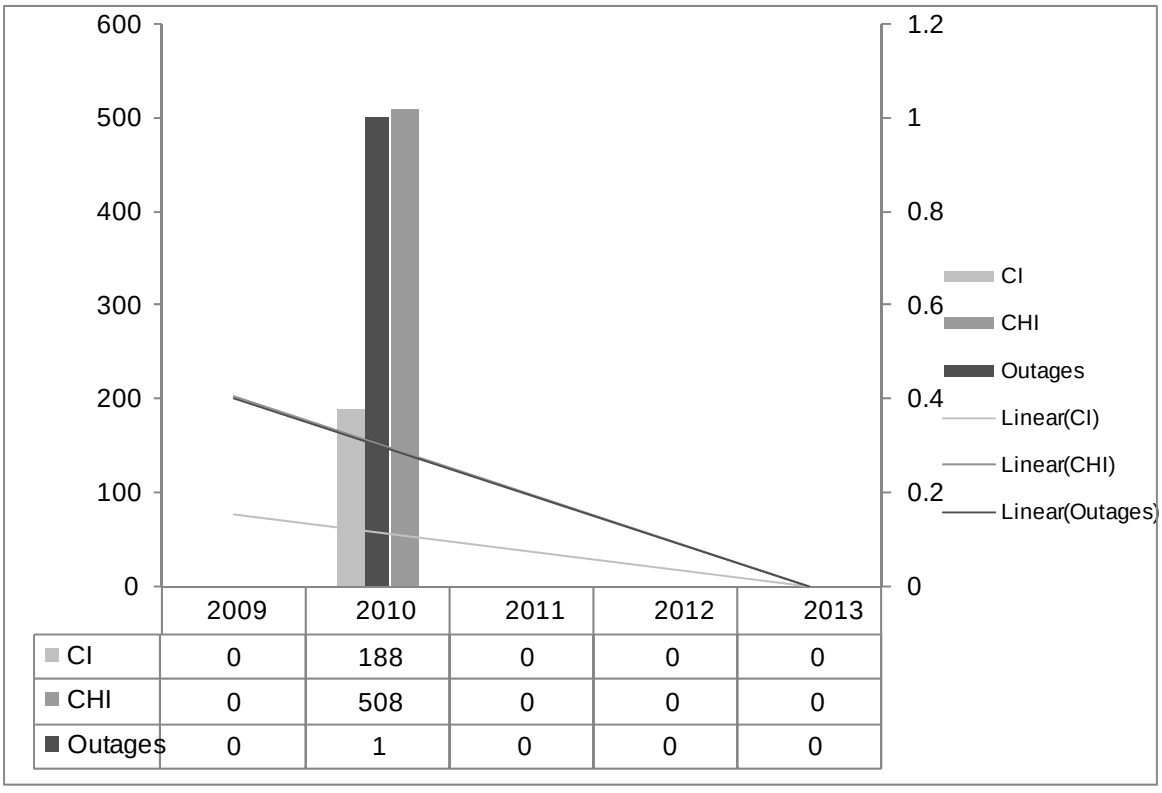
(ii) Scope of Work

TABLE 46: SCOPE OF WORK DETAILS

District Neighborhood	Willowdale
Station(s):	Burbank MS, Leslie TS
Feeder(s):	NYSS38F2, NY51M8

(iii) Justification & Benefits

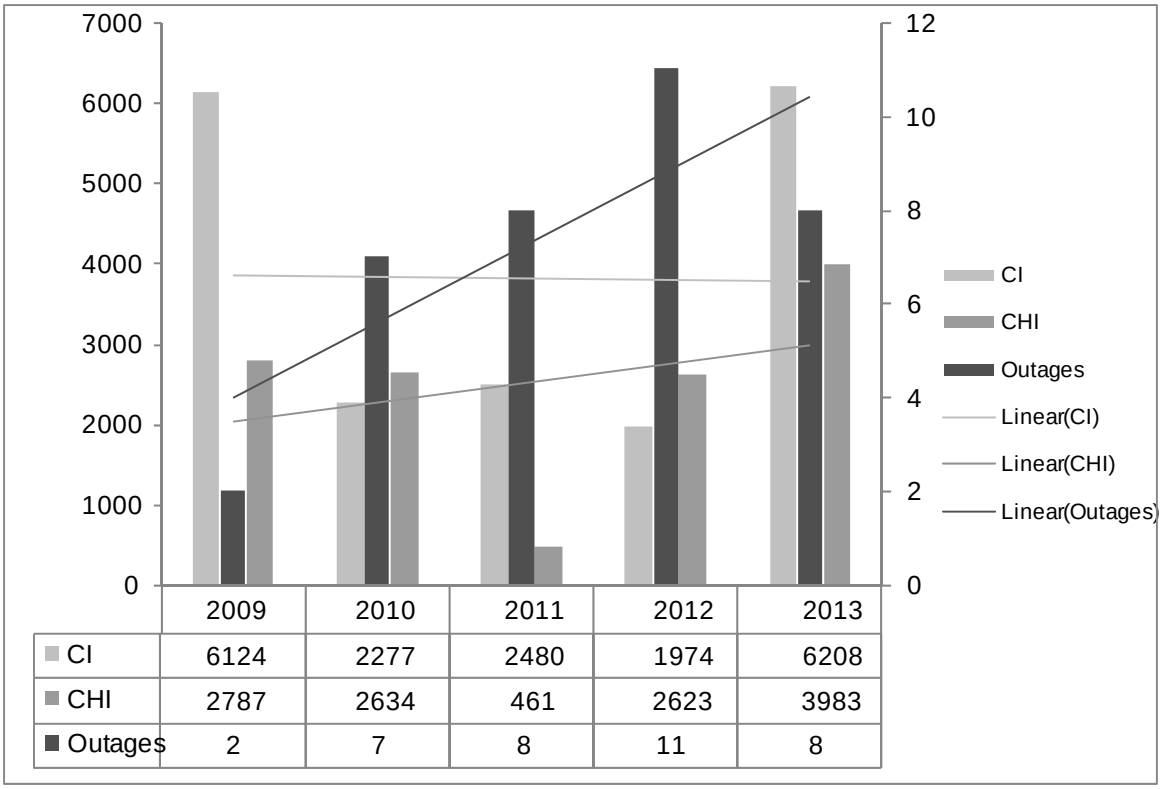
This project was created to replace the aged and unreliable assets to minimize both failure risk to the system and safety risk to field crews and the public while maintaining system reliability.



NOTE:

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 47: SUPPLEMENTAL DETAILS



Supplemental Details	Description
Age/Condition	x Switches, transformers and direct buried cable ƒ Assets installed 1957 (57 years old)
Reliability	ƒ Instead of rebuilding of unreliable 4kV distribution, the existing load from Burbank MS is to be converted to 27.6kV that offers better back up supply in the event of contingency condition
Other (i.e. road moratoriums, etc)	ƒ N/A

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 49 and 50.

E12428, E12380 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Rebuild of NY51M4 Consumers Rd & Victoria Park Areas – Civil/ Electrical NY51M4

Project Number: E12428, E12380

Project Year: 2015

Estimated Cost: $ 1,882,546.00

(i) Objective

Replace aged and failing assets along the feeder, proactively to increase system reliability and service to customers.

E12428 will install the civil infrastructure necessary to complete the project. E12380 will complete the electrical portion of the project.

(ii) Scope of Work

TABLE 51: SCOPE OF WORK DETAILS

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

E13046 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E13046 NY53M26 UG Rebuild in Curlew and Victoria Park areas – Civil

Project Number: E13046

Project Year: 2015

Estimated Cost: $348,912

(i) Objective

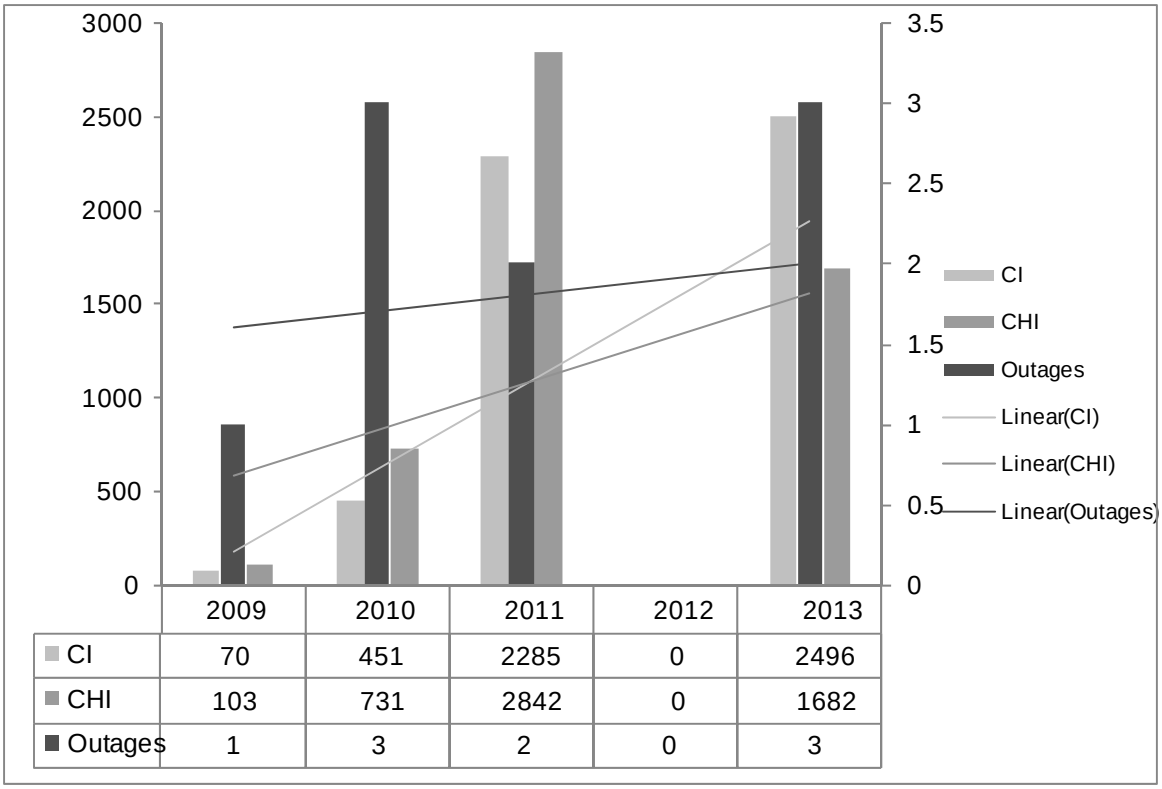
This project is to provide the necessary civil structures when solid-core direct buried cables are removed from the feeder in scope E13039 and replaced with those enclosed concrete encased ducts.

Replace the existing direct buried solid-core cables with TR-XLPE cable in concrete encased duct. E13046 will install the civil infrastructure necessary to complete the project.

(ii) Scope of Work

TABLE 73: SCOPE OF WORK DETAILS

District Neighborhood	Don Valley East
Station(s):	Bermondsey TS
Feeder(s):	NY53M26



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 74: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ Direct buried cables ƒ Installed 1976 (38 years old)
Reliability	ƒ N/A
Other (i.e. road moratoriums, etc)	ƒ Direct buried cables in project area are operating past their estimated useful service life and need to be addressed before failures occur

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 62.

Assets to be Replaced

E13065 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Rebuild of SCNAE5-1M25 by Brimley Rd and Skagway Avenue - Electrical

Project Number: E13065

Project Year: 2015

Estimated Cost: $392,239

(i) Objective

To address the cable failure reported in December 2010 per ITIS incident: F-2010-1473; proactively reduce the probability of a system failure by replacing the aged direct buried cable. E13065 will complete the electrical portion of the ICM approved project.

(ii) Scope of Work

TABLE 75: SCOPE OF WORK DETAILS

District Neighborhood	Don Valley East
Station(s):	Leslie 1 TS
Feeder(s):	SCNAE5-1M25

E13069 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E13069 NY51M24 UG Rebuild North of Finch – Civil

Project Number: E13069

Project Year: 2015

Estimated Cost: $430,208

(i) Objective

Replace aged direct buried cable from NY51M24 in the area northwest area of Finch Avenue E and Don Mills road intersection. E13069 will install the civil infrastructure necessary to complete the ICM approved project.

(ii) Scope of Work

TABLE 78: SCOPE OF WORK DETAILS

E13621 Project Description

Investment Category: **System Renewal**

Program: **Underground Circuit Renewal**

Project Title: **Brandy Court P and C Civil/Elec NY53M24**

Project Number: **E13621**

Project Year: **2015**

Estimated Cost: **$113,533**

(i) Objective

Replace US96182 with an SF6, PMH-9 equivalent pad switch as the current switch has a protection/control issue. E13621 replaces assets that pose a higher reliability risk to the system. To increase efficiency, this project combines the civil and electrical work.

(ii) Scope of Work

E14116 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E14116 DB Cable Replacements on SS63F1-Cummer & Maxome area-Civil

Project Number: E14116

Project Year: 2015

Estimated Cost: $262,347

(i) Objective

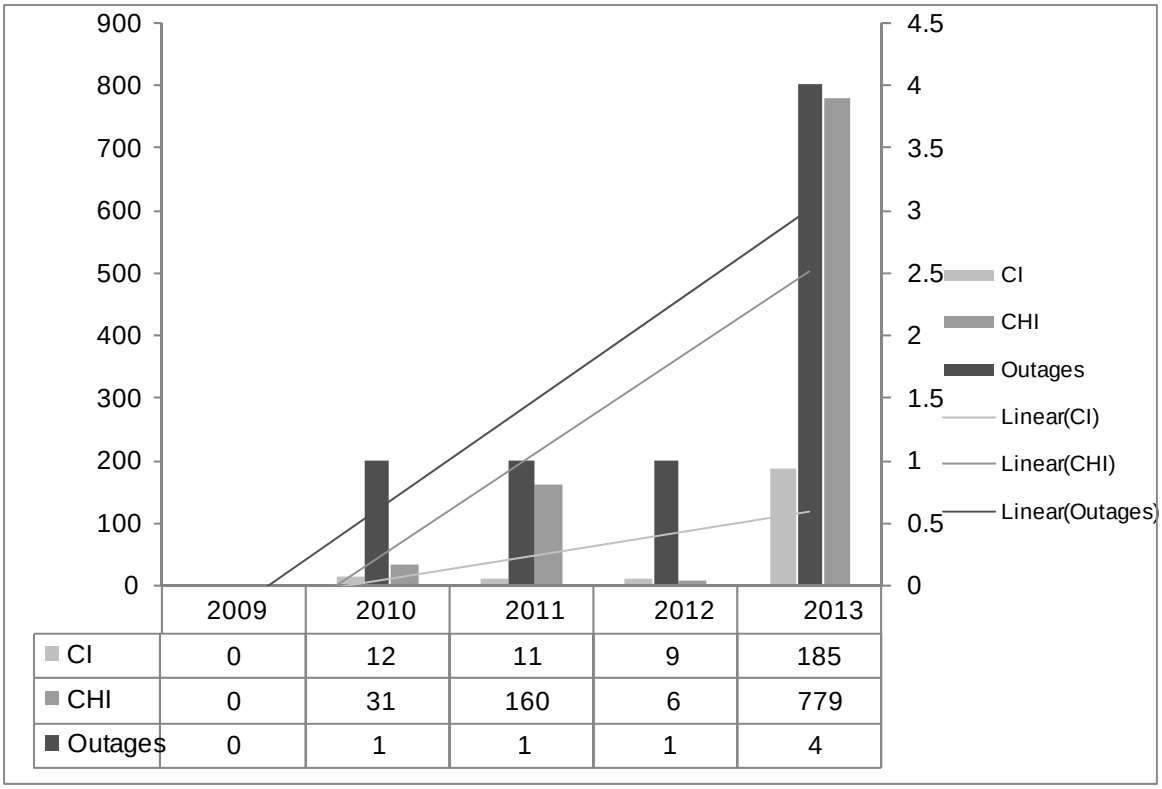
Replace direct buried cable along feeder NYSS63F1 specifically along Algo Court, Donna Court and the stretch from Maxome Avenue to Cummer Valley MS - areas located near Maxome Avenue and Cummer Avenue intersection in North York. This will help improve reliability and service to customer.

E14116 will install the civil infrastructure necessary to complete the project.

(i) Scope of Work

TABLE 96: SCOPE OF WORK DETAILS

District Neighborhood	Willowdale
Station(s):	Estelle MS
Feeder(s):	NYSS63F1, NY80M4



(ii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 97: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	x Switches, transformers and direct buried cable ƒ Assets installed 1958 (56 years old)
Reliability	ƒ Estelle MS has experienced power outage each year from 2009 to 2012 and escalated to 4 power outages in 2013
Other (i.e. road moratoriums, etc)	ƒ Result of an inspection in May 2011 confirmed the presence of Friable Asbestos, Corrosion, Dirt, Debris and Contamination as well as damaged doors in Estelle MS

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 74.

E14141 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E14141 UG Rebuild 502M32 Eastwood SD- Civil

Project Number: E14141

Project Year: 2015

Estimated Cost: $1,442,504

(i) Objective

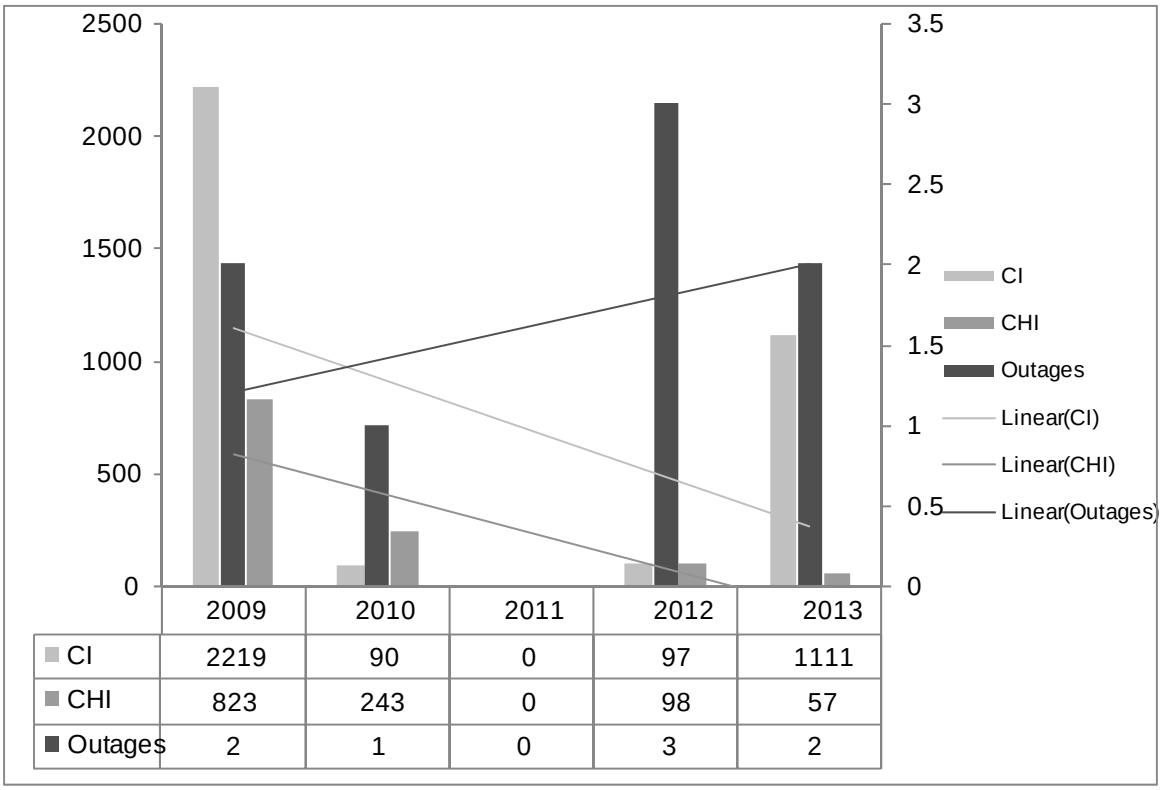
Replace the old and failing primary cables in the area of Brownspring Rd, Hallbank Terr, Charterhouse Rd, Lawnmere Cres, Tidworth Sq, Hayward Cres, Keyworth Trail and a section of Pilfield Rd (area known as Eastwood subdivision) supplied by feeder NAE502M32. E14141 will install the civil infrastructure necessary to complete the project.

(ii) Scope of Work

TABLE 98: SCOPE OF WORK DETAILS

District Neighborhood	Scarborough-Rouge River
Station(s):	Cavanaugh TS (27.6kV)
Feeder(s):	SCNA502M32

(iii) Justification & Benefits



Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 99: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ Cable in direct buried duct ƒ Installed 1988 (26 years old)
Reliability	ƒ Moderate reliability along this feeder ƒ Majority of underground outages have been due to submersible

Supplemental Details	Description
	transformers which are targeted for replacement in the Underground Circuit Renewal program
Other (i.e. road moratoriums, etc)	ƒ All transformers in the project area are due for replacement in 2015 ƒ Cables in direct buried duct are due for replacement in 2017; ƒ It is more prudent and cost effective to initiate the replacement in 2015. In this way the project will be completed by 2016 (i.e. cables replaced a year earlier and transformers replaced a year later than scheduled)

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 75.

E14322 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E14322 Establish Neilson Tapscott R26M34 Main – Electrical

Project Number: E14322

Project Year: 2015

Estimated Cost: $737,921

(i) Objective

To establish Neilson to Tapscott R26M34 feeder main (running along Finch Ave) by replacing the existing old and direct buried cable. Operations needs this circuit as part of feeder main linking R26M22. E14322 will complete the electrical portion of the ICM approved project.

(ii) Scope of Work

TABLE 119: SCOPE OF WORK DETAILS

District Neighborhood	Scarborough Rouge River
Station(s):	Malvern TS (27.6kV)
Feeder(s):	SCNAR26M34

TABLE 120: ASSETS TO BE REPLACED

E14411 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E14411 Crow Tr Remaining UG Rebuild Civ and Elec R26M34 SCNAR26M34

Project Number: E14411

Project Year: 2015

Estimated Cost: $473,989

(i) Objective

To complete the rebuild of the crow trail distribution by replacing the old direct buried cables in the remaining area. This project will install a SCADA SF6 pad switch (PMH-11 type) replacing the existing air insulated one. This was an operational requirement suggested by Operations group. E 14411 will install the civil infrastructure necessary to complete the project.

(ii) Scope of Work

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E15233 Woody Vineway & Curly Vineway UG renewal 51M6 NY51M6

Project Number: E15233

Project Year: 2015

Estimated Cost: $290,478

(i) Objective

Replace aged underground assets installed in the area of "Woody Vineway" and "Curly Vineway" on Leslie St south of Fince Av. E. E15233 will complete the electrical portion of the project.

(ii) Scope of Work

TABLE 149: SCOPE OF WORK DETAILS

District Neighborhood	Don Valley East

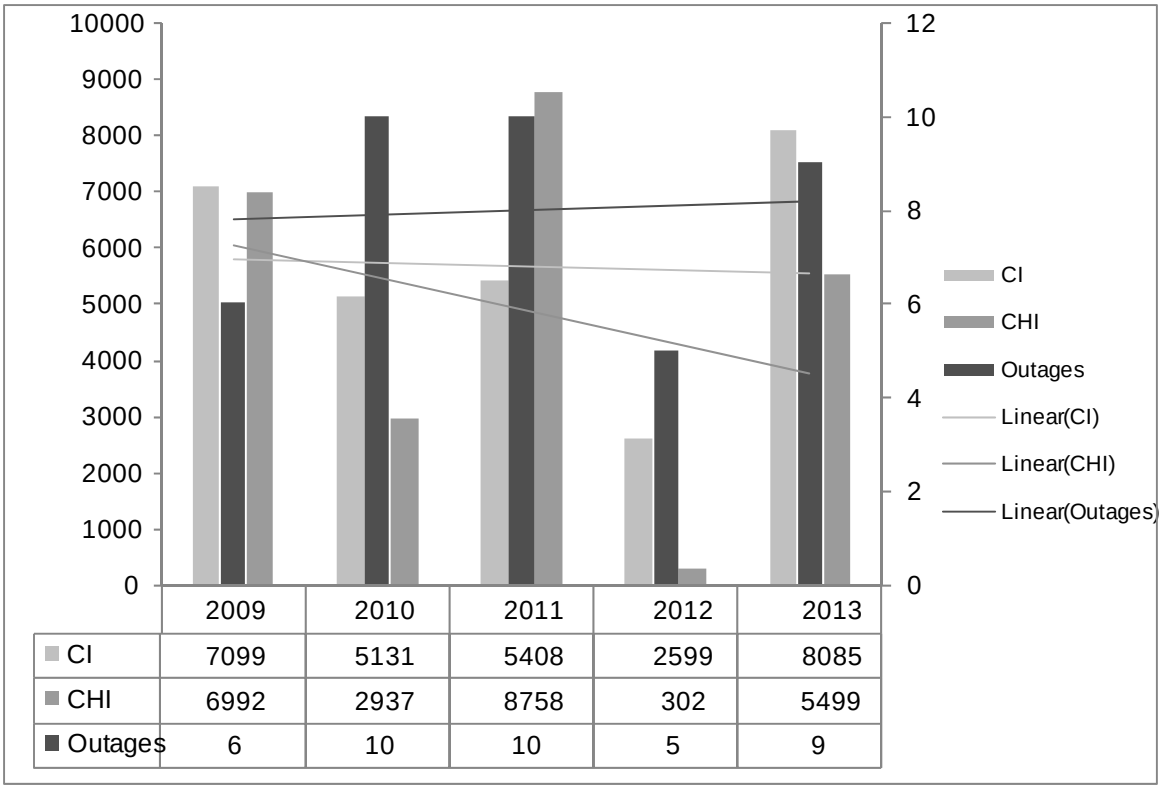
Underground Transformers	18
Underground Switchgear	1
Poles	0
Overhead Transformer	0
Overhead Switch	0



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 151: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ Direct buried cable ƒ Installed around 1950 (approx. 64 years old)
Reliability	ƒ 51M6 has been performing poorly with an average of 8 power outages per year during the past 5 years ƒ Majority of failures seen in the past five years due to primary cable and submersible transformers; both of which are targeted for replacement in the Underground Circuit Renewal program
Other (i.e. road moratoriums, etc)	ƒ This is the electrical portion of the project and needs to be completed to help improve reliability in the area

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 95.

E15267 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: E15267 -P162 Bermondsey Trunk UG Renewal Elec 53M2, M12, M27, M28 NY

Project Number: E15267

Project Year: 2015

Estimated Cost: $1,687,487

(i) Objective

Replace assets on feeders 53M2, 53M12, 53M27 and 53M28 which have reached and/or exceeded their estimated useful service life. E15267 will complete the electrical portion of the project.

(ii) Scope of Work

TABLE 152: SCOPE OF WORK DETAILS

E15390, E15392, E15393, E15397 E16131 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Scunthorpe Invergordon UG Rebuild Phases B, D, E and G - Civil SCNAH9M26; Scunthorpe Invergordon UG Rebuild Phase D - Electrical SCNAH9M26

Project Number: E15390, E15392, E15393, E15397, E16131

Project Year: 2015

Estimated Cost: $5,421,180

(i) Objective

Replace old, direct-buried primary cables in the area of Scunthrope Rd and Invergordon Ave. The distribution will be reconfigured to have more operational flexibility and better protection. E15390 will install the civil infrastructure necessary to complete this project.

E15392 will install the civil infrastructure necessary to replace the single phase direct-buried primary cables in the area of West Burton Ct, Prince William Crt, 5021 Sheppard Ave TH, Wyper Sq, part of Massie St and Thistlewaite Cres,. E16131 will complete the electrical portion of this project.

E15393 will install the civil infrastructure necessary to replace the single phase old direct-buried primary cables in the area of Plum Brook Cres, sections of Massie St, Thistlewaite Cres, Invergordon Ave.

E15397 will install the civil infrastructure necessary to replace the single phase old direct-buried primary cables in the area of Spring Forest Sq, Pennybrook Ln and Scunthorpe Rd.

(ii) Scope of Work

Assets to be Replaced	
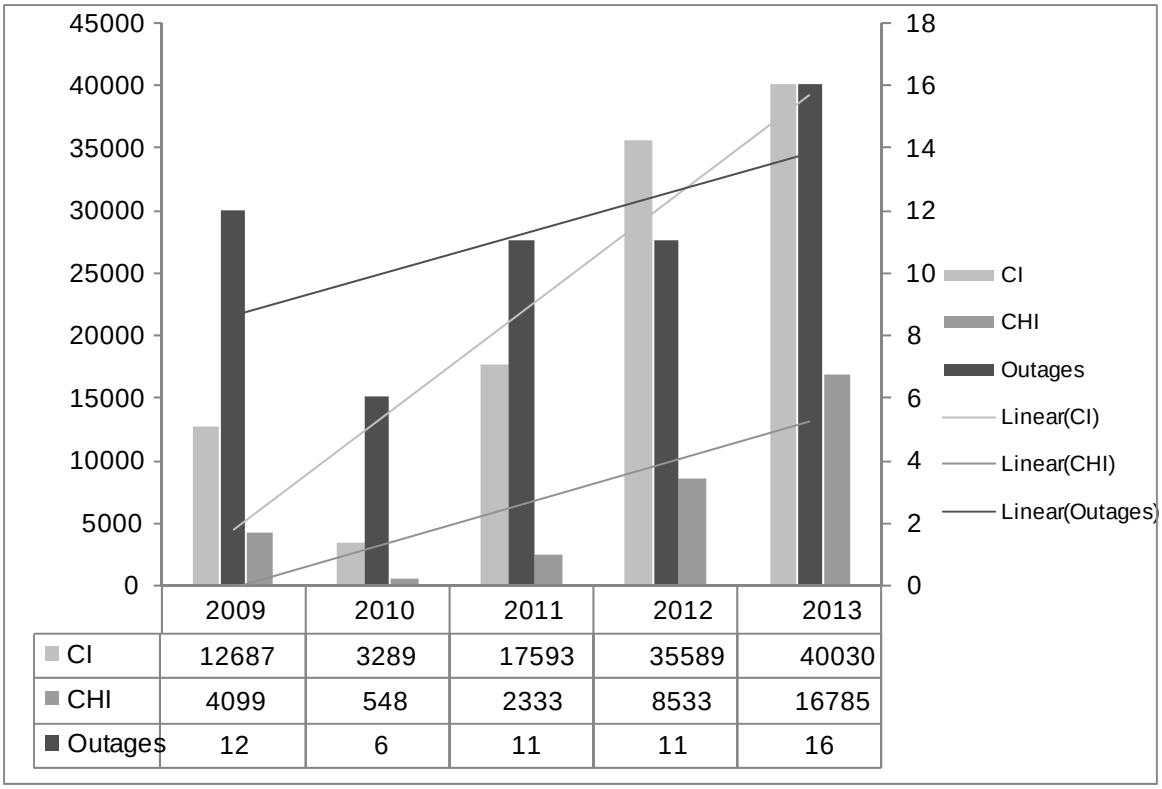
Primary Cable	1,815.68m
Underground Transformers	0
Underground Switchgear	0
Poles	0
Overhead Transformer	0
Overhead Switch	0



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 209: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	• Cable in duct • Installed around 1980 (approx. 34 years old)
Reliability	• The feeders within the cable chambers have experience six outages due to underground failure • The egress cable (overhead or underground) is one of the most important sections of the feeder, since it is the supply point from the circuit breaker to the feeder. If the egress cable fails, the entire feeder and all customers connected will experience and outage • Three out of four underground egress cables in the project area are Paper Insulated Lead Covered (PILC) cable and one is XLPE unshielded cable • Heat generated from the XLPE unshielded cable is causing the PILC to fail significantly sooner than expected. • PILC cables have started to melt due to the heat resulting in outages within the cable chambers • Field inspections and photos have shown the damage and the deterioration of the cable
Other (i.e. road moratoriums, etc)	• PILC cable is not a standard cable due to high cost, work difficulties and environmental concerns • This is the electrical portion of the project and needs to be completed to help improve reliability in the area

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 120.

Project Number: W12308

Project Year: 2015

Estimated Cost: $1,290,728

(i) Objective

Replace direct buried primary with new TRXLPE. E12308 will complete the electrical portion of the project.

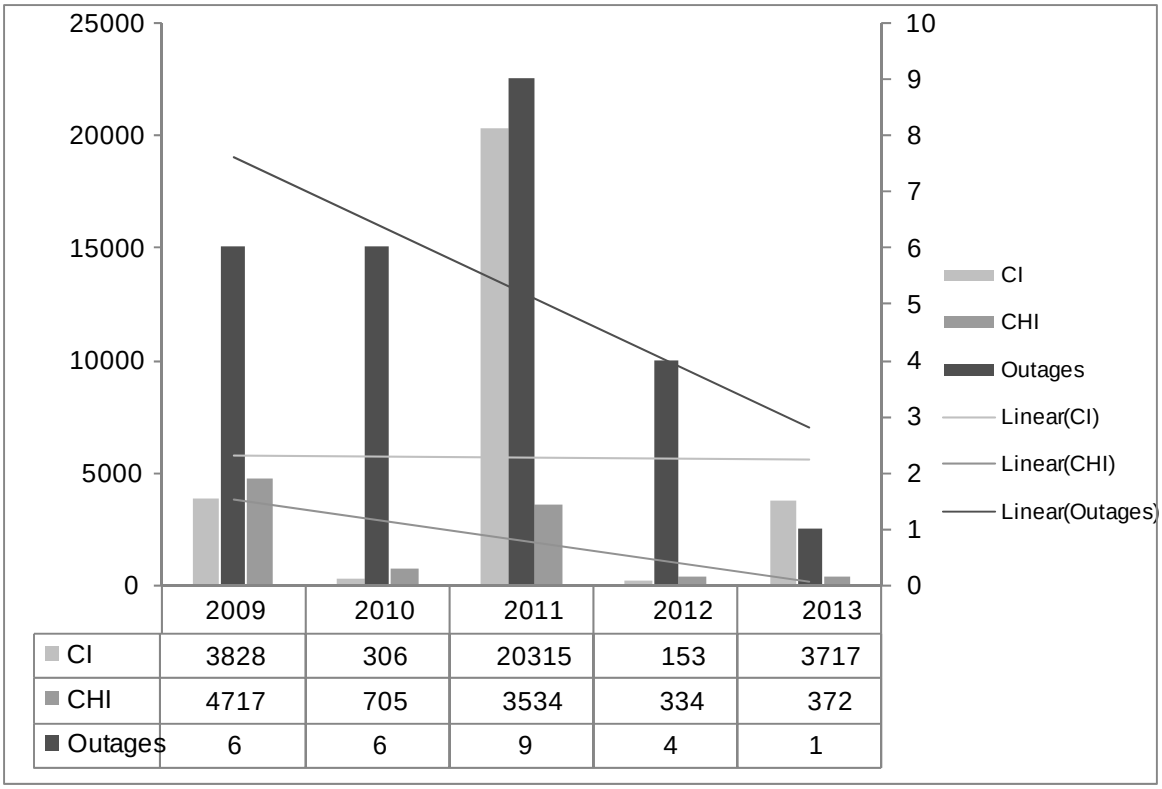
(ii) Scope of Work

TABLE 224: SCOPE OF WORK DETAILS

District Neighborhood	Etobicoke North
Station(s):	Finch II TS (27.6 kV)
Feeder(s):	NY55M25

TABLE 225: ASSETS TO BE REPLACED

Assets to be Replaced	
Primary Cable	1,469.31 m
Underground Transformers	6
Underground Switchgear	0
Poles	2
Overhead Transformer	1
Overhead Switch	0



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 226: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	• Direct buried cable • Installed around 1982 - 1988 (approx. between 26 - 32 years old)
Reliability	• The overall reliability of the feeder has improved over the past five years • The feeder still continues to experience outages due to poor performance of assets that are past their end of life like underground transformers and cable
Other (i.e. road moratoriums, etc)	• Project will include a reconfiguration of the area • This is the electrical portion of the project and needs to be completed to help improve reliability in the area

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 127.

W12480, W13114 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Primary Trunk Cable Replacement - The East Mall

Project Number: W12480, W13114

Project Year: 2015

Estimated Cost: $1,182,468

(i) Objective

To improve reliability of poorly performing feeders: ETHL-F1 and ETHL-H3. W12480 combines the civil and electrical work required to complete the project.

(ii) Scope of Work

TABLE 227: SCOPE OF WORK DETAILS

District Neighborhood	Etobicoke Centre
Station(s):	Blaketon (4.16kV)
Feeder(s):	ETHL-F1, ETHL-F3

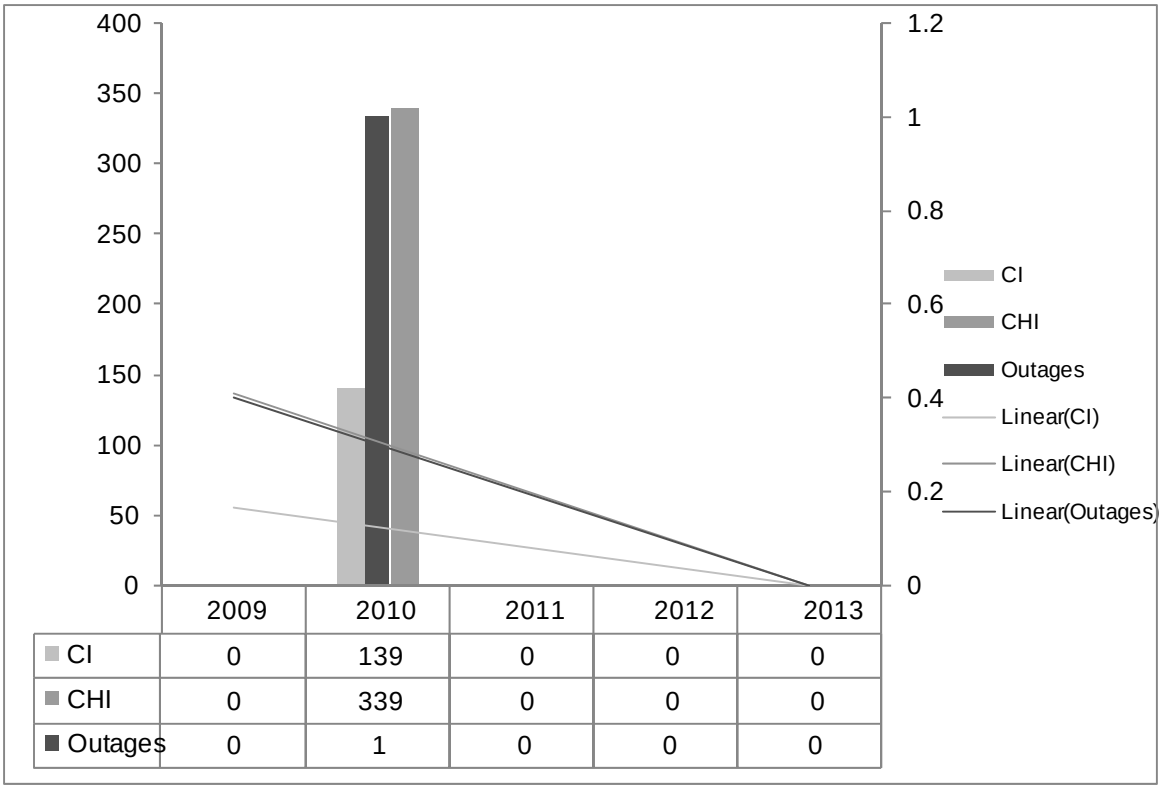
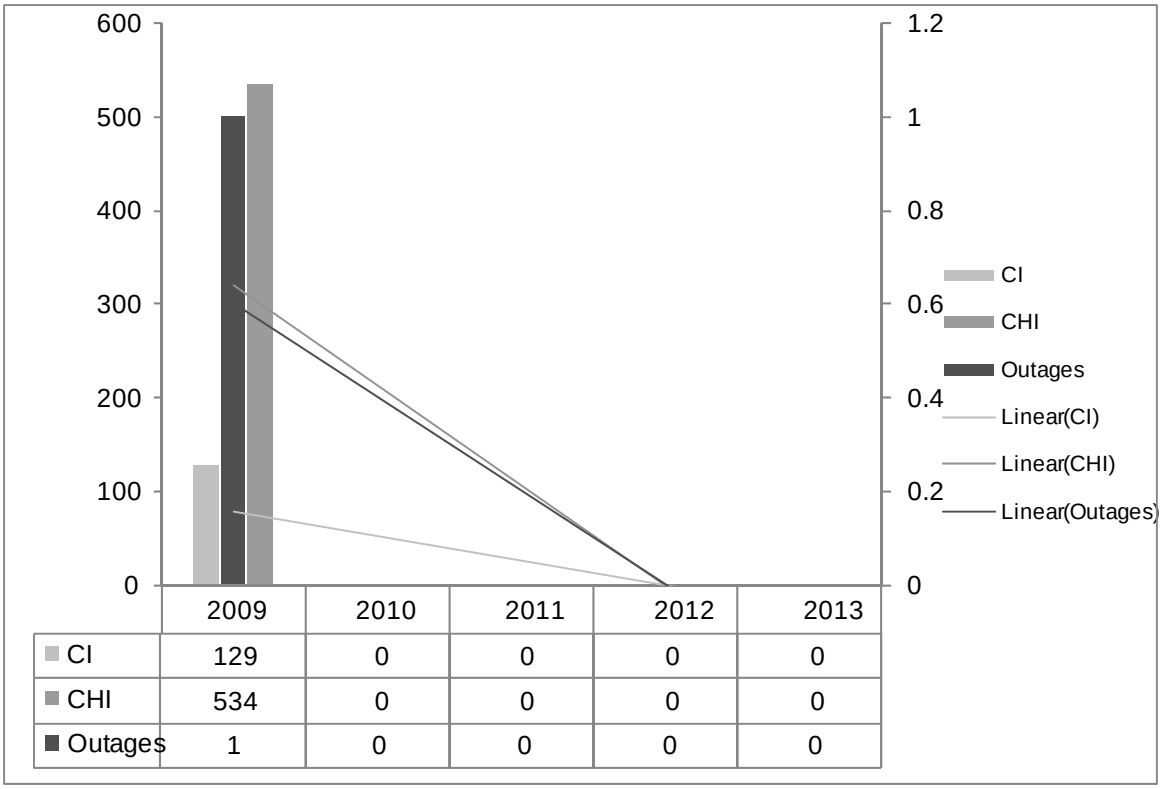
Overhead Switch	0



(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 229: SUPPLEMENTAL DETAILS



Supplemental Details	Description
Age/Condition	ƒ End of life switches, transformers and cable in duct ƒ Assets installed around 1964 (over 50 years old)
Reliability	ƒ Reliability weakening along feeders ƒ Increasing CI, CHI and Outages seen along HLF2, HLF3 and HLF4
Other (i.e. road moratoriums, etc)	ƒ Customers in the area had complained of the high incidence of outages in 2013 ƒ Cables include egress from Blaketon MS which makes failures high impact as all 275 customers are served by cables to be replaced by these scopes

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 128 and 129.

W14130 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Rebuild Russfax & Twin Circle Crt

Project Number: W14130

Project Year: 2015

Estimated Cost: $439,236

(i) Objective

Rebuild the OH and UG distribution on Russfax and Twin Circle Crt to improve reliability. W14130 combines both the civil and electrical work required to complete the project.

(ii) Scope of Work

TABLE 233: SCOPE OF WORK DETAILS

District Neighborhood	York Centre
Station(s):	Bathurst TS (27.6kV)
Feeder(s):	NY85M7

W14653 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: W14653-P01-Richview Feeder Egress via Kelfield Rd

Project Number: W14653

Project Year: 2015

Estimated Cost: $1,341,461

(i) Objective

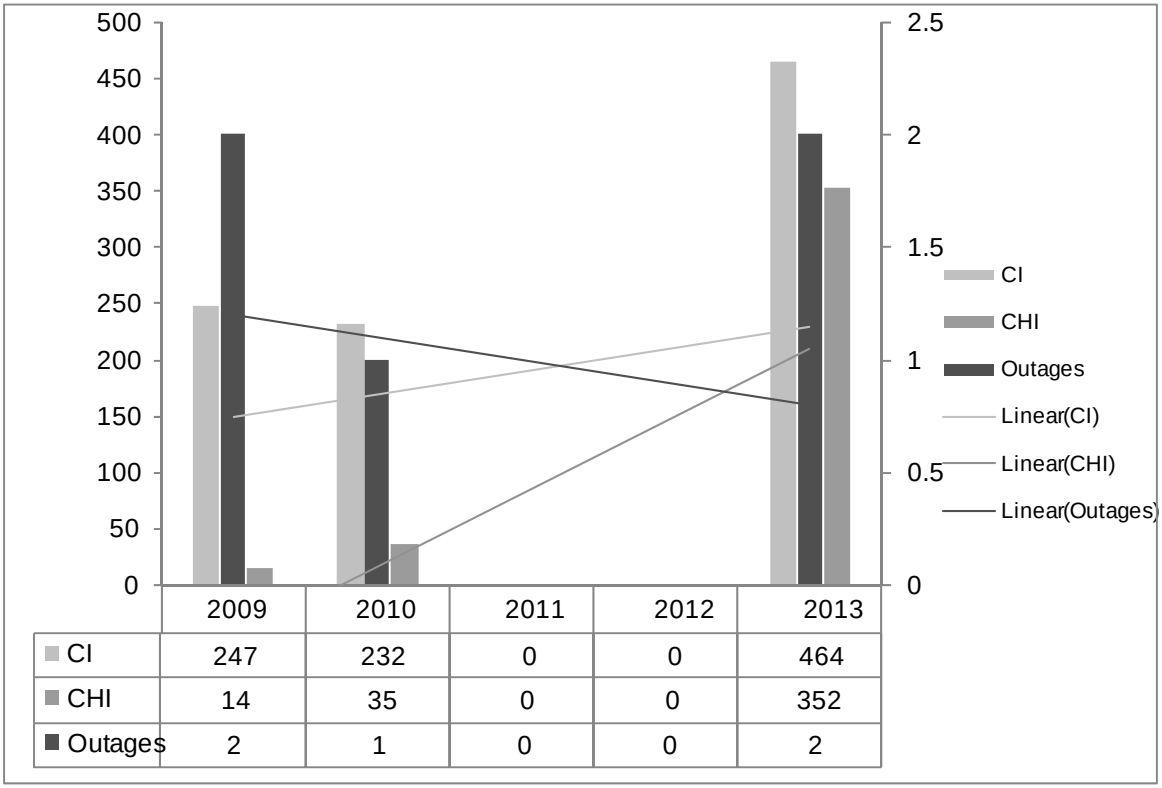
Build an underground egress for feeders to exit Richview TS and extend beyond the congested ROW and highways around the station. W14653 installs the civil infrastructure necessary to complete the ICM approved project.

(ii) Scope of Work

TABLE 241: SCOPE OF WORK DETAILS

District Neighborhood	Etobicoke York
Station(s):	Richview (27.6kV)
Feeder(s):	88 M3

(iii) Justification & Benefits



Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 242: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ N/A (project created to accommodate new egress cables)
Reliability	ƒ Will provide capacity relief to South Etobicoke and power Eglinton LRT

Supplemental Details	Description
	ƒ Provide contingency to re-supply areas that are high loaded and are at risk of being stranded during an outage
Other (i.e. road moratoriums, etc)	ƒ New duct banks to accommodate new feeders out of Richview TS ƒ Egress to extend cables out of congested area and right of ways ƒ Moratorium on Dixon expires in 2015 ƒ Extension in 2016 to at risk areas

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 134.

W15268, W15269 Project Description

Investment Category: **System Renewal**

Program: **Underground Circuit Renewal**

Project Title: **P01 - Red Robinway & Arnott UG Direct-Buried Cable Renewal Civil/Electrical**

Project Number: **W15268, W15269**

Project Year: **2015**

Estimated Cost: **$1,086,141**

(i) Objective

Rebuild the direct-buried cable in the Robinway and Arnott area distribution, which has been subjected to multiple historical cable failures.

W15268 will install the civil infrastructure necessary to complete the project; W15269 will complete the electrical portion of the project.

(ii) Scope of Work

W15278 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: W15278 The East Mall area UG Voltage Conversion Civil LDF1, LDF2 and LDF3 LDF1

Project Number: W15278

Project Year: 2015

Estimated Cost: $622,916

(i) Objective

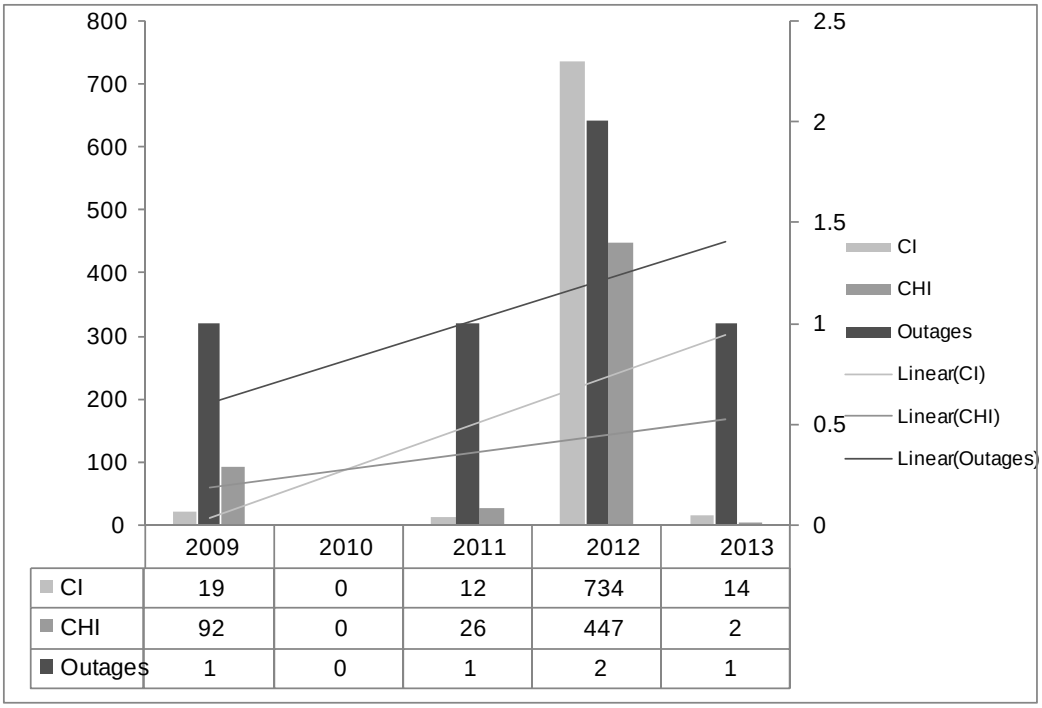
Rebuild laterals off the OH feeder 38M10 to renew the aging and mal-operating infrastructure thereby restoring distribution reliability in the area. W15278 will install the civil infrastructure necessary to complete the project.

(ii) Scope of Work

TABLE 248: SCOPE OF WORK DETAILS

District Neighborhood	Etobicoke Lakeshore
Station(s):	Cloverdale MS
Feeder(s):	LDF1, LDF2 and LDF3

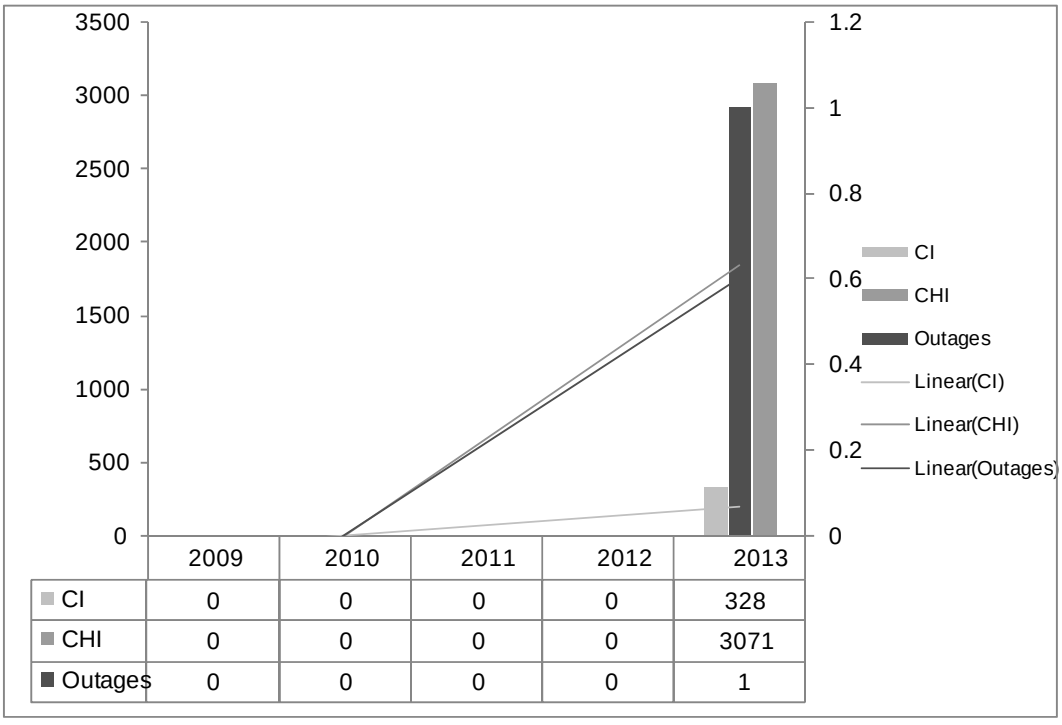
(iii) Justification & Benefits



Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 249: SUPPLEMENTAL DETAILS

Supplemental Details	Description
Age/Condition	ƒ End of life switches, transformers and cable in duct ƒ Assets installed around 1964 (over 50 years old) ƒ Feeder patrols in the summer of 2013 have confirmed that the condition of Cloverdale MS feeders LDF1, LDF2 and LDF3 are



Supplemental Details	Description
	deteriorated and need to be replaced with newer assets (via this voltage conversion project)
Reliability	• Reliability has been weakening over past two years for both LDF-1 and LDF-2 • Increasing CI and CHI for the past two years • The renewal OH and UG infrastructure in the scope addresses and mitigates the increasing number of outage incidents due to feeder equipment defects and failures
Other (i.e. road moratoriums, etc)	• Customers in the area had complained of the high incidence of outages in 2013 • Cloverdale MS has a difficult operating situation as there are currently no RTUs in the station. This scope enables the complete close-out of the substation, avoiding the need for capital investment in new communication equipment

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 137 and 138.

W15298 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: W15298 West of Kipling Avenue, UG Voltage Conversion AHF2, AHF5

Project Number: W15298

Project Year: 2015

Estimated Cost: $573,753

(i) Objective

Rebuild parts of the Fieldway MS feeders west of Kipling Avenue via voltage conversion before the end of 2015 to avoid islanding of the distribution in the area after feeders from Shaver MS and West Islington MS have been converted by scopes W14658, W14659 and W15276 in 2014. W15298 will combine the civil and electrical work required to complete the project.

(ii) Scope of Work

TABLE 252: SCOPE OF WORK DETAILS

W15462 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: W15462 Alcester Crt Underground Rebuild 35M7

Project Number: W15462

Project Year: 2015

Estimated Cost: $304,772

(i) Objective

Rebuild the underground direct buried supply at Alcester Crt. W15462 will combine the civil and electrical work required to complete this project.

(ii) Scope of Work

X15590 Project Description

Investment Category: System Renewal

Program: Underground Circuit Renewal

Project Title: Electrical Work for the Replacement of A60CS and A61CS

Project Number: X15590

Project Year: 2015

Estimated Cost: $72,565

(i) Objective

Replace existing A60CS and A61CS which are currently suspended underneath the first segment of the Prince Edward Viaduct, over Rosedale Valley Rd, via messenger cable. X15590 will complete the electrical portion of the project.

(ii) Scope of Work

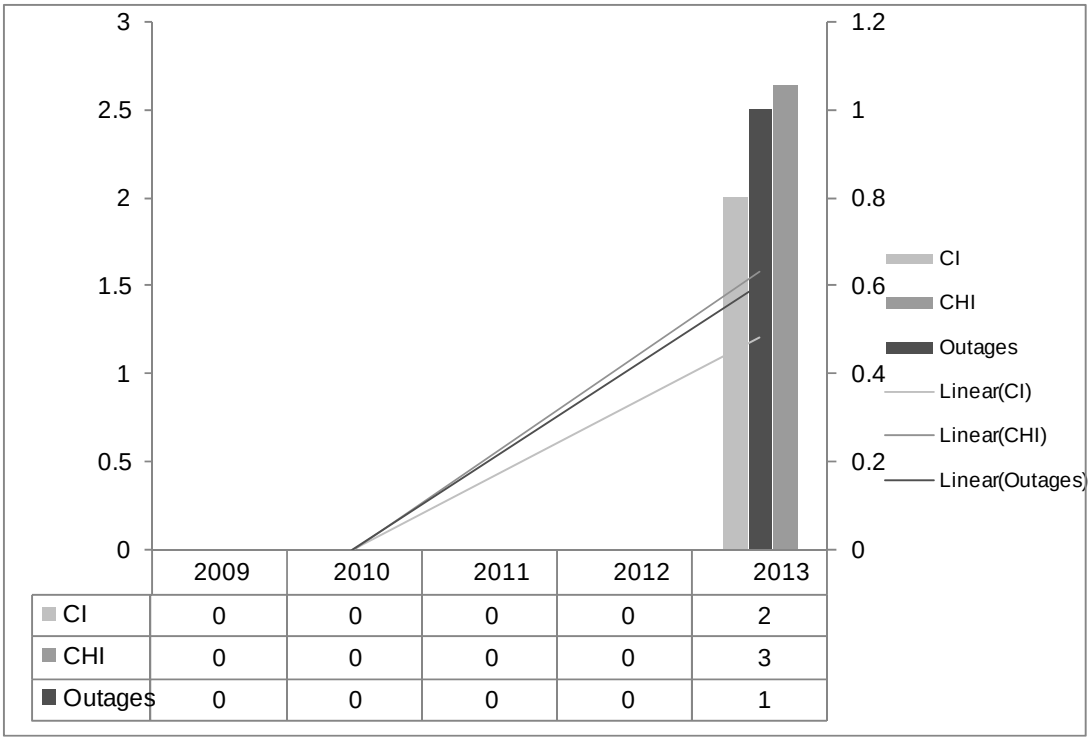
(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 274: SUPPLEMENTAL DETAILS



Supplemental Details	Description
Age/Condition	• Cable located under bridge (not in duct) – suspended via messenger cable • Installed 1962 (52 years old)
Reliability	• Historical failures in the project area have occurred on segments adjacent to the bridge crossing • Reactive crews indicate that if the cable fails again it will need to be completely replaced • Cables are network/dual radial configured therefore a large outage impact is not shown in figures XYZ and XYZ • All three incidents recorded here were cable faults which tripped the station breaker, taking out the entire feeder placing the network under a first contingency
Other (i.e. road moratoriums, etc)	• There is no resupply option on the other side of the bridge suitable to supply the TTC station • Replacement of the infrastructure under the bridge is the most prudent option to maintain reliability to customers fed from these feeders • Other options would require significant new civil infrastructure to be built

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 149 and 150.

E6.2 Paper-Insulated Lead-Covered Leakers & Cable Piece-Outs

SUSPENDED PILC CABLES

E6.2.1 Summary

Program Description

The Paper-Insulated Lead-Covered (PILC) Leakers & Cable Piece-Outs program is a continuation of the activities previously described in the Ontario Energy Board (OEB) approved PILC Cable – Piece Outs and Leakers segment of Toronto Hydro's 2012-2014 rate application[1].

The objective of this ongoing program is to replace and repair leaking PILC cables and to piece-out and properly rack any cable in congested chambers. As outlined in Toronto Hydro's previous rate filing, the PILC Piece-Out and Leakers program involves three activities that address three distinct issues with existing PILC cable:

- Repair/Replacement of leaking PILC cables
- Replacement of PILC cables on the High Level TS – Bridgman TS (B-HL) express feeder
- "Piecing out" of PILC cable in congested cable chambers[2]

[1] EB-2012-0064, Tab 4, Schedule B2.

The anticipated benefits of the Paper-Insulated Lead-Covered (PILC) Leakers and Cable Piece-Out program are as follows:

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduced risk of prolonged outages for Toronto Hydro customers
Reliability	ƒ Reduced repair time on underground feeders in cable chambers with leaking PILC cables
Safety	ƒ Improved working conditions in cable chambers for Toronto Hydro employees ƒ Improved public safety: reduced risk of faults in cable chambers mitigates the risk of cable chamber lids dislodging.
Efficiency	ƒ Improved operational flexibility during contingency events ƒ Enhanced efficiency of underground crews during service restoration efforts ƒ Reduced resource time on leaking PILC cable enables crews to perform additional planned capital or maintenance work
Environment	ƒ Mitigates possible negative impacts on the environment

Program Drivers

As established in Toronto Hydro's 2012-2014 rate application, the PILC Leakers and Cable Piece-Outs program is required to manage the substantial asset failure risks associated with leaking cables and to mitigate safety hazards that have caused injuries and near misses to underground workers in the past.

The trigger and secondary drivers for the PILC Leakers and Cable Piece-Outs program are as follows.

TABLE B: PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	Failure Risk	ƒ Water ingress in corroded cables leads to higher failure risk ƒ Cable cannot predictably perform at an acceptable standard as it deteriorates ƒ Cracked and leaking cables have reduced insulation,

[2] As discussed more fully in Section E6.2.2.3, "piecing out" refers to the process of extending a cable in a chamber, usually by adding an additional piece of cable, such that it has the correct length to allow placement on cable racks, thereby permitting ample clearance for personnel entering a cable chamber, and also providing proper support to prevent damage to the cable.

	Drivers	Reasoning
		reducing dielectric strength and increasing the risk of failure and potential flashover ƒ Increased mechanical stresses due to cable being suspended in congested chambers
Secondary Drivers	Safety	ƒ Compromised insulation can lead to electrical contact hazards ƒ Reduced dielectric strength can lead to faults or arc flashes ƒ Congested chambers often contain trip hazards ƒ Congested chambers lack proper clearance to handle cable
	Reliability	ƒ Requirement to de-energize and repair all feeders with leakers prior to crews' entry into the cable chambers prolongs outage duration ƒ Operating in congested cable chambers slows power restoration efforts.

Preferred Alternative

The PILC Leakers and Cable Piece-Out program analyzed and evaluated the following options

(1) Do nothing and replace on a reactive basis only

(2) To mitigate safety risks, de-energize all of the PILC primary cables in a given cable chamber prior to entry of a worker

(3) Repair leading cables and perform piece outs on an emergency basis

(4) Proactive repair of leakers and piece out of cable chambers

Option IV is the preferred alternative, as it allows work to proceed in a planned and cost-efficient way, focusing on the highest priority areas. Feeders with multiple leakers and chambers requiring piecing out can be scheduled for isolation and all of the associated hazards and defects can be addressed at the same time while the feeder is out of service.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $3.89 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets. Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.44 million, confirming the economic prudence of the investments.

Timing and Pacing

Toronto Hydro is committed to substantially reducing the backlog of known leakers and congested chambers within a reasonably short timeframe in order to mitigate associated failure and safety risks. With the exception of the 2012 and 2013 budget years (which are lower due to the timing of the decision for Phase 1 of Toronto Hydro's 2012-2014 rate filing), historical expenditures reflect the urgency of the work required and the emphasis Toronto Hydro has placed on removing leaking cable.

Table C provides a summary of the five year historical spend on the Underground Circuit Renewal program or its equivalent as well as projected spending from 2015 to 2019.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	5.47	1.47	2.44	4.73	3.45	1.38	0.73	0.81	0.51

Once the B-HL tie-feeder replacement project and the majority of the known piece out and leaker issues are rectified, Toronto Hydro anticipates a reduction in capital spending required in the latter years of the 2015-2019 planning horizon, as PILC cable is gradually replaced throughout the system through other capital projects and customer connections.

The estimated total capital budget for this program is $6.9 million for the 2015-2019 forecast period.

E6.2.2 Program Description

The objective of Toronto Hydro's ongoing Paper-Insulated Lead-Covered (PILC) Leakers and Cable Piece-Outs program is to replace and repair leaking PILC cables and to piece-out and properly rack any cable in congested chambers.

PILC cable is a type of underground cable that has supplied Toronto's downtown core since the early 1900s. The cable consists of a conductor that is insulated by oil-impregnated paper and protected by an outer lead sheath that prevents exposure of the cable to environmental and mechanical elements. There is approximately 12,946 km of underground cable in Toronto Hydro's distribution system and of that, approximately 3,969 km is PILC. The remaining cable supplies several commercial and industrial customers on the 13.8 kV and 4.16 kV distribution systems and in some instances used on the "express" feeders that link one substation to another.

As outlined in Toronto Hydro's previous rate filing, the PILC Piece-Outs and Leakers program involves three activities that address three distinct issues with existing PILC cable:

- Repair/Replacement of leaking PILC cables
- Replacement of PILC cables on the High Level TS – Bridgman TS (B-HL) express feeder
- "Piecing out" of PILC cable in congested cable chambers[3]

Each of these activities is described in detail in the following subsections. Toronto Hydro estimates that the total cost of this program will be approximately $6.89 million over the 2015-2019 planning horizon.

In total, the PILC Leakers and Piece-Outs program will be replacing approximately 15 km of PILC cable over the five-year period as illustrated in Table 1. Approximately 4 km of this is associated directly with the B-HL tie feeder replacement project in 2014 and the remaining amount is for the leaking cable replacement and cable piece out projects as described in E6.2.2.1 and E6.2.2.3 respectively.

TABLE 1 : ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
PILC Cable (km)	5.39	3.66	2.59	2.66	0.70	15.00

[3] As discussed more fully in Section E6.2.2.3; "piecing out" refers to the process of extending a cable in a chamber, usually by adding an additional piece of cable, such that it has the correct length to allow placement on cable racks, thereby permitting ample clearance for personnel entering a cable chamber, and also providing proper support to prevent damage to the cable.

E6.2.2.1 Repair/Replacement of PILC Leaker Cables

Over time, due to load fluctuations and physical stresses on feeder cables, the outer covers of PILC cables can develop cracks, causing oil from the paper insulation to leak from the cable and pool on the cable chamber floor. Figure 1 shows PILC cables that have oil leaking from the cable and from the splice.

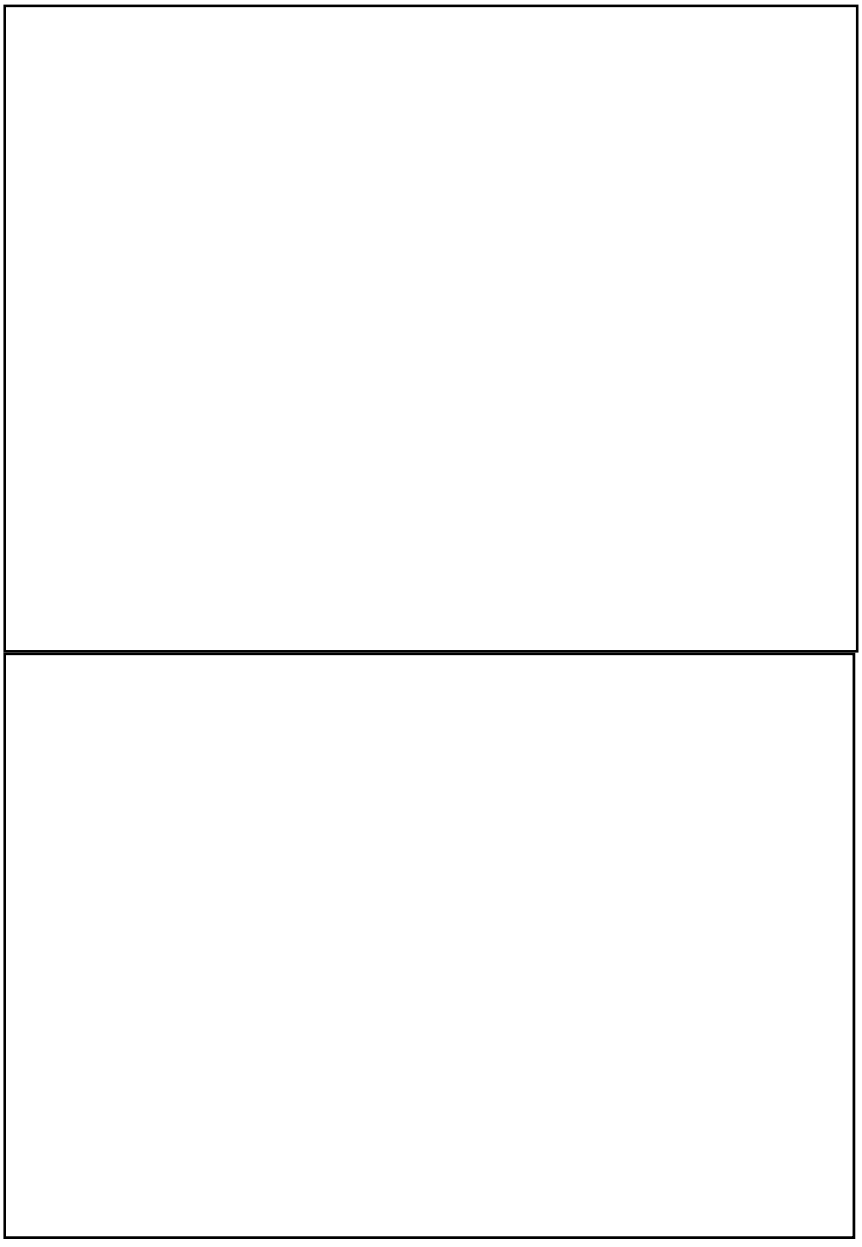

FIGURE 1: LEAKING PILC CABLE WITH OIL POOLED ON FLOOR OF CHAMBER

Leaking PILC cables can present risks to crew safety, system reliability and environmental integrity (these risks and impacts are detailed and further discussed in section E6.2.3). Toronto Hydro maintains a list of all known locations with leaking PILC cables and continues to address these cables through discrete, geographically-based repair and replacement projects that are established using several prioritization criteria (refer to section E6.2.4.1 for details). Prior to designing and executing a repair/replacement project, crews typically inspect the identified leaker sites in the defined area and identify any new leaks that have occurred since the last inspection. For each leaking splice or segment of cable, the designer and crews determine whether (a) the use of a heat shrink splice repair (Raychem) kit, (b) installation of a new sleeve, or (c) installing a new segment of cable is the best course of action.

E6.2.2.2 B-HL Express Feeder Leaker Replacement

The express feeders supplying Toronto Hydro's High Level Transformer Station (TS) from the Hydro One Networks Inc. (HONI) power transformers at Bridgman Transformer Station (TS) are a unique case of PILC leakers. Collectively known as the B-HL feeders, these station ties contain leakers in several cable chambers along the route, to the extent that existing cable segments are beyond repair (Figure 2). The leaking B-HL cables have been the primary cause of over 20 feeder faults since 2011, with all of these faults subsequently tripping HONI's station protection schemes. These faults have a large impact on the reliability of Toronto Hydro's supply to High Level TS, which serves approximately 13,600 customers in the St. Paul's area of Toronto. To prevent further issues along this critical supply path, Toronto Hydro will continue replacing the damaged cables along the feeder route.

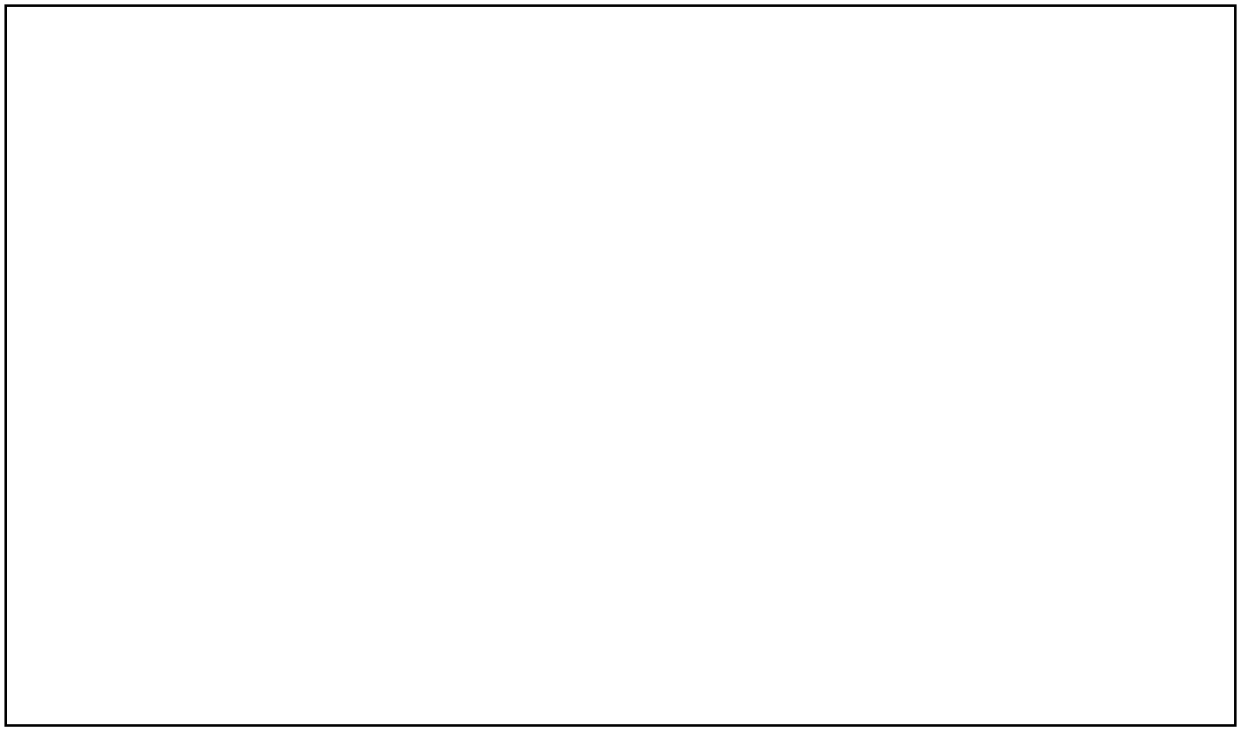

FIGURE 2: AREA OF WORK FOR B-HL TIE FEEDERS PROPOSED FOR REPLACEMENT

This is a larger scale project that Toronto Hydro is addressing in several phases over a planned multi year period that began in 2013 and has continued through 2014. The first three phases of the project, which included the installation of new civil infrastructure to enable the replacement of the B-HL tie feeders, were included in the OEB approved PILC Leakers and Piece-Outs segment in the May 2012 ICM Phase 1 application and the 2014 Phase 2 update. Table 2 below shows the actual capital spending for each phase of the previous filing (as of April 2014).

TABLE 2: HISTORICAL SPENDING FOR B-HL CABLE REPLACEMENT

Year	Actuals ($M)
2012-2013 (Total)	1.27
2014 (YTD as of April)	1.04
2014 (Total Forecast)	3.48

Due to the magnitude and the complexity of this project, Toronto Hydro expects to complete the replacement of the identified B-HL tie feeders by 2017. (Remaining proposed forecasted spending is detailed in section E6.2.4.)

E6.2.2.3 Piecing Out PILC in Congested Cable Chambers

In addition to rectifying the instances of leaking PILC cables, Toronto Hydro continues to address the congestion and cluttering of cables that is common in downtown cable chambers. As the system has grown, many cable chambers have become congested with the addition of new customers and services in the downtown core. With new connections and increasing loads, the addition of primary and secondary cables in old and small legacy "football" shaped cable chambers as led to congestion and cluttered work spaces. In some instances, cable chambers were rebuilt to provide additional space, however existing cables were left suspended or hanging.

The process of extending and racking the existing cable is termed "piecing out" the cables and entails adding sufficient length to the existing cable to allow for its placement on cable racks. Toronto Hydro's practice is now to piece out cables to allow crews safe access and egress after a chamber rebuild is complete. As seen in Figure 3, the cables in the chamber are not racked and are instead tied and bundled in an arrangement that leads to congestion and difficult work spaces.

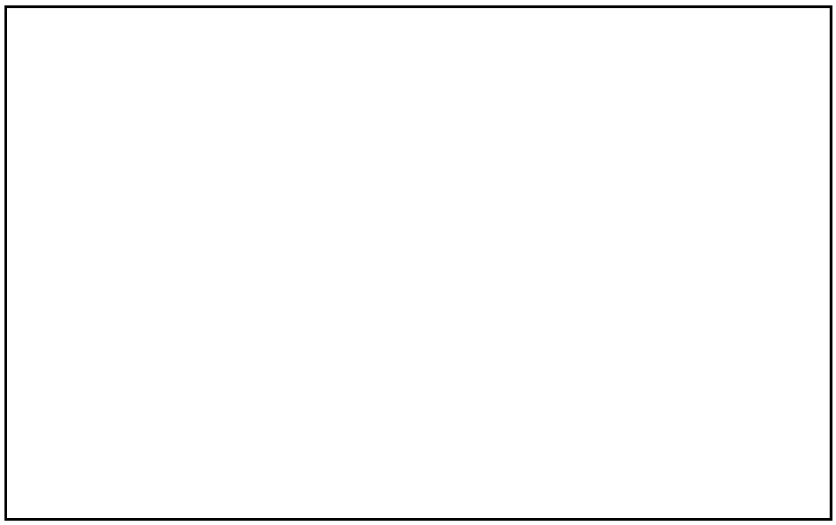

FIGURE 3: CABLE CHAMBER WITH CABLES THAT REQUIRE PIECING OUT

Toronto Hydro plans to continue to address the issue of congested chambers by inspecting each identified chamber and formulating a detailed work plan to restore the chambers to a proper arrangement as per Toronto Hydro standards. In addition, this work will also ensure that Toronto Hydro is in compliance with Electrical Utilities Safety Rules (EUSR) provision 141 (7) which requires cables to be properly supported. Figure 4 shows a chamber with properly racked cable after a piece out.

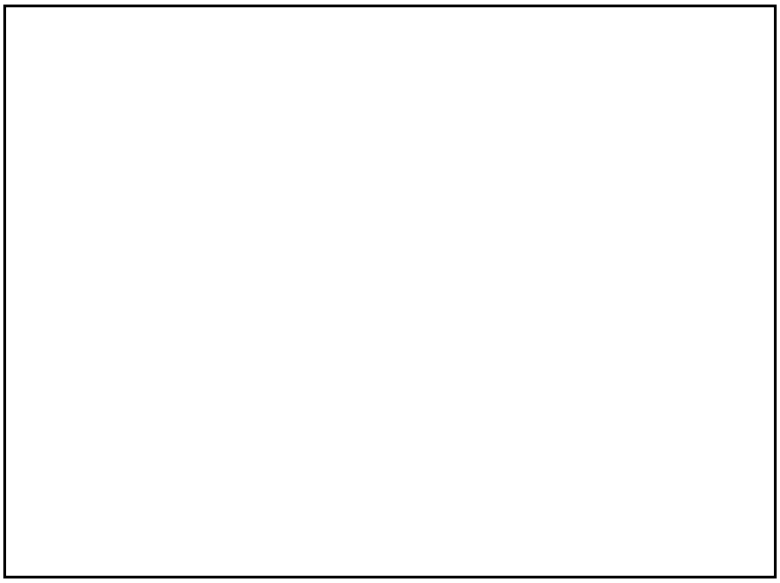

FIGURE 4: CABLE CHAMBER WITH PROPERLY RACKED CABLES

Figure 5 illustrates all proposed locations of work for this program over the 2015-2019 period across the Toronto Hydro system.

FIGURE 5: MAP OF CABLE CHAMBER LOCATIONS REQUIRING PIECING OUT OR LEAKERS REPAIR

As detailed in the three activities outlined above, Toronto Hydro anticipates that the PILC Leakers and Cable Piece Outs program will deliver several program benefits. These are summarized in Table 3 below.

TABLE 3: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduced risk of prolonged outages for Toronto Hydro customers ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $3.89 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.2.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.44 million, confirming the economic prudence of the investments (see Section E6.2.7).
Reliability	ƒ Reduced repair time on underground feeders in cable chambers with leaking PILC cables. ƒ Reduced risk of prolonged outages for Toronto Hydro customers
Safety	ƒ Improved working conditions in cable chambers for Toronto Hydro employees ƒ Improved public safety: reduced risk of faults in cable chambers mitigates the risk of cable chamber lids dislodging.
Efficiency	ƒ Improved operational flexibility during contingency events ƒ Enhanced efficiency of underground crews during service restoration efforts ƒ Reduced resource time on leaking PILC cable enables crews to perform additional planned capital or maintenance work
Environment	ƒ Mitigates possible negative impacts on the environment

E6.2.3 Why the Program is Needed

As established in Toronto Hydro's previous rate filing, the PILC Leakers and Cable Piece-Outs program is required to manage the substantial asset failure risks associated with leaking cables and to mitigate safety hazards that have caused injuries and near misses to underground workers in the past.

Until about 1990, Toronto Hydro did not consider cracked and leaking cables to be defective and confined space work practices had not yet matured. It was normal operating practice to work in and around the energized leaking PILC cable and move the energized cable out of the way to make enough room to enter, work in and exit chambers. Over the past 20 years, work practices have matured and, today, leaking PILC cables like the one shown in Figure 6 below are

considered defective and a source of potential safety hazards to workers, environmental concerns and remediation requirements.

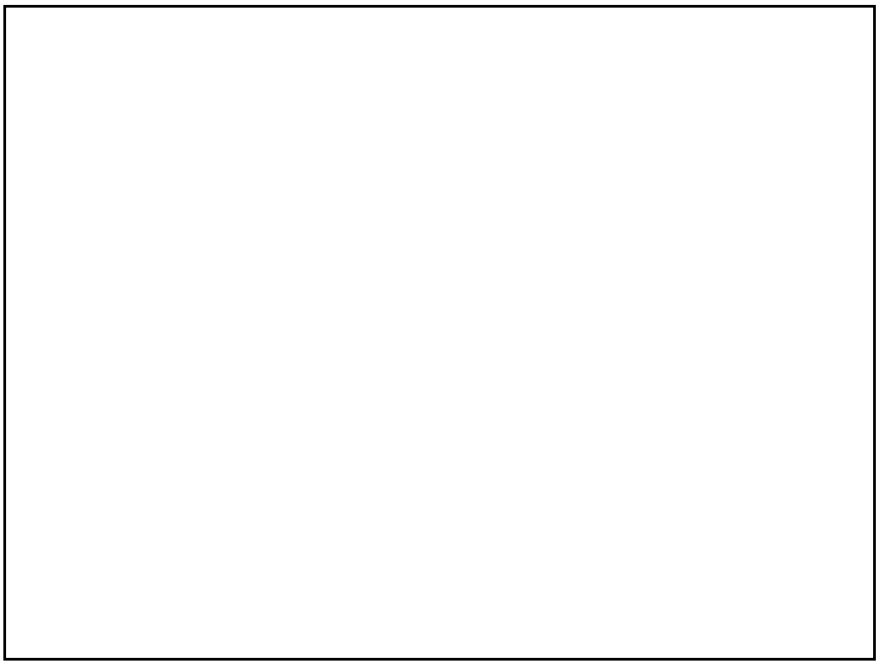

FIGURE 6: OIL LEAKING FROM PILC CABLE

The chambers that require piecing out are also safety hazards, as the crews cannot generally enter them without exposing themselves to trip hazards and work space limitations. Moreover, by piecing out and properly racking the cables in the newly rebuilt chambers, Toronto Hydro ensures that crews can quickly and safely access all cables in a chamber in the event of a fault. As discussed in section E6.2.3.2, this can reduce the likelihood of prolonged outages on the underground system, which can occur if crews are required to operate in congested cable chambers or cable chambers containing leaking PILC cables.

E6.2.3.1 Program Drivers

Table 4 presents the primary and secondary drivers for the PILC Leakers and Cable Piece-Outs program. This program is a System Renewal initiative because the primary driver is Failure Risk.

TABLE 4: PROGRAM DRIVERS

	Drivers	Reasoning
Primary Driver	Failure Risk	ƒ Water ingress in corroded cables leads to higher failure risk ƒ Cable cannot predictably perform at an acceptable standard ƒ Reduced insulation to cable, reducing dielectric strength ƒ Increased mechanical stresses due to cable being suspended
Secondary Drivers	Safety	ƒ Compromised insulation can lead to electrical contact hazards ƒ Reduced dielectric strength can lead to faults or arc flashes ƒ Congested chambers may contain trip hazards ƒ Congested chambers lack proper clearance to handle cable
	Reliability	ƒ Requirement to de-energize and repair all feeders with leakers prior to crews' entry into the cable chambers prolongs outage duration ƒ Operating in cluttered cable chambers slows down the crews' power restoration efforts.

Failure risk is the primary driver for the PILC piece out and leakers program. The compromised state of leaking PILC cable prevents it from performing at its rated capacity and standard. This is because the insulation of the leaking cable is now reduced due to the continuous water ingress as a result of the cables being submerged under water in flooded cable chambers. This reduced insulation results in an increased probability of failure. In addition, the escaping oil from the leaking cable compromises the dielectric strength of the cable. This increases the cable's potential to fault or cause an arc flash. The resulting failures can have substantial cascading impacts on customer outages, safety and reliability.

Similarly, failure risk is an issue for hanging cable and congested cable chambers. Over time, when a cable is left hanging or suspended in a position similar to the one identified in Figure 3 shown in section E6.2.2.3, a mechanical stress is exerted on the cable which will weaken the cable insulation and jacket. This leads to more rapid cable deterioration and combined with increased probability of movement and physical contact due to the congestion, the failure risk for these cables is higher.

While the risk of cable failure is itself a reliability and potential safety risk, leaking and hanging cable further impacts reliability because of the need to de-energize the cable and repair all defects prior to performing additional work in a chamber. These required work practice

procedures can prolong contingency situations where customers are at risk of extended outages. These scenarios and their resulting impacts are discussed in detail in the Asset Failures Impact subsection in the following Asset Details section.

Safety is also a critical secondary driver of this program. Being an inherently weak point on the feeder as described above, leaking PILC cable introduces the risk of sudden feeder faults, arc flashes, and electrical contact hazards to workers. Congested chambers and hanging cable also create potentially hazardous working conditions for crews when performing work in the chamber. Cluttered cables result in tripping hazards as well less working space for crews to handle cable. By removing these risks from the system, risks to worker as well as public safety can be mitigated. Limiting crew exposure to faulty and cluttered cable will reduce the likelihood of the types of injuries and near misses described below:

Arc Flash Hazards – In December 2011, a PILC cable on the B-HL tie feeders faulted and resulted in a near-miss arc flash while the crews were working in the chambers. Upon investigation of the incident, crews discovered numerous leaking PILC cables in the cable chambers along the feeder route. Crews have now flagged these chambers as hazardous and can potentially refuse entry for work.

Flash Burns from an Improperly Racked PILC Splice – In April 2007, while descending into a cable chamber, a worker made contact with a PILC cable splice that required piecing out. The cable in question was not properly racked, but running unsupported and directly beneath the cable chamber opening. The worker received flash burns to his face, neck and shins, and sustained further fall-related injuries.

Cable Splice Fault – In May 2013, an incident occurred resulting in damage to five feeders and a catastrophic failure that propelled the chamber lid off the roof and onto the road. The crews investigating the incident reported that the cable chamber contained a PILC splice that was extremely damaged, which likely led to improper insulation and possible leaking. A cable splice in this condition may not be able to withstand fault current passing through it and the result could be enough heat and force to propel the chamber lid in the air. Figure 7 below shows the splice after the incident occurred.

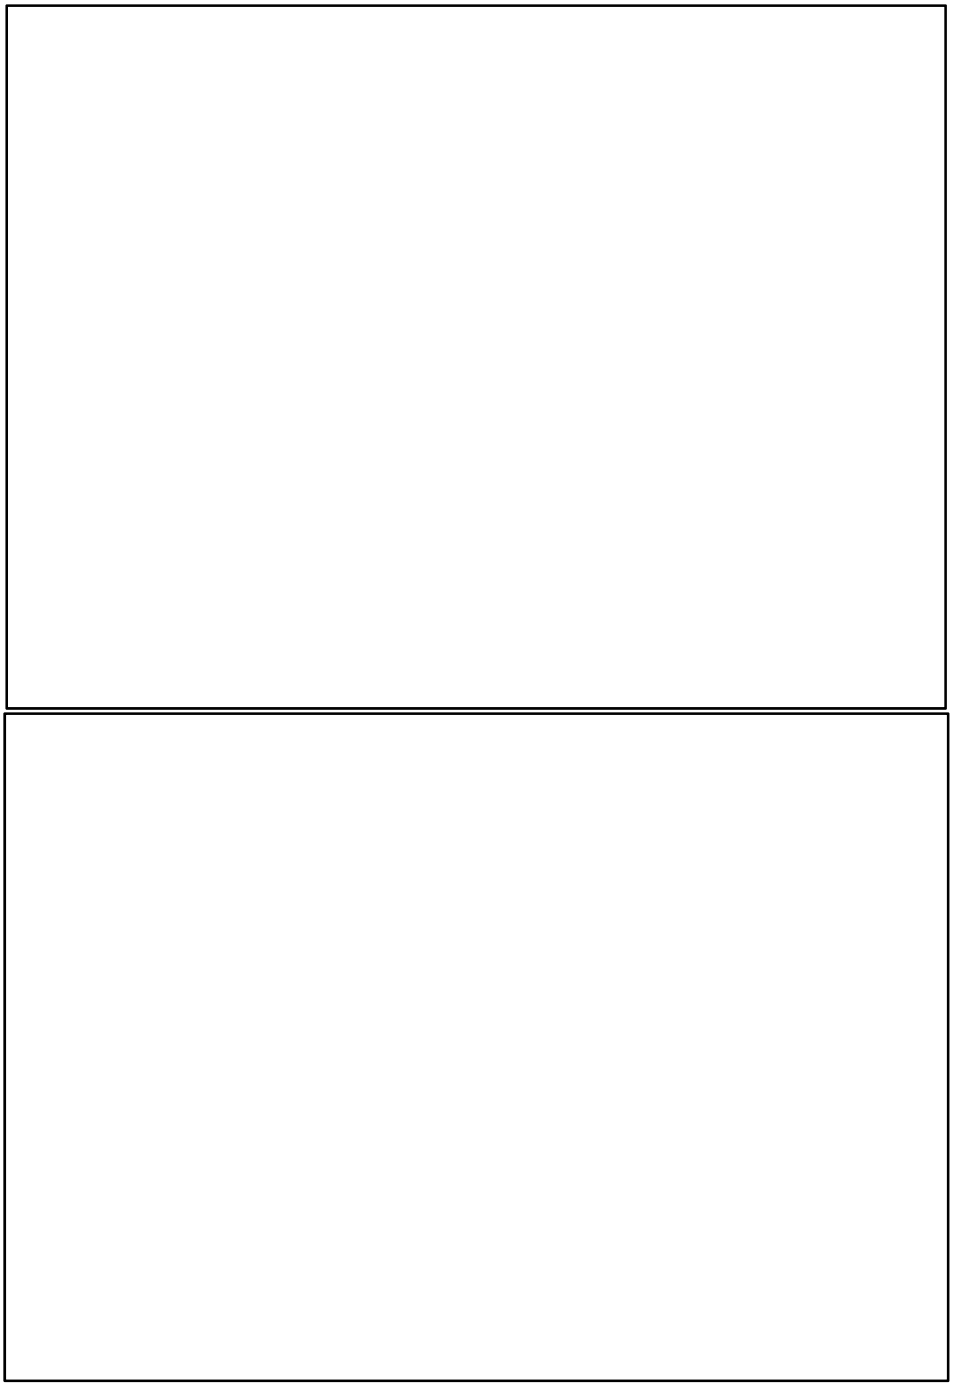

FIGURE 7: PILC SPLICES FROM MAY 2013 INCIDENT

E6.2.3.2 Asset Details

(i) Asset Lifecycle

The majority of cable to be replaced or repaired under this program is over 25 years old. While PILC cable can be reliable and operational for over 75 years, the cable being targeted in the PILC Leakers portion of the program are all segments of cable that have reduced reliability and increased failure risk due to the presence of pinhole leaks on the cable or at the splice due to cracking or stress fractures. The need for intervention stems from these deficiencies that significantly reduce the reliability of the asset.

If the cable surface is damaged, moisture can penetrate into the insulation, causing rapid degradation of the insulation itself and the expulsion of oil that helps maintain the cable's dielectric properties. These deficiencies compromise the cable's insulation properties and increase the electrical stress on the conductor, thereby reducing cable reliability.

An illustrative example of PILC cables with reduced useful life is the aforementioned B-HL tie feeders scenario. On average, the cables comprising the feeder are 60 years old, which is within the normal 75-year lifecycle. However, control room reports and outage data indicate that there have been approximately 22 cable-related faults on the B-HL feeders during the 36 month period between January 2011 and December 2013. (Moreover, during the week of November 24 to November 30, 2012, the same tie feeders reportedly tripped 5 times.) Figure 8 illustrates these outages on the B-HL tie feeders which all lasted over 12 hours.

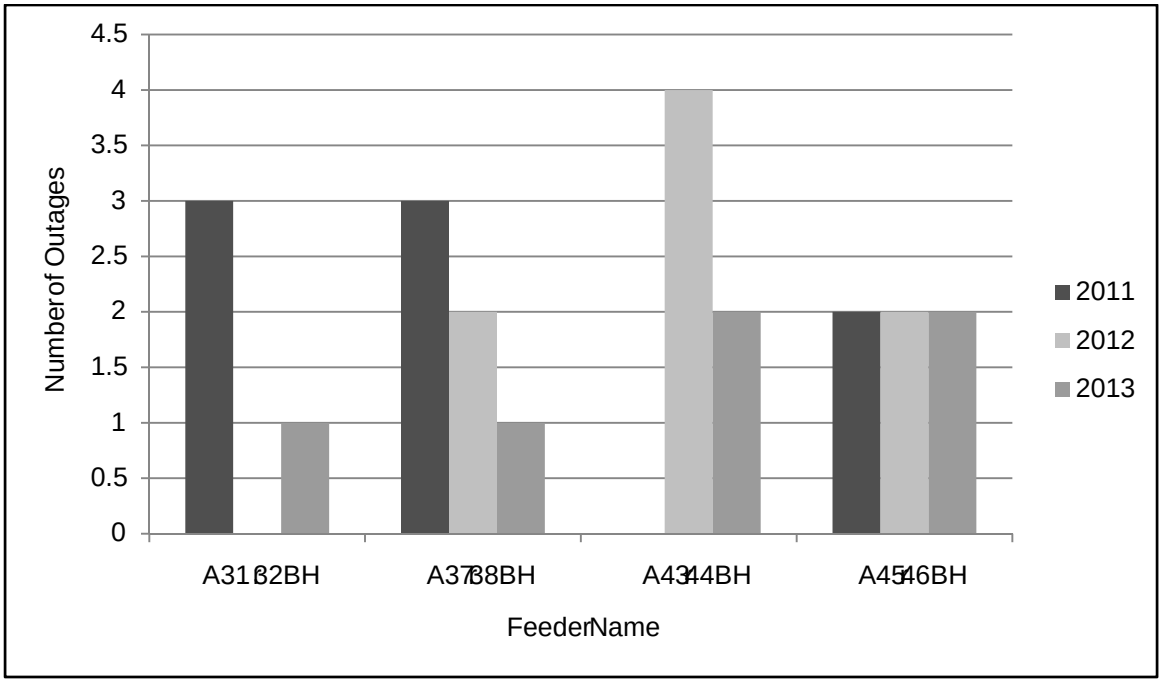

FIGURE 8: HISTORICAL FEEDER OUTAGES FOR B-HL TIE FEEDERS

By replacing these leaking cables in this program, Toronto Hydro can eliminate these unnecessary outages and improve reliability for customers in the St. Paul's area.

(ii) Asset Failure Impacts

PILC Leakers

Cable chambers in Toronto are treated as confined spaces. Due to the possibility of electrical contact and other hazards related to defective PILC cable, Toronto Hydro operating procedures require that cables with identified leakers be de-energized prior to crews entering the cable chamber. In addition, Toronto Hydro work practices dictate that all leaking PILC cables replaced or repaired before the crews leave the site. While this requirement improves the safety of Toronto Hydro employees, it can prolong the duration of outages and put an increased stress on the system.

When a downtown feeder suffers a cable fault, standard operating procedures dictate that all customers on the feeder should be transferred to their respective standby feeders. Downtown feeders have an average of 12 customers per feeder and it typically takes 45 minutes to restore the first customer and 15 minutes for every subsequent customer. Therefore, Toronto Hydro's average time to restore all customers on a faulted downtown feeder is approximately 3.5 hours.

This translates to an average outage duration of 1.5 hours for the affected customers. To avoid further customer interruptions and enable the crews to safely enter the chamber, Toronto Hydro must perform additional switching until all leaking feeders are de-energized. Doing so can take an additional 3.5 hours per feeder (based on the same averages described above), thus further prolonging the time that the system operates under an N-1 contingency[4]. Along with rectifying the source(s) of the fault, Toronto Hydro operating procedures dictate that the crews must address the cable leaks in the chamber. Given that each PILC leaker takes about four hours to repair, the presence of leaking PILC cables extends the duration of the N-1 event to a minimum of eight hours (longer if multiple PILC leaks are present in the cable chamber).

While the design of Toronto Hydro's system allows it to operate acceptably without damaging any assets during an N-1 contingency, doing so for a prolonged period of time is violates good utility practice, as it limits the utility's ability to perform switching to enable planned maintenance work or capital project execution.

In addition, while under N-1 contingency, the entire system and its customers face a greater prolonged outage risk and lower reliability as a second fault or outage may result in feeders and customers that cannot be restored quickly. The minimum typical outage duration from a second fault during N-1 contingency is 12 hours – over three times the outage duration of a "normal" outage – due to the fact that existing feeders are already out of service for fault locating or repair because of the presence of leaking cable.

The impact of PILC cable failure on the B-HL tie feeders is even more pronounced. Apart from compromising the security of supply for Toronto Hydro's customers in the St Paul's area, the cable faults can have a significant failure impact on the upstream HONI assets. Each incident that causes HONI's transformers at Bridgman TS to trip requires a thorough investigation and, as a result, requires HONI to take remedial action to verify the health of their transformers following each incident. Given the number of incidents affecting HONI's equipment in the recent past, Toronto Hydro must address the situation with the B-HL tie feeders in a timely and sustainable manner.

Cable Piece Outs

Similar to leaking cable, congested chambers with improperly racked cables can negatively impact Toronto Hydro crews and customers alike. Suspended or hanging cable has a higher failure risk as described earlier in Section E6.2.3.1 and a congested chamber also creates an

[4] The system under normal operation with all feeders energized is in an N-0 state. An N-1 contingency is a scenario where the system is operating with one asset failed or out of service.

unsafe working environment for Toronto Hydro crews due to tripping hazards and restricted space for labour intensive activities like the pulling of new cable and installation of cable joints and splices.

Moreover, chamber congestion can prolong underground outages and extend the duration of N-1 contingency events. When cable faults occur in congested cable chambers, crews require significantly more time to access and repair the faulty equipment, as cluttered cables restrict their movements and require significant efforts to move them aside. In situations where a piece-out is required to address a congested chamber, the cable will require an outage for as long as it takes to install and splice new cable. Similar to a leaker issue as detailed above, the additional switching and cable replacement repair time in these scenarios extends the amount of time the system is under N-1 contingency to a minimum of eight hours for every piece of cluttered cable present. The longer the Toronto Hydro system is under N-1 contingency, the surrounding distribution system and its customers face a greater prolonged outage risk and lower reliability as a second fault or outage may result in feeders and customers that cannot be restored quickly. The minimum typical outage duration from a second fault during N-1 contingency is 12 hours, over three times the outage duration of a "normal" outage.

E6.2.4 Timing & Pacing of the Program

Table 5 shows the estimated costs for the PILC Leakers and Piece-Outs program over the 2015 to 2019 period and the historical costs from 2010 to 2014.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	5.47	1.47	2.44	4.73	3.45	1.38	0.73	0.81	0.51

Toronto Hydro is committed to substantially reducing the backlog of known leakers and congested chambers within a reasonably short timeframe in order to mitigate associated failure and safety risks. With the exception of the 2012 and 2013 budget years (which are lower due to the timing of the decision for Phase 1 of Toronto Hydro's 2012-2014 rate filing), historical expenditures reflect the urgency of the work required and the emphasis Toronto Hydro has placed on removing leaking cable. As illustrated in Table 5, the majority of the program spending for the forecast period is concentrated in 2015 and 2016. This pace of spending is partly attributable to ongoing replacement of the leaking B-HL feeder tie cables. Due to the complexity of the project and the civil construction and coordination required, the costs associated with the

replacement of these feeders form a significant portion of the spending in the first two forecast years.

Toronto Hydro expects that deferral of the forecasted work beyond the planning horizon will result in the worsening of identified problems. Old and defective cables on the system will continue to leak oil, increasing the risks of cable faults, prolonging repair and restoration time, reducing system reliability and potentially increasing the safety risk to Toronto Hydro workers. Also, the ongoing work to rectify the leaking cables for the B-HL feeder ties has already begun and cannot be deferred without incurring operational risks. Approximately $4.73 million has already been invested into this project, which was notionally approved by the OEB as part segment B2 in Toronto Hydro's May 2012 ICM Phase 1 filing and the subsequent 2014 Phase 2 update. This spending was to construct approximately 500 metres of new civil infrastructure in order to install new 1500 kcmil cable for the B-HL tie feeders. Any delays or deferrals to replace the feeders will put the system at risk and crews will no longer be able to enter any of the impacted cable chambers to perform work. The new civil infrastructure already constructed will also not be utilized and will remain empty until such time that the remainder of the project is executed.

Once the B-HL tie-feeder replacement project and the majority of the known piece out and leaker issues are rectified, Toronto Hydro anticipates a reduction in capital spending required in the latter years of the 2015-2019 planning horizon, as PILC cable is gradually replaced throughout the system through other capital projects and customer connections.

E6.2.4.1 Ranking & Prioritization

As discussed in Section E6.2.2, Toronto Hydro has compiled a "Deficiencies List" of all known PILC leaker and congested cable chamber locations. When determining the sequencing of work execution from among the identified deficiencies, the utility considers several factors. These include:

Magnitude of the Problem – Areas with a concentrated number of reported cable leaks and congested chambers receive priority over those with isolated and scattered incidents.

Surrounding Work in the Area – surrounding work in the same geographical area is considered in the prioritization in order to avoid possible conflicts with other Toronto Hydro capital work and City of Toronto projects.

Feeder Outage Availability – The availability for the control room to schedule feeder outages is also given consideration. If numerous projects or a major project is being executed in the same area as a piece-out and leaker project, feeder outages may not be granted by the control room

due to system restraints and other feeders already out of service. This impact is considered as well in the prioritization to avoid conflict in feeder and resource scheduling.

The B-HL feeder performance issue is high-priority due to the magnitude of the associated failure impacts on Toronto Hydro's system and workers and the operation of upstream HONI transmission equipment. A detailed discussion of the impact of the leaking cable on the B-HL circuits is provided in Sections E6.2.2.2 and E6.2.3.2.

E6.2.5 Program Execution

As described in Section E6.2.2, this program will address all existing and known leaking PILC cables. Toronto Hydro will inspect each chamber on the deficiencies list and formulate a work plan to address any identified leaking cable. Field crew workers, in collaboration with planning and control room staff, will arrange the necessary feeder outage schedule and ensure that all work coordination is in place. For each leaking splice or segment of cable, the designer and crews will determine if the leak can be fixed using one of three methods:

A splice repair – Performing a splice repair is ideal for minor leaks as the repairs meet all requirements of cable test specifications and its internal moisture seals protect the cable from water ingress. Crews complete a splice repair using a heat-shrink adhesive polymeric sleeve called a Raychem kit. The Raychem kit is fast and pre-engineered for installations that reduce time and repair costs.

A new sleeve – Where the damage is too extensive to repair with a Raychem kit, the crews will remove the existing sleeve and break down the insulating material used to fill the splice. Once the crews clean and re-tape the cable, they install a new lead sleeve and fill it with the new insulating material prior to sealing the sleeve through the process known as "wiping."

A new segment of cable – If neither the Raychem kit nor a new sleeve can adequately address the damage, the crews will remove the existing cable and/or splice and will pull a new segment of cable from the adjacent cable chamber, prior to installing a new splice.

For congested cable chambers, crews will move the cable and properly rack it on chamber walls. If segments of cables are too short or too long to allow for proper racking, crews will install (or remove) a new segment of cable and complete the proper splicing. In certain cases the crews will also have to install new cable racks along the chamber walls and/or make other modifications to the chamber itself.

E6.2.5.1 Proposed Work Plan

Table 6 outlines Toronto Hydro's forecasted work plan for the 2015-2019 period by feeder and station .

TABLE 6: 2015-2019 LONG TERM PLAN

Year	Feeder	Station
2015-2016	A31/32HB, A37/38HB	Bridgman – High Level
2015	Various	Charles
2015	Various	Bridgman
2015-6	Various	Windsor
2016-2017	A43/44HB, A45/46HB	Bridgman – High Level
2016	Various	Dufferin
2017	Various	Strachan
2017	Various	Various 4 kV MS
2018	Various	High Level
2019	Various	Various Downtown 13.8 kV TS

E6.2.5.2 Program Risks

The following are risks to program completion that Toronto Hydro considers when planning and executing the PILC leaker repairs and piecing out work.

Civil Asset Obstacles : Due to the age of the surrounding civil assets, the original ducts may have shifted or collapsed, trapping the cable inside. The existing cable may also be bent within the ducts, making it difficult to pull out. These obstacles are difficult to foresee until the projects are underway. Project delays and cost increases can also occur where significant rebuild of civil infrastructure is required. To best anticipate this risk, Toronto Hydro will consider and review the age and type of ducts in the area for each project in order to assess the probability of collapsed ducts and trapped cable, and this risk assessment will inform the scheduling and cost estimation for each individual project.

Resource Availability : Working with PILC cable and performing the lead splice replacement requires specialized training and experience. While Toronto Hydro has a number of crews with the required expertise, these crews are typically in high demand to perform other planned or reactive work on the utility's underground system. Toronto Hydro is mitigating this risk through its comprehensive staffing strategy, which features a multi-faceted approach to meeting the utility's

resource requirements. To mitigate this risk, Toronto Hydro has begun working with external contractors to increase resources available to work on PILC cable.

Managing Feeder Outages : Prior to rectifying PILC leaks, Toronto Hydro must de-energize the damaged feeders. This requires switching crews to be available to transfer all affected customers to a standby feeder. Given that switching crews may be at any time deployed to higher-priority projects, the execution of the Leakers and Piece-Outs program depends on their availability. To mitigate this risk, Toronto Hydro has begun a feeder scheduling planning review to optimize and better coordinate the work on de-energized feeders.

Summer Outage Restrictions : Some feeders containing PILC leakers may be on Toronto Hydro's Summer Switching Restriction List, which identifies the feeders with high loading that are not available for planned outages during the summer peak conditions. Inability to obtain outages on necessary feeders can result in project delays. In order to reduce the number of feeders on the Summer Switching Restriction List, Toronto Hydro has initiated projects to relieve demand from heavily loaded feeders which in turn will allow them to be removed from the restrictions list. These projects are referenced in the Load Demand narrative (Section E5.4).

E6.2.6 Evaluation of Alternatives

Toronto Hydro has evaluated three alternative approaches for addressing the issues identified in this program. These options are detailed below.

(i) Status Quo

Deferring the work in this program is essentially a run-to-failure option. This approach does not address the existing risks to workers associated with working in confined spaces where defective primary cable is in service. This option also exposes customers to the risk of extensive outages from collateral cable damage in a chamber should a cable fail. Finally, it reduces the choices for routing new underground cable, as the chambers will remain congested. For all these reasons, this option is not preferred.

(ii) De-energizing all of the PILC primary cables in the chamber prior to entry

This option would eliminate many of the associated hazards for workers and would comply with work practices. However, in the downtown core, the service and standby cables often run in the same chambers and de-energizing both of them would create outages. With up to ten primary cables in a single downtown chamber, each with a capacity of 10 MVA, this option would create multiple outages for a significant number of customers on a regular basis. As a result, this option is not feasible.

(iii) Repair leaking cables and perform piece outs on an emergency basis

In many cases, workers are dispatched to cable chambers to investigate an event only to find that there are leakers or piece-out requirements that prevent them from addressing the situation that originally caused them to be there. If the original task was to restore power because of a cable failure, or some other urgent need, the leaking cables or piecing out work must be completed first. These operating restrictions become unmanageable as the backlog of leakers and feeders requiring piecing out increases. This situation also adds to the control room's switching and operating workload. Selecting this option for dealing with leakers and piece out requirements would mean that the work was unplanned. The result of unplanned work is often failure to complete all aspects of the job, or a requirement for substantial overtime. This option is not preferred because it prolongs the time to complete the original task and its cost.

(iv) Proactive repair of leakers and piece out of chambers

This option allows work to proceed in a planned way, focusing on the highest priority areas. Feeders with multiple leakers and chambers requiring piecing out can be scheduled for isolation and all of the associated hazards and defects can be addressed at the same time while the feeder is out of service. This approach is the most efficient and preferred approach.

The cost of ownership (ûCOO) and program net benefit (NPV) associated with the PILC Leakers and Cable Piece-Outs program is further detailed in Table 8. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities in this program. The cost of ownership reflects the risk of asset failure for a given state, including both direct and indirect costs. These costs include customer interruptions, emergency repairs, and asset replacements associated with the given design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first year of activities, the PILC Leakers and Cable Piece-Outs program produces a net benefit (NPV) value of $0.44 million, as shown in Tables 8 and 9.

TABLE 7: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$5.06
Non Asset Risk [NAR_E]	0
Maintenance Cost [MC_E]	0
Additional Quantifiable Benefits [AQB_E]	0
Cost of Ownership of Existing Assets [COO_E]	$5.06

TABLE 8: BOX CONSTRUCTION CONVERSI ON BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: Conversion to Standardized Equipments	
Asset Risk [AR_N]	$1.17
Non Asset Risk [NAR_N]	0
Maintenance Cost [MC_N]	0
Additional Quantifiable Benefits [AQB_N]	0
Cost of Ownership of New Assets [COO_N]	$1.17
Option 1: Program Net Benefit (NPV)	
Difference in Cost of Ownership [$\Delta COO_2 = (COO_E - COO_N)$]	$3.89
Program Cost [PC_2]	$3.45
Program Net Benefit [NPV = ($\Delta COO_2 - PC_2$)]	$0.44

E6.2.7 2015 Projects

Table 10 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

- previously filed projects that appeared as jobs in the OEB approved PILC Cable – Piece Outs and Leakers segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and
- projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 9: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Projects	CIR Projects
$1.79	$1.66

Table 11 lists all projects that are planned for partial or complete execution as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 10: 2015 PROJECTS

Project Number	Project Name	Total Project Cost ($M)	Start Date	Project Type (ICM or CIR)
29776	X15039 - Bridgman High Level Tie Feeder Replacement Phase 4: Electrical Part 1 (A31,32HB & A37,38HB)	0.78	2015	CIR

E6.2.7.1 X15039 Project Description

Portfolio: U/G Grid System

Program: Paper Insulated Lead Covered (PILC) Piece-Outs and Leakers

Project Title: Bridgman High Level Tie Feeder Replacement Phase 4: Electrical Part 1 (A31, 32HB & A37, 38HB)

Project Number: X15039

Project Year: 2015

Estimated Cost: $778,599

(i) Objective

Objective of this project is to replace cable for four of the Bridgman High Level tie feeders. The four feeders to be replaced are A31,32HB and A37,38HB. This project is phase four of five.

(ii) Scope of Work

Replace tie feeders A31,32HB and A37,38HB from T12X and T13X at Bridgman Station to A7-8H switchgear at High Level Station by pulling four new circuits (12 cables total) of 1500 kcmil TRXLPE cable through the new civil infrastructure built in Phase 1-3 of this project.

TABLE 11: X15039 SCOPE OF WORK DETAILS

District Neighborhood	ST PAUL'S
Station(s)	BRIDGMAN, HIGH LEVEL
Feeder(s)	A31BH, A21BH, A37BH, A38BH

TABLE 12: X15039 ASSETS REPLACED

Assets (Units)	2015
1500 kcmil PILC cable (km)	1.95

(iii) Justification & Benefits

The Bridgman High Level tie feeders have been identified as leaking and have been the primary cause of several cable faults over the past three years. These faults have a large impact on not only the distribution system and the customers in the St Paul's area of Toronto, but also the upstream HONI transmission protection schemes.

By replacing these feeders, Toronto Hydro expects there to be a significant improvement in reliability.

E6.2.7.2 X15585 Project Description

Portfolio: U/G Grid System

Program: Paper Insulated Lead Covered (PILC) Piece-Outs and Leakers

Project Title: Charles Station Pi ece Out and Leakers Phase 1: Civil

Project Number: X15585

Project Year: 2015

Estimated Cost: $390,090

(i) Objective

Objective of this project is to repair the leaking PILC cable and piece out any required feeders to rectify any chamber congestion in the Charles Station egress area. This project is phase one of two and focuses on the civil work to rebuild and construct new cable chambers and ducts.

(ii) Scope of Work

- Breakout of east side of CC7002 and run a duct structure to the existing duct run which runs from the station to CC9880
- Breakout of both the north side of CC7002 and the east station wall and run duct to a new chamber south of CC6995 and CC9880 (referred to as New Chamber #1)
- Run duct from the north wall of New Chamber #1 to another new chamber (New Chamber #2) to the east of CC6999.
- Run duct from the east wall of New Chamber #2 and break into the adjacent duct structure running to CC5550.

TABLE 13: E12345 SCOPE OF WORK DETAILS

District Neighborhood	ROSEDALE
Station(s)	CHARLES
Feeder(s)	NONE

TABLE 14: X15585 ASSETS REPLACED

Assets (Units)	2015
Cable Chambers (EA)	2

(iii) Justification & Benefits

The egress chambers for the Charles Station area were reported by crews to be congested. New civil infrastructure is required so the feeders can be rerouted out of congested chambers creating additional space for cable to be properly installed and racked. This scope focuses on civil work required on the east side of the station.

By completing this work, Toronto Hydro will remove numerous tripping hazards and create safer working conditions within the chamber for crews. The work is also expected to allow for quicker restoration time and improved reliability when repairing faulted cable for a feeder that runs through these chambers outside Charles TS.

E6.2.7.3 X15586 Project Description

Portfolio: U/G Grid System

Program: Paper Insulated Lead Covered (PILC) Piece-Outs and Leakers

Project Title: Charles Station Piece Out and Leakers Phase 2: Electrical

Project Number: X15586

Project Year: 2015

Estimated Cost: $489,247

(i) Objective

Objective of this project is to repair the leaking PILC cable and piece out any required feeders to rectify any chamber congestion in the Charles Station egress area. This project is phase two of two and focuses on the electrical work to repair leaking cable and piece out cluttered cable.

(ii) Scope of Work

- Relocate feeders A60CS, A61CS and A65CS from the ducts from CC6996 to CC6995 on the south side of Charles St to the ducts from CC6996 and CC6880 also on the south side of Charles St.
- Transfer Network Locations N1023 and N1077 from A50CS, A53CS and A55CS to A91CS, A92CS and A93CS and remove congested cables through chambers outside Charles Station.
- Relocate feeder A8CS from the ducts on the south side of Charles St from CC9880 to CC6996 to the ducts south of Charles TS from CC7002 to CC6996.
- Relocate feeders A7CS, A9CS, A52CS and A54CS from the ducts from Charles TS to CC6995 on the North East side of the station to the new cable chambers built in Project X15585.

TABLE 15: X15586 SCOPE OF WORK DETAILS

Feeder(s)	A60CS, A61CS, A65CS, A50CS, A53CS, A55CS, A91CS, A92CS, A93CS, A8CS,

TABLE 16: X15586 ASSETS REPLACED

Assets (Units)	2015
500 kcmil PILC Cable (km)	1.4

(iii) Justification & Benefits

The egress chambers for the Charles Station area were reported by crews to be congested. This electrical work is required so the feeders can be rerouted out of congested chambers creating additional space for cable to be properly installed and racked.

By completing this work, Toronto Hydro will remove numerous tripping hazards and create safer working conditions within the chamber for crews. The work is also expected to allow for quicker restoration time and improved reliability when repairing faulted cable for a feeder that runs through these chambers outside Charles TS.

E6.2.7.4 X14362 Project Description

Portfolio: U/G Grid System

Program: Paper Insulated Lead Covered (PILC) Piece-Outs and Leakers

Project Title: Bridgman Station Piece Out and Leakers

Project Number: X14362

Project Year: 2015

Estimated Cost: $348,480

(i) Objective

Objective of this project is to piece out cables as well as repair any leaking cable within cable chambers with feeders that originate from Bridgman Station.

(ii) Scope of Work

In the following identified cable chambers and vaults, inspect and confirm all feeders requiring piece out or feeders that are leaking. If a leaker is identified, repair cable by; installing a heat shrink splice repair, installing a new sleeve or installing a new segment of cable. If a piece out is identified install a new segment of cable and properly rack new cable.

- CC4233, CC4227, CCN440, CCN441, CC4971, CC4769, CC8753, CC6096, CC8233, CC6478, CC4234.

TABLE 18: X14362 ASSETS REPLACED

Assets (Units)	2015
500 kcmil PILC cable (km)	1.19

(iii) Justification & Benefits

The identified chambers have been reported to contain leaking PILC cable or unracked and cluttered feeders. This work is required to repair all leaking cable as leaking cable does not perform at its rated capacity and standard and is more susceptible to a fault or flashover.

By completing this work, Toronto Hydro will remove numerous tripping hazards and create safer working conditions within the chamber for crews. The work is also expected to allow for quicker restoration time and improved reliability when repairing faulted cable.

E6.2.7.5 X12160 Project Description

Portfolio: U/G Grid System

Program: Paper Insulated Lead Covered (PILC) Piece-Outs and Leakers

Project Title: Windsor Station Piece Out and Leakers

Project Number: X12160

Project Year: 2015

Estimated Cost: $1,444,417

(i) Objective

Objective of this project is to install new civil assets and perform the required electrical work in order to piece out congested and cluttered cable chambers that were created by a number of new connections and installations over the past decade in the growing business area of York and Front.

(ii) Scope of Work

- On Front St between Simcoe St and York St break out and install new ducts from CC9672 to CC3009 on the north side of Front St.
- Relocate feeders A58WR, A54WR and A50WR from the south side of Front St to the north side of Front St using the new civil infrastructure installed in previous step above.
- At the corner of Simcoe St and Bremner Blvd break out and install new ducts from CC10863 to CC10865.
- At the corner of York St and Bremner Blvd rebuild existing CC3275 and install new ducts to CC10913.
- Replace and new install new cable for feeders A71WR and A72WR along Bremner Blvd from CC10863 to CC3275 in the new civil infrastructure installed in previous two steps as described above.

TABLE 19: X12160 SCOPE OF WORK DETAILS

TABLE 20: X12160 ASSETS REPLACED

Assets (Units)	2015
500 kcmil PILC cable (km)	0.85
Cable Chambers (EA)	1

(iii) Justification & Benefits

The identified chambers were reported by crews to be congested due to several new services and feeders being installed in the area in order to accommodate new buildings being constructed and energized in the early 2000s. During that time, the work was completed without proper rebuilding of chambers or racking or cables. This project is required so the feeders can be rerouted out of congested chambers creating additional space for cable to be properly installed and racked.

By completing this work, Toronto Hydro will remove numerous tripping hazards and create safer working conditions within the chamber for crews. The work is also expected to allow for quicker restoration time and improved reliability when repairing faulted cable for a feeder that runs through these chambers.

E6.3 Underground Legacy Infrastructure

POWERLITE SWITCH INSTALLED IN A VAULT

E6.3.1 Summary

Program Description

Underground legacy infrastructure (ULI) refers to non-standard underground equipment and configurations throughout Toronto Hydro's distribution system. The ULI program addresses specific groups of legacy assets that are reaching the end of their useful lives and that lack suitable like-for-like replacements due to functional obsolescence.

(1) Sachsenwerk switch and fuse units are reaching end-of-life, no longer manufactured, and at risk of catastrophic failure since they are known to flashover during operation. Toronto Hydro plans to replace all 48 remaining units by 2018.

(2) Distribution equipment in the Thorncliffe Park distribution area is of a unique legacy design that has a number of issues, including the condition of the equipment, the availability of replacements and the lengthy duration of outages that are required to replace certain equipment. Toronto Hydro plans to reconfigure the distribution system by removing all submersible five-way and six-way switches and replacing them with a combination of pad-mounted and submersible four-way and three-way switches within the 2015-2019 period.

(3) Transclosures are a style of transformer that was installed in Toronto Hydro's system prior to the mid-1980s. Many of these units are in poor condition and are at or approaching end-of-life, with the newest units having been installed over 30 years ago.

Performing maintenance and reactive work on these units is difficult for field crews since their poor condition poses a potential safety hazards in the form of arc flashes. Toronto Hydro plans to replace approximately a quarter (42 units) of the total known transclosure population by the end of the 2015-2019 period.

(4) Powerlite switches , a type of secondary transfer switch, were originally installed in the mid-1960s, and are no longer manufactured. In the late 1980s, due to large overloads at locations on the Danforth (greater than 100%) and the abnormal configuration, Toronto Hydro undertook conversion projects to remove many of these units. However, there are still 10 remaining locations that need to be partially or completely replaced. Toronto Hydro plans to replace all of remaining units in the 2015-2019 period, and, in 2018-2019, will revisit locations that had been partially replaced reactively (due to safety concerns) to complete the conversion.

(5) Vault step transformers were installed at various times from the late 1950s through the early 1980s to provide customers with multiple service voltages. These transformers are legacy assets because Toronto Hydro no longer provides multiple service voltages in this manner. Toronto Hydro has identified seven sets of step-transformers that will be targeted by this replacement program during the 2015 to 2019 period. The replacement option for these units differs from location to location depending on the equipment and supply voltages that are installed in the vicinity. The ideal replacement option, if available, is to extend a secondary service of the required voltage from a nearby location. An alternative is to install a new primary transformer to distribute the required secondary voltage.

(6) In the past seven years, Toronto Hydro has recorded twenty-four incidents of cable chamber covers not being property seated on the chamber neck, i.e. ejected. Fortunately, none of these incidents have resulted in injury. However, incidents resulting in injuries and death have occurred in other jurisdictions. An ejected lid results from an eruption occurring inside a cable chamber. This eruption is caused by deteriorated cables heating up, arcing, and igniting gases, which can create a powerful shock wave. Toronto Hydro plans to address the cable chamber cover problem proactively by replacing 1,500 of the highest risk existing cable chamber covers with a new design that allows gas pressure to be released safely.

The anticipated benefits of the Underground legacy infrastructure (ULI) program are as follows:

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduces lengthy outages that can severely inconvenience customers. ƒ Improves public safety by replacing assets such as cable chamber lids and transclosures. ƒ Improves the aesthetic of neighborhoods, particularly in the case of transclosures, which are rusted, corroded and are often in highly visible locations.
Reliability	ƒ Mitigates outages caused by failed underground equipment (28% of total system outages). ƒ Removes certain operating restrictions posed by some legacy assets.
Safety	ƒ Mitigates the risk of current cable chamber lids being ejected into the air, which poses potential safety risks for pedestrians. ƒ Minimizes safety issues associated with crews being exposed to equipment flashover when operating switch and fuse units, as well as hazardous work environment in Powerlite locations
Efficiency	ƒ The use of engineering resources to deal with asset failure on a reactive basis is avoided, improving organizational efficiency. ƒ Installing a current standard asset, opposed to using a like-for-like legacy asset (if available) is more efficient from a cost/procurement/standards perspective (i.e. wanting to maintain few stock coded items and critical spares).
Other	ƒ New equipment being installed (CRD/CLD switches and pad-mount switches) have the ability to be retrofitted to be remote operable.

Program Drivers

The trigger and secondary drivers for the Underground legacy infrastructure (ULI) program are:

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Most of the equipment targeted by this program is no longer manufactured and therefore difficult to acquire replacements when needed ƒ Vastly improved assets have become available since the infrastructure targeted by this program was originally installed. The modern assets have additional functionality and safety measures when compared to the currently installed legacy equipment. ƒ There are no longer any construction standards which can be used by Toronto Hydro for replacing/maintaining these assets in a like-for-like manner.
Secondary Drivers	ƒ Reasoning
Safety	ƒ Degradation of assets can pose safety hazards for field crews when operating and/or maintaining the equipment.

Reliability	ƒ Often a like-for-like replacement option is not available for equipment targeted by this program. As a result, when this equipment fails, the system can be left in a contingency situation for long durations while a solution is developed and executed. Until the solution is implemented and the system resumes normal operation, customers are exposed to additional outage risk. ƒ Assets are at or near the end of their useful life and/or prone to failure, presenting an outage risk.
Failure Risk	ƒ Assets are at or near the end of their useful life. As a result, they are more likely to fail and will require reactive replacement.

Preferred Alternative

Toronto Hydro evaluated the following options for addressing the assets in this program:

(1) Do nothing and replace on a reactive basis only, incurring the risk of equipment failures and potential safety concerns.

(2) Proactively replace these assets with current standard equipment to eliminate the safety and reliability risks.

Option II is the preferred alternative as it will enable Toronto Hydro to mitigate the risks posed by the currently installed assets in the most cost effective manner.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $3.52 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets. Accounting for capital program costs, the first year's activities deliver a positive NPV of $1.46 million, confirming the economic prudence of the investments.

Timing and Pacing

The pace of replacement for the different asset types was determined based on the risk of failure of the assets as determined by age and condition, the expected impact of asset failure and the overall number of units.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	-	-	-	-	2.06	6.69	6.64	6.48	5.52

E6.3.2 Program Description

Underground legacy infrastructure (ULI) refers to non-standard underground equipment and configurations throughout Toronto Hydro's distribution system. The ULI program addresses specific groups of legacy assets that are reaching the end of their useful lives, including:

- Sachsenwerk switch and fuse units,
- specific equipment in the Thorncliffe Park distribution area,
- transclosures,
- Powerlite switches,
- vault step transformers, and
- cable chamber covers.

These assets and asset types are functionally obsolete because they can no longer perform their intended function to current standards; they often pose safety hazards and/or cause operating constraints. Replacement options vary from asset to asset because each has a unique function in the underground distribution system. Generally, Toronto Hydro will replace all of the ULI assets with current standard equipment and configurations.

Toronto Hydro standardizes in-service equipment as part of its efforts to make its system more efficient. As an amalgamated utility, Toronto Hydro's system contains remnants of several old standards and equipment that have become functionally obsolete. Attempting to stock like-for-like replacements for legacy equipment and performing reactive replacements is inefficient given the relatively small number of legacy assets currently in use as compared to the total number of assets in Toronto Hydro's system. As well, there is often a dearth of like-for-like replacement options for assets targeted by this program since in many cases, they are no longer manufactured because they are, or a lack of manufacturing results in them being, non-standard. Due to the difficulty and time required to settle on a suitable solution, locate a replacement and implement the corrective action when these legacy assets fail, their failure can lead to longer than average outage durations and/or lengthy contingency scenarios.

Toronto Hydro plans to spend an estimated $27.39 million on the ULI program over the 2015 to 2019 period. The locations of assets targeted by the ULI program are noted in Figure 1.

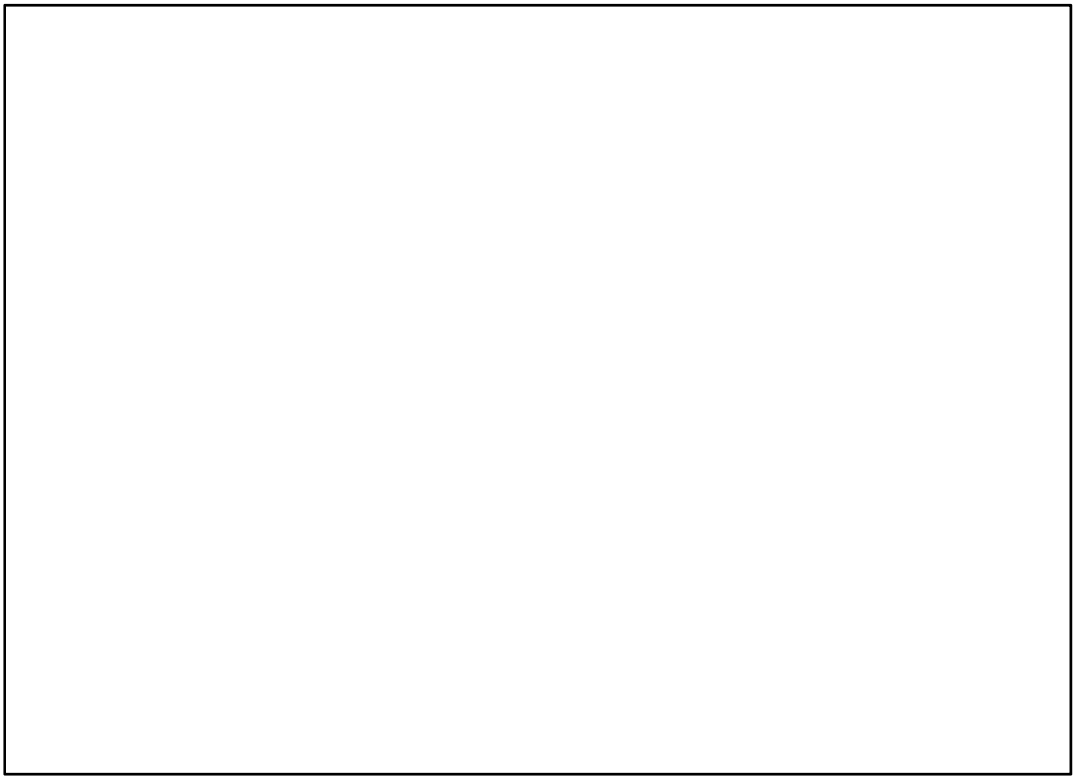

FIGURE 1: MAP OF LOCATIONS FOR ASSETS TARGETED IN THE REPLACEMENT OF UNDERGROUND LEGACY INFRASTRUCTURE PROGRAM

The following subsections discuss each of the sub-programs of the ULI program and the specific assets and asset types that are targeted.

E6.3.2.1 Replacement of Sachsenwerk Switch and Fuse Units with Compact Loop (CLD) or Compact Radial (CRD) Design

Sachsenwerk switch and fuse units were installed in Toronto Hydro's system during the mid to late 1980s. They were installed in pairs, with one switch normally open and the other normally closed, referred to as a dual radial configuration. This configuration provides a customer with the advantage of a standby power supply when normal supply experiences an outage. As well, using this configuration, the standard equipment used to replace existing units could be more easily maintained and replaced.

The switches themselves are air insulated and operate using a spring-loaded mechanism. Since the Sachsenwerk switches were originally installed, dual radial supply equipment has gone through several iterations and generations of technological improvement. Manufacturers and

standards have evolved to produce better alternatives as described below. As a result, Sachsenwerk units are no longer manufactured.

Forty-eight Sachsenwerk switch and fuse units remain in 24 locations across Toronto Hydro's system. The Sachsenwerk units in Toronto Hydro's system are at risk of catastrophic failure since they are known to flashover during operation, giving rise to serious potential safety and operational issues, described in detail in the Program Drivers and Asset Details sections. Given these risks and issues, Toronto Hydro proposes changing out Sachsenwerk units; however, these change outs would not be like-for-like replacements.

FIGURE 2: PHOTO "A" SHOWS THE SWITCH REMOVED FROM ITS CABINET, PHOTO "B" SHOWS THE SWITCH AND FUSE UNITS (NOTE SEPARATE COMPARTMENTS FOR EACH) AND THE SWITCH HANDLE BEING OPERATED. THERE IS AN ADDITIONAL EXTERNAL DOOR WHICH IS OPEN IN THIS PHOTO.

The primary replacement options for Sachsenwerk switch and fuse units are CRD or Compact Loop Design (CLD) equipment, two of Toronto Hydro's current standard switch designs. The use of either the CRD or CLD depends on the existing configuration of the switch and fuse location. Both options are submersible units insulated with SF_6 gas, as opposed to air. The CRD and CLD units are less susceptible to degradation and catastrophic flash-over when compared to existing air insulated units. In cases where the location's load can be accommodated by other means, alternative replacement options will be studied and the most efficient and practical replacement option will be implemented.

FIGURE 3: CRD EQUIPMENT INSTALLED IN AN EXISTING CRD VAULT

This sub-program is expected to remove all Sachsenwerk switch and fuse units from the system, with completion targeted for the end of 2018 due to the high priority nature of the work.

E6.3.2.2 Reconfiguring Thorncliffe Park Area Distribution Equipment

The configuration of the distribution system in the Thorncliffe Park area is a legacy design installed by the former East York Hydro. The system was installed in the early 1990s as an economical replacement for the network style system that was previously in place. The current Thorncliffe Park system was designed to mimic a spot network configuration by having five-way and six-way SF_6 switches, with multiple incoming primary feeders radially feeding the transformer vaults (Figure 12, below, is a photo of a six-way switch). These units are equipped with primary side automatic transfer switches (ATS). An ATS is a controlled motor operator that allows the switch to open or close as necessary when a feeder is taken out of service. The intended benefit of this configuration was that customers would only experience a momentary outage during a fault since the ATS operates quickly when a primary fault occurs.

There are a number of issues associated with this configuration, including the condition of the equipment, the availability of replacements and the lengthy duration of outages that are required to replace certain equipment. These issues and their reliability impact are discussed in detail in sections E6.3.3.1 and E6.3.3.2.

To remedy the situation in Thorncliffe Park, Toronto Hydro plans to reconfigure the distribution system by removing all submersible five-way and six-way switches and replacing them with a combination of pad-mounted and submersible four-way and three-way switches. Customers are currently radially fed from the five-way and six-way units. Reconfiguration will create a looped configuration between multiple three-way and four-way switches. This will allow Toronto Hydro to continue serving customers when a switch is taken out of service and will decrease outage times during reactive situations. A schematic of what the reconfiguration entails is shown in Figure 4.

FIGURE 4: EXAMPLE OF THE PLANNED RECONFIGURATION WORK FOR THE THORNCLIFFE PARK AREA

Reconfiguring Thorncliffe Park Area distribution equipment is expected to reduce outage times, since having multiple switches in place in a looped configuration will increase the ability of system operators to isolate the faulted section. The use of pad-mounted equipment in certain cases also eliminates concerns over the impacts of flooding on the currently installed equipment. Despite the

use of sump pumps, the Thorncliffe area has a history of flooded vaults that cause damage to equipment; discussed further in the Thorncliffe section of the Program Drivers section (E6.3.3.1). Toronto Hydro plans to replace all five-way and six-way switches, six switches total, in the Thorncliffe Park area over the 2015-2019 period as part of this sub-program.

E6.3.2.3 Conversion of Legacy Transclosure Equipment

Transclosures are a style of transformer that were installed in Toronto Hydro's system prior to the mid-1980s. A transclosure consists of an overhead pole-top or non-submersible vault style transformer placed on the ground inside a metal enclosure (Figures 5 and 13 are examples of typical transclosure units).

FIGURE 5: TYPICAL TRANSCLOSURE UNIT

FIGURE 6: EXAMPLE OF A PAD-MOUNTED TRANSFORMER (ONE REPLACEMENT OPTION FOR TRANSCLOSURES)

Many of these units are in poor condition and are at or approaching end-of-life, with the newest units having been installed over 30 years ago. Performing maintenance and reactive work on these units is difficult for field crews since their poor condition poses potential safety hazards in the form of arc flashes, discussed in more detail in the Program Drivers section (E6.3.3.1). Contemporary underground and pad-mounted transformers mitigate the safety issues posed by the legacy transclosure design.

Replacement options for transclosures include: (1) installing standard pad-mounted transformers, (2) installing submersible transformers in a vault, or (3) conversion to overhead using pole-mounted units. Each of these options typically requires both civil and electrical reconfiguration work. These replacement options will provide several benefits, including improved worker safety and the mitigation of long-lasting outages. In choosing a replacement option, Toronto Hydro considers the amount of load served and equipment cost. Existing transclosures supplying a service of 200 A or less will be replaced with an equivalent pole-mounted transformer. Units with a service size greater than 200 A will be replaced with a pad-mounted transformer. Submersible units are the most expensive replacement option and are not included in the current replacement plan because they would require a larger load to be economically justifiable.

In many cases, where the existing transclosure is radially fed, the replacement project will integrate the location into a looped system in order to provide more reliable service and decrease the failure impact of the new equipment going forward.

This program includes the planned replacement of six transclosure units in 2015 and is paced such that approximately a quarter (42 units) of the total known transclosure population are planned to be replaced by the end of the 2015 to 2019 period. Some units that are not included in this program may be replaced under the underground rebuild work in the Underground Circuit Renewal program as described in Section E6.1 in order to gain efficiency by incorporating the transclosure replacement within a larger feeder rebuild project, where appropriate.

E6.3.2.4 Conversion of Power-lite Switches to Network and CRD

Powerlite switches, a type of secondary transfer switch, are installed in single-phase radial vaults, typically found servicing shops along the Bloor/Danforth corridor. These switches have two incoming supply feeders and a tie in between, designed to auto transfer if one feeder experiences an outage. These units were originally installed in the mid 1960s. In the late 1980s, due to large overloads at locations on the Danforth (greater than 100%) and the abnormal configuration, Toronto Hydro undertook conversion projects to remove many of these units. However, there are still 10 remaining locations that need to be partially or completely replaced. Most of these locations are on Bloor St., since the previous conversion projects targeted the Danforth locations. This program is intended to remove all remaining Powerlite switches from the system.

FIGURE 7: POWERLITE SWITCH INSTALLED IN A VAULT. NOTE THE THREE CABINETS – ONE FOR EACH SWITCH. LOCKS ON THE FRONT ARE ON THE SWITCH OPERATING MECHANISM.

Powerlite, the original manufacturer, no longer produces these switches and there is no like-for-like replacement option available. These locations are also atypical because they are single-phase underground locations fed off of feeders that normally only service three-phase locations.

During the original conversion of these locations, customers had their secondary voltage converted from 120/240 V (single phase) to a 120/208 V (three phase) service. The conversion was required since a 120/240V service cannot be supplied from a three-phase supply. This type of secondary voltage conversion requires communication with affected customers and, in some cases, replacement or modification of customer equipment. These requirements make this work difficult to execute properly in a reactive situation.

Recently there have been reported safety hazards associated with Powerlite locations due to hazardous work environments, described in detail in the Program Drivers section (E6.3.3.1). These safety hazards were addressed reactively by replacing the failed Powerlite switches with three phase switches (CRD type), but with only one phase being utilized. In the later years of this program, 2018-2019, the locations that were originally addressed reactively will be revisited for conversion to three-phase supply. The CRD switches that were initially installed will be reused because they are three phase switches. Toronto Hydro plans to add a three-phase transformer and re-cabling services to the customers from 120/240 V to 120/208 V as part of this work.

By replacing the remaining Powerlite switches, Toronto Hydro can supply customers using standard configurations that are suitable for the long-term. Vaults with Powerlite switches will either be converted to three-phase network locations (network is an underground distribution configuration used in dense downtown areas) or to CRD locations. The selected conversion option will depend on the load at the location and the amount of space available in the existing vault. In some cases the vault size may necessitate rebuilding the vault in order to install either type of equipment. Secondary voltage conversion is required under either replacement option.

E6.3.2.5 Decommissioning of Vault Step Transformers

Step-up or step-down transformers exist in some underground vaults to provide customers with multiple service voltages. These step transformers take the secondary voltage from a distribution transformer and step it up or down. For example, the 13.8 kV distribution transformer provides a 120/208 V supply, but the customer may also require 347/600 V supply. In this example, the vault may have a step transformer to take part of the 120/208 V supply and step it up to 347/600 V. These units are usually small, dry type transformers (see Figure 8) or small submersible units (see Figure 9). Dry type transformers use air as their insulating medium instead of traditional oil insulation. Toronto Hydro has identified seven sets of step-transformers that will be targeted by this replacement program during the 2015 to 2019 period.

Toronto Hydro installed these units throughout the system at various times from the late 1950s through the early 1980s. These transformers are legacy assets because Toronto Hydro no longer provides multiple service voltages in this manner. Due to the small number of these transformer units installed and the wide array of sizes (both kVA and voltage) found among the in-service units, Toronto Hydro does not stock these units.

FIGURE 8: DRY TYPE STEP TRANSFORMERS IN VAULT LOCATION 1808 ON MERTON ST

FIGURE 9: SUBMERSIBLE OIL FILLED STEP UP TRANSFORMERS

The replacement option for these units differs from location to location depending on the equipment and supply voltages that are installed in the vicinity. The ideal replacement option, if available, is to extend a secondary service of the required voltage from a nearby location. An alternative is to install a new primary transformer to distribute the required secondary voltage.

E6.3.2.6 Replacement of Cable Chamber Covers

Cable chambers are underground structures where crews can access the cables running through the concrete duct banks in the underground system. Cable chamber covers are used to cover up cable chamber entrances on city streets. Figure 10 shows a typical cable chamber installation in the City of Toronto.

FIGURE 10: STANDARD CABLE CHAMBER COVERS INSTALLED IN TORONTO

In the past seven years, Toronto Hydro has recorded twenty-four incidents of cable chamber covers not being property seated on the chamber neck, i.e. ejected. Fortunately, none of these incidents have resulted in injury. However, incidents resulting in injuries and death have occurred in other jurisdictions, discussed in detail in the Program Drivers section (E6.3.3.1).

As described in more detail in section E6.3.3.1, an ejected lid results from an eruption occurring inside a cable chamber. This eruption is caused by deteriorated cables heating up, arcing, and igniting gases, which can create a powerful shock wave. Toronto Hydro plans to address the cable chamber cover problem proactively by replacing the existing cable chamber covers with a new design that allows gas pressure to be released safely. The design of the replacement covers allows the gases to vent (possibly preventing the eruption) and the covers themselves are able to

withstand the force of the possible shock wave without being launched into the air. Two examples of replacement options can be seen in Figure 11.

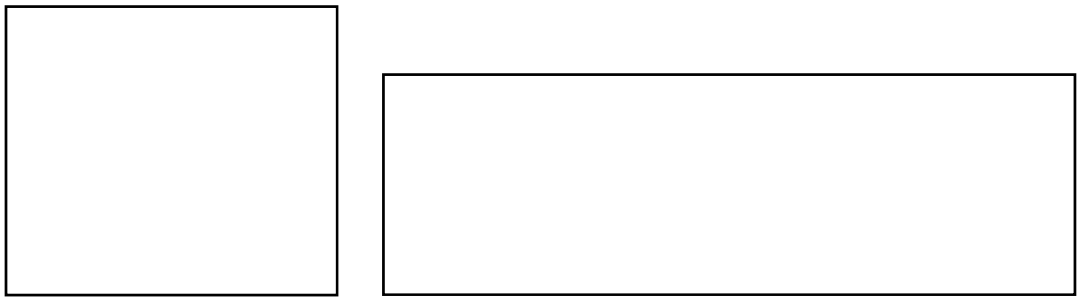

FIGURE 11: TWO OF THE REPLACEMENT OPTIONS BEING EVALUATED FOR CABLE CHAMBER COVERS. BOTH PROVIDE A MECHANISM FOR EXPLOSIVE GASES TO BE VENTED.

There are 10,572 cable chambers in the city of Toronto. Table 1 provides a breakdown of the number of cable chambers in each former utility.

TABLE 1: INVENTORY OF CABLE CHAMBERS BY FORMER UTILITY

Cable Chambers Location	Number of cable chambers
East York	355
Etobicoke	918
North York	848
Scarborough	221
Toronto	8,112
York	118
Total	10,572

In the first year of this sub-program, Toronto Hydro plans to replace 25 cable chamber lids with the new design. Toronto Hydro plans to replace a limited number in the first year because the new cable chamber lid must be tested for proper functionality in both the winter and summer months to ensure they operate in the multitude of conditions that they will be exposed to. If the new lid design passes the necessary testing, Toronto Hydro plans to replace a total of 1,475 cable chambers in the remaining four years of the program.

The three variables that impact the risk and consequences of an eruption are (1) the number primary conductors in the cable chamber, (2) the age of the conductors in the cable chamber and (3) the number of pedestrians in the area. Toronto Hydro has taken into consideration the most

vulnerable cable chambers based on these identified variables, and will execute the replacement program to address the highest risk cable chambers. A portion of the cable chamber lids that have not been identified in this program for immediate replacement may be replaced in future proactive programs; however the majority of cable chamber lids that do not pose a risk will only be replaced when the chamber is rebuilt or the lid reaches its end-of-life.

E6.3.2.7 Summary of Program Benefits

Table 2 summarizes the anticipated benefits generated by the ULI program.

TABLE 2: PROGRAM BENEFITS

Customer Value	ƒ Reduces lengthy outages that can severely inconvenience customers. ƒ Improves public safety by replacing assets such as cable chamber lids and transclosures. ƒ Improves the aesthetic of neighborhoods, particularly in the case of transclosures, which are rusted, corroded and are often located in high visibility areas. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $3.52 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.3.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $1.46 million, confirming the economic prudence of the investments (see Section E6.3.7).
Reliability	ƒ Mitigates outages caused by failed underground equipment (28% of total system outages). ƒ Decreases the duration of outages. ƒ Removes certain operating restrictions posed by some legacy assets.
Safety	ƒ Mitigates the risk of current cable chamber lids being ejected into the air, which poses risks for both pedestrians and property. ƒ Minimizes safety issues associated with crews being exposed to: o equipment flashover when operating switch and fuse units, o a potentially hazardous work environment in Powerlite locations, and o arc-flash.

Efficiency	ƒ The use of engineering resources to deal with asset failure on a reactive basis is avoided, improving organizational efficiency. ƒ Installing a current standard asset, opposed to using a like-for-like legacy asset (if available) is more efficient from a cost/procurement/standards perspective (i.e. wanting to maintain few stock coded items and critical spares). ƒ Limiting the number of different types of assets in the system results in maintenance related savings as fewer equipment types with varying maintenance needs are used.
Other	ƒ New equipment being installed (CRD/CLD switches and pad-mount switches) have the ability to be retrofitted to be remote operable.

E6.3.3 Why the Program is Needed

The ULI program is needed to address non-standard equipment and configurations located throughout Toronto Hydro's underground system. These asset types and configurations are functionally obsolete and many of the legacy assets are at a high risk of failure due to their age and/or design defects. As previously discussed, because the assets are non-standard, failure could have a significant impact on reliability due to the lack of like-for-like replacements available. In many cases this equipment also poses potential safety risks to the public and/or Toronto Hydro crews.

E6.3.3.1 Program Drivers

Table 3 summarizes the trigger and secondary drivers for replacing ULI. This program is a System Renewal initiative with a trigger driver of functional obsolescence.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Most of the equipment targeted by this program is no longer manufactured and, therefore, it is difficult to acquire replacements when needed. These assets are becoming more likely to fail as many are near end-of-life. ƒ Vastly improved assets have become available since the infrastructure targeted by this program was originally installed. The modern assets have additional functionality and safety measures when compared to the currently installed legacy equipment. ƒ There are no longer any construction standards which can be used by Toronto Hydro for replacing/maintaining these assets in a like-for-like manner.
Secondary Drivers	Reasoning

Safety	ƒ Degradation of assets can pose safety hazards for field crews when operating and/or maintaining the equipment. ƒ Certain assets (i.e. cable chamber lids) create public safety issues.
Reliability	ƒ Often a like-for-like replacement option is not available for equipment targeted by this program. As a result, when this equipment fails, the system can be left in a contingency situation for long durations while a solution is developed and executed. Until the solution is implemented and the system resumes normal operation, customers are exposed to additional outage risk. ƒ Assets are at or near the end of their useful life and/or prone to failure, presenting an outage risk.
Failure Risk	ƒ Assets are at or near the end of their useful life. As a result, they are more likely to fail and will require reactive replacement.

The various assets and installations addressed by this program share functional obsolescence as the trigger driver for proactive replacement. If and when these assets require reactive replacement (i.e. if they are allowed to fail while in service), the lack of like-for-like replacement options or alternative equipment may result in prolonged outages for customers. Custom engineered solutions are regularly needed to fully resolve issues across all assets targeted with this program, with the exception of cable chamber covers. The time it takes to develop these solutions often means that the system must be left in a contingency situation for an extended period of time until an appropriate solution can be implemented.

Many of these assets have reached, or are approaching, end-of-life and/or are at risk of failure due to design defects, which raises the urgency to proactively replace these obsolete assets. Proactively replacing these assets is expected to help minimize operational, reliability and safety risks and will allow for more efficient use of resources.

The following sub-sections provide additional detail on the investment drivers for the specific asset types and configurations addressed in this program.

(i) Sachsenwerk Switch and Fuse Units

Toronto Hydro must proactively replace Sachsenwerk switch and fuse units in order to ensure worker safety, maintain operability of the system and to mitigate the risk of unplanned outages. As describe in section E6.3.2.1, Sachsenwerk switch and fuse units are used in dual radial configurations. The switches have been deemed unsafe because they have drawn a dangerous arc current (i.e. the unit “flashed over”) in multiple cases due to a consistent failure mode explained below. Two examples of recent failures of the Sachsenwerk switch and fuse units are the November 2012 failure at 30-40 Holly St (location MDH in the discussion below) and the April

2011 failure at 66 Walpole Ave (location GWD in the discussion below). Figure 12 shows photos of the switch compartments post-failure. Scorching on the top of the phase barriers/dividers is visible in both cases.

FIGURE 12: PHOTOS OF SWITCH COMPARTMENT (DOOR OPEN) FROM MDH (LEFT) AND GWD (RIGHT) AFTER THEIR FLASH-OVER INCIDENTS

The failure at MDH resulted in a near miss incident (i.e. injury could have occurred but did not). The Sachsenwerk unit flashed over (i.e. discharged electricity in a high current arc) while being manually operated to transfer a customer to its standby supply. The unit failure occurred because the spring-loaded mechanism, which enables the fast movement of the switch blades on opening and closing, did not engage. This caused the switch blades to move in time with the operating handle, drawing an electrical arc, which caused the fault.

The incident at MDH caused the customer to go without power supply for over 40 hours (during a portion of this time they were supplied via generator). Since the outage resulted in two primary feeders being put out of service, the customer's normal and standby supply, a total of seven customers were affected by the outage including a public library, a school, a retirement residence, an office building and two apartment buildings, with the shortest outage time being just over 100 minutes. The total customer minutes out (CMO) for this outage was 1,398 and the total Customers Interrupted (CI) was seven. The relatively low CI figure is explained by the fact that the customers affected were bulk metered customers.

Safety concerns with these units have limited the ability of system operators to use the equipment as originally intended, negatively impacting reliability. A safety bulletin was issued by Toronto Hydro to its employees, specifying special instructions for switching these units following the November 2012 incident. The bulletin indicated that before operating a Sachsenwerk switch and

fuse unit to make or break full load, crews must contact their supervisor so that a collaborative onsite assessment and evaluation can be undertaken. This evaluation includes an inspection of the switch to determine if the switch can be operated. If operation of the switch proceeds and the initial operation is unsuccessful (the switch does not operate properly), a second attempt is not made; instead, the system operator must be notified immediately.

As discussed, in certain circumstances it may be unsafe for crews to operate these switches as load break/make switches. This means that the switches can only be used in paralleled operations because otherwise, the primary feeder that supplies the switch would need to be taken out of service before switching could occur in an outage restoration situation.

Due to the failure history of these units, and the risk posed to crews operating the switches, Toronto Hydro plans to remove all Sachsenwerk switch and fuse units from the system. Prior to this failure mode being identified, Toronto Hydro was in the process of replacing existing switch and fuse units at end-of-life with retrofitted units.

(ii) Thorncliffe Park Area Distribution Equipment

Toronto Hydro plans to proactively reconfigure and replace equipment in the Thorncliffe Park area in order to mitigate the risk of prolonged outages. The distribution system in the Thorncliffe Park area is a legacy design of the former East York Hydro, as described in section E6.3.2.2.

The main issues with the existing configuration are (1) corrosive and flooded vault environments causing the ATSs to malfunction, (2) the fact that no six-way SF_6 switches are currently stocked due to the limited number in the system and since the supplier no longer manufacturers them, and (3) radial customers supplied by the five-way and six-way switches cannot remain energized if the switch is taken out of service for replacement (i.e., when a switch is scheduled for replacement, customers will experience a planned outage of up to four hours until the replacement is complete).

These inherent problems in the design of the Thorncliffe Park area directly contributed to a 29-hour long outage on March 10, 2013. The event was caused by a six-way submersible switch failing. Finding the fault proved difficult since the configuration requires complex switching procedures to determine on what segment of the feeder the failed equipment is located on. Once the fault was found, customers supplied directly from the six-way switch had to wait for the switch to be replaced before their power could be restored.

As an alternative solution, Toronto Hydro arranged for one of the three primary feeders to bypass the switch and a five-way switch was installed in place of the failed six-way switch. The

customers fed from this switch were out of power until this five-way switch could be installed. The entire process of finding the fault, performing switching to isolate the fault, determining a replacement option and completing the work took over 29 hours. The total CMO for this outage was 50,083 and the total number of CI was 70. Many of the customers were bulk metered apartment buildings, so the actual number of people affected by the outage was much greater than the CI figure indicates. The outage was so severe that it attracted extensive public and media interest.[1]

Figure 13 shows a photograph of the six-way switch in vault V4488 that failed on March 10, 2013.

FIGURE 13: THE 6-WAY SF6 SWITCH WHICH FLASHED-OVER IN THE OUTAGE IN MARCH OF 2013. THIS PHOTO WAS TAKEN AFTER THE FAULT HAD OCCURRED; FAULT WAS INTERNAL TO THE SWITCH. NOTICE THE RED TAG ON SWITCH POSITION VS216 INDICATING THE ATS FOR THAT POSITION WAS NOT FUNCTIONAL.

As noted above in Section E6.3.2.2, the ATS installed on the five-way and six-way switches in this area are associated with reliability issues. Under normal circumstances, the ATS is supposed to transfer over to a backup feeder when the normal primary supply is lost. However, many of these ATS are no longer functional due to flooding in the vaults, despite sump pumps being installed. The excessive flooding in this area is due to an underground river. This has damaged the circuitry controlling the ATS, resulting in additional maintenance costs and resources to continuously fix and inspect the ATS units. An outage in the area on April 23, 2008 had an extended impact due to an ATS failing to transfer.

(iii) Legacy Transclosure Equipment

Toronto Hydro must proactively replace transclosures in order to mitigate the risk of lengthy outages and to maintain a safe working environment. As described above in section E6.3.2.3, transclosures are pole-mounted or non-submersible vault style transformers within a metal enclosure (vault style shown in Figure 14). Pole-top and non-submersible vault style transformers are not intended for use in the corrosive and dirty environment of enclosures located at ground level. The primary connection to this transformer is not performed through an elbow connector, which is the standard for most underground or pad-mounted transformers. Instead, the connection terminates directly at the primary bushing of the transformer. This means that these units are "live-front" (exposed terminations/bushings are energized), making them potentially unsafe for crews since the primary termination is more easily exposed to dirt and debris and thus more prone to tracking (i.e. the gradual breakdown of the insulator under electrical field stress) and flashovers.

FIGURE 14: VAULT STYLE TRANSFORMER IN AN ENCLOSURE

FIGURE 15: CORRODED AND DAMAGED TRANSCLOSURE ENCLOSURES

The majority of the transclosures in the system are nearing end-of-life and are in poor condition, with enclosures that have rusted through (Figure 15). The poor physical condition of the transclosures is a potential safety hazard to both the public and Toronto Hydro crews. Since transclosures are a legacy design and have no like-for-like replacement option, they are difficult to address in the event of an outage, which leads to long restoration times. In August 2013, a worker was exposed to an arc flash hazard when working on the primary termination at a transclosure location. Fortunately the worker was not harmed but this "near miss" incident could potentially have resulted in serious injury.

(iv) Powerlite Switches

Powerlite switches should be replaced in order to mitigate risk of failure and address potential worker safety concerns. Powerlite switches are secondary switches located in single-phase radial vaults. The switch is designed to auto-transfer when a primary feeder goes out. This auto-transfer mechanism has become increasingly likely to fail due, in part, to the age of the equipment. In 2013, two switches failed to operate autonomously.

The switch itself is not a stock coded item (since it is no longer manufactured) and no like-for-like replacement can be obtained. In addition, manual switching can be a safety hazard due to the poor condition of these switches (spring mechanism does not engage) and the limited space in the vault for manual operation. Each replacement requires an engineered solution dependent upon the location's load and the amount of space in the existing vault structure.

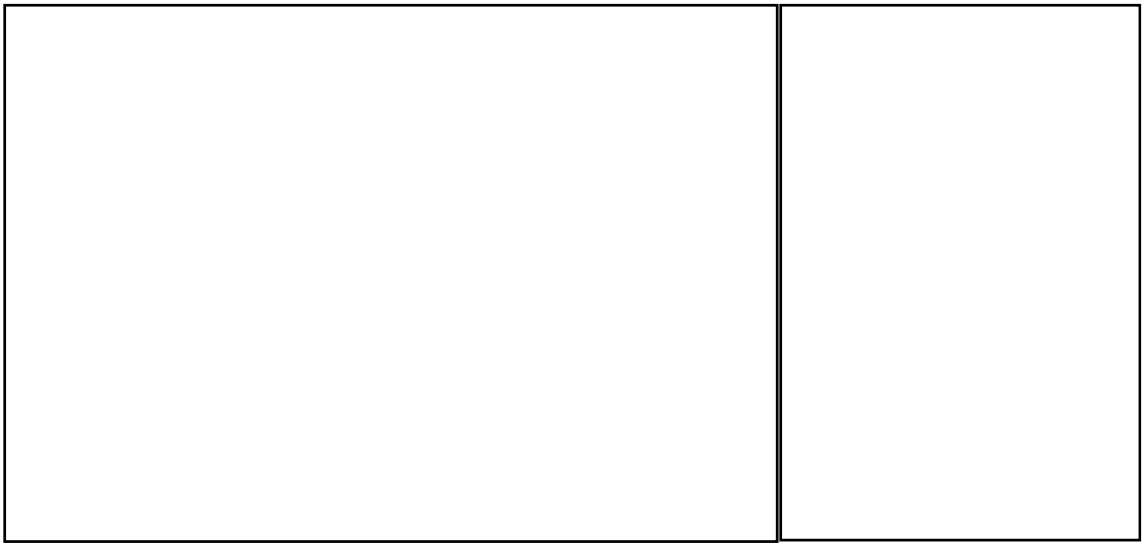

FIGURE 16: POWERLITE SWITCH AND SINGLE-PHASE TRANSFORMER

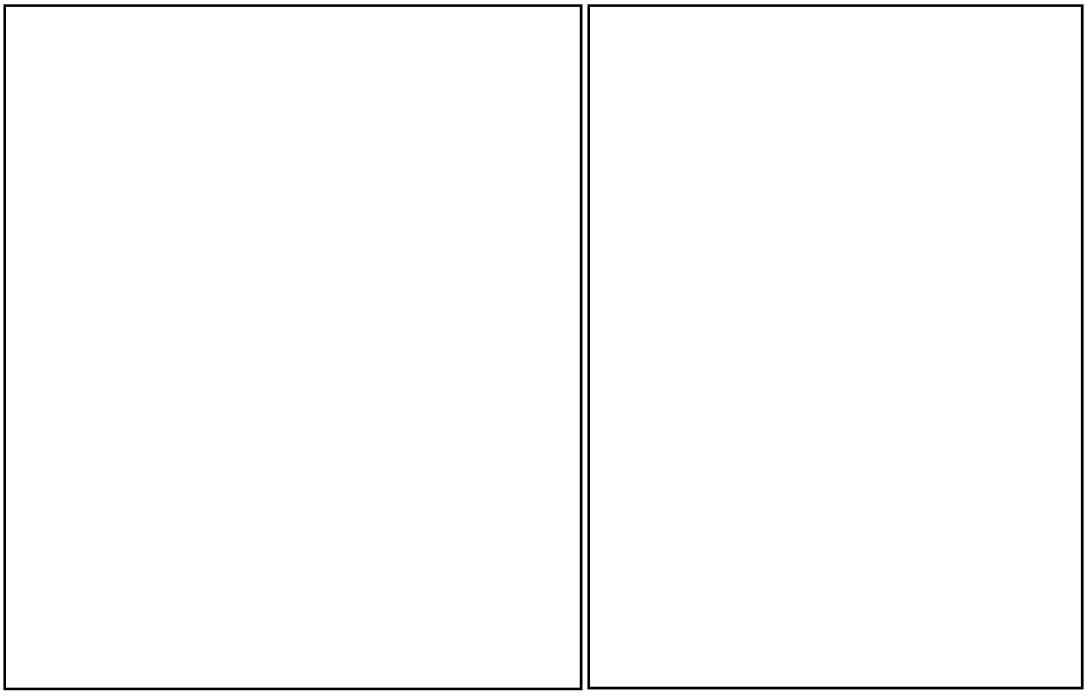

FIGURE 17: INTERNAL SWITCH MECHANISM OF THE POWERLITE SWITCH (DOOR OPEN)

In the spring of 2013, one Powerlite location on the Danforth was deemed too hazardous to continue to operate. As a result, the switch at this location had to be proactively changed out to ensure that customers could be restored in the case of an outage. The response was not able to match the urgency of the situation due to the lead times associated with a planned solution engineered specifically for this site.

The Powerlite switch in this situation had to be reactively replaced with CRD switches. However, the conversion to a CRD set-up was incomplete since there is still a single phase primary supply. This is not a preferred solution going forward since (1) the location becomes atypical relative to the distribution system as a whole, which could cause crew or operator confusion, (2) single phase loads could cause imbalance (excessive neutral currents) and subsequent inadvertent tripping of the station relay, and (3) there is the potential to get an 8 kV voltage on the system neutral while conducting work if proper precautions are not followed.

(v) Vault Step Transformers

Toronto Hydro must replace existing vault step transformers (described in section E6.3.2.5) in order to mitigate the anticipated negative reliability impacts should this obsolete and non-standard equipment fail while in service. Toronto Hydro no longer stocks step transformers for the reasons discussed above in section E6.3.2.5. As such, the lack of a like-for-like replacement option would lead to an extended outage for customers if a unit were to fail.

The majority of the step transformer units are of a dry type, meaning that the windings are insulated using air (described in section E6.3.2.5). This design exposes the transformers to failure from vault flooding. One such incident occurred in late 2013, interrupting the 600 V service to a local school. Solutions to allow for removal of these units could involve customers being fed from additional secondary circuits in the area, although each location may require a unique approach.

(vi) Cable Chamber Covers

There are 10,572 cable chambers in the City of Toronto. Toronto Hydro must replace cable chamber covers in order to mitigate the safety hazard associated with flying lids caused by eruptions in the chamber. As shown in Figure 18, there have been 24 incidents of flying lids in the past seven years; while this failure mode is not overly common, it can result in harm to people and property. Other utilities have also experienced cable chamber eruptions with some causing serious injuries[2].

FIGURE 18: NUMBER OF EJECTED CHAMBER COVER INCIDENTS AT TORONTO HYDRO BY YEAR

Cable chamber covers in Toronto Hydro's current infrastructure are made of cast iron and have a minimum mass of 150 kg. Shock waves caused by an eruption inside the cable chamber can send the cable chamber cover into the air, posing safety risks to people and property nearby. Explosions can occur when overloaded or compromised cables generate excess heat that causes their insulation to begin to melt. The insulation then smolders and catches fire, releasing gases that then build up inside the cable chamber. With the insulation compromised, the conductor may then arc and ignite the built-up gases, causing a powerful explosion. This explosion can then eject the cable chamber cover, as shown in Figure 19

FIGURE 19: CAUSE OF EJECTED CABLE CHAMBER COVER [3]

Depending on the amount of gas-pressure built up inside the cable chamber the force of the eruption generated may cause the cover to flip over or be launched several feet in the air. Toronto Hydro estimates that the potential explosive force of the shock waves which can be generated is sufficient to send a cover up to 65 feet high at a speed of up 20 meters per second. Current cable chambers covers cannot withstand or dissipate cable chamber eruptions.

The current lid design may also be contributing to the severity of some outages. Since the current cover design does not allow for ventilation of gas, there is an increased the likelihood of an eruptions occurring due to gases being present in the chamber when a fault is experienced. These eruptions cause the chamber covers to be launched into the air and also cause damage to the cables surrounding the faulted cable. If more than one cable becomes damaged, the system is placed into a multiple contingency situation.

The new cable chamber covers that will be installed have ventilation capabilities for gases and can withstand the force of the potential shock waves. This allows them to address the potential an

[3] How Stuff Works: How Exploding Manholes Work, Kevin Bonsor: http://science.howstuffworks.com/environmental/energy/exploding-manhole1.htm

eruption inside the cable chamber in a controlled and safe manner. As well, by installing a cable chamber cover design that vents gases, Toronto Hydro plans to reduce the possibility of an eruption so that cable fault damage may be more easily contained to one feeder.

E6.3.3.2 Asset Details

(i) Asset Lifecycle This program targets the replacement of underground legacy assets and assets in non-standard configurations at, or nearing, the end of their useful lives. Due to the age of these assets, the probability of failure is high.

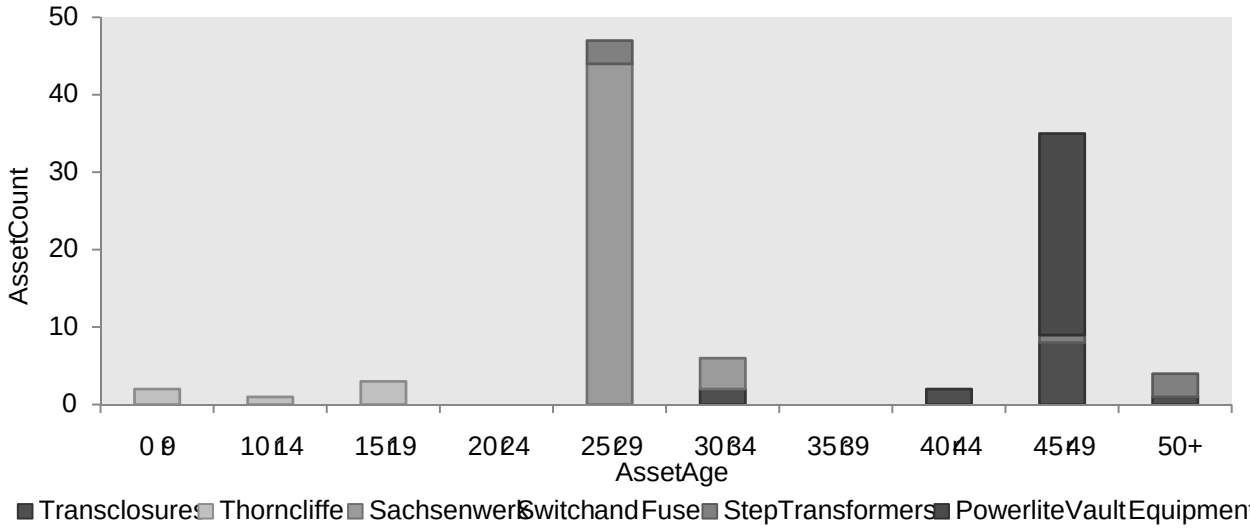

FIGURE 20: ASSET AGES FOR EXISTING IDENTIFIED LEGACY ASSETS TARGETED BY THIS PROGRAM (NOTE: SACHSENWERK AGE DATA INCLUDES UNITS BEING REPLACED IN NETWORK CIRCUIT RECONFIGURATION PROGRAM)

Figure 20 provides the age of assets to be replaced as part of this program. The 48 Sachsenwerk units planned for replacement (eight of which are being replaced in the Network Circuit Reconfiguration program) are no longer manufactured and are all 25 years and older, with four units being more than 30 years old. The transclosure units being replaced in 2015 to 2016 are at their end-of-life (or will be by their scheduled replacement dates) and are not currently stocked by Toronto Hydro as they are a legacy asset (end of life for pad or vault style transformers is 35 years). In many cases, these units show corrosion (see Figure 15) and are generally in poor condition. As their condition deteriorates, they also pose an arc flash hazard, described in further detail in the transclosure segment of section E6.3.3.1.

As can be seen in Figure 20, all of the Powerlite units are 45 years or older. This switch type is no longer manufactured. These units have past the end of their useful lives (end of life for ATS switches – a similar asset – is 40 years) and no longer operate as intended, often requiring manual switching in ways that could pose risks to operating crews. Assets included in the Powerlite vault equipment represented in Figure 20 include the Powerlite switches and single phase transformer units that will be changed out at the same time as the switches. Two of these locations have had CRD equipment installed reactively but still have single-phase transformers that will require replacement.

There are seven sets of step transformers being replaced in this program, all of which are nearing end-of-life (30 years for submersible transformers, 35 years for vault transformers) and are therefore at risk of failure. Asset age is taken into account during prioritization so that older units are replaced in the earlier years of the program. More detailed information regarding prioritization data can be found in section E6.3.4.1.

The switches in the Thorncliffe Park distribution area are the newest legacy assets being replaced through this program. The replacement of this equipment is driven primarily by an obsolete configuration that could lead to long outage durations. The SF_6 switches (SF_6 is the insulating medium for switches in the Thorncliffe Park area) are considered sealed for life by their manufacturer. Typically this life guaranteed by the manufacturer of the submersible SF_6 switches in Toronto Hydro's system is 20 years, which is shorter than that of more traditional assets. Once a switch has leaked to the point where it cannot be operated safely, it has, for all intents and purposes, failed. In the case of the outage experienced at Thorncliffe Park in the spring of 2013, a switch had leaked to the point where a fault was able to occur within the switch without any switching action taking place. The switch that failed was of the same vintage (late 1990s) as most of the other switches in Thorncliffe Park that this programs targets for replacement. Two of the switches are newer because they are the result of reactive replacements (one replaced in 2008 and one in spring 2013). For more details on the outage in March 2013 please refer to section E6.3.5.2.

(ii) Asset Failure Impacts

The ULI program improves reliability by helping mitigate equipment failures, which are one of the most common causes of outages on Toronto Hydro's system. Approximately 50% of the outages on Toronto Hydro's system during the last five years (2008-2013) were attributable to failed (i.e. defective) equipment, with 28% due to failed underground equipment. Failed underground equipment can be further broken out into cable assets (i.e. cables and splices) and other assets (e.g. transformers, switches). Failure of underground assets excluding cable related assets

represents 11% of all forced outages throughout the entire system as per Figure 21 below. Legacy assets targeted by this program have an increased failure risk because they are at, or nearing, the end of their expected useful lives.

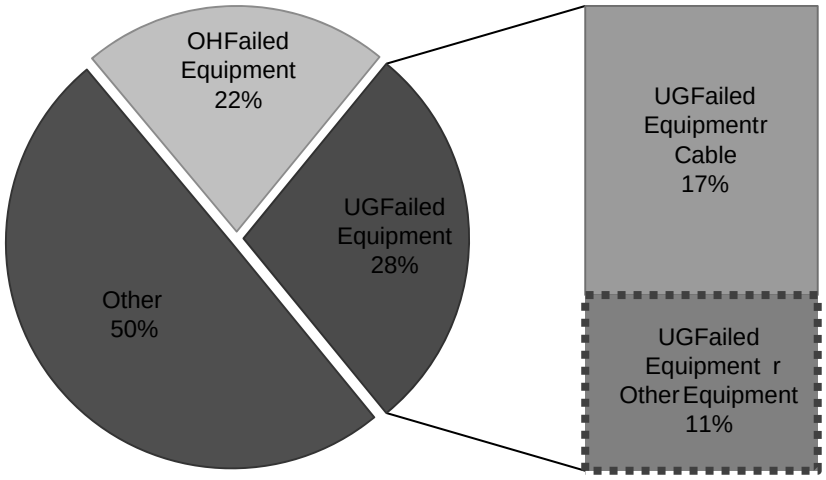

FIGURE 21: BREAKDOWN OF SYSTEM OUTAGES OVER THE PAST FIVE YEARS (2008-2013) BY OUTAGE CAUSE

If an underground equipment failure is caused by a legacy asset, outage restoration times will be lengthened due to a lack of like-for-like replacement options and/or difficulties that crews may have restoring non-standard configurations. The solution is typically dependent on site-specific conditions (e.g., vault size and customer load). As a result, legacy asset failures tend to result in relatively lengthy outages.

Failure Causing Secondary/Local Outage

The failure mode that would impact the least number of customers would be an outage that only affects customers downstream of a distribution transformer or on a segment of a feeder. This is referred to as a secondary or localized outage. While the system is designed to handle a first contingency, a contingency plan does not always exist at this level due to the relatively low number of customers impacted; therefore, restoration requires that the equipment be replaced or some other form of resupply is done.

If a failure of a transclosure feeding a commercial site occurs, all customers fed by the unit would experience an outage. If the transformer was damaged beyond repair, the outage could last up to 16 hours, since there is no standard replacement option.

In a reactive scenario, the goal is to restore power as quickly as possible. In order to accomplish this goal, Toronto Hydro must reconnect the customer to the new transformer in a delta configuration (the three phase wiring of the failed transclosure unit) in order to match their service, even though this new transformer's secondary side will be a three phase wye configuration, which has a fourth grounding wire and is the current standard. At a later date, an electrician would need to make the necessary changes to the customer's electrical supply and meter base, requiring a second (planned) outage to bring in the fourth wire (ground) to the customer. This would be the case with the failure of any delta transformer in the system, since delta transformers themselves are a legacy design.

When a residential transclosure fails, the unplanned outage would de-energize the entire residential loop so that field crews could safely work on the non-standard unit. This process results in long outages to other customers who are fed from healthy assets in the loop.

When replacements are performed proactively for these units, the outage experienced by the customer is reduced from approximately 16 hours to around six to eight hours. The proactive approach allows the necessary preparatory work to be completed in advance (i.e., civil work and electrician services) so that the customer will only be de-energized while the connections are made.

The step transformers present a similar failure scenario. While the units service small loads, if they fail, it could take a substantial amount of time to restore service if there is no nearby supply of the required voltage. Many of the step transformer units service schools; accordingly, lengthy outage durations would cause considerable difficulties and inconvenience to the public.

Failure Causing a First Contingency Feeder Outage

The failure mode that has a more severe impact on customers is an outage that takes out an entire primary feeder, referred to as a first contingency feeder outage. The system is designed to handle a first contingency, so while customers on a feeder will still be interrupted by a failure, they can be restored before the source of the failure is completely resolved. Outage restoration time will depend on the number of customers on a feeder.

Sachsenwerk switch and fuse units are prone to flashing over (faulting to ground) when operated. When this occurs, the station breaker will open and all dual radial customers on that feeder will

lose power. A flash-over of a switch and fuse unit will always cause a primary feeder outage, resulting in customers being interrupted with the number of customers affected dependent on the feeder.

Powerlite vaults provide a second example of this failure mode. The transformers in Powerlite locations are of the same vintage as the switches (mid 1960s) and have no upstream protection. If these transformers fail, the entire primary feeder will fault to ground and all customers that are supplied by the feeder will lose service.

Failure Causing a Second/Multiple Contingency Feeder Outage

The failure mode that would have the most severe impact on customers is an outage that takes out multiple primary feeders, referred to as a second or multiple contingency feeder outage. Since the system is not designed to handle a multiple contingency, customers on the interrupted feeders may not be restored until the source of the failure is resolved. Outage restoration time will depend on the severity of the damage on each feeder.

The non-standard system configuration in Thorncliffe Park features transformer vaults that are fed radially from five-way and six-way switches. When a failure of the five-way or six-way switch occurs it can take out all the primary feeders which terminate on the switch. This means a large number of customers are affected by the outage and fault locating and restoration become more difficult, lengthening outage duration. Refer to Figure 22 for a diagram showing the current configuration of a six-way switch in the Thorncliffe Park area.

FIGURE 22: VAULT V4488 CONTAINS A 6-WAY SWITCH THAT HAS THREE INCOMING PRIMARY FEEDERS AND SUPPLIES THREE TRANSFORMER VAULTS (V4478, V4616, AND V4465). IN THE EVENT OF EQUIPMENT FAILURE WITH THE 6-WAY SWITCH, THERE IS NO WAY TO SUPPLY THE THREE RADIALLY FED TRANSFORMER VAULTS AND ALL THREE PRIMARY FEEDERS WOULD EXPERIENCE AN OUTAGE.

Failure Causing System Operating Constraints

A final failure mode that would impact customers is a failure causing an operating constraint. This type of failure refers to a situation when equipment can no longer be operated as intended. When this happens, forced feeder outages may be required in order to operate the system. The impact of these outages varies based on the equipment involved and could affect multiple primary feeders. Most outages incurred due to operating constraints are momentary outages.

The Powerlite switch is an example of this type of failure. Powerlite switches can fail to automatically transfer feeders during an outage. When this type of failure occurs, customers will see an outage to half of their service (since customers have half their panel supplied by each transformer in this arrangement, see Figure 23). Crews must go to the site and manually operate the switch to fully restore customers. This can result in an outage lasting up to an hour while the crew is dispatched.

FIGURE 23: INTERNAL SET-UP OF A POWERLITE VAULT (NOTE: EACH SWITCH IS SERVICING HALF OF EACH 120/240V SUPPLY)

The spring mechanism inside the Powerlite switch does not always engage properly. In these situations, crews are forced to operate the switches by alternate means in order to restore the customer. These operations can represent a potential safety hazard for Toronto Hydro crews. Typically, vault environments are cramped, making it difficult and relatively unsafe to operate the switch by alternate means. If crews cannot operate the switch safely while it is live, the controller would need to drop an additional feeder in order to switch with both feeders de-energized. In this situation, additional customers supplied by both those feeders would experience an outage.

A similar situation presents itself with the switch and fuse units. If they are deemed unsafe to switch, a multiple contingency situation could arise when additional feeders need to be de-energized in order to restore customers (explained in more detail in section E6.3.5.2).

A final example would be a low gas switch, like those found in the Thorncliffe area. If the switch needs to be operated on low gas, all the incoming primary feeders must be de-energized before that operation could proceed. This de-energization could result in two to three primary feeders experiencing momentary outages.

E6.3.4 Timing & Pacing of the Program

Table 4 details the number of assets that Toronto Hydro plans to replace in each year of the 2015 to 2019 planning period.

TABLE 4: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Sachsenwerk Switch and Fuse Units	6	12	12	10	0	40*
Powerlite Switches	0	2	2	2	2	8
Single Phase Submersible Transformers	0	4	4	4	4	16
Step Transformers	0	2	2	2	1	7
Transclosures	6	9	9	9	9	42
SF_6 Switches	2	1	2	1	0	6
Cable Chamber Covers	25	375	375	375	350	1,500

* Note: 8 remaining switch and fuse units are planned to be removed within the Network Circuit Reconfiguration Program

The pace of replacement for the different asset types was determined based on the risk of failure of the assets as determined by age and condition, the expected impact of asset failure and the overall number of units.

Table 5 provides projected program spending from 2015-2019. After the initial year, the aggregate yearly budget for the program is relatively consistent, with only small fluctuations year over year until 2019. Spending in 2015 is planned to be lower than in subsequent years due to resource constraints.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	2.06	6.69	6.64	6.48	5.52

Some assets, such as the Sachsenwerk switch and fuse units, are of relatively higher priority. These units must be removed as soon as possible to mitigate the increased safety and operational risks that they present. The program costs are forecasted to drop in 2018 and 2019 following the planned removal of higher-risk assets by 2017.

Toronto Hydro established yearly replacement rates for Sachsenwerk switches by taking the current rate of replacement for change-outs being undertaken reactively by Toronto Hydro crews (seven locations in 2013 and 10 in 2014) and adjusting for some additional units that could be

completed given the advantages of planning out the work (3 locations for 2015, 6 locations in 2016, and an additional four in the Network Circuit Reconfiguration Program, 6 locations in 2017 and 5 locations in 2018).

A small number of cable chamber covers are planned for replacement in 2015, followed by a steady replacement rate throughout the remainder of the five year period. Toronto Hydro plans to only replace a relatively small number of units in 2015 to allow for the proper testing of the new equipment design. In 2016 to 2019, Toronto Hydro plans to replace 350-375 cable chamber covers a year. This more aggressive pace was chosen in order to minimize safety risks, considering the number of chamber covers located in busy pedestrian traffic locations, while taking into account resource constraints.

Toronto Hydro plans to also replace Powerlite switches, step transformers and transclosures at a steady pace beginning in 2016, which corresponds to the increase in spending from 2015 to 2016. Toronto Hydro created a plan to address all units within the five year period while accommodating the needs of other programs. The work on these units relies on resources that are used in the switch and fuse change outs; accordingly, the replacement rate for these assets is reflective of the high-priority given to switch and fuse units due to safety concerns.

Toronto Hydro plans to execute the Thorncliffe Park area work by grouping locations fed by sets of two five-way or six-way switches so that looping between the replacement pad-mounted switches can be achieved (see section E6.3.2.2 for more information on the switch replacement).

E6.3.4.1 Ranking & Prioritization

Toronto Hydro prioritized the sub-projects of the ULI program based on the failure risk of the asset, such as the age and condition, potential safety risks, as well as how many customers that equipment supplies or would be impacted by its failure.

Maintenance inspection data, when available, is the main source of asset condition data. For the Sachsenwerk units, additional inspections were conducted following the switch failure that occurred in November 2012 (see section E6.3.5.2 for more detail). These inspections rated the units on a scale of one to four, where a one rating required immediate action and a four rating could be addressed at a later date. This information was used to select units for crews to change out in 2013 and 2014 and to prioritize the remaining units for future replacement.

In the Thorncliffe area, locations were prioritized based on which ATS switches do not operate properly, which switching vaults have flooding history, and the historical reliability of specific

locations. The two locations planned for replacement in 2015 will help prevent a recurrence of the incident that occurred in March 2013. See section E6.3.5.2 for more details of this incident.

Loading information was also used to prioritize work. If the equipment is serving a large load, or if the equipment's failure would affect customers upstream, like in the case of the Sachsenwerk switch and fuse units, then that equipment is considered to be of a higher priority.

Projects are also prioritized in order to coordinate them with work in other programs, which may be addressing either nearby equipment or the same primary feeder. Efforts are made to group work so that it can be executed as efficiently as possible and avoid situations where conflicts between projects could negatively affect project execution.

E6.3.5 Program Execution

A large majority of the assets that Toronto Hydro plans to address in the ULI program are located on the 13.8 kV underground system (Sachsenwerk switch and fuse units, Powerlite switches and equipment in the Thorncliffe area), while some, like transclosures, are found on the underground 27.6 kV and 4.16 kV systems. Toronto Hydro plans to address these assets through a series of discrete projects from 2015 through 2019. The planned order of execution for 2015 projects is outlined in section E6.3.8. For a more general outline of the execution in the 2015-2019 period see section E6.3.6.1 below.

E6.3.5.1 Proposed Work Plan

As discussed previously, the work to be performed pursuant to the ULI program is scattered throughout the city. For many of the assets in this program (transclosures, step transformers, switch and fuse units) the year of execution is determined based on the unit's priority relative to the other units in the same asset class (prioritization discussed in section E6.3.4.1). There is often little overlap between the feeders these assets are on, so feeders do not provide a mechanism for organizing work into execution years. When possible, however, assets on the same feeder will be grouped so that they are addressed in the same execution year in order to minimize the required feeder scheduling. The work plan ensures the assets outlined for replacement in Table 5 are replaced by the end of the 2015 to 2019 period.

Some asset replacements, like cable chamber lids, Powerlite vaults and Thorncliffe reconfigurations can be organized and executed by geographic area. This approach creates efficiencies for these projects because, in the case of Thorncliffe and Powerlites, the reconfigurations/conversions can build off one another as the program progresses year-over-year. The first three years of Powerlite replacements is planned to target the Bloor St W/Dufferin

St areas, with the final year targeting the remaining Danforth Ave. locations. Reconfiguration in the Thorncliffe area will address pairs of switches in each year, building off the looped configuration built by the previous pair's replacement. The cable chamber lids replacement plan is projected to address one to two areas of high pedestrian traffic each year by targeting all the lids in those areas, specifically targeting areas with the most foot traffic.

TABLE 6: 2017-2019 LONG TERM PLAN

Year	Targeted Asset
2015	3 Switch and Fuse Replacement Projects (6 units)
2015	Phase 1 of Thorncliffe Park Reconfiguration
2015	Cable Chamber Lid Test Installation
2015	2 Transclosure Replacement Projects (6 units)
2016	6 Switch and Fuse Replacement Projects (12 units)
2016	Phase 2 of Thorncliffe Park Reconfiguration
2016	Cable Chamber Lid Installation Phase 1
2016	9 Transclosure Replacement Projects
2016	2 Powerlite Replacement Projects (Bloor St W)
2016	2 Step Transformer Replacement Projects
2017	6 Switch and Fuse Replacements Projects (12 units)
2017	Phase 3 of Thorncliffe Park Reconfiguration
2017	Cable Chamber Lid Replacement Phase 2
2017	9 Transclosure Replacement Projects
2017	2 Powerlite Replacement Projects (Bloor St W)
2017	2 Step Transformer Replacement Projects
2018	5 Switch and Fuse Replacement Projects (10 units) – Final year
2018	Phase 4 of Thorncliffe Park Reconfiguration
2018	Cable Chamber Lid Replacement Phase 3
2018	9 Transclosure Replacement Projects
2018	2 Powerlite Replacement Projects (Bloor St W)
2018	2 Step Transformer Replacement Projects
2019	Phase 5 of Thorncliffe Park Reconfiguration
2019	Cable Chamber Lid Replacement Phase 4
2019	9 Transclosure Replacement Projects
2019	2 Powerlite Replacement Projects (Danforth Ave) 1 Powerlite Replacement Project (Bloor St W)

E6.3.5.2 Program Risks

(i) Summer Switching Restrictions

Legacy underground infrastructure is often found in the downtown area on feeders that may be subject to summer switching restrictions. That operational constraint is further explained within the Load Demand program (Section E5.4). If an asset is being replaced on one of these feeders, the time available for the executing the work will be limited. This risk is mitigated by the work proposed in the Load Demand program and by accounting for the switching restrictions during the scheduling of work early in the year.

(ii) Premature Asset Failure

The assets in the ULI program are often nearing end-of-life and could require reactive replacement due to failure or worsening condition before the planned work is executed. This would necessitate changes to the planned work program. To mitigate the risk of changing the planned work program, asset condition is used as an important factor during project prioritization (see section E6.3.4.1).

(iii) Inaccurate Records

Specifically with respect to the Thorncliffe Park distribution area, limitations of the existing design records lead to a higher probability of conflicts between what is planned and what is executable during the detailed design and construction phase. This limited information may result in a need for re-design, or cause the delay of certain aspects of projects. This risk exists to some degree with most projects, but has been identified as more likely in this area due to past experience involving inaccurate records in this service area. To mitigate this risk, efforts have been undertaken and are ongoing to update and confirm these records. If delays were to arise, scheduling flexibility over the 2015-2019 period would allow the work to be completed.

(iv) Condition of Customer Owned Locations

Finally, some of these legacy infrastructure assets may be in customer owned locations. Since this infrastructure has been in place for a long time, there may be unforeseen issues with craning space and vault access or the vault condition. These issues may require the customer to perform civil work before Toronto Hydro can continue with certain projects, resulting in project delays. This risk is mitigated by the use of inspection records when planning work. Toronto Hydro built scheduling flexibility into the 2015-2019 planning period so that work can still be completed within the planning period if delays arise.

E6.3.6 Evaluation of Alternatives

E6.3.6.1 Quantification/Evaluation of Options

(i) Status Quo

Deferring the work in the ULI program would be equivalent to a run-to-failure scenario. This approach would not recognize that the equipment is at or nearing end of life and is at risk of failure. Customers would be exposed to excessively long outage durations because there is no like-for-like replacement option for many legacy assets when failure does occur. It also would not address the worker and public safety concerns associated with certain pieces of legacy equipment.

(ii) Replacement with Standard Equipment

This approach addresses the equipment obsolescence, failure risk and safety concerns. As described in E6.3.2, this option entails replacing legacy assets with current technical and economical standard solutions available for each distinct asset.

The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities within this program. The cost of ownership (COO) of a state reflects the risk of asset failure including both direct and indirect costs; these costs include customer interruptions, emergency repairs, and asset replacements associated with a given design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_N) state. Non-asset risks are further explained in Section D3.3.

Any additional benefit that is associated with the program that is external to the asset and non-asset related risk evaluation is quantified for both the existing state (AQB_E) and new state (AQB_N); in the case of this program the AQB_N is associated with the scrap value recovered during cable chamber lid replacements. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Underground Legacy Infrastructure program produces a net benefit (NPV) value of $1.46 million, as shown in Table 7.

TABLE 7: UNDERGROUND LEGACY INFRASTRUCTURE BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: Replacement with Standard Equipment (N1)	
Asset Risk [AR_N]	10.31
Non Asset Risk [NAR_N]	0
Maintenance Cost [MC_N]	0
Additional Quantifiable Benefits [AQB_N]	-0.001
Cost of Ownership of New Assets [COO_N]	10.31
Option 1: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	3.52
Program Cost [PC_1]	2.06
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	1.46

E6.3.7 2015 Projects

Table 8 is a list of Underground Legacy Infrastructure projects that are planned for execution in 2015. Details on projects for 2015 are provided in the following sections.

TABLE 8: 2015 PROJECTS

Project Number	Project Name	Total Project Cost ($ Millions)	Start Date
X15405	Replacement of Switch and Fuse Gear at TGC (U9001)	0.13	2015
X15412	Replacement of Switch and Fuse Gear at ODR (U8033)	0.13	2015
X15428	Replacement of Switch and Fuse Gear at EPU (U8026)	0.13	2015
E15403	Replace transclosure pad transformers on feeders of EJ and ZE SCEJF1	0.77	2015
E15435	Ellendale-Kennedy Transclosure Replacement Civ-Elec SCFBF4	0.09	2015
X15352	Thorncliffe Rebuild (Phase 1)	0.69	2015
X15544	Replacement of Cable Chamber Lids (Test)	0.11	2015

E6.3.7.1 X15405 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Replacement of Switch and Fuse Gear at TGC (U9001)

Project Number: X15405

Project Year: 2015

Estimated Cost: $133,436

(i) Objective

To replace the Saschenwerk switch and fuse gear at location TCG (U9001). The switch and fuse gear present a known hazard to crews switching (when making and breaking load). This hazard is described above in section E6.3.3.1. Toronto Hydro plans to replace the equipment with submersible CRD 2-way SF_6 switches, a replacement option which is described in section E6.3.2.1. The existing distribution transformer will be maintained.

(ii) Scope of Work

TABLE 9: X15301 SCOPE OF WORK DETAILS

District Neighborhood	YONGE & COLLEGE
Station(s)	WINDSOR
Feeder(s)	A7CE, A5CE

TABLE 10: X15301 ASSETS REPLACED

Assets (Units)	2015
Switch and Fuse Unit	2

(iii) Justification & Benefits

Saschenwerk switch and fuse units pose a hazard to the switching crews for load make or break operations. This hazard is described earlier in section E6.3.3.1. Due to this hazard, operational constraints have been placed on the system where Saschenwerk switch and fuse gear is present (can only be operated when paralleled). These units are being replaced with CRD two-way SF_6 switches, in order to relieve this operating constraint and safety hazard.

The location of TGC (U9001) has been inspected by crews and has sufficient space for CRD equipment. The replacement of the switch and fuse units with new CRD equipment will resolve the arc flash hazard that currently exists at this location. This unit is 27 years old.

E6.3.7.2 X15412 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Replacement of Switch and Fuse Gear at ODR (U8033)

Project Number: X15412

Project Year: 2015

Estimated Cost: $133,193

(i) Objective

To replace the Saschenwerk switch and fuse gear at location ODR (U8033). The switch and fuse gear presents a known hazard to crews switching (when making and breaking load). This hazard is described above in section E6.3.3.1. The equipment will be replaced with submersible CRD two-way SF_6 switches. The existing distribution transformer will be maintained.

(ii) Scope of Work

TABLE 11: X15301 SCOPE OF WORK DETAILS

District Neighborhood	FINANCIAL DISTRICT - TRICHMOND & SHEPPARD
Station(s)	WINDSOR
Feeder(s)	A51WR, A55WR

TABLE 12: X15301 ASSETS REPLACED

Assets (Units)	2015
Switch and Fuse Unit	2

(iii) Justification & Benefits

Saschenwerk switch and fuse units pose a hazard to the switching crews for load make or break operations. This hazard is described in section E6.3.3.1 above. Due to this hazard, operational constraints have been placed on the system where Saschenwerk switch and fuse gear is present (can only be operated when paralleled). These units are being replaced with CRD two-way SF_6 switches, in order to relieve this operating constraint and safety hazard.

The location of ORD (U8033) has been inspected by crews and has sufficient space for CRD equipment. The feeders supplying this location are network feeders and were placed in high

priority because if a double contingency (described previously in section E6.3.3.2) were to arise on the network system, the entire network for that bus may need to be dropped. The replacement of the switch and fuse units with new CRD equipment will resolve the arc flash hazard that currently exists at this location. This unit is 26 years old.

E6.3.7.3 X15428 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Replacement of Switch and Fuse Gear at EPU (U8026)

Project Number: X15428

Project Year: 2015

Estimated Cost: $133,193

(i) Objective

To replace the Saschenwerk switch and fuse gear at location EPU (U8026). The switch and fuse gear presents a known hazard to crews switching (when making and breaking load). This hazard is described above in section E6.3.3.1. The equipment will be replaced with submersible CRD two-way SF_6 switches. The existing distribution transformer will be maintained.

(ii) Scope of Work

TABLE 13: X15301 SCOPE OF WORK DETAILS

District Neighborhood	FINANCIAL DISTRICT, FRONT & UNIVERSITY
Station(s)	WINDSOR
Feeder(s)	A51WR, A55WR

TABLE 14: X15301 ASSETS REPLACED

Assets (Units)	2015
Switch and Fuse Unit	2

(iii) Justification & Benefits

Saschenwerk switch and fuse units pose a hazard to the switching crews for load make or break operations. This hazard is described in section E6.3.3.1 above. Due to this hazard, operational constraints have been placed on the system where Saschenwerk switch and fuse gear is present (can only be operated when paralleled). These units are being replaced with CRD two-way SF_6 switches, in order to relieve this operating constraint and safety hazard.

The location of EPU (U8026) has been inspected by crews and has sufficient space for CRD equipment. The feeders supplying this location are network feeders and were placed in high

priority because if a double contingency (described previously in section E6.3.3.2) were to arise on the network system, the entire network for that bus may need to be dropped. The replacement of the switch and fuse units with new CRD equipment will resolve the arc flash hazard that currently exists at this location. This unit is 26 years old.

E6.3.7.4 E15403 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Replace transclosure pad transformers on feeders of EJ and ZE SCEJF1

Project Number: E15403

Project Year: 2015

Estimated Cost: $766,519

(i) Objective

The objective of this project is to replace old, rusted, and non-standard transclosures at five different locations supplied by feeders of FJ and ZE since they are a failure risk. They also pose a safety concern to both Toronto Hydro crews and the public, as described previously in E6.3.2.3 and the transclosure section of E6.3.3.1.

Location 1: PT47621 (SCEJF2)

Existing transformer is a 3 phase - 225kVA 600V Delta transclosure unit and it is 47 years old. Proposed work is to install a new standard pad-mounted 300kVA 600/347V transformer beside the existing transclosure pad, followed bythe new cables and terminations including the secondary connections (converted to 4 wires Y) to the customer.

Location 2: PT56550 (SCEJF1)

Existing transformer is a 3 phase - 112kVA 600V Delta transclosure unit and it is 47 years old. Proposed work is to install a new standard pad-mounted 150kVA 600/347V transformer beside the existing transclosure pad, followed by the new cables and terminations including the secondary connections (converted to 4 wires Y) to the customer.

Location 3: PT27773 (SCZEF3)

Existing transformer is a 3 phase - 225kVA 208/120V transclosure unit and it is 33 years old. Proposed work is to convert the 4.16 kV OH lateral which supplies the UG cable to PT27773, as well as pole top transformer OT38614. A new standard pad-mounted 300kVA 208/120V transformer will be installed beside the existing transclosure pad, followed by the new cabling and terminations. This includes the secondary connections to the customer.

Location 4: PT47412 (SCEJF2)

Existing transformer is a 3 phase - 112kVA 600/347V transclosure unit and it is 50 years old. Proposed work is to install a new standard pad-mounted 150kVA 600/347V transformer beside the existing transclosure pad, followd by the new cables and. This includes the secondary connections to the customer. Location 5: PT5650 (SCEJF1)

Existing transformer is a 3 phase - 150kVA 600V Delta transclosure unit and it is 44 years old. Proposed work is to install a new standard pad-mounted 150 or 300kVA 600/347V transformer beside the existing transclosure pad, followed by the new cables and terminations including the secondary connections (converted to 4 wire Y) to the customer.

(ii) Scope of Work

TABLE 15: E15403 SCOPE OF WORK DETAILS

District Neighborhood	HWY401 & KENNEDY
Station(s)	CANADIEN, MIDLAND (4.16 KV), MIDLAND, LAWRENCE (4.16 KV)
Feeder(s)	SCEJF1, SCEJF2, SCZEF3

TABLE 16: E15403 ASSETS REPLACED

Assets (Units)	2015
Transclosures	5

(iii) Justification & Benefits

All five of these locations are transclosures. The low quality of the metal used to construct the enclosures around the transformers has caused rusting, making the transformers unsafe to operate and maintain. This is described in greater detail in E6.3.2.3 and the transclosure section of E6.3.3.1.

For these five locations, a standard pad transformer will replace the existing transclosures. The new pad transformer will be installed beside the existing transclosure and, when ready, with minimum outage, the new cables and terminations can be carried out. This work includes the secondary connections to the customer's panel. This pad unit will provide additional safety for both the public and Toronto Hydro crews since it will be "dead-front".

Inspections show the units are in poor condition and require replacement. Additionally, the units being replaced in this scope are all at or nearing end of life (oldest unit is 50 years old, newest unit is 33 years old). Replacement will mitigate the impact of failure, improve worker safety and improve the overall neighborhood aesthetic.

E6.3.7.3 E15435 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Ellendale-Kennedy Transclosure Replacement Civ-Elec SCFBF4

Project Number: E15435

Project Year: 2015

Estimated Cost: $88,413

(i) Objective

The objective of this project is to replace the old, rusted, and non-standard transclosure PT44494, proactively bringing it up to standard.

Currently the existing transformer is fed from FB-F4 (13.8kV) and is a wye-wye configured transformer. Replacing the transclosure will require converting the customer line from 13.8kV to 27.6kV (i.e., the customer will not be fed from FB-F4 but rather from E5-M30).

Proposed work includes the installation of a three phase 208/120V (1x150kVA) pad-mounted transformer that will be supplied from a dip from the adjacent 27.6kV line. A new switch will need to be installed on the overhead pole to facilitate this. Following this, existing 13.8 kV cables will be dead-ended and the transclosure pad will be completely removed from the customer's site

(ii) Scope of Work

TABLE 17: E15435 SCOPE OF WORK DETAILS

District Neighborhood	ELLENDALE & KENNEDY
Station(s)	CANADIEN, MIDLAND (4.16 KV), MIDLAND LAWRENCE (4.16 KV)
Feeder(s)	SCARBOROUGH

TABLE 18: E15435 ASSETS REPLACED

Assets (Units)	2015
Transclosures	1

(iii) Justification & Benefits

PT44494 is a transclosure, a non-standard transformer with an enclosure build around it as described above in sections E6.3.2.3 and E6.3.3.1. The enclosure was not made of standard grade steel and is showing signs of decay, posing a potential safety hazard to public.

As well, due to the non-standard internal configuration (i.e., "live-front"), this transclosure poses a potential safety hazard to field crews. Inspections show the unit is in poor condition and needs replacement. Replacement will mitigate the impact of failure, improve worker safety and improve overall neighborhood aesthetic.

Doing this work should mean that the customer will see a significantly shorter outage since the customer's power will be maintained while all connections are set up and only disconnected when crews are ready to transfer power.

Since the secondary service is roughly 600A the customer requires a pad-mounted transformer. The transformer cannot be replaced with an OH bank-type transformer. As well, since the customer is already wye-wye connected it does not require a new meter-base or secondary ancillary (as was required for multiple units in E15403).

E6.3.7.4 X15352 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Thorncliffe Rebuild (Phase 1)

Project Number: X15352

Project Year: 2015

Estimated Cost: $691,775

(i) Objective

The existing distribution system in the Thorncliffe Park area is ULI (non-standard), and is susceptible to flooding (high water table area). It is also vulnerable to extended outages when there is equipment failure on the five-way and six-way switches, as experienced on March 10, 2013 (29-hour outage). These issues are described in detail earlier on in sections E6.3.2.2 and E6.3.3.1.

This project is the first of Toronto Hydro's planned five phases to remove five and six-way switches from this area and to reconfigure the system into a standard looped system. Figure E6.3-4 in section E6.3.2.2 shows the proposed reconfiguration/replacement of the 5-way and 6-way switches, V4488 and V4489, respectively.

(ii) Scope of Work

TABLE 19: X15352 SCOPE OF WORK DETAILS

District Neighborhood	THORNCLIFFE PARK (OVERLEA BLVD)
Station(s)	LEASIDE
Feeder(s)	EYA10L, EYA5L, EYA6L

TABLE 20: X15352 ASSETS REPLACED

Assets (Units)	2015
5 way and 6 way Submersible SF6 Switches	2

(iii) Justification & Benefits

On March 10, 2013, the Thorncliffe Park area experienced an extended 29 hour outage after a six-way switch failed. This outage is described in greater detail in the Thorncliffe section of E6.3.3.1.

The new configuration for this area requires pad-mounted switches, instead of the existing underground 5-way and 6-way switches, to alleviate flooding issues. It also requires a looped system using 3-way switches in the transformer vaults rather than the existing single radial feeds from the switches to transformer vaults.

This new configuration will mitigate the impact of future equipment failures or planned work.

E6.3.7.5 X15544 Project Description

Investment Category: System Renewal

Program: Underground Legacy Infrastructure

Project Title: Replacement of Cable Chamber Lids (Test)

Project Number: X15544

Project Year: 2015

Estimated Cost: $114,030

(i) Objective

The objective of this project is to replace 25 existing cable chamber lids with the new lid design that will be able to vent pent up gases from the chamber and withstand the force of shock waves that would be generated if an eruption occurred.

(ii) Scope of Work

TABLE 21: X15544 SCOPE OF WORK DETAILS

District Neighborhood	HIGH PEDESTRIAN AREAS DOWNTOWN
Station(s)	N/A
Feeder(s)	N/A

TABLE 22: X15544 ASSETS REPLACED

Assets (Units)	2015
Cable chamber lids	25

(iii) Justification & Benefits

This project replaces 25 lids with the new lid design. The reason for the limited number of replacements in the first year is because the lids need to go through standard testing procedures for new equipment, including testing operations in both the summer and winter months.

The replacements target areas of high pedestrian traffic and chambers that have a greater number of feeders passing through them, since these are at greater risk of experiencing an explosion.

E6.4 Overhead Circuit Renewal

NEW INLINE DISCONNECT SWITCH

E6.4.1 Summary

Program Description

Toronto Hydro's Overhead Circuit Renewal program is a continuation of activities previously described in the Ontario Energy Board (OEB) approved Overhead Infrastructure segment as part of the 2012-2014 IRM/ICM rate-setting application. This program replaces assets that have aged, are in poor condition and that are functionally obsolete. These assets contribute to the overall failure risk of the utility's overhead distribution system. The program's investments are focused on the replacement of poles, switches, transformers and overhead accessories. This program also includes former street lighting assets that were found to be distribution assets by the Ontario Energy Board (OEB) in the Transfer Decision ("former street lighting assets").[1]

End-of-life and/or obsolete assets that are replaced in this program include: wood poles, concrete poles, overhead switches, end-of-life transformers (including obsolete completely self-protected ("CSP") transformers), and porcelain and non-standard accessories (including non-standard animal guards). The Overhead Circuit Renewal program consists primarily of projects that are considered complete rebuilds, where a substantial number of assets in a geographical area are at a high risk of failure and are therefore replaced simultaneously on a 'like-for-like' basis. The like-for-like approach means that the aged assets are replaced with new and standardized assets that

[1] EB-2009-0180,0182,0183, Decision and Order (February 11, 2010) at page 8. For additional information, please refer to Exhibit 2A, Tab 5.

have the same essential specifications and functions. Standardizing overhead assets that are at risk of failure will mitigate costs that would otherwise be incurred during repair and restoration efforts.

The anticipated benefits of the Overhead Circuit Renewal program are as follows.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improves service reliability for customers on the targeted feeders; the trunk-related outages to be mitigated can affect up to 7,000 customers and can cause adverse power quality issues for large industrial facilities on the same station bus.
Reliability	ƒ Improves system reliability by mitigating failure risk and limiting the frequency and impact of overhead defective equipment outages through the timeline like-for-like replacement of end-of-life overhead assets
Safety	ƒ Polymeric insulating material has less destructive failure modes than currently used porcelain material. ƒ Prevents poles from falling due to rotting bases. ƒ Standardized transformers have a longer working distance compared to CSP transformers. ƒ Avoids sub-optimal illumination for drivers and pedestrians caused by defective street light pole outages.
Efficiency	ƒ Avoids unnecessary costs that are incurred for repair and restoration efforts on defective overhead equipment.

Program Drivers

The trigger and secondary drivers for the Overhead Circuit Renewal program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Aged and deteriorating wood and concrete poles ƒ Overhead transformer deterioration ƒ Aging and obsolete switches and controls ƒ Deteriorating and obsolete ancillary equipment
Secondary Drivers	**Reasoning**
Safety	ƒ Pole deterioration weakens structures ƒ Porcelain insulating material is susceptible to contamination build-up and electrical tracking, which can cause cracking, rupture and catastrophic failures

Functional Obsolescence	ƒ Obsolete animal guards ƒ Obsolete remote switching communication systems

Preferred Alternative

Toronto Hydro considered the following alternatives for addressing the assets in this program:

(1) Do nothing and replace on a reactive basis only, incurring the risk of equipment failures and potential safety concerns.

(2) Short term mitigation or rehabilitation of deteriorated assets, such as replacement of only the porcelain insulators or switches, leaving other assets in place (e.g., an aged pole).

(3) Proactively replace end-of-life overhead equipment, which includes aged, poor condition, and functionally obsolete equipment that is at the highest risk of failure over the next five years in a coordinated fashion.

Option III is the preferred alternative as it is expected to enable Toronto Hydro to most effectively mitigate the risks posed by the currently installed assets in the most cost-efficient manner. Option I is likely to result in deterioration of overhead system reliability performance and high costs associated with reactive equipment replacement. Option II may provide short-term performance stability, similar to the Worst Performing Feeder program (E6.21) but would ultimately result in unnecessary costs due to the inefficiency of rebuilding overhead feeders in a piecemeal fashion.

The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $39.94 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.4.7).

Timing and Pacing

The Overhead Circuit Renewal program will ensure that Toronto Hydro is replenishing aged and deteriorating infrastructure at an appropriate pace in order to mitigate failure and safety risk.

Table C summarizes historical and projected program spending. A high number of overhead defective equipment outages occurred between 2008 and 2010, prompting an increase in spending levels from 2010 and onwards. Outages began to rise again from 2012 to 2013, prompting another increase in proactive renewal spending to address the growing backlog of

aging overhead assets. Future spending levels are somewhat reduced compared to the ICM period (2012-2014) expenditures; this is made possible due to the fact that the overall DSP contains an expanded suite of programs that includes complementary renewal and modernization efforts that will enable more cost-effective management of overhead system performance (e.g. Overhead Infrastructure Relocation, E6.5; Feeder Automation, E7.3).

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	$25.8	$28.3	$23.2	$49.0	$53.3	$44.0	$23.0	$24.9	$25.3	$30.3

E6.4.2 Program Description

Toronto Hydro's Overhead Circuit Renewal program replaces assets that have aged, are in poor condition and that are functionally obsolete; these assets contribute to the overall failure risk of the utility's overhead distribution system. The program's investments are focused on the replacement of poles, switches, transformers, overhead accessories.

This program also includes former street lighting assets that were found to be distribution assets by the Ontario Energy Board (OEB) in the Transfer Decision ("former street lighting assets").[2]

The Overhead Circuit Renewal program consists primarily of projects that are considered complete rebuilds, where a substantial number of assets in a geographical area are at high failure risk and are therefore replaced simultaneously on a "like-for-like" basis. In some cases, abnormally high failure risk may warrant stand-alone replacements of assets in multiple locations. The like-for-like approach means that the aged assets are replaced with new and standardized assets that have the same essential specifications and functions. Also as part of this program, voltage conversions will target 4.16 kV or 13.8 kV equipment that is aged and in poor condition, replacing the existing assets with new assets at higher voltage levels.

Standardizing overhead assets that are at risk of failure is expected to mitigate costs that would otherwise be incurred in connection with repair and restoration efforts. Typically, outages related to defective overhead equipment necessitate the replacement of a major asset. In these scenarios, Toronto Hydro crew members must transport new assets to the location of the outage and conduct on-site installation to restore power.

The Overhead Circuit Renewal program will cost an estimated $147.4 million over the 2015 to 2019 period and is expected to deliver $39.94 million in avoided risk costs. The following subsections describe the various assets that are being renewed through the Overhead Circuit Renewal program.

E6.4.2.1 Replacement of Aging Poles

Toronto Hydro uses two types of poles in its overhead system: wood poles and concrete poles which are typically former street lighting assets. Poles act as support structures to route power distribution lines and accommodate other electrical distribution assets. The Overhead Circuit Renewal program includes proactive replacement of deteriorating poles that are unfit for

[2] EB-2009-0180,0182,0183, Decision and Order (February 11, 2010) at page 8. For more information, please refer to Exhibit 2A, Tab 5.

continued use. These replacements will mitigate failure and safety risks associated with aged and poor condition poles, as detailed in section E6.4.3.

(i) Wood Poles

The wood poles used throughout Toronto Hydro's overhead system have an expected useful life of 45 years. Approximately 31% of existing poles are at or near end-of-life and will require proactive replacement during the 2015-2019 period. Toronto Hydro plans to replace these poles with new butt-treated Western Red Cedar poles. Pole heights range from 30 feet to 55 feet depending on the area (e.g., residential, industrial/commercial or arterial roadway) and the mix of assets attached to the pole (e.g. number of primary and secondary circuits, the presence of third party attachments, transformers, underground terminations, switches, etc.).

Wood pole replacements include the replacement of ancillary support structures, like fiberglass cross arms and new brackets, and new accessories, like insulators and arrestors. These ancillary support structures are usually the same vintage as the wood pole itself since they are typically installed during the construction of the pole. Replacing the ancillary structures at the same time as the poles allows Toronto Hydro to utilize its resources more efficiently.

Figure 1 illustrates a standard wood pole with new ancillary support structures.

FIGURE 1: NEW WOOD POLE

(ii) Concrete Poles

In addition to distribution wood poles, the Overhead Circuit Renewal program intends to replace aged and poor condition concrete poles that have an expected useful life of 60 years. Approximately 4-5% of existing concrete poles are at or near end-of-life and will require proactive replacement during the 2015-2019 period. These are typically former street lighting poles, which accommodate brackets, luminaries, and service wires inside brackets. They are mostly concrete with reinforced rods (rebar) or, in some cases, aluminum.

The new poles range in height from 28 feet to 35 feet and selection will vary depending on the application. Figure 2 below illustrates a standard concrete pole with a bracket and luminaries attachment.

FIGURE 2: NEW CONCRETE STREET LIGHT POLE

E6.4.2.2 Replacement of Aging Switches

Overhead switches used throughout Toronto Hydro's overhead system have an expected useful life of 45 years. Approximately 33% of existing switches are at or near their end-of-life and will require proactive replacement during the 2015-2019 period. Overhead switches allow Toronto Hydro to isolate feeder sections or equipment for maintenance, or to interrupt load for load shifting and other operating requirements on three-phase systems. They also allow workers to work safely by isolating feeder sections and creating zones that are free of energized equipment.

Toronto Hydro uses three types of switches in its overhead system: in-line disconnect switches, manual load break switches and SCADA-mate switches. The consequence of aging switches is natural deterioration due to wear as parts move against one another, resulting in the binding of moving components and eventually, the inability to operate. Also, environmental conditions can

lead to corrosion and rust. The Overhead Circuit Renewal program includes a like-for-like replacement of these assets with new standard switches in order to reduce the failure risk of these assets.

(i) In-line Disconnect Switches

Toronto Hydro uses in-line disconnect switches as isolation points on portions of feeders. The switches are operated manually and are opened one electrical phase at a time. They are used to electrically isolate sections of overhead when performing maintenance or asset replacement tasks. In-line disconnect switches that have reached their end of life will be replaced with updated assets.

(ii) Manual Loadbreak Switches

Manual loadbreak switches are designed to manually open and close all three electrical phases simultaneously (i.e. a "gang-operated" switch) using an operating handle or motor-driven operating rod. These switches are used to sectionalize circuits to reduce the size of outages during fault conditions. Under this program, old obsolete switches will be replaced with new manual load break switches that have solid blades mounted in a three-phase switchgear. These loadbreak switches use load interrupters and an air gap to provide isolation.

(iii) SCADA-Mate Switches

SCADA-Mate load break switches are gang-operated switches that can be operated using an electric motor. This type of switch is meant to be operated remotely, though it can also be manually operated if required. The supervisory control and data acquisition (SCADA) system enables remote operation and provides sensors for three-phase monitoring of line current and line-to-neutral voltages. Remote operability allows for faster restoration of customers during an outage as compared to manually operated switches. As an ancillary benefit, it mitigates safety risks associated with manual switching such as potential for flashover during operation.

Components of SCADA-Mate switches are prone to corrosion, including the housing and internal moving parts, and can experience mechanical deterioration of bearings, loose connections, motor winding deterioration, contamination of the circuitry, or the failure of electronic equipment as they age. Furthermore, particular SCADA-Mate switch locations in the Etobicoke area use the Motorola radio communication system (DARCOM radio system and MOSCAD Terminals). This technology has reached the end of its useful life and the equipment is obsolete.

The replacement of aged SCADA-Mate switches will be done as part of rebuild projects. In some cases, obsolete SCADA-Mate MOSCAD RTUs and DARCOM radios in Etobicoke will be targeted for replacement as part of self-contained projects due to the high failure risk associated with these aged and obsolete assets. This program targets non-R1 SCADA-Mate switches that are end-of-life or utilize MOSCAD RTUs and DARCOM radios in Etobicoke. Defective SCADA-Mate R1 switches are being proactively placed at a more accelerated pace in the SCADA-Mate R1 Renewal program (refer to section E6.8 of the Distribution System Plan).

E6.4.2.3 Replacement of Legacy Overhead & CSP Transformers with Standardized Pole-Top Transformers

Overhead transformers used throughout Toronto Hydro's overhead system have an expected useful life of 40 years. Approximately 24% of existing overhead transformers are at or near end-of-life and will require proactive replacement during the 2015-2019 period to reduce failure risk.

Pole-mounted transformers are an important component of the 27.6 kV overhead system. Age, condition, and loading contribute to the increasing failure risk of overhead transformers over time. All pole-mounted transformers are single phase units rated at 16.0 kV for the 27.6 kV system and can be mounted as one single-phase unit or a cluster of three single-phase transformers forming a three-phase unit.

Under this program, pole mounted transformers that have reached their end of life will be replaced. The three standard sizes of pole-mounted transformers are 50 kVA, 100 kVA, and 167 kVA. The size of the transformer used in a particular circumstance generally correlates to the anticipated load and is located near the load centre to maximize bus utilization and reduce voltage drop. Figure 3 shows a new overhead transformer.

FIGURE 3: NEW OVERHEAD TRANSFORMER

E6.4.2.4 Replacement of Porcelain & Non-Standard Accessories with Standardized Accessories

The replacement of overhead accessories as part of this program includes animal guards and porcelain hardware. These assets are located on transformers, poles and switches that are proposed for replacement as part of this program.

(i) Porcelain Hardware

In Toronto Hydro's overhead plant, porcelain material was used as insulation for switches, lightning arrestors, terminators, and line post insulators. The porcelain material tends to carry a higher risk of failure due to its tendency for contamination build up that leads to electrical tracking (i.e. the breakdown of insulation materials, which can lead to faults). The new standard technology to be installed under this program uses polymeric material that is less susceptible to contamination in high corrosion areas, minimizing the leakage current that can cause tracking.

(ii) Animal Guards

Existing legacy wildlife protection on Toronto Hydro's overhead distribution system consists of "Guthrie" guard animal protectors. The Guthrie guard creates a physical barrier that attaches to the bushings of overhead transformers, repelling animal contact with a mild shock that prevents

them from contacting the energized transformer bushing. However, animal contacts with energized components of the transformer still occur. The new standard animal guards to be installed through this program use a cone shaped guard on the bushing, with an accompanying insulated drop wire. This design provides improved physical non-conductive barriers to deter animals.

FIGURE 4: MAP OF OVERHEAD CIRCUIT RENEWAL AREAS FOR 2015

The following table summarizes the anticipated benefits Overhead Circuit Renewal program.

TABLE 1: PROGRAM BENEFITS

Customer Value	***f*** Improves service reliability for customers on the targeted feeders; the trunk-related outages to be mitigated can affect up to 7,000 customers and can cause adverse power quality issues for large industrial facilities on the same station bus. *f* The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $39.94 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.4.7).
Reliability	*f* Improves system reliability by mitigating failure risk and limiting the frequency and impact of Overhead defective outages through the like-for-life replacement of end-of-life overhead assets
Safety	*f* Polymeric insulating material has less destructive failure modes than currently used porcelain material. *f* Prevents poles from falling due to rotting bases. *f* Standardized transformers have an external disconnect switch to provide a visible positive affirmation of an “open” or “close” state and longer working distances, as opposed to CSP transformers. *f* Avoids sub-optimal illumination for drivers and pedestrians caused by defective street light pole outages.
Efficiency	*f* Reduces unexpected costs that are incurred for repair and restoration efforts as part of overhead defective equipment.

Table 2 below provides details of the estimated number of assets forecasted for replacement from 2015 to 2019.

TABLE 2: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Poles	2,838	1,735	1,900	1,934	2,313	11,214
Overhead Switches	218	160	166	154	207	981
Overhead Transformers	937	511	478	598	673	3,232

/C

E6.4.3 Why the Program is Needed

Toronto Hydro’s Overhead Circuit Renewal program targets assets that are aged and deteriorated, leading to a high risk of failure. The failure of these assets will negatively impact service reliability to customers on the overhead system and could pose safety concerns for employees and the general public. As discussed in Section E6.4.5.2, defective overhead equipment is a significant source of outages.

Figure 5 shows historical trending of outages due to overhead defective equipment in terms of customers interrupted (CI), customer hours interrupted (CHI), and frequency of outages. Sustained interruptions on Toronto Hydro's overhead system stabilized over the 2011 to 2013 period, as shown in Figure 5, due to increased overhead renewal spending levels from 2010 and onwards (refer to Table 6). There was an increase in outages due to overhead defective equipment from 2012 to 2013.

FIGURE 5: OVERHEAD DEFECTIVE EQUIPMENT HISTORICAL RELIABILITY

As per Figure 6, overhead equipment continues to be a major contributor to sustained interruptions every year, over the past five years, compared to other major failure types.

FIGURE 6: SYSTEM WIDE OUTAGE FREQUENCY 2008-2013

The overhead system is a significant contributor to SAIDI and SAIFI. On average, overhead defective equipment contributes to about 22% of all system wide outages every year.

Figure 7 breaks down the frequency of overhead system outages.

FIGURE 7: OVERHEAD CORE ASSETS OUTAGE FREQUENCY

The figure above demonstrates that overhead transformers and animal contacts contribute most to the frequency of overhead type outages.

E6.4.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for the Overhead Circuit Renewal program.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Aged and deteriorating wood and concrete poles. ƒ Overhead transformers deterioration. ƒ Aging and obsolete switches and controls. ƒ Deteriorating and obsolete ancillary equipment.
Secondary Drivers	**Reasoning**
Safety	ƒ Pole deterioration weakens structures ƒ Porcelain insulating material is susceptible to contamination build-up and electrical tracking, which can cause cracking, rupture and catastrophic failures ƒ Older pole mount transformers lack visible disconnect switch for positive confirmation of being open or closed
Functional Obsolescence	ƒ Obsolete animal guards. ƒ Obsolete communication systems. ƒ Pole mount transformers lack of external fuses, as required by new standards.

(i) Aging Poles

Aging & Deteriorating Wood Poles

The risk of failure for wood poles is related to both their age and condition. Given that wood is a natural material, the degradation process is somewhat different from those that affect other distribution system assets. For example, pole rot is caused by naturally-occurring fungi that attack and degrade wood, resulting in decay. Birds and insects can also damage poles. The nature and severity of the resulting degradation depends both on the type of wood and the environmental conditions. Certain fungi will attack the external surfaces of the pole, while others will target the internal heartwood. Degradation may occur internally, externally, or both. Depending on the

particular pole, a number of degradation modes such as feathering, internal rot, decay at the ground line, shell rot and infestation may combine to reduce pole strength.

Figures 8 and 9 demonstrate pole-top feathering. The top portion of the pole is critical because it contains the necessary attachments for insulators, brackets and other hardware used to secure the overhead conductors to the line.

FIGURE 8: POLE-TOP FEATHERING

FIGURE 9: POLE-TOP FEATHERING

Figures 10 and 11 show internal base rot. This type of deterioration weakens the pole base, which can cause the pole to fall.

FIGURE 10: INTERNAL BASE ROT

FIGURE 11: INTERNAL BASE ROT

Figures 12, 13 and 14 show major cracks, holes, and evidence of rot.

FIGURE 12: AND FIGURE 13: MAJOR POLE CRACKS, HOLES, AND ROT

FIGURE 14: MAJOR POLE CRACKS, HOLES, AND ROT

The expected useful life of a wooden pole is 45 years. The Overhead Circuit Renewal program will address all poles that have reached end-of-life and that are in poor and very poor condition according to Toronto Hydro's Asset Condition Assessment (ACA) program (see section E6.4.3.2 (i) for additional details). Toronto Hydro expects to address all of these poles during the 2015-2019 period. This work is required to mitigate the reliability and safety concerns associated with the risk of pole failure. The failure impacts of wooden poles are discussed in more detail in section E6.4.3.2 (ii).

Concrete Poles

The majority of concrete poles are mostly made of concrete with metal reinforced rods (rebar), and in some cases, aluminum. These poles degrade in the same manner as other concrete structures. Initially, moisture enters cracks or voids inside the concrete material and accumulates. Freezing temperatures cause moisture to expand and enlarge the crack in the concrete resulting in the exposure of internal metal rebar. As well, road salt can enter the cracks and, over time, corrode the metal rebar, reducing pole strength and ultimately reducing the useful service life of the pole. Aluminum poles degrade from corrosion due to road salt and moisture exposure. The failure of these assets can potentially mean an outage to the street lighting system in the area which in turn can lead to customer complaints and potential safety issues. Figure 15 shows a deteriorated concrete pole.

FIGURE 15: CONCRETE POLE DETERIORATION

The Overhead Circuit Renewal program will address all concrete poles that have reached end-of-life of 60 years and that are in poor and very poor condition. Toronto Hydro plans to address all of these poles during the 2015-2019 period. This work is required mitigate the reliability and safety concerns associated with the risk of pole failure.

(ii) End-of-Life & CSP Overhead Transformers

Age, condition, and loading contribute to the failure risk of overhead transformers. A transformer's useful life is heavily dependent on the state of the transformer winding insulation system. The insulation media is comprised of paper wrapped around the conductors in the transformer's coils, and the paper and coils are submerged in insulating oil. Over time, the normal operation of a distribution transformer naturally degrades the paper insulation within the transformer oil. As this occurs, the oil gradually turns to sludge, and its own insulating properties are reduced. The combined loss of dielectric strength from both the paper and oil insulation can result in an internal failure of the transformer and an outage to connected customers.

The application of a voltage over a long period of time induces electromagnetic stresses that lead to insulation breakdown and the loss of dielectric strength. Therefore, loading profiles and the length of time in service are key determinants of an in-service transformer's useful life. Also, when any transformer exceeds its loading capacity, the increased heat travelling through the winding coil can accelerate the degradation of both the winding paper insulation as well as the dielectric transformer oil.

Some of Toronto Hydro's older units are known as completely self-protected (CSP) transformers because they are of a legacy design that features primary fusing contained inside the transformer tank. Once a CSP transformer fails in the field or the primary fuse has operated, the transformer must be replaced. In contrast, Toronto Hydro's current standard for overhead, pole-mounted transformers requires the fuse to be externally-located, providing a visible isolation point and the ability to re-fuse the transformer. The visible isolation point provides crews positive affirmation that the transformer is disconnected from the primary line, whereas a defective CSP transformer would have the open fuse hidden inside the transformer tank. In about 50% of the outages related to standard non-CSP transformers, transformer replacement is not required because the external fuse can be replaced while leaving the transformer in place.

Most CSP transformers are located in north-central Toronto, with a smaller number located in Etobicoke and Scarborough. Since amalgamation, CSP transformers have been replaced by standard non-CSP pole-mounted transformers. CSP transformers are typically installed on 35-foot poles. The additional external hardware above the transformer for the non-CSP transformers requires these assets to be installed on taller poles. Figure 16 and Figure 17 show a typical overhead CSP transformer.

FIGURE 16: CSP TRANSFORMER

FIGURE 17: TYPICAL CSP TRANSFORMER POLE INSTALLATION

CSP transformers create potential safety risks for Toronto Hydro crews because they lack the external fuse and visible disconnect switch that can be used as an isolation point when restoring standardized non-CSP transformers. An external and visible disconnect switch provides a positive affirmation of an "open" or "close" state. In addition, CSP transformer restoration requires that crew members be closer to the transformer when working on it. In contrast, the use of longer equipment for standard non-CSP transformers increases the distance between the crew worker and the transformer during operation, thereby minimizing any potential safety risks that may arise.

The expected useful life of a transformer is 40 years. The Overhead Circuit Renewal program will address all transformers that have reached end-of-life and severe loading issues. Toronto Hydro plans to address all of these transformers during the 2015-2019 period. This work is required mitigate the reliability and safety concerns associated with the transformers. The failure impacts of transformers are discussed in more detail in section E6.4.3.2 (ii).

(iii) Aging Legacy Overhead Switches

All switches are susceptible to corrosion and rust, and can cause seizing of moving parts.. This can render the switch inoperable. Environmental conditions can corrode the blades in a switch, which results in the loss of the material's mechanical strength. Figure 18 below shows a severely corroded switch blade.

FIGURE 18: SEVERELY CORRODED SWITCH BLADE.

Manual overhead gang-operated switches use air as an insulation medium to extinguish the arc created by interrupting normal load current. Any contaminants present on the switch blade during a load break operation may cause the electrical arc to elongate, which can lead to excessive and premature damage to the blade itself. Furthermore, age results in operating mechanism to seize, making the disconnect switch inoperable. When blades fall out of alignment, excessive arcing may result. Air pollution, which typically occurs in heavy industrial areas or where road salt is used, can also affect support insulators reducing the useful lifespan of the switch.

Many components of non-R1 SCADA-Mate switches are prone to corrosion, including the housing and moving parts, and can experience mechanical deterioration of bearings, loose connections, motor winding deterioration, contamination of the circuitry, or the failure of electronic equipment.

In addition to failures during manual operation, switches also fail while in service. The safest way to remedy this situation is generally to open the next upstream isolation device so that a Toronto Hydro crew can replace the broken switch. The resulting outage may impact a large number of customers for an extended time.

MOSCAD Upgrades

Particular non-R1 SCADA-Mate switch locations in the Etobicoke area use the Motorola radio communication system (DARCOM radio system and MOSCAD Terminals). This technology has reached the end of its useful life and the equipment is obsolete. As a result, when the communication of the SCADA infrastructure fails, control for switching restoration is unavailable, increasing the risk of longer customer outages.

This technology has not been supported by the manufacturer for over ten years and Toronto Hydro has exhausted all methods of acquiring components in third party markets. The concern is the backup master radio units; it is anticipated that their reliability may be compromised because of the age of the spares. If replacement of these master radios exceeds these spares, the SCADA-based communication could be interrupted in Etobicoke as more than half of the SCADA switches in Etobicoke operate on the MOSCAD/DARCOM system.

SCADA-Mate switches offer remote control capability to restore load in the event of sustained trunk outages. The loss of remote operability of MOSCAD controlled SCADA switches, as a result of the failure of two aged Master Radios, will result in increased restoration time among Etobicoke feeders due to a lack of spare parts. Furthermore, it will complicate the restoration of sustained trunk outages since fault detection will need to done manually and manual switches will need to be operated.

Figure 19 below shows that existing SCADA infrastructure is helping to improve restoration time. However, MOSCAD obsolete equipment has significant failure risk that will compromise this existing stable state.

FIGURE 19: HISTORICAL RELIABILITY OF FEEDERS WITH MOSCAD-CONTROLLED SCADA SWITCHES

The expected useful life of an overhead switch is 45 years. The Overhead Circuit Renewal program will address all overhead switches that have reached end-of-life and that are in poor and very poor condition according to Toronto Hydro's ACA program (see section E6.4.3.2 (i) for additional details). Toronto Hydro expects to address all of these overhead switches during the 2015-2019 period. This work is required mitigate the reliability and safety concerns associated with the risk of switch failure. The failure of switches is discussed in section E6.4.3.2 (ii).

(iv) Legacy Porcelain Accessories & Non-Standard Animal Guards

Legacy Porcelain Accessories

Porcelain insulation material is used in overhead assets such as line post insulators, switches, lightning arrestors, and terminators. Over the last decade, porcelain has been phased out in favour of polymer-based materials because of safety and system performance issues. Porcelain is susceptible to:

- hairline cracks that can lead to failure;

- potential catastrophic failure caused by electrical tracking;
- higher tracking, leakage current, and system losses; and
- incompatibility with tree-proof conductors, which are essential for improving feeder reliability in heavily treed areas.

Historically, porcelain was used for insulating electrical overhead hardware mainly because of its sound electrical insulation characteristics. However, porcelain is susceptible to contamination build-up and electrical tracking, which can cause cracking, rupture and potential catastrophic failure. Electrical tracking is a leakage of electric current from one point to another, separated by an insulating material, and is caused by dirt, carbon particles, moisture, etc. It leads to a semi-conductive track that, over time, further weakens the insulator.

This also presents an injury risk to Toronto Hydro employees or members of the public who are in close proximity to the switch at the time of failure, as failure could result in debris falling from the overhead distribution system. Toronto Hydro no longer installs switches containing porcelain insulation.

Figures 20 and 21 illustrate instances of failed porcelain insulators.

FIGURE 20: BROKEN PORCELAIN INSULATOR

FIGURE 21: BROKEN PORCELAIN INSULATOR

Figures 22 and 23 below show an example of damage to the porcelain insulator of a manual load break switch, caused by electrical tracking over time along the surface.

FIGURE 22: BROKEN INSULATOR OF MANUAL LOAD BREAK SWITCH DUE TO TRACKING

FIGURE 23: BROKEN INSULATOR OF MANUAL LOAD BREAK SWITCH DUE TO TRACKING

See Figure 24 below for example of typical line post porcelain insulator installation.

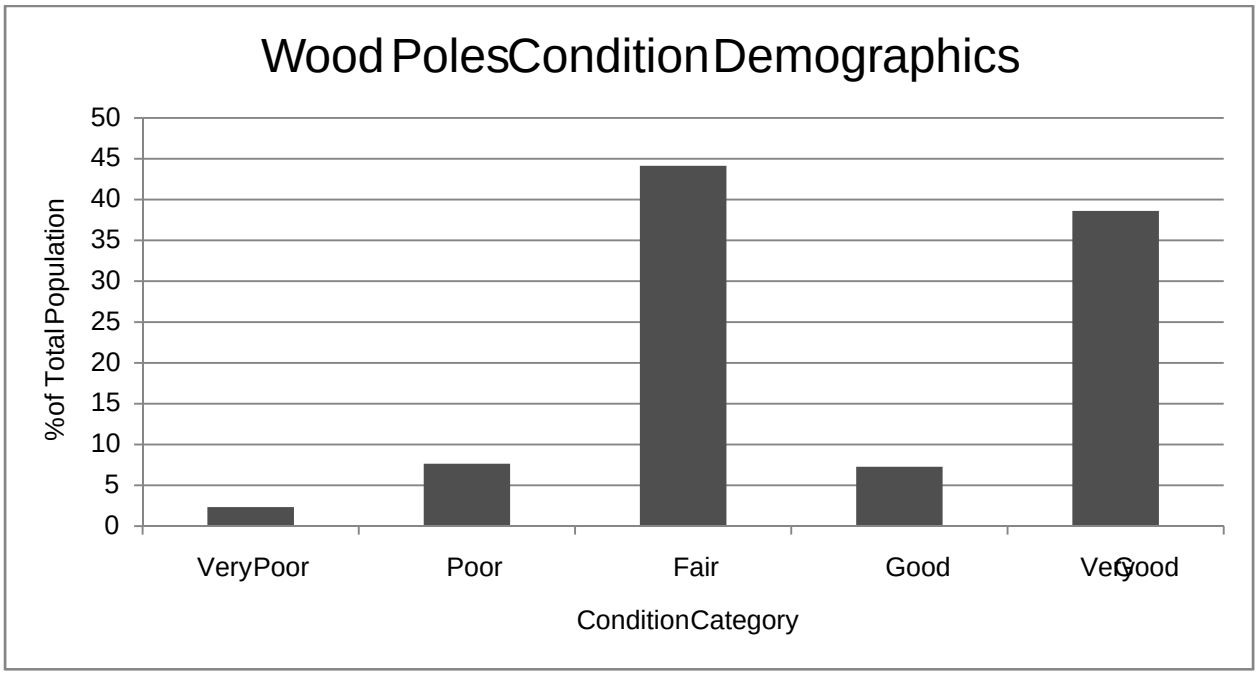
FIGURE 24: TYPICAL PORCELAIN INSULATOR INSTALLATION

The majority of the failure modes for assets with porcelain insulating material are typically cracking and falling apart, posing a safety risk to operating line personnel and members of the public in proximity to the failure. In some cases, discharge of fragments due to weakening structural integrity of the material could occur as a result of a failure. Tracking causes the switch to fail, either by cracking the insulation and rendering the switch inoperable. The structural integrity of the switch has been reduced to a point that prevents the switch from safely withstanding the force required to open or close it, causing a potential flashover.

With regards to porcelain SMD-20s, in order to maintain safe clearance from the switch during operation, a hot stick is used to operate the switch from a distance. Operation from a distance means that a switch could be severely cracked which can result in significantly reduced structural integrity, without these cracks being noticeable. This can create a potential safety risk for the crew when a switch breaks during operation.

Animal Guards

The currently used Guthrie guard is a type of wildlife protection that attaches to the bushings of overhead transformers to repel animal contact. It is electrostatic and acts as a physical barrier between the transformer and the animal. Animals receive a non-lethal, mild shock that prevents them from contacting the energized transformer bushing. However, animal contact with energized components of the transformer still occurs with this guard.



The new standard uses a cone shaped guard on the bushing with an accompanying insulated drop wire. It could curtail the number of outages related to animal contact which has a discernable trend as shown in Figure 7.

E6.4.3.2 Asset Details

In this section, the lifecycle and failure impacts of assets that will be replaced through this program are discussed in greater detail.

(i) Asset Lifecycle

As detailed in D3.1 Asset Replacement & Refurbishment Policies, Toronto Hydro utilizes an ACA program to monitor the condition of various key asset classes within its system and produce a health index score to support project planning. Figure 25 shows available condition demographics of wood poles. From a population of 123, 280 wood poles in the system, 37.66% of poles were sampled.

1 FIGURE 25: CONDITION DEMOGRAPHICS OF WOOD POLES

2 All electrical equipment inevitably ages during its service life and gradually deteriorates. This
3 deterioration can be further exacerbated by abnormal environmental and loading conditions.
4 Aging and its impact on overhead asset conditions, are detailed E6.4.3.1.

5 Table 4 shows the average useful life for the core overhead assets addressed in this program.

6 TABLE 4 : AVERAGE USEFUL LIFE

Asset	Average Useful Life (Years)
Wood Pole	45
Concrete Pole	60
Overhead Transformer	40
Overhead Switch	45

7 Figure 26 shows the age distribution of overhead major assets being targeted as part of this
8 program. Many of these assets, including 42,043 wooden poles, 2,685 overhead switches, and
9 7,252 overhead transformers, are past their useful lives.

FIGURE 26: AGE DISTRIBUTION OF OVERHEAD CORE ASSETS

The Overhead Circuit Renewal program focuses on replacing overhead assets that have the highest probability of failure, based on a combination of having reached its average useful life and being in poor and very poor conditions. In some cases, assets that have not have reached, or just approaching their useful life, may display deteriorated conditions that warrant an earlier replacement. This will ensure the mitigation of failure risk and safety concerns associated with end-of-life overhead equipment.

(ii) Asset Failure Impacts

Figures 27 and 28 show the number of CI and CHI, respectively, to depict historical impact trends of the overhead assets being addressed through the Overhead Circuit Renewal program.

FIGURE 27: OVERHEAD CORE ASSETS CI CONTRIBUTION

FIGURE 28: OVERHEAD CORE ASSETS CHI CONTRIBUTION

The figures above demonstrate that switches, porcelain equipment, and animal contact have the greatest impact on CI and CHI.

The following incidents portray the type and severity of impact due to the failure of overhead equipment being addressed in this program. The Overhead Circuit Renewal program alleviates these types of failure impacts through like-for-like replacement of end of life and poor condition equipment.

Poles

A catastrophic failure was reported on Midland Avenue in June 2011, where 13 poles fell during a windstorm. After inspection, these poles had signs of shell rot (refer to Figure 29), which led to the deterioration of their bases, causing them to fall during the storm.

FIGURE 29: MIDLAND AVE, JUNE 2011 – POLE SHELL ROT

As a result of the windstorm, a cascading failure took place shortly after the first pole failed and fell to the ground. This failure caused the rest of the poles in the line to fall as well (refer to Figures 30 and 31). Investigation of this incident also found evidence of an ant infestation, as shown in Figure 32. This type of infestation cannot be completely eliminated and can affect any pole, independent of age. Fortunately, this incident resulted in no injuries and did not require the payment of any property damage claims; however, it had the potential to cause significant injury and property damage.

FIGURE 30: MIDLAND AVE, JUNE 2011 - POLE COLLAPSE

FIGURE 31: MIDLAND AVE, JUNE 2011 - POLE COLLAPSE

FIGURE 32: MIDLAND AVE, JUNE 2011 – ANT INFESTATION

A pole failure took place at Fairbanks TS, where field staff reported a broken pole on Glencairn Avenue, affecting about 2,000 customers. The resulting outage lasted more than 11 hours. Similarly, in another incident at Manby TS, field staff reported a rotten pole on Riverbank Drive affecting 27 customers, and resulting in an outage lasting more than ten hours. It is evident from these cases that pole related outages lead to long outage durations. This is mainly due to complexities associated with installing a new pole such as new framing depending on number of circuits, poor condition of assets on pole that may no longer be reusable, and specialized equipment such as sucker trucks.

The degradation of poles can lead to irreversible damage including loss of pole strength, cross-arm rot, woodpecker or carpenter ant damage, surface rot at various levels of the pole, pole top feathering, wood loss and mechanical fire damage. Extreme deterioration and weakness, combined with external environmental forces, can cause poles to topple and create safety hazards for the public. Also, a fallen pole with a transformer could potentially result in adverse environmental repercussions.

Another incident involving wood poles occurred on Pape Avenue during a voltage conversion project. Once the crew had completed the approved procedures for the project, they cut the conductor in order to remove it. After so doing, one of the wood poles began to lean over. As shown in Figure 33 and Figure 34, this pole fell on a fence and porch roof with the conductors still attached.

The incident was caused by an aging pole with a rotten base (illustrated in Figures 33 and 34 below) and resulted in a property damage claim against Toronto Hydro.

FIGURE 33: PAPE AVE POLE FAILURE

FIGURE 34: PAPE AVE POLE FAILURE

A more serious incident occurred on Acacia Road. In this incident, a pole fell onto a residence causing it substantial damage, as illustrated in Figures 35, 36 and 37. This incident was a result of the poor condition of the pole, which had a rotten base at ground level. The pole, and the transformer attached to it, fell onto the residence, striking the second floor, roof, eaves, rafters, and front door, and damaging personal property belonging to the tenant. The resulting oil leak from the damaged transformer spread across the interior of the home. Fortunately, no one was injured, but the incident had the potential to cause injuries to individuals in the residence or standing in the front yard.

1

2 FIGURE 35: ACADIA ROAD POLE FAILURE

FIGURE 36: ACADIA ROAD POLE FAILURE

3 FIGURE 37: ACADIA ROAD POLE FAILURE

CSP

On CSP transformers, the internal fuse is designed to coordinate with the current limiting fuse (CLF) outside the transformer, but the effectiveness of this coordination depends on the nature of the internal fault. For example, a CLF was burning at CSP Transformer T13102 on feeder 85M23 on July 5, 2004 and became a potential safety risk for crews at the scene since the fire could have spread to the pole and other equipment. As another example, on March 18, 2010, a crew arrived to find a lid blown off at CSP Transformer T8040 on feeder SS58-F1 that could have caused injury to the public.

Overhead Switches

The failure of a gang-operated overhead switch can result in entire trunk portions of feeders experiencing an outage. Furthermore, the communication system upgrades in Etobicoke ensure that remote operation of SCADA switches in this part of the system is available during a trunk outage and contingency scenarios. If the master radios fail, there is no method of communication between old MOSCAD-controlled SCADA switches and the control room; this will result in Etobicoke losing remote functionality through SCADA switches and having adverse restoration times in the event of a trunk outage.

Porcelain

Porcelain pothead terminations also have the potential to fail in a catastrophic manner, releasing porcelain shards and dispersing oil; this can damage other nearby electrical equipment and public property. In addition, the dispersion of oil from the damaged terminations may result in a fire or an environmental hazard.

In 2009, Toronto Hydro received a Public Safety Concern from the ESA as a result of a porcelain pothead failure sending shards of porcelain onto the balcony of a nearby home, shattering the window of the family room and causing damage to the windshield of a nearby police car. The effects of the failure are seen in Figure 38. Toronto Hydro replaced the failed porcelain pothead with a new polymer termination.

FIGURE 38: PORCELAIN POTHEAD FAILURE IMPACT

Figure 39 below shows a situation where one of the center-phase porcelain insulators had broken and fallen off on a manual load break switch. The porcelain components of these switches are susceptible to contamination, which leads to tracking across the insulator and eventually failure.

FIGURE 39: PORCELAIN INSULATOR FAILURE ON MANUAL LOAD BREAK SWITCH

Figure 40 below illustrates an in-line disconnect switch where part of the porcelain insulation has broken off. This is a potential safety risk as large pieces of porcelain could fall to the ground from switches mounted up to 50 feet 1 (15.24 metres) high, could injure someone or damage nearby property.

FIGURE 40: BROKEN PORCELAIN INSULATOR FROM IN-LINE DISCONNECT SWITCH

Figure 41 below shows a broken porcelain insulator on a pole to string conductor. In addition to the safety concerns about falling debris, porcelain fragments could also potentially trigger pole fires.

FIGURE 41: BROKEN PORCELAIN INSULATOR ON POLE

The program addresses overhead assets at risk of failure. Because these assets are located on both trunk and lateral portions of feeders, the extent of outages can vary from a localized group of customers downstream of a fuse to all customers on a feeder. The customers impacted by these types of outages range from low-volume residential to large industrial power consumers.

Replacing overhead equipment near or past its end of life in a proactive fashion is expected to curtail the frequency of outages caused by defective overhead equipment, reducing customer interruptions and mitigating safety risks as discussed earlier in this exhibit.

E6.4.4 Timing & Pacing of the Program

As per the table below, the total cost of the Overhead Circuit Renewal program over the 2015-2019 period is $147.4 M.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	$25.8	$28.3	$23.2	$49.0	$53.3	$44.0	$23.0	$24.9	$25.3	$30.3

The Overhead Circuit Renewal program will help ensure that Toronto Hydro is replenishing its aged and deteriorating infrastructure at a strategic pace in order to mitigate failure and safety risks. The deferral of the projects in this program will result in the excess accumulation of an aged and poor conditioned overhead distribution plant. If Toronto Hydro does not replace these assets between 2015 and 2019, assets operating beyond useful life and in deteriorating conditions will be compounded and renewal efforts will likely be insufficient to maintain existing levels of system reliability.

The table above provides historical spending figures as well. A significantly high number of overhead defective equipment outages occurred from 2008–2010, which prompted an increase in spending levels from 2010 and onwards. Outages began to rise again from 2012-2013, prompting a large spending increase to address the issue. Future spending levels are lower than past ICM expenditures due to the fact that the overall DSP contains core renewal work that will be supplemented by modernization efforts in order to better manage the overhead system.

E6.4.4.1 Ranking & Prioritization

Individual projects under this program are prioritized based on criteria such as age, asset condition, and historic performance.

Age and asset condition are the primary drivers of asset failure. Therefore, as is the case for the majority of System Renewal programs, older and poorer condition assets will generally be replaced first. In addition, the number of customers that an asset could interrupt in the case of a failure is also factored into the timing of individual projects. Finally, consideration is given to assets that pose specific reliability concerns or other risks based on their past reliability performance.

Generally, overhead assets on lower primary voltages of 4.16 kV or 13.8 kV are at their end of useful life. The transformers, switches and other equipment at this voltage level are at or close to end of their useful life. Municipal Stations (MS) that supply the 4.16 kV and 13.8 kV distribution systems are 50 or 60 years old and slated for decommissioning. Overhead circuit renewal of 4.16 kV and 13.8 kV feeders, via voltage conversion, also provides the ancillary benefit of decommissioning MS stations that have aged/obsolete equipment. By converting these feeders necessary to decommission the MS, Toronto Hydro aims not only to decrease failure risk of the aged 4.16 kV and 13.8 kV systems, but also to avoid the need to maintain the aged and obsolete equipment in the MS. Thus, voltage conversion jobs were also considered in prioritizing overhead circuit renewal jobs and in complementing necessary station work.

E6.4.6 Program Execution

Toronto Hydro's approach is to identify common geographical areas that contain a significant number of at-risk assets and execute full overhead rebuilds. Overhead rebuilds involve the replacement of an entire group of assets, which includes pole line replacements, re-stringing new conductor, installing new overhead transformers, new switches, and upgrading all associated overhead accessories. In some cases, abnormally high failure risk may warrant stand-alone replacements of assets in multiple locations.

Voltage Conversions target aged and poor condition 4.16 kV or 13.8 kV equipment that have high failure risk, and replace it with new assets at higher voltage levels. Voltage conversions eventually allow Toronto Hydro to decommission aged Municipal Substations (MS) that are 50-60 years old once all of the feeders emanating from them have been converted.

Large overhead circuit renewal projects are broken into smaller phases for better manageability and coordination, providing greater flexibility for scheduling and assigning resources. Staging also reduces the number of scheduled outages and disruptions that customers will experience. Customer notifications are communicated prior to scheduled power outages to minimize the inconvenience they cause. Efforts are also made to coordinate overhead circuit renewal work with other capital projects wherever practical.

E6.4.6.1 Program Risks

Large overhead rebuild projects can be complicated by work undertaken by other utilities operating in the area. This can result in conflicts leading to incremental costs and delays. In some cases, overhead work that involves poles on sidewalks may be in conflict with existing sidewalk moratoriums. The Toronto Public Utilities Coordinating Committee (TPUCC) is a consortium that aims to resolve such conflicts and sidewalk moratoriums between multiple utilities by establishing schedules in a sequential manner that mutually benefits all parties involved. Toronto Hydro participates in this forum to mitigate the conflict risks with other utilities and the City.

The program also entails entire overhead plant rebuilds that may present easement issues. Existing third-party attachments must be contacted to explore other options and may delay execution timeline. Delays in obtaining permits from the City of Toronto, Ministry of Transportation, or even CN railways may require extra design time. In some areas of Toronto, arborist consultation may be required to comply with Toronto and Region Conservation Authority requirements and obtain permits. Identifying and making efforts to accommodate these issues during planning stages can mitigate much of this risk.

E6.4.6.2 Standard & Regulation Adherence

Toronto Hydro plans, designs and construct the current distribution system assets in accordance with approved standards, which are developed to achieve the objectives of public and employee safety in compliance with the requirements of Ontario Regulation 22/04. This program has been established to upgrade legacy assets to bring them into compliance with current construction standards.

E6.4.7 Evaluation of Alternatives

In addition to the reasons and benefits outlined in E6.4.3 and E6.4.5, the preferred option of proactively replacing overhead equipment has a lower cost of ownership than keeping the

existing configuration. This is primarily due to avoided annualized risk costs and maintenance costs that are otherwise incurred on an annual basis.

E6.4.7.1 Quantification/Evaluation of Options

(i) Option 1: Status Quo

The 'Status Quo' option involves deferring the activities in the Overhead Circuit Renewal program past the five-year planning horizon of 2015 to 2019. Under this scenario, Toronto Hydro can expect to continue experiencing a large number of overhead-caused outages. Defective overhead equipment contributed to approximately 22% of all system-wide outages. Assets would continue to deteriorate and fail, likely requiring an increasing amount of reactive replacement work while generating operational issues as a result. This option would also fail to mitigate the safety concerns discussed earlier.

(ii) Option 2: Rehabilitation of Assets

Another option considered was to provide short term mitigation rehabilitation in the form of upgrading overhead accessories (insulators, switches, transformers, etc.) only. This method is similar to a Worst Performing Feeder approach where, at the minimum, it provides a means to curtail an abnormal amount of particular outages with minimal work until a complete replacement rebuild is scheduled.

This option is not recommended because it does not address the underlying issue of system-wide overhead equipment failures that are primarily caused by asset aging and deterioration. Another disadvantage is that most aged core assets (poles) do not easily accommodate the new standard accessories. New polymeric insulators would be bolted on feathered pole tops where its mechanical strength has deteriorated. New animal guard installations on aged CSP transformers require modifications to the guards.

(iii) Option 3: Replacement of Assets

The preferred option is to replace end-of-life overhead equipment, which includes aged, poor conditioned, and functionally obsolete equipment that is at the highest risk of failure over the next five years in a coordinated fashion. This alternative will generate all of the benefits discussed throughout the narrative.

The anticipated execution strategy is to address these issues by identifying and rebuilding assets together in the same area that has a significant accumulated risk of failure. This also includes voltage conversions that help aid the removal of 4.16 kV and 13.8 kV MS stations.

Executing the first year of planned activities in the Overhead Circuit Renewal program in the first year as opposed to deferring these activities until 2020 is anticipated to result in an avoided estimated risk cost (ARC) of approximately $39.94 million. The ARC takes into account the probability of failure of the assets and multiplies this figure by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. For further details on the ARC approach is provided in Section D3.3.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$70.09
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$30.14
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$39.94

E6.6.9 2015 Project Details

Table 7 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) Previously filed projects that appeared as jobs in the OEB approved in the Overhead Infrastructure segment, as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 7: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	CIR Projects
10.78	33.20

Table 8 lists all projects that will be partially or fully executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

W14344, W14345 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Voltage Conversion Westmount MS – Phase 1 to 4

Project Number: W14344, W14345

Project Year: 2015

Estimated Cost: $805,125.83

(i) Objective

The objective of these projects is to renew the distribution system along Dixon Road (between Islington Avenue and Scarlett Road) by replacing the deteriorating 4.16kV distribution assets and converting the area to 27.6kV in order to prepare the substation for decommissioning.

(ii) Scope of Work

TABLE 9

District Neighbourhood:	Etobicoke North
Station(s):	Westmount MS (4.16kV)
Feeder(s):	ETRBF1, ETRBF2, ETRBF3

X12196 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: FESI Bathurst Lawrence OH Rebuild Ph3 NY35M5

Project Number: X12196

Project Year: 2015

Estimated Cost: $2,594,998.76

(i) Objective

The objective of this project is to address failure modes related to defective overhead equipment outages by rebuilding the overhead infrastructure on feeder 35M5 as well as replacing undersized and de-rated conductor within the project area.

(ii) Scope of Work

TABLE 12

District Neighbourhood:	Eglinton-Lawrence

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 14

Supplemental Details	Description
Age/Condition	ƒ The project involves a rebuild of the overhead primary distribution system in the area of Lawrence Avenue West, Bathurst Street, Coldstream Avenue and Edgecombe Avenue ƒ Field inspections have shown that the overhead infrastructure along the feeder is in deteriorating conditions as well as portions of the overhead conductors to be undersized
Reliability	ƒ 27% of the outages on the feeder are due to defective overhead equipment ƒ Feeder has an increase trend over the five years with nine outages in 2013
Other (i.e. local failures, etc)	ƒ This project hopes to mitigate the risk presented by deteriorating assets and non-standard equipment in the area through a proactive rebuild of feeder NY35M5

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 45.

FIGURE 45: HISTORICAL RELIABILITY DETAILS FOR 35M5

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

X11732 Project Descriptions

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: NY35M11 Marlee Ave Primary Detailing

Project Number: X11732

Project Year: 2015

Estimated Cost: $44,147.08

(i) Objective

The objective of this project is to install new standard animal guards on feeder NY35M11 in the area of Lawrence Avenue West and Allen Road.

(ii) Scope of Work

TABLE 15

W15277 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: West of Kipling Avenue Overhead Voltage Conversion of AHF2, AHF5

Project Number: W15277

Project Year: 2015

Estimated Cost: $1,358,099.02

(i) Objective

The objective of this project is to rebuild parts of Fieldway MS feeders that are aging as confirmed by feeder patrol of the area in the summer of 2013.

(ii) Scope of Work

TABLE 18

District Neighbourhood:	Etobicoke Lakeshore
Station(s):	Fieldway MS

Fuse	2
Switchgear	0
*Conductor Length (m)	7,900

*Cable Length (m)	0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 20

Supplemental Details	Description
Age/Condition	• The scope through the voltage conversion, will replace aged 4kV feeder assets of feeder AHF2 and AHF5 that are already in deteriorated condition as confirmed by feeder patrol of the area in the summer of 2013, with brand new 27.6kV equipment.
Reliability	• The renewal OH and UG infrastructure in the scope addresses and stems the increasing number of outage incidents due to feeder equipment defects and failures. • A total of 3 forced outages, 368 CI and 509 CHI on feeder AHF2 since 2009 • A total of 5 forced outages, 390 CI and 137 CHI on feeder AHF5 since 2009 • 81% of the CI and 99% of the CHI occurred in the last two years while 96% of the CI and 65% of the CHI occurred in the last year showing an increasingly dire reliability situation in the area.
Other (i.e. moratorium, etc)	• Feeders in the area, from West Islington MS, Cloverdale MS and Shaver MS will all be completely converted to 27kV by the end of 2015 leaving parts of the feeders AHF2 and AHF5 west of Kipling Avenue with no back-up. For this reason it is critical to complete this voltage conversion job in 2015.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figures 47 and 48.

FIGURE 47: HISTORICAL RELIABILITY DETAILS FOR AHF2

W12491 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: FESI Rebuild and CSP replacement PH#3

Project Number: W12491

Project Year: 2015

Estimated Cost: $1,531,152.65

(i) Objective

The objective of this project is to rebuild the overhead infrastructure on feeder NY85M1 due to poor reliability. The scope is intended to replace Completely-Self-Protected (CSP) transformers, glass insulators and arrestors as well as installing primary distribution with tree proof conductor.

(ii) Scope of Work

TABLE 21

W14216, W14220 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Rehab & VC of ETKKF2 Phase 1 to 3

Project Number: W14216 and W14220

Project Year: 2015

Estimated Cost: $1,131,124.03

(i) Objective

The objective of these projects is to convert the distribution system in the Burnhamthorpe – Mill area by replacing the deteriorating 4.16kV system and converting the area to 27.6kV.

(ii) Scope of Work

TABLE 27

District Neighbourhood:	Etobicoke Centre

TABLE 32

Supplemental Details	Description
Age/Condition	ƒ The assets in the general area of Drewry and Cactus supplied from 80M2 are in poor condition, aged, and functionally obsolete ƒ Spot condition assessments shows may poles have a score of below 50 in the ACA assessment.
Reliability	ƒ There have been a significant amount of outages from 2009 - 2012
Other (i.e. moratorium, etc)	ƒ This project is intended to mitigate failure risk of these assets and improve reliability

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 52.

FIGURE 52: HISTORICAL RELIABILITY DETAILS FOR 80M2

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

E15036, E15037 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Voltage Conversion of Shep-Ken MS SCREF3 Phase 2 and 3

Project Number: E15036, E15037

Project Year: 2015

Estimated Cost: $443,275.43

(i) Objective

The objective of these projects is to convert feeder SCREF3 due to the poor asset condition.

(ii) Scope of Work

TABLE 33:

District Neighbourhood:	Scarborough Agincourt
Station(s):	Shepherd Kennedy MS (4.16kV)

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

X12179 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Replacement of CSP transformers YK35M10

Project Number: X12179

Project Year: 2015

Estimated Cost: $1,050,711.40

(i) Objective

The objective of this project is to rebuild the overhead infrastructure on feeder YK35M10 from Fairbanks TS due to poor reliability and to replace end-of-life infrastructure.

(ii) Scope of Work

TABLE 35:

District Neighbourhood:	York South-Weston
Station(s):	Fairbanks TS (27.6kV)
Feeder(s):	YK35M10

Fuse	0
Switchgear	0
*Conductor Length (m)	8,400.0

*Cable Length (m)	640.0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 37

Supplemental Details	Description
Age/Condition	ƒ Feeder YK35M10 has experienced many overhead reliability issues within the boundaries of this project ƒ This project was initiated due to the poor overhead infrastructure condition and poor reliability of the assets on feeder ƒ As determined by a feeder patrol, the majority of the assets along this feeder are past their useful service life and will be replaced
Reliability	ƒ Feeder YK35M10 is one of the worst performing feeders in the system with a total of 11 outages in 2011, 11 outages in 2012 and 16 outages in 2013. ƒ Due to the number of interruptions the feeder has experienced, the area is to be rebuilt with standard equipment to minimize the outages caused by defective equipment. ƒ The feeder has experienced at least six failures per year ƒ The major failure mode for this feeder is overhead equipment.
Other (i.e. local failures, etc)	ƒ In addition to the overhead infrastructure renewal, the project covers an underground section of the feeders and involves replacing underground transformers and underground cable as well as incorporating civil infrastructure for the installation of new underground cable

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 54.

FIGURE 54: HISTORICAL RELIABILITY DETAILS FOR 35M10

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

X13191 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: NY35M11 - Lawrence and Brucewood Crescent Rebuild

Project Number: X13191

Project Year: 2015

Estimated Cost: $1,796,532.68

(i) Objective

The objective of this project is to rebuild the overhead infrastructure on feeder NY35M11 on Lawrence Avenue West from W.R. Allen Rd to Brucewood Crescent.

(ii) Scope of Work

TABLE 38:

District Neighbourhood:	Eglinton-Lawrence
Station(s):	Fairbanks TS (27.6kV)
Feeder(s):	NY35M11

Transformer	28
Manual Switch	2
SCADA Switch	0
Fuse	2
Switchgear	0
*Conductor Length (m)	6,906.00

*Cable Length (m)	0.00

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 40

Supplemental Details	Description
Age/Condition	• The identified streets under this job, supplied by NY 35M11 require a rebuilt due to the deteriorating conditions of the overhead infrastructure. • Feeder possesses a significant count of non-standard equipment and assets past their useful life • Recent feeder patrol reports have shown that most of the poles in the job area are aged and feathered at the top
Reliability	• Feeder 35M11 has experienced a high number of interruptions due to overhead equipment • Overhead defective equipment accounts for 33% of the outages on the feeder • 30% of the outages are due to animal related contacts. This project will be installing animal guards with new overhead transformers in the area • There is an urgent need to upgrade deteriorating assets on this feeder, which have contributed the increase in the customers interrupted in 2013
Other (i.e. local failures, etc)	• This project is intended to mitigate failure risk of these assets and improve reliability.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 55.

FIGURE 55: HISTORICAL RELIABILITY DETAILS FOR 35M11

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

W13206 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Refurbish Feeder Laterals - Phase 1 of 2

Project Number: W13206

Project Year: 2015

Estimated Cost: $1,272,900.88

(i) Objective

The objective of this project is to rebuild/replace the aging and non standard primary overhead distribution equipment on feeder NY85M10 in order to improve reliability and replace the XLPE lateral services with TRXLPE cable to improve reliability.

(ii) Scope of Work

TABLE 41:

District Neighbourhood:	York Centre
Station(s):	Bathurst TS (27.6kV)
Feeder(s):	NY85M10

*Cable Length (m)	1,100.0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 43

Supplemental Details	Description
Age/Condition	• To rebuild OH feeder 85M10 by replacing aging and/or non-standard distribution equipment including, but not limited to, poles, lines and transformers along (predominantly) single phase laterals. • The area is bounded by Dufferin, Whitley, Keele and Powell.
Reliability	• There has been an average of 5 outages a year during 2009-2013.
Other (i.e. moratorium, etc)	• This project is intended to mitigate failure risk of these assets and improve reliability.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 56.

FIGURE 56: HISTORICAL RELIABILITY DETAILS FOR 85M10

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

W14658, W14661, W14659 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: P05-Conversion of W est Islington feeder AF1, AF2, AF6

Project Number: W14658, W14659, W14661

Project Year: 2015

Estimated Cost: $983,605.22

(i) Objective

The objective of these projects is to renew the distribution system in the area of Etobicoke-Lakeshore by rebuilding the deteriorated West Islington MS 4.16kV feeders and convert them to 27.6kV.

(ii) Scope of Work

TABLE 44:

District Neighbourhood:	Etobicoke-Lakeshore
Station(s):	West Islington MS; Wingrove MS
Feeder(s):	AF1, AF2, AF6, VNF4

Fuse	5
Switchgear	0

Asset	Count
Conductor Length (m)	9,200.00
Cable Length (m)	30

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

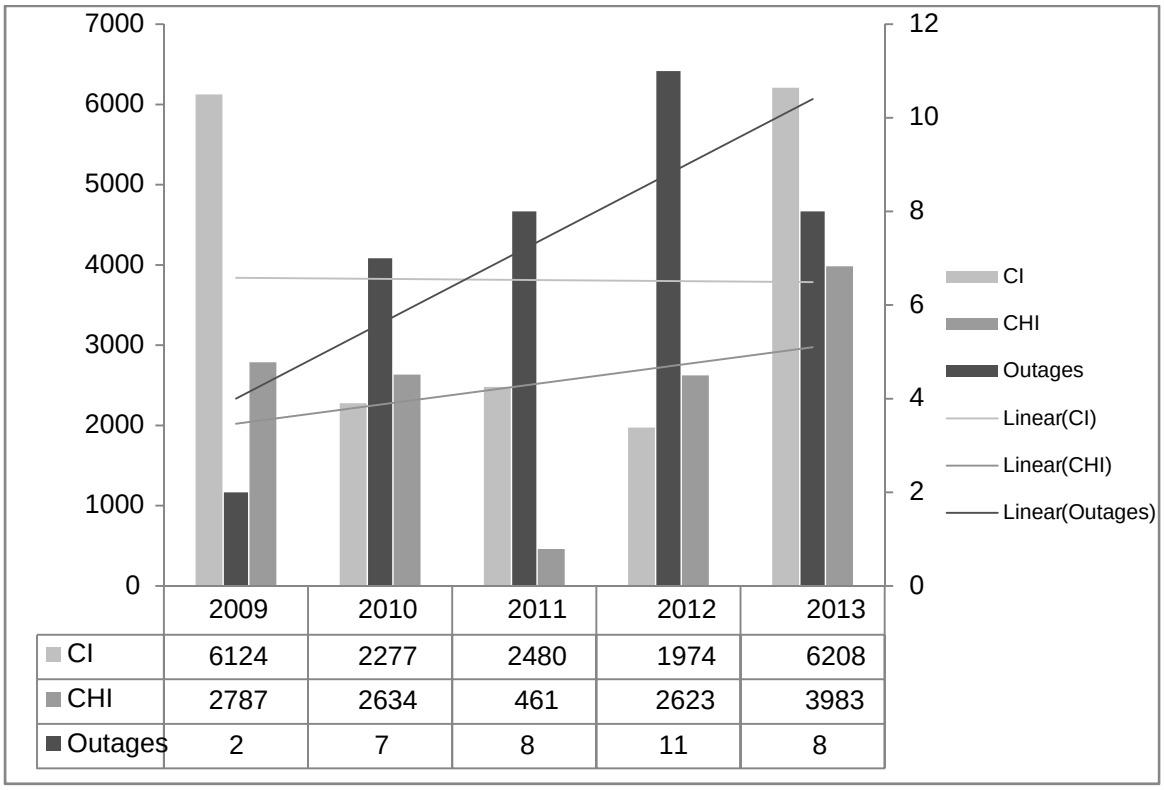

TABLE 46

Supplemental Details	Description
Age/Condition	ƒ Scope upgrades undersized feeder trunk conductors along The East Mall from 4/0 to THESI standard 556 kcmil.
Reliability	ƒ Scope upgrades distribution assets along 38M10 in the area order to stem the residents' experience of outages which was particularly high in 2013. ƒ A total of 5 forced outages, 8378 CI and 4910 CHI on feeder 38M10 since 2009 with 80% of the outages in 2013 showing an increasingly dire reliability situation along the feeder.
Other (i.e. moratorium, etc)	ƒ Customers in the area had complained of the high incidence of outages in 2013.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 57 to 59.

W14073 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Overhead Rebuild at Steels Ave W and Weston Road NY55M31

Project Number: W14073

Project Year: 2015

Estimated Cost: $768,158.43

(i) Objective

The objective of this project is to rebuild feeder NY55M31, bounded by Weston Road (East), Fenmar Drive (North), Steeles Ave (West), and Kenhar Drive (South), through the replacement of poles, insulators and Completely-Self-Protected (CSP) transformers.

(ii) Scope of Work

W14174, W14175 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Lambton MS VC PH#1 - PH#2

Project Number: W14174, W14175

Project Year: 2015

Estimated Cost: $1,638,659.82

(i) Objective

The objective of this project is to renew the distribution area of Etobicoke-Lakeshore by rebuilding the deteriorated Lambton 4.16kV feeders and converting them to 27.6kV in order to prepare the station for decommissioning.

(ii) Scope of Work

TABLE 50

District Neighbourhood:	Etobicoke-Lakeshore
Station(s):	Lambton MS (4.16kV), Kingsway MS (4.16kV)
Feeder(s):	ETVBF2-1, ETVBF5-1, TEF5-1, TEF1

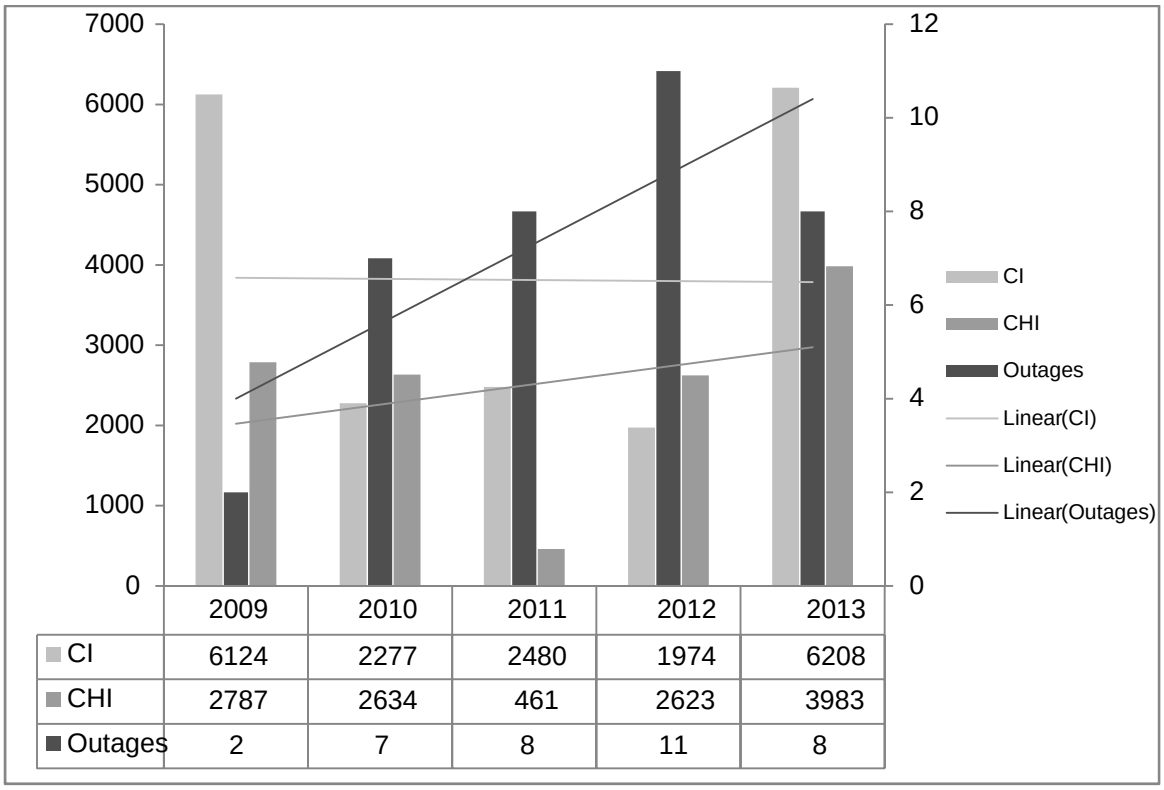
*Cable Length (m)	100

(iii) Justification & Benefits



Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 52

Supplemental Details	Description
Age/Condition	ƒ 60 yr old Lambton 4kV distribution assets of Lambton MS feeder VBF5 approaching end of service life to be replaced with brand new 27.6kV equipment. ƒ Replacement of deteriorated switchgear at Lambton substation withheld because of this scope
Reliability	ƒ The scope replaces overloaded transformers with bigger units and aged direct buried cables are replaced with new TRXLPE cables in concrete encased ducts stemming the probability of outage incidents and reducing restoration times. ƒ A total of 1 forced outage, 22 CI and 154 CHI on feeder VBF5 since 2009
Other (i.e. moratorium, etc)	ƒ Grid reconfiguration in the project improves operational flexibility in the area. ƒ The voltage conversion of the Lambton MS feeder VBF5 in this scope enables the decommissioning of the Lambton substation that will eliminate growing maintenance costs at the municipal station, obsolete construction standards and deteriorated plant condition.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 61 to 64.

W15492, W15494 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: P05 - MOSCAD/DARCOM Controller Replacement - Richview TS, Manby TS, Horner TS, Rexdale TS, Woodbridge TS

Project Number: W15492, W15494

Project Year: 2015

Estimated Cost: $759,904.05

(i) Objective

The objective of these projects is to replace the obsolete MOSCAD RTU and radio SCADA system with the current standard.

(ii) Scope of Work

TABLE 56

District Neighbourhood:	Etobicoke Centre
Station(s):	Richview TS, Manby TS, Horner TS, Rexdale TS, Woodbridge TS
Feeder(s):	88M1, 88M8, 88M11, 88M13, 88M14, 88M46, 30M2, 30M5, 30M7, 30M8, 38M1, 38M10, 38M13, 38M5, 29M2, 29M3, 29M33, 29M34, 29M4, 29M5, D6M4, D6M1

Manual Switch	0
SCADA Switch	1

Asset	Count
RTU	29
Fuse	0
Switchgear	0
*Conductor Length (m)	0.0
*Cable Length (m)	0.0

(iii) Justification & Benefits

The MOSCAD RTU was developed by Motorola and uses the DARCOM radio system. This technology was used as the predominate control and radio technology on many SCADA switches and MS stations in Etobicoke. This technology has not been supported by the manufacturer for over ten years and Toronto Hydro has exhausted all methods of acquiring components in third party markets. The main concern is the backup for the master radio units. Toronto Hydro currently has two spare units in its possession if there is a need to replace the existing ones in service. There is a risk that due to the age of the spares that the ability to perform reliably and the extended period of in-service time will be reduced. If replacement of these master radios exceeds these spares, Etobicoke's SCADA system will not be able to communicate and will lose all remote functionality.

E12891 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Voltage Conversion of NYSS38 F1 F2 from Burbank MS - Install Poles

Project Number: E12891

Project Year: 2015

Estimated Cost: $182,991.63

(i) Objective

The objective of this project is to convert the early fifties 4.16kV primary distribution system fed by the Burbank Municipal Substation by rebuilding and converting both outgoing feeders F1 and F2 to the 27.6kV system level.

(ii) Scope of Work

TABLE 58

*Cable Length (m)	0.0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 72

Supplemental Details	Description
Age/Condition	• Feeder patrols have identified that most poles on this feeder are in poor condition. These poles will be replaced due to high failure risk. • The feeder is primarily comprised of non-standard poor performing assets such as CSP transformers, glass insulators, arrestors, and switches.
Reliability	• Feeder has experienced 22 overhead outages since 2011, which were identified on the overhead equipment, likely to be attributed due to the poor asset condition
Other (i.e. local failures, etc)	• Rebuilding feeder NY55M1 will improve the reliability of the feeder.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 73.

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: FESI Feeder Rehab and Change out Phase 2

Project Number: W13115

Project Year: 2015

Estimated Cost: $431,678.87

(i) Objective

The objective if this project us to replace poles, conductor, Completely-Self-Protected (CSP) transformers, glass insulators and arrestors on feeder NY80M8 to reduce failure risk, safety issues, and functional obsolescence.

(ii) Scope of Work

TABLE 73

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 75

Supplemental Details	Description
Age/Condition	• The assets in the Finch and Bathurst area are aged and in poor condition • Assets being replaced include aged poles, transformers, and porcelain equipment
Reliability	• There has been an average of 6 outages a year during 2009-2013
Other (i.e. moratorium, etc)	• This project is intended to mitigate failure risk of these assets and improve reliability

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 74.

FIGURE 74: HISTORICAL RELIABILITY DETAILS FOR 80M8

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

W14289 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Overhead Rebuild off Gary Avenue

Project Number: W14289

Project Year: 2015

Estimated Cost: $773,556.93

(i) Objective

The objective of this project is to rebuild the overhead infrastructure on feeder NY55M23 to improve reliability and mitigate failure risk of obsolete equipment.

(ii) Scope of Work

TABLE 76

District Neighbourhood:	York South-Weston
Station(s):	Finch II TS (27.6kV)
Feeder(s):	NY55M23

Switchgear	0
*Conductor Length (m)	2,625

*Cable Length (m)	0.0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 78

Supplemental Details	Description
Age/Condition	• Feeder NY55M23 is primarily comprised of non-standard poor performing assets such as CSP transformers, glass insulators, arrestors, and switches. • Feeder patrols have identified that most poles on this feeder are in poor condition • The project covers an underground section of the feeders and involves replacing underground transformers and underground cable as well as incorporating civil infrastructure for the installation of new underground cable
Reliability	• Feeder NY55M23 has shown evidence of deteriorating reliability in the past few years • The feeder has experienced at least six failures per year • The major failure mode for this feeder is overhead equipment.
Other (i.e. local failures, etc)	• The project will help mitigate future risk associated with asset failure and will help improve the reliability and performance of NY55M23.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 75.

FIGURE 75: HISTORICAL RELIABILITY DETAILS FOR 55M23

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

W12265, W12269 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Overhead Rebuild on 55M26 Ph 1 and 2

Project Number: W12265, W12269

Project Year: 2015

Estimated Cost: $2,378,133.78

(i) Objective

The objective of these projects is to rebuild areas of feeder NY55M26 due to poor performance of the feeder which is related to modes related to defective overhead equipment outages.

(ii) Scope of Work

TABLE 79

District Neighbourhood:	York West
Station(s):	Finch II TS (27.6kV)

*Cable Length (m)	0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 81

Supplemental Details	Description
Age/Condition	• The primary overhead distribution on feeder NY55M26 requires an overhead rebuild in order to address failure risk • Feeder patrol conducted show that equipment had reached its end of life, in particular aging poles
Reliability	• NY55M26 has experienced approximately 20 outages due to poor conditions of the overhead infrastructure in the project area • The major failure mode for this feeder is overhead equipment.
Other (i.e. local failures, etc)	• The project will help mitigate future risk associated with asset failure and will help improve reliability and performance of NY55M26

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 76.

FIGURE 76: HISTORICAL RELIABILITY DETAILS FOR 55M26

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

W10461 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: FESI Scarlett-St.Clair Overh ead Rebuild YK11M7 Project Number: W10461

Project Year: 2015

Estimated Cost: $1,667,149.33

(i) Objective

The objective of this project is to rebuild areas of feeder YK11M7 due to poor performance of the feeder which is related to modes related to defective overhead equipment outages.

(ii) Scope of Work

TABLE 82

District Neighbourhood:	Parkdale-High Park

W15335, W15336, W15338 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Ranee and Ameer overhead Area Circuit Renewal PH1, PH2, PH3

Project Number: W15335, W15336, W15338

Project Year: 2015

Estimated Cost: $2,521,219.75

(i) Objective

The objective of these projects is to rebuild/replace the aging and non standard primary overhead distribution equipment on feeder NY85M26 in order to improve reliability.

(ii) Scope of Work

TABLE 88

District Neighbourhood:	Eglinton Lawrence, York West

*Cable Length (m)	0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 90

Supplemental Details	Description
Age/Condition	• The primary objective of this scope entails renewing the OH plant in the Ranee Ave. and Bathurst St. area, which is comprised of aged and poor condition OH assets
Reliability	• 85M26 has had an average of 4 outages a year during 2009-2013 • The urgency for a rebuild in the Ranee Ave and Bathurst St neighbourhood stems from 11 total outages contained in this area from 2009-2013. In 2013, 80% of all outages were due to OH defective equipment in this region alone.
Other (i.e. moratorium, etc)	• This project is intended to mitigate failure risk of these assets and improve reliability

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure XYZ.

FIGURE 79: HISTORICAL RELIABILITY DETAILS FOR 85M26

NOTE:

A table of assets to be replaced is not provided for the civil portion of the project since none of the existing assets are replaced in this phase.

W15169 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: East mall/Dundas Overhead Renewal ET38M10

Project Number: W15169

Project Year: 2015

Estimated Cost: $535,631.24

(i) Objective

The objective of this project is to rebuild the trunk portions of the overhead infrastructure on feeder ET38M10 in order to avoid failure risk due to aging and mal-operating infrastructure.

(ii) Scope of Work

TABLE 91

District Neighbourhood:	Etobicoke Lakeshore
Station(s):	Manby TS
Feeder(s):	ET38M10

*Cable Length (m)	0.0

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 93

Supplemental Details	Description
Age/Condition	Scope upgrades undersized feeder trunk conductors along The East Mall from 4/0 to THESI standard 556 kcmil.
Reliability	Scope upgrades distribution assets along 38M10 in the area order to stem outages, which were particularly high in 2013. A total of 5 forced outages, 8378 CI and 4910 CHI on feeder 38M10 since 2009 with 80% of the outages in 2013 showing an increasingly serious reliability situation along the feeder.
Other (i.e. moratorium, etc)	Customers in the area had complained of the high incidence of outages in 2013.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeder are given in Figure 80.

FIGURE 80: HISTORICAL RELIABILITY DETAILS FOR 38M10

NOTE:

E14097 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Voltage Conversion of SS63F1 to NY80M4 - Between Yonge & Bayview

Project Number: E14097

Project Year: 2015

Estimated Cost: $1,217,582.02

(i) Objective

The objective of this project is to rebuild the overhead aged 4.16kV primary distribution fed by the Estelle Municipal Substation by upgrading assets on the feeder route to 27.6kV rating and sourcing power to the assets directly from the adjacent feeder NY80M4.

(ii) Scope of Work

TABLE 94

District Neighbourhood:	Willowdale
Station(s):	Estelle MS
Feeder(s):	NY SS63F1, NY80M4

X12318 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Replacement of Manual Switch & Installation of SCADA Switch 34M1

Project Number: X12318

Project Year: 2015

Estimated Cost: $109,932.35

(i) Objective

The objective of this project is to replace manual switches with SCADAmate switches at two locations on feeder 34M1.

(ii) Scope of Work

TABLE 97

District Neighbourhood:	Scarborough Centre
Station(s):	Leaside TS (27.6kV)
Feeder(s):	34M1

TABLE 98

Asset	Count
Pole	0
Transformer	0

E14286 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Overhead Rebuild 64F2 Ruddington MS VC

Project Number: E14286

Project Year: 2015

Estimated Cost: $980,460.58

(i) Objective

The objective of this project is to rebuild the aging 4.16kV primary distribution system fed by Ruddington Municipal Station and converting it to 27.6kV.

(ii) (ii) Scope of Work

TABLE 100

District Neighbourhood:	Scarborough Centre

W13634 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: P05 Extension of 30M12 eastwards along Evans Ave into 30M1 and 30M8

Project Number: W13634

Project Year: 2015

Estimated Cost: $867,886.96

(i) Objective

The objective of this project is to relieve feeders R30M1 and R30M8 from the Horner TS east of Kipling Avenue by upgrading and extending the new feeder R30M12 powered out of the Horner TS and slightly modifying the configuration of the existing Horner TS feeders south of The Queensway.

(ii) Scope of Work

TABLE 103

District/Neighbourhood:	York West
Station(s):	Horner TS
Feeder(s):	R30M1; R30M8; R30M12

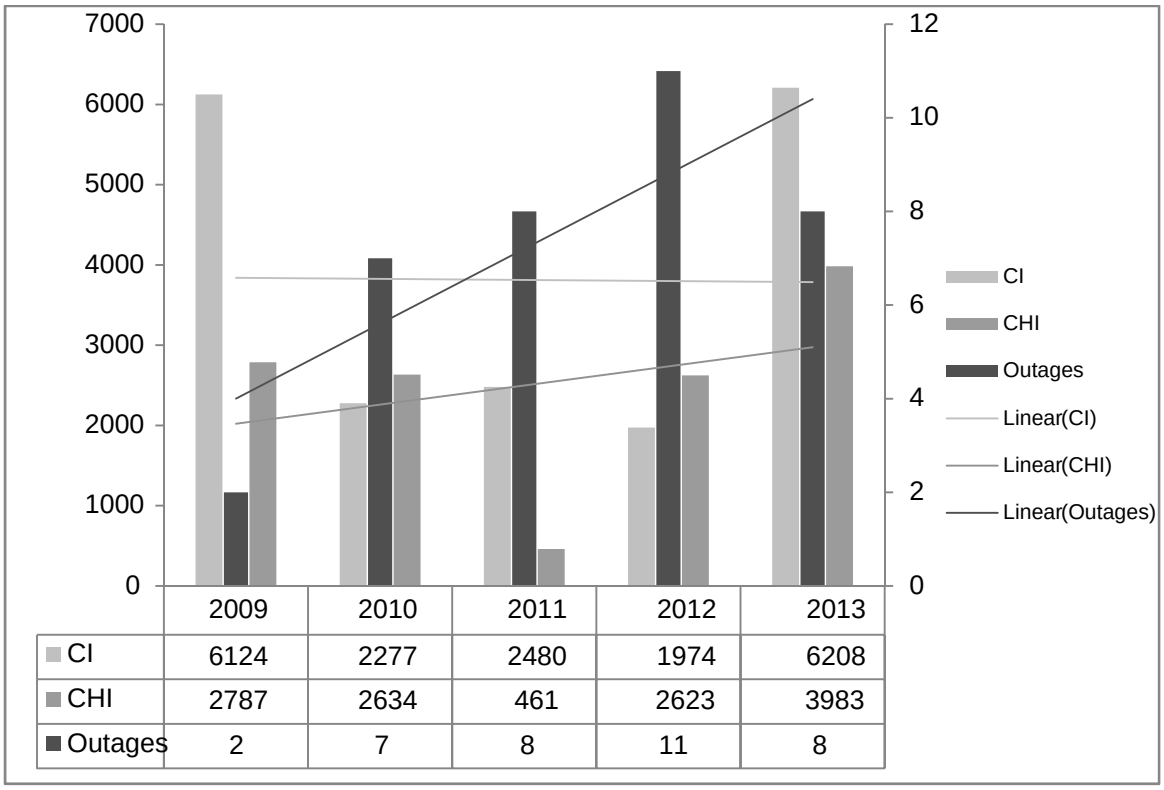
*Conductor Length (m)	3,000
*Cable Length (m)	750

(iii) Justification & Benefits



Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 105

Supplemental Details	Description
Age/Condition	ƒ The scope replaces aging poles and conductors along Evans Avenue while converting the erstwhile single circuit to a double circuit
Reliability	ƒ This scope builds a new feeder that introduces capacity (of about 25 MVA) for emergency load transfers during contingencies that would reduce outage restoration times for customers in the area. ƒ R30M1 had a total of 11 forced outages, 8017 CI and 6566 CHI since 2009, ƒ R30M8 had a total of 9 forced outages, 7912 CI and 3397 CHI since 2009
Other (i.e. moratorium, etc)	ƒ The scope relieves capacity from R30M1, R30M8 and other Horner TS feeders in the distribution area immediately enabling them to accommodate the rising tide of feeder requests from new building developments. ƒ This project will rebuild feeder lines to accommodate the new circuit and provide the capacity relief required

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 85 and 86.

W14677 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: P05 - Manby Richview Load Cascades, Part 2

Project Number: W14677

Project Year: 2015

Estimated Cost: $578,591.31

(i) Objective

The object of this project is to relieve Manby TS bus pairs Q-Z and B-Y of overload and provide capacity for system expansion by converting some 4.16 kV in the area of Burnhamthorpe Road.

(ii) Scope of Work

TABLE 106

District Neighbourhood:	Etobicoke Centre

*Cable Length (m)	1,500

(iii) Justification & Benefits

Supplemental details pertaining to the justification and benefits of this project are summarized as follows:

TABLE 108

Supplemental Details	Description
Age/Condition	• Scope includes system renewal needed to replace aging 51 yr old 4kV OH and UG assets of Islington MS that are already in poor service condition.
Reliability	• System expansion in the scope includes extending feeder lines and installing additional tie points and sectionalizers that will improve system restoration times and reduce outage impact.
Other (i.e. moratorium, etc)	• The scope transfers 8MVA load off Manby TS buses Q2Z and B1Y that are currently loaded to the extents of their capacity in order to enable new customers to access the grid.

Historical reliability including number of customers interrupted (CI), customer hours interrupted (CHI) and outages along the feeders are given in Figures 87 and 88.

E14734 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: P05 Comstock Faulklands MS Decommission Feeders

Project Number: E14734

Project Year: 2015

Estimated Cost: $206,764.29

(i) Objective

The objective of this project to permanently remove the lines from Comstock Faulklands Municipal Station. The transformers at the station are un-reparable and are to be taken offline. The Municipal station can no longer provide backup contingency power.

(ii) Scope of Work

TABLE 109

W13238 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Brenthall MS to Fairchild TS VC Mascot and Kingsbridge

Project Number: W13238

Project Year: 2015

Estimated Cost: $426,176.32

(i) Objective

The objective of this project is to renew the 4.16kV distribution system for feeder NYSS26F1 at Benthall Municipal station by converting them to 27.6kV using Fairchild station feeder NY80M8.

(ii) Scope of Work

TABLE 115

E12326 Project Description

Investment Category: System Renewal

Program: Overhead Circuit Renewal

Project Title: Voltage Conversion of NYSS38F1 and NYSS38F2 from Burbank MS

Project Number: E12326

Project Year: 2015

Estimated Cost: $870,487.47

(i) Objective

The objective of this project is to rebuild the early fifties 4.16kV primary distribution system fed by the Burbank Municipal Substation by converting both outgoing feeders to 27.6kV system.

(ii) Scope of Work

TABLE 118

District Neighbourhood:	Willowdale

E6.5 Overhead Infrastructure Relocation

OVERHEAD EGRESS CONGESTION

E6.5.1 Summary

Program Description

The objective of the Overhead Infrastructure Relocation program is to mitigate safety and reliability risks by targeting overhead infrastructure assets that are part of unacceptably high risk and therefore functionally obsolete feeder designs. The existing overhead infrastructure will be relocated to locations that are more accessible to Toronto Hydro crews, have a reduced safety and reliability risk in the event of a failure, and a reduced probability of failure. The program addresses various assets throughout the overhead system that have reached end-of-life and encompasses all primary voltage levels. The three main scenarios necessitating overhead infrastructure relocation are the following.

- Overhead assets that are in areas with limited or difficult access , such as heavily treed ravines. These locations can be especially vulnerable during major storm events such as heavy rainfall, floods, and ice storms. Restoration efforts following major storms can also be extremely challenging in this areas. Toronto Hydro plans to relocate these assets to more accessible and less vulnerable routes.

- Overhead station egress lines carrying three or more circuits . The congested nature of these pole lines means that there is an unacceptably high risk that a significant asset

failure along the line could interrupt three or more entire feeders, resulting in potentially long duration outages to thousands of customers. Toronto Hydro plans to separate the circuits where possible, or, if necessary, convert the egress section to underground infrastructure where it will be less susceptible to the simultaneous interruption of multiple feeders.

- Overhead assets crossing highways . Toronto Hydro plans to replace these overhead crossings with underground crossings to avoid the risk and impact of primary power lines falling onto highways.

The anticipated benefits of the Overhead Infrastructure Relocation program are as follows.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	• Improve outage restoration times • Mitigate public safety risk
Reliability	• Minimize failure impact on existing overhead egress feeders • Help minimize vegetation related outages • Mitigate the risk of momentary interruptions on feeders • Remove high risk asset configurations that are especially vulnerable to major storm events
Safety	• Improve public safety by relocating overhead wires that cross highways Improve Toronto Hydro crew member safety by improving access to assets, including poles.
Efficiency	• Improve maintenance activities by facilitating better access to critical infrastructure, including the ability to use needed equipment

Program Drivers

The trigger and secondary drivers for the Overhead Infrastructure Relocation program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	• Obsolete system layout can complicate and extend feeder restoration efforts. • Certain assets are installed in areas where access is very limited. • There is a considerable number of assets past their useful lives
Secondary Driver	**Reasoning**
Safety	• Overhead highway crossings pose potential safety risks if the energized lines fall to the ground.

	ƒ Overhead infrastructure in areas with limited access (steep terrain or heavily treed areas with no road access) present safety hazards for field crews.
Reliability	ƒ Restoration times are impacted by assets that are difficult to access. ƒ Vegetation in difficult to access areas reduces the reliability of the overhead system. ƒ Feeders in some locations are more susceptible to a high number of momentary interruptions during adverse weather conditions.

Preferred Alternative

Toronto Hydro evaluated the following options for addressing the assets in this program:

(1) Do nothing and replace on a reactive basis only, incurring the risk of equipment failures and potential safety concerns

(2) Replace the aged assets on a like-for-like basis, temporarily reducing the probability, but not the impact, of asset failure

(3) Replacement of the aged assets and relocation of the plant to avoid safety and reliability issues associated with its current location

Option III is the preferred alternative as it provides the most value by minimizing the safety and reliability risks associated with the assets, while reducing the time and effort required when restoring power in the event of an outage.

The difference in the cost of ownership between existing and renewed assets ("COO") for the first year of the program is $1.76 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.5.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $1.02 million, confirming the economic prudence of the investments (see Section E6.5.7). For comparison, the NPV of the like-for-like replacement option is -$0.69 million.

Timing and Pacing

Table C provides historical and projected program spending. The program requires an investment of approximately $9.87 million over the five year planning horizon. Due to the large backlog of assets that have reached end-of-life, Toronto Hydro plans to increase yearly expenditures throughout the 2015-2019 period.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0.74	1.38	1.83	2.28	3.64

By the end of the program period, it is anticipated that approximately 32% of the assets that require relocation will have been addressed. Accordingly, Toronto Hydro plans to continue relocation efforts beyond the 2015-2019 planning period.

E6.5.2 Program Description

The Overhead Infrastructure Relocation program will target overhead infrastructure assets that are part of functionally obsolete feeder designs. Similar to Toronto Hydro's larger Box Construction Conversion (Section E6.7) and Rear Lot Conversion (Section E6.6) programs, the feeder designs addressed by this program no longer align with Toronto Hydro's current planning and work practices and their failure could result in significant reliability impacts. The program is expected to mitigate safety and reliability risks associated with functionally obsolete feeder designs by relocating the existing overhead infrastructure to locations that are more accessible to Toronto Hydro crews and that lower the potential likelihood and impact of failure. The program addresses assets of all voltages throughout the overhead system and that have reached end-of-life.

There are three primary activities that constitute this program.

- Relocation of overhead assets that are in areas with limited or difficult access
- Relocation of overhead station egress assets carrying three or more circuits
- Relocation of overhead assets crossing highways

Each of these activities is described in detail in the following subsections. Toronto Hydro's estimated cost for the program is $9.87 million over the 2015 to 2019 period.

E6.5.2.1 Relocation of Difficult-to-Access Overhead Plant

Overhead assets in certain parts of the city are located in areas that are difficult or are impossible for Toronto Hydro employees to access. Figure 1 shows the location of assets that are in undesirable locations.

FIGURE 1: LOCATIONS OF ASSETS IN THE OVERHE AD SYSTEM THAT ARE DIFFICULT OR IMPOSSIBLE TO ACCESS

Toronto Hydro plans to relocate these pole lines, including primary conductors, poles, insulators, lightning arrestors, transformers and switches. The program will replace these overhead sections with new construction located in more accessible areas, e.g., overhead distribution on nearby roadways, underground distribution on boulevards, or ducts on bridges.

An example of assets that are difficult to reach is illustrated in Figure 2. The yellow line traces the path of two operational feeders and two abandoned feeders from Leaside TS that are running through a ravine where access is limited and heavy vegetation impacts reliability. As well, most of the poles and cross-arms in the ravine are in poor condition with signs of pole top "feathering" and cracks, indicating a relatively high risk of failure due to asset deterioration. The relocation of these feeders will be completed throughout different phases due to the extension of the work. Customers will have to re-supply throughout different routes in order to remove the two feeders from the ravine. The planned work for this section of Leaside TS is planned for completion within the 2015-2019 period.

FIGURE 2: LEASIDE TS FEEDERS RUNNING IN RAVINE

Toronto Hydro plans to reconfigure the feeders to relocate these assets from the ravine in order to improve accessibility for Toronto Hydro crew members and to reduce vulnerability to outages in adverse weather conditions. This relocation will reduce safety risks, such as slips, trips or fall hazards due uneven terrains and by enabling the use of bucket trucks in place of having to climb poles to perform certain activities. Currently, when climbing poles to work on energized lines, crews may not have sufficient support, increasing the risk of them coming into contact with live lines. The use a bucket trucks is the most secure way for crews to reach the assets located on poles since the crews will be working on a stable and an insulated aerial device. In general, the reconfiguration and relocation will reduce restoration times in the event of an outage.

E6.5.2.2 Relocation of Over-head Station Egress Plant

One of the most important and vulnerable aspects of a feeder is its egress portion, the initial section of the feeder that begins at the station circuit breaker at continues until the first sectionalizing switch. This initial path out of the substation is critical because it carries the entire feeder load; a fault on the egress portion of a feeder will result in an interruption to all customers on the feeder. When egress conductors are overhead, they are exposed to a variety of external

harms such as tree contact, animal and human interference, adverse weather conditions and lightning.

The Overhead Infrastructure Relocation program targets stations with a high density of overhead egress assets, i.e., three or more feeders on the same pole. Figure 3 shows the locations of stations with three or more overhead circuits on a single pole line. Under this program, the Richview Station will be addressed during the 2015-2019 period.

Toronto Hydro has determined that a single pole line carrying three or more feeder egresses represents an unacceptably high level of risk to the reliability of power due to the amount of load connected in a single physical location; should a failure occur that impacts the pole line, three or more feeders could experience an outage, resulting in an unacceptably high number of customer interruptions. In addition, risk of falling wires on city streets creates considerable safety risks to the general public. Toronto Hydro plans to reconfigure these assets such that there are no more than two feeders on a pole line. In some cases, this will involve replacing overhead egress with new underground tree-retardant cross-linked polyethylene (TR-XLPE) cable in concrete-encased conduit. The circuit will be underground from the circuit breaker to a point where it can return to overhead.

FIGURE 3: OVERHEAD EGRESS STATION

E6.5.2.3 Relocation of Overhead Plant Crossing Highways

Toronto Hydro plans to relocate overhead primary conductors that currently cross major highways in order to eliminate the risk and impact of primary power lines falling onto the highway. Figure 4 shows a map of the identified locations where primary overhead conductors currently cross major highways. The program will relocate these assets underground by building ducts and installing new underground cable.

FIGURE 4: OVERHEAD HIGHWAY CROSSINGS

The primary activities that constitute the Overhead Infrastructure Relocation program will convert obsolete and difficult to access location feeder sections to modern and efficient configurations. Toronto Hydro anticipates that these relocations will improve efficiency to maintenance activities and restoration time as well as reducing the safety risks associated with better accessibility for Toronto Hydro crews. Table 1 shows the estimated number of assets forecasted for replacement through the Infrastructure Relocation program during the 2015-2019 period.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Poles		32		27	8	
OH Conductor (mts)		5,656			3,400	
OH Switches		10		6	6	
OH Transformers		22		1		
Underground Cable Chamber	2		18			
Underground Duct (mts)	110		3,000	165	200	

In general, the Overhead Infrastructure Relocation program is expected to produce benefits related to increased reliability, outage restoration efficiency and timing, and safety. Table 2 summarizes the anticipated benefits of the program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improve outage restoration times by relocating assets in locations with limited accessibility, like ravines and railway tracks ƒ Mitigate public safety risk by relocating overhead wires from highway crossings x The difference in the cost of ownership between existing and renewed assets (ôCOO) for the first year of the program is $1.76 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.5.7). x Accounting for capital program costs, the first year's activities deliver a positive NPV of $1.02 million, confirming the economic prudence of the investments (see Section E6.5.7).
Reliability	ƒ Minimize failure impact on existing overhead egress feeders ƒ Help minimize vegetation related outages, such as tree contacts ƒ Mitigate the risk of momentary interruptions on feeders currently in locations susceptible such as ravines
Safety	ƒ Improve public safety by relocating overhead wires that cross highways underground ƒ Improve Toronto Hydro crew member safety by improving access to assets, including poles. Currently, limited vehicle access and the need to climb poles to make repairs create potential safety hazards
Efficiency	ƒ Improve maintenance activities by facilitating better access to critical infrastructure, including the ability to use needed equipment

E6.5.3 Why the Program is Needed

Certain portions of the overhead grid are functionally obsolete from a design perspective, as they do not align with Toronto Hydro's planning and work practices. Many of the assets on these feeders are approaching end-of-life and carry an especially high failure risk due to their current locations or configurations. These feeders have been contributing an increasing share of overall system outages during the last five years. In order to permanently address the heightened risks to reliability and crew and public safety associated with these assets, Toronto Hydro plans to rebuild these feeders to an improved design standard by either relocating overhead pole lines to a safer and more accessible location, or by moving critical sections of certain egress feeders underground as appropriate.

E6.5.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for the Overhead Infrastructure Relocation program. The program addresses functionally obsolete overhead feeder designs that do not align with Toronto Hydro's current planning and work practices, as they have a number of reliability and safety deficiencies. Compared to standard overhead feeders, these assets, by virtue of their location and configuration, carry higher reliability and safety risks, including with respect to performance during major storm events. Toronto Hydro has categorized this program as a System Renewal activity.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Obsolete system layout can complicate and extend feeder restoration efforts. ƒ Certain assets are installed in areas where access is very limited. ƒ Overhead highway crossings and high density overhead egress circuits are functionally obsolete designs. ƒ There is a considerable amount of assets in use that are past their useful lives
Secondary Drivers	**Reasoning**
Safety	ƒ Overhead highway crossings pose potential safety risks if the energized lines fall to the ground. ƒ Overhead infrastructure in areas with limited access (steep terrain or heavily treed areas with no road access) present safety hazards for field crews.
Reliability	ƒ Restoration times are impacted by assets that are difficult to access. ƒ Ever-growing vegetation reduces the reliability of the system as it affects overhead infrastructure and the egress section of the feeder. Overhead station egress can impact a large number of customers.

	ƒ Feeders in some locations (for example, ravines) are more susceptible to a high number of momentary interruptions during adverse weather conditions.

Figures 5 and 6 provide a graphical representation of the number of Customers Interrupted (CI) and Customers Hours Interrupted (CHI) over the 2009-2013 period generated by the feeders that are targeted by the Overhead Infrastructure Relocation program. The information is split out between feeder trunks (i.e., the main section of the feeder emanating from the station breaker) and laterals (i.e., the fuse protected branches off of the trunk).

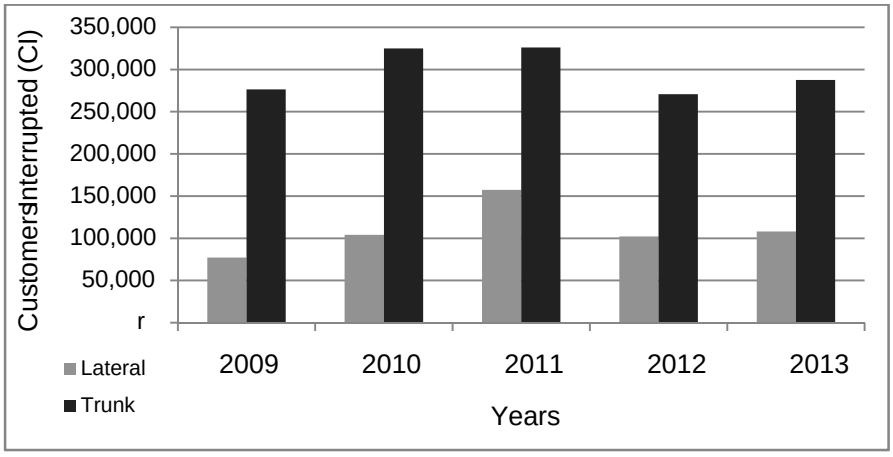

FIGURE 5: AVERAGE CUSTOMER INTERRUPTED (CI) – TRUNK VS. LATERAL

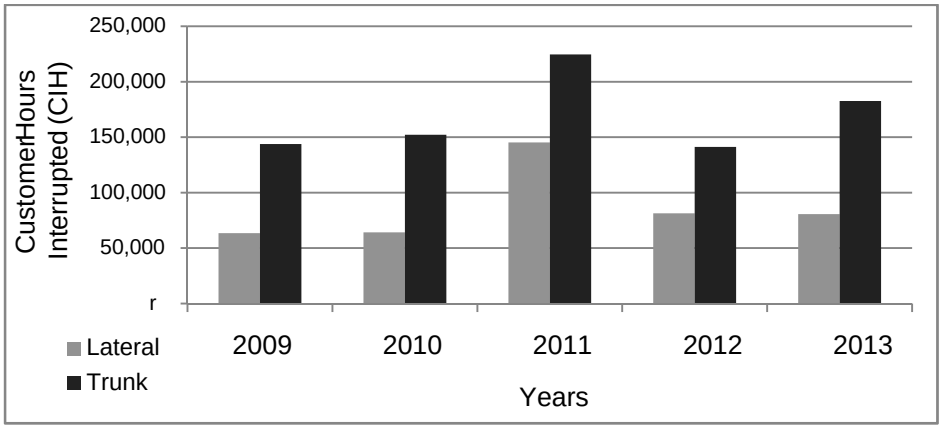

FIGURE 6: AVERAGE CUSTOMER HOURS INTERRUPTED (CHI) – TRUNK VS. LATERAL

As seen in the above two figures, the trunk portion of the circuits contribute a high number of CIs and CHIs. Prolonged outages are common, especially where the assets are located in areas that are difficult to access. In many instances, the trunk portion of the circuit is vulnerable to outages caused by coming into contact with trees, animals, and moisture.

As well, overhead feeder egress sections are exposed to outages caused by the weather, animal contacts and human impact, such as vehicles hitting poles. Moving high density egress sections underground is expected to significantly mitigate these risks. As part of these projects, a SCADA switch will be installed where the egress eventually rises into the overhead circuit (at a safe distance from the transformer station). The SCADA switch will be installed at the riser point to detect and remotely isolate any underground cable faults.

For the 2009-2013 timeframe, 30% to 40% of system-wide CIs were caused by feeders that will be addressed by the Overhead Infrastructure Relocation program, as shown in Figure 7. Figure 8 shows that, over the same time period, approximately 20% of all CHIs were related to feeders addressed by this program. As can be seen in both figures, there is a discernable upward trend in the percentage of interruptions attributable to feeders that are targeted by this program. Accordingly, the Overhead Infrastructure Relocation program is designed to address this issue and is expected to improve reliability going forward.

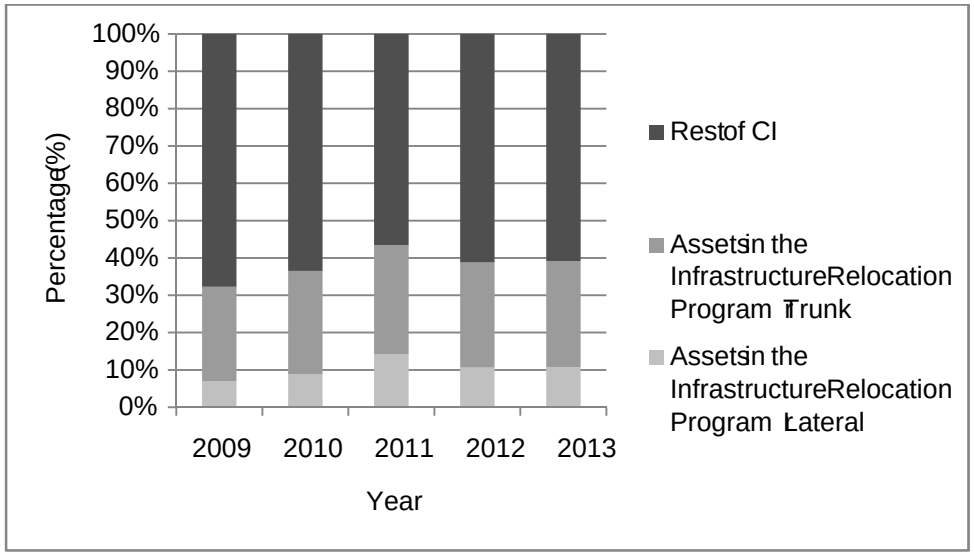

FIGURE 7: CUSTOMER INTERRUPTED PERCENTAGE COMPARED TO THE SYSTEM WIDE

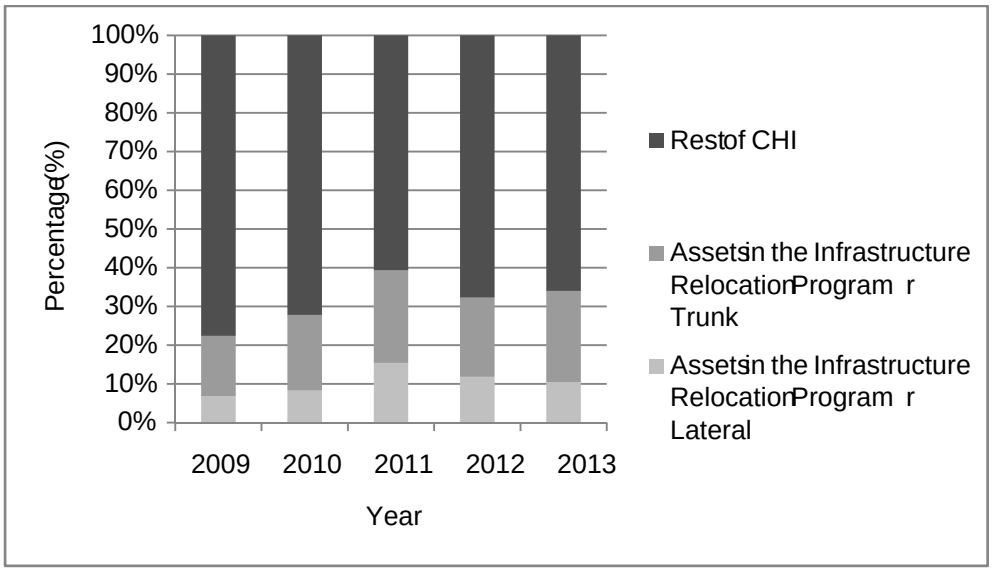

FIGURE 8: CUSTOMER HOURS INTERRUPTED PERCENTAGE COMPARED TO THE SYSTEM WIDE

As discussed in the Program Description section, the Overhead Infrastructure Relocation program will predominantly target three forms of overhead infrastructure: (i) difficult-to-access overhead plant, (ii) overhead egress plant, and (iii) overhead plant crossing highways. These issues are further described below.

(i) Difficult-to-access overhead plant

Assets located in areas with limited access were installed when multiple electrical utilities co-existed as part of the Metropolitan Toronto area. The purpose of feeders running along these areas was to use them as back-up connection points between neighboring districts (for example, between Scarborough, East York, North York, York, Etobicoke and Toronto). These utilities used the shortest and most economical routes – including ravines and railway corridors – which would have been more accessible at the time of construction than they are today. As these locations have developed and as surrounding vegetation has become increasingly dense and intrusive, it has become increasingly difficult and complex for personnel and equipment to access these locations in order to perform necessary work.

Figure 9 shows existing overhead infrastructure that passes through a ravine. To perform restoration or maintenance procedures on these assets, Toronto Hydro employees must work around trees and climb along the steep terrain, which can be saturated with ice or mud, resulting

in an elevated risk of slip, trip or fall hazard. Also, Toronto Hydro personnel are unable to make use of bucket trucks to access equipment in these locations, and instead resort to less safe options, such as climbing poles.

FIGURE 9: FEEDERS RUNNING THROUGH A RAVINE

Figure 10 shows Toronto Hydro distribution lines running along a railway track and over the Don Valley Parkway. If these poles were to fail, they could potentially fall on the railway track or on the highway. The space that crews are required to work within is limited and vehicle access is only available from the railway track or the highway. The problems associated with this work are exacerbated by the fact that the railway track is active and the highway is busy throughout the day and night, making it difficult for crews to move equipment due to highway and railway traffic. In the event that repair work is required on these assets, rail and highway traffic would need to be halted or the number of traffic lanes would need to be reduced.

FIGURE 10: LIMITED ACCESS AND NARROW PATHWAYS

Figures 11 and 12 show the steep terrains that must be traversed to access some poles. In this case, crews would be required to carry heavy assets by hand, such as poles and transformers, to perform repairs, increasing potential risks to crew members and extending repair times, particularly at night and in the winter where visibility is limited and snow, ice and muddy conditions make it more difficult to walk and carry equipment.

FIGURE 11: LIMITED ACCESS AND STEEP TERRAINS

FIGURE 12: LIMITED ACCESS AND NARROW PATHWAYS

(ii) Overhead Egress Plant

As described previously, the egress portion of a feeder trunk circuit is the initial route of power from the circuit breaker at the substation to the rest of the circuit. This initial path out of the substation plays a critical role in the distribution of power to the rest of the feeder since the entire feeder load will flow through this section. As a result, failure on the egress portion of the feeder

will translate into a circuit breaker operation that will affect all customers connected to the feeder. In multiple locations across the city, the egress portion was originally installed overhead, exposing the feeder to numerous risks that can impact the reliability of the feeder or multiple feeders.

Having three or more different circuits running on one pole line outside of the transformer station considerably increases the potential impact of failure. If this portion of the pole line experiences a significant failure, all connected customers on the feeders may experience an outage. Section E6.5.3.2 describes a historical example of such a failure on the Toronto Hydro system. The down wires also represent a safety concern to the public, since they could be electrocuted if they were to come in contact with energized wires.

The program is planned to target overhead egress sections where there are three or more different circuits installed on a pole line. The program will minimize the risk of failure on the feeders by reconfiguring and relocating the feeders to a different location or by undergrounding the circuits. Figures 13 and 14 show existing stations with overhead egress congestion.

FIGURE 13: PICTURES OF OVERHEAD EGRESS CONGESTION

FIGURE 14: PICTURES OF OVERHEAD EGRESS CONGESTION

(iii) Relocation of overhead plant crossing highways

The Overhead Infrastructure Relocation program also is also planned to target overhead infrastructure that crosses major highways. At these particular locations, there is an increased public safety risk due to the possibility of energized lines or assets falling onto oncoming traffic. Due to the high rate of speed at which vehicles travel on a major highway, falling overhead infrastructure presents a serious potential safety risk to the public. The public may not always understand the hazards associated with energized cables lying on the streets. This situation is a serious safety risk since individuals can severely injure themselves if they come in contact with energized lines.

Accessing overhead infrastructure that crosses a highway for repair work is also challenging because it may require closure of the highway and/or special equipment (due to height). Figure 15 is an example of overhead highway crossing in Toronto. Section E6.5.3.2 (ii) describes a

recent historical example of an overhead highway crossing failure on the Gardiner Expressway in Toronto.

FIGURE 15: OVERHEAD HIGHWAY CROSSINGS

E6.5.3.2 Asset Details

(i) Asset Lifecycle

Assets targeted by the Overhead Infrastructure Relocation program were evaluated based on their end-of-life criteria. Figure 16 illustrates the breakdown of the assets by age. The assets targeted by this program are overhead transformers, overhead switches and poles. Roughly 39% of assets are categorized as 30 years of age or older, surpassing their respective asset lifecycle, with an additional 23% approaching end-of-life in the next decade. These assets must be replaced in a timely manner to mitigate elevated reliability risks associated with these obsolete feeder designs.

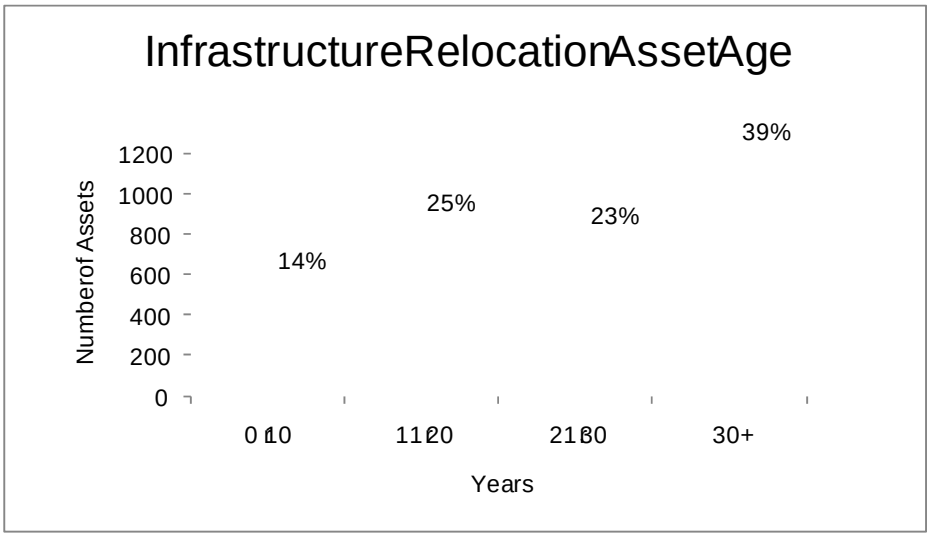

FIGURE 16: INFRASTRUCTURE RELOCATION ASSET AGE

(ii) Asset Failure Impacts

Difficult to access overhead feeders

Overhead portions of feeders that are located in areas with limited accessibility are mostly feeder trunks. Interruptions on these sections can impact more than 3,000 customers and typically take approximately two and a half times longer to restore than outages affecting assets that are more accessible. Poor accessibility also results in complications with respect to maintenance activities and poses risks of slips, trips and falls for Toronto Hydro crews.

These risks became an issue during the December 2013 ice storm on a feeder from Leaside TS in the area of Bayview Avenue and Lawrence Avenue East. Crews had to work in a ravine for two days to restore power to customers, with the prolonged duration due in part to the fact that the crew was unable to use proper machinery. Also, due to the accumulation of ice on the trees, branches frequently fell on the conductors during repair work.

Overhead highway crossings

The possibility of energized lines or other overhead highway crossing assets falling into oncoming traffic poses a significant public safety risk. The safety risk is high because of the rate of speed at which vehicles travel on highways and other major routes. In 2011, the overhead conductors

crossing the Gardiner Expressway near Royal York Road fell on the highway during a snow storm (see Figures 17 and 18). This caused significant disruption to traffic. Fortunately, the conductors had already been isolated and de-energized for removal due to an ongoing project before the incident happened. If the conductor had been energized, cars may have come into contact with live lines. It took approximately one hour to remove the cables and for the lanes to be reopened.

FIGURE 17: FALLEN OVERHEAD CONDUCTORS ON THE GARDINER EXPRESSWAY

FIGURE 18: FALLEN OVERHEAD CONDUCTORS ON THE GARDINER EXPRESSWAY

Congested overhead station egress

The egress portion of a feeder trunk circuit out of a substation plays a critical role in the distribution of power. If this portion of the feeder experiences a failure, all connected customers will experience an outage. This impact of failure can become extreme when there are three or more feeders on a single pole line. An example of an egress incident of this magnitude occurred on June 7, 2011, when thirteen poles collapsed due to a severe windstorm. The investigation of this incident also found evidence of an ant infestation. The severe wind and the weak poles resulted in a lengthy outage that took down three feeders coming out of Agincourt Station. The outage took approximate 8.5 hours to restore and affected close to 6,000 customers. Figure 19 shows the failure of the poles.

FIGURE 19: OVERHEAD EGRESS OUTAGE

E6.5.4 Timing & Pacing of the Program

Table 4 provides the estimated cost of the program for the 2015-2019 forecast period.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0.74	1.38	1.83	2.28	3.64

Many assets within the Overhead Infrastructure Relocation program have reached end-of-life and pose a risk to the reliability of the system and the safety of customers and Toronto Hydro personnel. Rather than undertaking a costly "like-for-like" replacement of end-of-life assets, it is prudent to relocate the infrastructure to improve feeder design, reliability, efficiency and safety. The program requires an investment of approximately $9.87 million over the five year planning horizon. Due to the large backlog of assets that have reached end-of-life, Toronto Hydro plans to

increase yearly expenditures throughout the 2015-2019 period. The timing of overhead relocation also takes into account capacity constraints with respect to Toronto Hydro's workforce.

By the end of the program period, it is anticipated that approximately 32% of the assets that need to be relocated will have been addressed. Accordingly, Toronto Hydro plans on continuing relocation efforts past the 2015-2019 planning period.

E6.5.4.1 Ranking & Prioritization

Sequencing of the work in the Overhead Infrastructure Relocation program is determined based on the following factors:

Asset condition and age: Assets projected to fail will have an impact on customer service, satisfaction and reliability. Toronto Hydro's sequencing of planned work accounts for the risk of failure by considering which assets are in poor condition and past useful life.

Failure risk: As with other basic overhead and underground renewal programs, failure risk (i.e. the likelihood of failure multiplied by the potential impact of failure) is considered the primary criteria when sequencing work within this program. Assessment of failure risk includes consideration of the asset condition and age as well as the number of customers on the feeder and number of circuits per pole.

Reliability : All other factors being equal, feeders that have experienced a significant amount of sustained trunk outages in the last five years will be ranked higher.

Toronto Hydro plans on beginning with the relocations of the circuits from Leaside TS (as detailed in Section E6.5.9). The area was selected due to the poor asset condition, reliability and accessibility of the area.

E6.5.6 Program Execution

The Program Execution discussion is divided into three sections: (i) Relocation of difficult-to-access overhead plant (ii) Relocation of overhead egress plant and (iii) Relocation of overhead plant crossing highways.

(i) Relocation of locations with limited accessibility to overhead plant

In the case of difficult-to-access locations, Toronto plans to remove assets from ravines and railway tracks to locations that are accessible to vehicles and crews year-round. Depending on

the location and street limitations, the new lines might be installed overhead or underground. As well, the installation of the circuit might be relocated to bridges.

If the lines are relocated overhead, the scope of work will require a new pole line to be installed and the use of new conductor and switches to provide transfer capability. If the work is to be relocated underground, the project will cover the installation of concrete encased ducts and new underground cable with riser poles. If the line is to be transferred to a bridge, ducts will be required to be built on the bridge and new underground cable will be installed along with the riser poles and switches. An example of this can be shown on Figure 20. The overhead lines will be relocated from the ravine to the bridge. The work involved includes the installation of ducts along the bridge with new underground tree-retardant cross-linked polyethylene (TR-XLPE) cable. Similar to the highway crossings, riser poles will be installed to transition from the overhead to underground on both sides of the bridge.

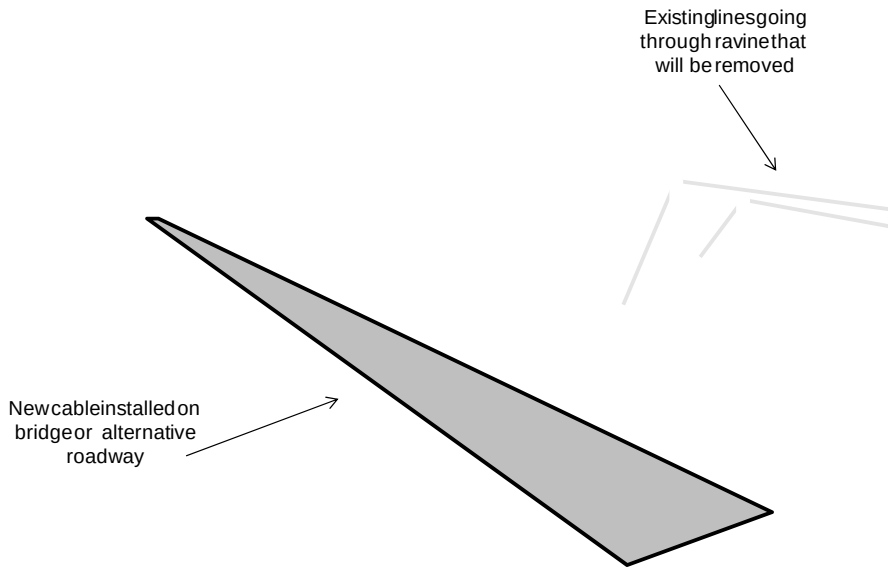

FIGURE 20: RELOCATION OF DIFFICULT ACCESS LOCATIONS

(ii) Relocation of Overhead Egress Plant

Toronto Hydro plans to relocate or move underground overhead egress circuits to reduce the failure risks associated with overhead outages. The scope of work will be limited to the relocation of feeders on pole lines with three or more circuits. Where the feeder is relocated underground, concrete encased ducts will be built with cable chambers and new underground cable. The concrete encased ducts will be built up to a point where the underground circuit will transition back to overhead. Where the feeder egress is relocated but kept overhead, work will involve the installation of poles, conductor, switches, framing hardware and other overhead accessories.

(iii) Relocation of Overhead Plant Crossing Highways

With respect to overhead highway crossings, the work will involve either tunneling, micro-, directional drilling, or jack and bore under the highway in order to build the ducts for the new underground cable. The work will involve the installation of new riser poles and switches to transition from the overhead to underground. New underground tree-retardant cross-linked polyethylene (TR-XLPE) cable will be installed. An example of this can be seen in Figure 21. A second option for the overhead highway crossing removal will is reconfiguring the feeder and routing the circuit through a different street. Each highway crossing has to be evaluated individually to determine if there is an alternative road for the new line. Undergrounding the highway crossing is typically the most effective solution as it will eliminate the risk of the circuits falling and it will great establish the civil infrastructure necessary for additional feeders to cross the highway in the future.

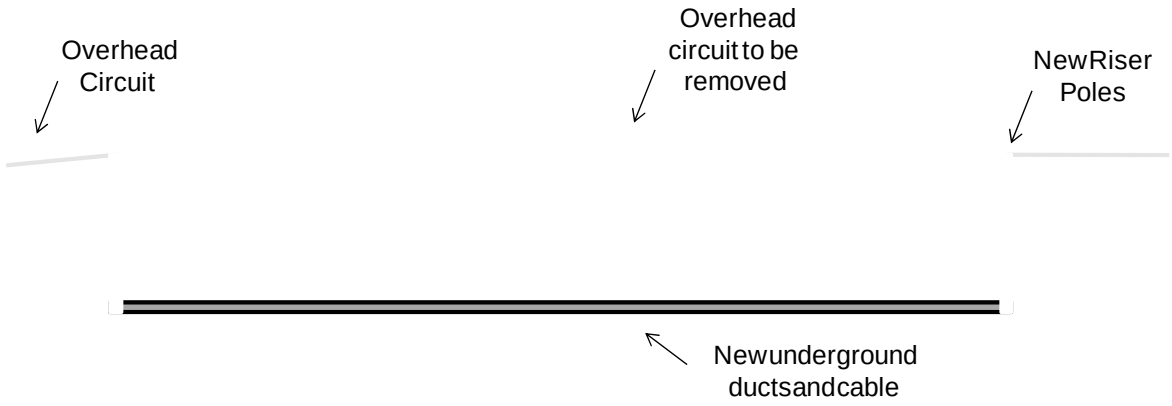

FIGURE 21: CONVERSION OF OVERHEAD HIGHWAY CROSSINGS TO UNDERGROUND

E6.5.6.1 Proposed Work Plan

The proposed work plan in the 2015-2019 period does not necessarily follow a station-by-station approach. Due to the complexity of some of these locations, projects will be scheduled by phases throughout the 2015-2019 period in order to complete the relocation of the assets. This incorporates best capability of executing and resources availability.

Table 5 represents the work plan for the program for the 2015-2019 period. Issues may arise that are specific to certain locations; however, current planning processes have not identified any major issues in years 2015-2019 other than the continued deterioration and aging of assets.

TABLE 5: 2015-2019 LONG TERM PLAN

Year	Station
2015	Leaside TS
2016	Leaside TS
2016	Belfield MS
2016	Manby TS
2017	Leaside TS
2017	Richview TS

Year	Station
2018	Leaside TS
2018	Richview TS
2018	Bermondsey TS
2019	Richview TS
2019	Finch TS

E6.5.6.2 Program Risks

Road moratoriums that follow municipal roadwork may be in place where Toronto Hydro plans to perform work under this program, which could delay some planned work within this program. To mitigate this risk, Toronto Hydro maintains communication with the City's planning staff to stay abreast of any moratoriums and to work around them and/or develop solutions in concert with the City.

A second risk relates to the need to involve provincial and municipal transportation to close highways for required work. Toronto Hydro will mitigate this risk by coordinating its work with the relevant authorities and removing the conductor at a time when traffic is low in order to minimize traffic disruption.

A third risk associated with the program is operational risk. When replacing egress cables, it is possible that several feeders will need to be de-energized in order to undertake the construction of the new design. The load of the feeder where the work is taking place will have to be transferred to adjacent feeders. Load transfers can be restricted in certain months of the year due to high usage of electricity, for example summer months. Overloading feeders can cause equipment deterioration due to heat generated by losses that can result in deterioration of the insulation material, transformers and others. Toronto Hydro will mitigate this risk by scheduling the work were lading restrictions are low.

E6.5.7 Evaluation of Alternatives

E6.5.7.1 Quantification/Evaluation of Options

In addition to the benefits outlined in section E6.5.2, the value derived from the Overhead Infrastructure Relocation program can be further quantified by examining the difference in cost of ownership between the existing infrastructure that will be replaced and the new system design

that will be installed. This difference in costs includes quantified risks, taking into account the probability of failure of the asset, and multiplying this figure by the direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs and replacement. The underlying methodology and processes associated with the business case results provided below are further explained within Section D3.

(i) Option 1: Status Quo

The status quo would have Toronto Hydro continue to maintain and repair assets targeted by the program. Due to the high number of assets at end-of-life on these feeders, maintaining the status quo will likely result in increasing maintenance costs and the continued worsening of system reliability associated with these circuits. The safety and operational issues discussed throughout this narrative would continue to arise and Toronto Hydro would have to address them in a reactive manner. The continued cost of ownership associated with the Status Quo option (COO_E) is highlighted in Table 6.

From a tree trimming perspective, foresters will be required to climb trees to perform the trimming, as opposed to working in a bucket truck. This introduces delays in execution of the work, and there is a greater risk of injury to the personnel performing the work. In some cases, due to the hazards of these locations, arrangements have to be made for a feeder outage in order to perform the trimming safely.

Additionally, the restoration time will be longer at inaccessible locations than a regular outage on a roadway. Repairing an outage for an asset in an inaccessible location can take up to two and a half times longer.

(ii) Option 2: Like-for-like Replacement

Like-for-like replacement would involve the replacement of the assets within the programs at their existing locations. Under this option, safety risks discussed earlier would remain. In addition, limited accessibility would continue to impact power restoration times. In all, the efficiency and reliability of the system would not gain the permanent improvements associated with relocation and customers would continue to experience longer than necessary outages.

The cost of ownership (COO_{N1}) and program net benefit (NPV_1) associated with like-for-like replacement is further detailed in Table 7. When the difference in cost of ownership (ΔCOO_1) is

compared to the associated program costs, the like-for-like replacement option receives a program net benefit (NPV_1) value of -$0.69 million for this option.

(iii) Option 3: Infrastructure Relocation

The Overhead Infrastructure Relocation program as described in this evidence is the preferred option. As noted, it provides the most cost effective option to increase restoration of outages, increase safety, and increase reliability.

The cost of ownership (COO_{N2}) and program net benefit (NPV_2) associated with Overhead Infrastructure Relocation program is further detailed in Figure E6.5-29. The COO is established for both the existing state (COO_E) and the proposed new state (COO_{N2}) based on the first year of activities within this program. The COO of a state reflects the risk of asset failure including both direct and indirect costs. These costs include the cost of customer interruptions, emergency repairs, and asset replacements associated with that design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_{N2}) state. Non-asset risks are further explained in Section D3.3. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO_2) is compared to the associated program costs (PC_2) for the first of activities, the Overhead Infrastructure Relocation program produces a NPV of $1.02 million, as shown in Table 8.

Program Net Benefit [$NPV_2 = (\Delta COO_2 - PC_2)$]	1.02

E6.5.9 Program Projects

Table 9 lists the projects that are planned for execution in 2015. Additional project details are available on the following page.

TABLE 9: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Start Date
E14565	Beechwood DVP reconfiguration tie Point Civil 34M2 EYM2L	$743,214	2015

E14565 Project Description

Investment Category: System Renewal

Program: Overhead Infrastructure Relocation

Project Title: Beechwood DVP reconfiguration tie Point (Civil) 34M2

Project Number: E14565

Project Year: 2015

Estimated Cost: $743,214

(i) Objective

The objective of this project is to remove a section of 34M2 that is installed on a hill in the area of Leaside TS with limited access beside the Don Valley Parkway. The tie point between 34M1 and 34M2 is to be re-established via a new underground connection on Beechwood Drive. This project involves the civil portion of the project. Electrical portion will be schedule for 2016.

(ii) Scope of Work

TABLE 10: E12345 SCOPE OF WORK DETAILS

District Neighborhood	DONVALLEY WEST
Station(s)	LEASIDE TS
Feeder(s)	34M1, 34M2

TABLE 11: E12345 ASSETS REPLACED

Assets (Units)	Count
Pole	
Transformer	
Switch	
Switchgear	
Conductor Lengths (mts)	
Cable Lengths (mts)	
Underground Cable Chamber	2
Underground Duct (mts)	110

(iii) Justification & Benefits

Leaside TS feeders 34M2 and 34M3 exit the station via overhead lines across a parking lot before extending into the Don Parkland. Both of these feeders are installed on cross arms in two separate pole lines In the Don Parkland, before crossing the CN railway and Don River, both lines are mounted on poles that are installed on hills and grass field without proper road access for vehicles.

Most of the poles and cross arms in the parkland and parking lot are in poor condition with sign of pole top "feathering" and cracks. Due to their physical location, access to the lines on the north side of the Don River via trucks is difficult to impossible depending on weather conditions. Any equipment failure in the parkland or on the ravines would result in a lengthy outage and present an unsafe work environment to Toronto Hydro crews. Due to the complexity of required work, it will be divided into a number of scopes. E14565 will install the civil infrastructure required to supply the customers currently feed from the line going through the ravine.

E6.6 Rear Lot Conversion

REAR LOT MAINTENANCE BY TORONTO HYDRO CREW MEMBER

E6.6.1 Summary

Program Description

The Rear Lot Conversion program continues the activities described in the Ontario Energy Board (OEB) approved Rear Lot Construction segment of Toronto Hydro's 2012-2014 rate filing[1]. The Rear Lot Conversion program targets the replacement of assets that are currently installed in the back yard, or rear lot, of residential areas. These assets were typically installed over 40 years ago and are now either at or beyond their useful lives. The assets include wood poles, transformers, switches, and overhead and underground conductors. This program eliminates the supply of power coming from the rear lot overhead and re-distribute power to the neighbourhoods via standard front lot underground supply.

The anticipated benefits of the Rear Lot Conversion program are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Crews will no longer have to enter customer property to perform services ƒ Maintains neighbourhood aesthetics by building future state assets underground

[1] EB-2012-0064, Tab 4, Schedule B6.

Reliability	ƒ Reduces frequency and duration of outages ƒ Reduces storm, tree and animal damage ƒ Reduces vulnerabilities of the existing system to major storm events
Safety	ƒ Improves public safety ƒ Clearances are brought up to standard ƒ Reduces the risk of field crew injury with respect to over exertion, constrained work spaces, poor visibility and unstable footing
Efficiency	ƒ Enables use of standard equipment and fault location methods ƒ Improves access to distribution equipment during restoration efforts

Program Drivers

The trigger and secondary drivers for the Rear Lot Conversion program are summarized in the table below.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ The rear lot configuration is a legacy design that is associated with operational constraints (limited access and non-standard design elements) and safety risks ƒ Leads to prolonged outage durations because it is difficult to locate and repair faults
Secondary Drivers	**Reasoning**
Safety	ƒ Constrained work spaces with poor visibility and poor footing conditions potentially endanger crew members. ƒ The need to manually move and access parts and equipment can lead to overexertion.
Reliability	ƒ The need to manually locate, isolate and restore outages prolongs outage durations. Heavy vegetation can impact the reliability of the system.
Failure Risk	ƒ Equipment past its useful life and more likely to fail. ƒ The majority of rear lot underground assets are direct buried, a design that is associated with an especially high failure risk.

Preferred Alternative

Toronto Hydro considered the following alternatives for addressing the assets in this program.

(1) Do nothing and replace on a reactive basis only, incurring the risk of equipment failures and potential safety concerns

(2) Rebuild the aged rear lot assets in a like-for-like manner, temporarily reducing the probability of a power outage without reducing the potential impact of failure and the operational constraints faced as the assets approach their end of life and begin to fail

(3) Replace the rear lot distribution with a front lot, overhead distribution system that may offer improved reliability, but may not be possible to actually construct due to the harm to the aesthetic value of customer property and the need to potentially remove mature trees in the neighbourhood

(4) Replace the rear lot distribution with a front lot, underground distribution system

Option IV is the preferred alternative as it provides the most cost effective option to increase the safety and reliability of the system, while reducing the time and effort required to respond to power outages in the area and maintaining neighbourhood aesthetics, thereby maximizing customer value derived from the necessary conversion projects.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $27.02 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.6.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.71 million, confirming the economic prudence of the investments (see Section E6.6.7).

Timing and Pacing

Table C provides historical and projected program spending.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	6.88	16.6	17.5	23.8	22.7	17.05	8.06	10.3	10.3	13.6

Rear Lot Conversion projects are resource intensive, relatively complex and require a steady moderate pace of construction. The amounts shown in the table above represent the amount of investment required to maintain a reasonable level of service and to ensure that an excessive

backlog of work does not accumulate over the 2015-2019 period. Deferral of the program to 2020 would create a larger backlog of increasingly critical rear lot projects, since equipment will continue to age and failure risks to increase. This backlog could become difficult to manage and could contribute to the further deterioration of system performance and safety.

E6.6.2 Program Description

The Rear Lot Conversion program continues the activities described in the Rear Lot Construction segment of Toronto Hydro's 2012-2014 rate filing, which was approved by the OEB. Toronto Hydro estimates that the Rear Lot Conversion program will cost $59 million over the 2015 to 2019 period, with spending averaging approximately $12 million per year. A summary of the major assets to be replaced by asset class is shown Table 1 below and a map of the rear lot areas to be address between 2015 and 2019 can be seen in Figure 1 at the end of this section.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Asset Type	2015	2016	2017	2018	2019	Total
Pole	352	23	210	133	122	840
Transformer	99	37	64	32	51	283
Manual Switch	44	10	15	10	7	86
Fuse	48	15	27	14	29	133
Riser	32	2	27	4	25	90
Conductor (m)	18,295	2,933	9,112	6,692	9,157	46,188
Cable (m)	2,853	9,858	2,694	3,062	8,552	27,018

IC

Rear Lot Service History

Rear lot service was implemented in certain Toronto neighbourhoods in the 1950s and 1960s. At the time, this configuration was seen as more cost effective compared to front lot underground service and aesthetically superior to front lot overhead systems. The rear lot systems were constructed along the easements between customer properties at their rear lines. Toronto Hydro now considers rear lot service to be functionally obsolete due to a number of reliability, operational efficiency and safety issues associated with the configuration. Accordingly, Toronto Hydro no longer uses rear lot service for new projects and plans on converting rear lots to front lots. Rear lot conversion may also occasionally be driven by the need to replace 4 kV feeders that are connected to aging stations that are set to be decommissioned.

While there are some portions of rear lot distribution circuits that are underground, most rear lot service is overhead. These facilities consist of cable, poles, transformers, switches and overhead conductors. The system also features minor non-standard components, such as porcelain arrestors and insulators.

Rear Lot Conversion

Toronto Hydro's Rear Lot Conversion program began in 2007, and to date, approximately 29 feeders have been converted to front lot underground configurations. Toronto Hydro plans to continue converting rear lot plant to front lot underground plant during the 2015-2019 period. Approximately 11,000 customers currently receive power from 42 rear lot feeders emanating from 20 Toronto Hydro substations. Figure 1 shows the location of rear lots within Toronto Hydro's distribution system, most of which are located in the west end of Toronto, with a few remaining areas in the east end.

FIGURE 1: REMAINING REAR LOT MAP

The remaining rear lot configurations feature multiple feeders that provide service across the same easement, making conversion activities relatively complex. These feeders depend on one another for load transfers, especially during contingency scenarios (i.e., during outages on any of the feeders). Feeders tie with one another and can be used to resupply each other if a feeder's primary source of power from a substation is disrupted due to a fault or work being done. Therefore, it is important that alternative sources of power remain available during conversion in the event of an emergency. These interconnections necessitate the careful staging of conversion jobs over several years.

The Rear Lot Conversion program addresses the geographic areas shown in Figure 1 in red. The neighbourhoods targeted for conversion during the forecast period were chosen based on safety, equipment condition assessments, reliability concerns and city restrictions. The program will convert and resupply rear lot customers using underground front lot services. This design will supply customers through concrete-encased lateral underground 27.6 kV primary circuits along the roadways with padmount or submersible transformers. Toronto Hydro will route the customer service cables that tap off the secondary bus underground in between the homes in order to connect to the existing meter location (meterbase), located at the rear of the residences. Once customers are connected, all remaining rear lot assets will be removed to eliminate any remaining safety risks. A standard design example can be seen in Figure 2 below.

FIGURE 2: STANDARD DESIGN EXAMPLE OF REAR LOT TO UNDERGROUND FRONT LOT CONVERSION

The Rear Lot Conversion program provides customer value by improving reliability, enhancing public safety, and maintaining neighbourhood aesthetics.

In removing the electrical plant from rear lots and replacing it with standard front lots underground, Toronto Hydro anticipates that customers will experience fewer and shorter outages, as the conversion will replace an aging and non-standard rear lot system. More

specifically, outages related to storms, tree contacts, and animal contacts will be significantly reduced. When an outage does occur, Toronto Hydro will be able to more quickly locate the fault and commence restoration activities, thereby reducing outage durations.

In addition to reliability benefits, the program will also mitigate a number of safety risks faced by local residents by reducing the possibility that the energized infrastructure will come into contact with individuals or their property and improving safety clearances for equipment.

Placing the newly transferred circuits underground will also maintain the aesthetics of streetscapes in the affected communities. Since many of these communities have an existing large tree canopy along the streets, placing the circuits underground avoids the extensive arborist work that would be required if the circuits were transferred to overhead assets. Figures 3 to 4 show some of the existing streetscapes.

FIGURE 3: FRONT LOT OF MARKLAND WOODS PROJECT – TREES THAT WOULD A OBSTRUCT A FRONT LOT OVERHEAD LINE

FIGURE 4: FRONT LOT OF THORNCREST PROJECT – TREES THAT WOULD OBSTRUCT A FRONT LOT OVERHEAD LINE

Rear lot conversion will yield a number operating efficiencies for Toronto Hydro. Firstly, Toronto Hydro will be able to use standard tools to complete capital and maintenance work on feeders and improved access to work sites. As well, crews will no longer need to access multiple customer backyards to determine fault locations and perform repairs. Finally, crews will no longer need to manually carry tools and materials to work sites and/or use heavy lifting equipment to move required tools into position.

The benefits of the program are not limited to those customers whose rear lots are being converted to underground front lots. Customers who are not directly affected by the rear lot conversion but who share a feeder with customers that are having their rear lots converted will benefit from the conversion to a modern 27.6 kV system from the existing 4.16 kV system. More specifically, they will enjoy improved reliability because the reliability issues associated with old, poor conditioned 4.16 kV assets will be eliminated.

The following table summarizes the anticipated benefits of the Rear Lot Conversion program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improves public safety ƒ Crews will no longer have to enter customer property to perform services ƒ Maintains neighbourhood aesthetics ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $27.02 million,

	representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.6.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.71 million, confirming the economic prudence of the investments (see Section E6.6.7).
Reliability	ƒ Reduces frequency of outages ƒ Reduces duration of outages ƒ Reduces storm, tree and animal damage
Safety	ƒ Improves public safety ƒ Clearances are brought up to standard ƒ Reduces the risk of field crew injury with respect to over exertion, constrained work spaces, poor visibility and unstable footing
Efficiency	ƒ Enables use of standard equipment in the future (i.e. bucket trucks) ƒ Improves access to distribution equipment

E6.6.3 Why the Program is Needed

The Rear Lot Conversion program addresses an aging and functionally obsolete type of overhead construction. The proactive conversion of aging rear lot assets is needed to address the safety risks and reliability issues associated with this legacy design.

E6.6.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for the Rear Lot Conversion program. The program is designated as a System Renewal initiative, with a primary driver of functional obsolescence.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ The rear lot configuration is a legacy design that is associated with operational constraints (limited access and non-standard design elements) and safety risks ƒ Leads to prolonged outage durations because it is difficult to locate and repair faults
Secondary Drivers	Reasoning

Safety	ƒ Constrained work spaces with poor visibility and poor footing conditions endanger crew members. ƒ The need to manually move and access parts and equipment can lead to overexertion. ƒ Customer equipment and amenities such as pools are located in close proximity to energized equipment.
Reliability	ƒ The need to manually locate, isolate and restore outages prolongs outage durations. Heavy vegetation can impact the reliability of the system. ƒ Reliability (and safety) performance of the rear lot system can be especially problematic during and after major storm events, such as high winds and ice storms, due to access, fault location, vegetation and asset condition issues.
Failure Risk	ƒ Equipment past its useful life and is more likely to fail. ƒ The majority of rear lot underground assets are direct buried, a design that is associated with an especially high failure risk ƒ Replacing failed non-standard equipment and locating faults on rear lot feeders with non-standard configurations can extend the duration of outages.

Toronto Hydro considers rear lot construction to be a functionally obsolete, non-standard legacy design. This is due to a number of disadvantages and deficiencies inherent in the configuration and location of rear lot plant. These issues are captured in the secondary drivers for the program and are discussed in detail in this section. While the trigger driver for replacement is functional obsolescence, the urgent need for a steadily paced, proactive renewal program is derived from a combination of the increasing average age of rear lot assets and the complexity of rear lot conversion projects, which must be staged over multiple years.

Access and Clearance Issues

Residential backyards are difficult work environments because they pose several access and clearance issues. Figure 5 depicts common access issues with rear lot plant. Often, a number of physical obstacles are scattered throughout the backyard such as outdoor recreational equipment and are home to structures such as home extensions, sheds, patios and pools. As well, limited space often forces Toronto Hydro crews to perform rear lot work manually, with restricted use of standard tools; at times the space is too limited to carry tools into the backyard and while at times feasible, it is not always possible to move tools into the backyard using a crane when required.

An addition access issue relates to permission to enter the backyard; Toronto Hydro requires authorization from the customer before entering the backyard to perform work.

FIGURE 5: ACCESS RESTRICTIONS

Figure 6 shows an example of a rear lot lateral circuit that supplies houses on three streets. The lateral branches off of the main feeder circuit and enters the neighbourhood in between two houses. The lateral is then routed in between the rear residential property lots. The primary lateral circuit (shown in black) supplies pole top transformers. The transformers step the primary circuit voltage down to the appropriate end-use voltage for the secondary bus circuit (signified in red). From the secondary bus circuit, the service lines branch off to the meter bases that supply each residence. As seen in the figure, there is no electrical infrastructure in the front lot with the exception of the streetlights that are supplied by the secondary bus, with spans of overhead conductor being routed between the properties. All of the electrical distribution assets are in the rear lot.

FIGURE 6: LATERAL CIRCUIT CONFIGURAT ION FROM THORNCREST NEIGHBOURHOOD

In some areas, minimum clearances prescribed by safety regulations are compromised due to cluttered outdoor equipment and structures, increasing the safety risks of rear lot work. Figure 7 is a real top view of the schematic from Figure 6 of the rear lot lateral circuit, showing obstacles such as heavily treed areas and swimming pools. The minimum horizontal clearance for pools is 16'-8", and in many locations, this clearance is not met. Aside from safety clearances, pools also specifically create access issues for crews by reducing the available workspace and acting as trip hazards, especially when work is required in the evening.

FIGURE 7: OVERHEAD VIEW OF REAR LOT EXAMPLE

Figures 8 and 9 show common clearance issues encountered with existing rear lot plant.

FIGURE 8: ACCESS AND CLEARANCES ISSUES WITH SWIMMING POOL

FIGURE 9: CLEARANCES NOT MET; FENCE MAKES IT DIFFICULT TO ACCESS POLE

Overgrown Vegetation

Mature tree canopy cover and poorly landscaped brush can cause visibility issues and additional access issues in rear lots. Reduced visibility is a safety concern when executing electrical work and can contribute to extended outage durations. As well, overgrown vegetation may require trimming on site to access the equipment safely. Figure 10 shows examples of overgrown vegetation.

FIGURE 10: ACCESS RESTRICTION DUE TO OVERGROWN TREES, SHEDS, AND FENCES

Poor Reliability and Inefficient Restoration

The majority of rear lot feeders operates at 4.16 kV and therefore lack advanced fault detection and isolation technologies like SCADA-mate switches. Without these technologies, field crews are required to manually determine the location of a fault. The poor access and visibility associated with rear lot feeders exacerbates this situation, contributing to prolonged outages and inefficient use of resources during fault location and outage restoration.

Spatial constraints such as trees and fences may prevent crews from walking an uninterrupted path along the feeder to locate the fault; instead, requiring them to enter multiple residential backyards along the circuit. Once the fault is located, crews often face the difficult task of repairing the fault and restoring the service. As previously mentioned, limited access can restrict the use of standard equipment such as bucket trucks, drilling machines and other machinery and implements. This also means that heavy materials such as poles and transformers must be hand-carried to the rear lot or even hoisted over the residence by a crane. For overhead rear lot feeders, specialized reactive crews are needed to physically climb the poles to access the equipment during repairs; for underground rear lot feeders, trenches must be manually dug to repair direct buried cable, which was the typical installation practice for the rear lot when it was designed.

The additional manual effort associated with rear lot work increases the average outage time by 2.2 hours as compared to Toronto Hydro's standard overhead distribution systems. In some cases, the outage duration can last for days because detection is dependent on a customer notifying Toronto Hydro of the issue and it may be difficult to locate and repair the fault. Table 4 lists several long outages events that have occurred in the rear lot.

TABLE 4: LONG DURATION EVENTS THAT HAVE OCCURRED IN THE REAR LOT

Date	Neighbourhood	Cause	Duration (Hrs)
20-Aug-09	Markland Wood	Adverse Weather - Lightning, Extreme Wind	44.68
20-Aug-09	Thorncrest	Tree Contact	42.15
9-Aug-09	Thorncrest	Lightning	26.70
1-Jun-12	Markland Wood	Adverse Weather - Wind Extreme	23.85
16-Sep-10	Markland Wood	Defective Underground Cable	18.85
19-Oct-11	Thorncrest	Tree Contact	15.62
5-Apr-11	Markland Wood	Tree Contacts, Adverse Weather	13.80
15-Jun-08	Thorncrest	Lightning	12.47
24-Feb-09	Markland Wood	Defective Underground Cable - Primary	12.37

Table 5 compares the average outage times of rear lot configurations and other designs used in Toronto Hydro's system. As the figure demonstrates, the average outage on a rear lot lasts 2.2 hours longer than those on other feeders.

TABLE 5: AVERAGE OUTAGE STATISTICS (2008-2013) BETWEEN TORONTO HYDRO DISTRIBUTION SYSTEMS

Average Outage Statistics (2008 - 2013)			
	Duration (Hrs)	CHI	CI
Rear lot	6.07	240.42	84.88
All Feeders	3.87	488.33	430.70

Safety

Table 6 summarizes the safety issues associated with rear lots.

TABLE 6: SAFETY ISSUES AND DESCRIPTIONS

Safety Issue	Description
Toronto Hydro Crew Access	ƒ Tight work spaces ƒ Manually carry equipment, increasing risk of physical exertion ƒ Poor visibility at night and poor footing in the winter ƒ Poles require climbing, in many cases pole is rotted and requires additional stability ƒ Interference due to fences, sheds, patio's, pools, etc
Public Safety	ƒ Energized equipment close to public equipment: sheds, buildings, patios ƒ Recreational equipment in close proximity: pools, trampolines ƒ Exposed energized equipment in close proximity to customer property that is not brought to Toronto Hydro's attention ƒ Homeowners using ladders may violate electric clearances to energized equipment (Toronto Hydro standard 03-2400)

Access limitations and the age and condition of rear lot equipment present a number of potential safety risks for Toronto Hydro crew members. Front lot systems are typically situated on city property and meet standard clearances, while rear lot systems are on easements on private property. These backyards have gardens, patios, pools, and recreational and gardening equipment that can obstruct the establishment of clear and stable work area for field personnel. This risk can be more prominent at night or in the winter when there is poor visibility and poor footing. As well, heavy lifting in unstable terrain on rear lots increases the risk of injury. Furthermore, field crews must manage the presence of pets, such as dogs, located in the backyards of customers who may not be home. In addition, due to vegetation overgrowth or structural modifications that were made after the original systems were installed, there are

numerous locations where the electrical distribution equipment is in close proximity to the customer's property, such that the required minimum safety clearances are no longer met.

Besides posing risks to Toronto Hydro personnel and the public, the violation of design clearances through the presence of sheds, decks, pools, trampolines, clotheslines and house extensions can result in increased risk of contact faults and damage to Toronto Hydro equipment (Appendix A provides a discussion of Toronto Hydro's design standards for minimum clearances.) Figures 11 and 12 show additional examples of access issues with respect to rear lot plant.

FIGURE 11: ACCESS ISSUES: BEWARE OF DOG, FENCING, LOW ROOF ON PATH, VEGETATION ON CLEARING

FIGURE 12: EXAMPLE OF REAR LOT THAT IS DIFFICULT TO ACCESS

The age and condition of the equipment in rear lots poses serious safety concerns. At times, Toronto Hydro crew are required to physically climb poles that may be unstable due to cracking and rotting; poor weather conditions only serve to worsen these safety issues.The time it takes for crews to secure a safe working area will increase as the system continues to age and deteriorate and as vegetation continues to grow. Work involved in securing a site can include activities like trimming branches or stabilizing the pole to make it safe to climb. During poor weather, there is also a risk of wires coming down, which may be hazardous for Toronto Hydro crew members and the general public.

Figures 13 and 14 illustrate field crew climbing a poor condition pole to replace a failed transformer. The pole is in close proximity to trees fences and a swimming pole.

FIGURE 13: FIELD CREWS REPLACING FAILED TRANSFORMER ON POLE IN POOR CONDITION

FIGURE 14: POOR CONDITION POLE IN CLOSE PROXIMITY TO SWIMMING POOL

An additional safety concern relates to equipment that is exposed, such as riser cables, because of damaged U-guards. This type of damage is difficult to predict because of the location of the equipment. An exposed riser cable can create an electrical contact hazard for customers in the area; the overhead equipment is close to homes or backyard structures and may come into contact with individuals. Figures 15 to 17 show a number of instances where proper clearances are violated, with energized equipment in close proximity to residential structures.

FIGURE 15: ENERGIZED POLE TOO CLOSE TO HOME AND CONDUCTOR CROSSING OVER ROOF

FIGURE 17: FENCE BUILT ON EASEMENT AN D EXPOSED CABLE FROM BROKEN GUARD

FIGURE 18: PHOTO OF RECREATIONAL EQUIPMENT UNDER ENERGIZED LINES

Failure Risk

From an operational perspective, rear lot circuits are more expensive to maintain than their front lot counterparts. The access issues described above significantly prolong the duration of visual inspection or vegetation maintenance work, while deteriorating assets operating near or beyond their useful lives as well as non-standard equipment require more frequent maintenance.

Aging assets pose a risk of failure as their condition deteriorates. For example, old and poor condition poles will have diminished structural strength. Many of these pole lines run through heavily treed areas where branches can fall and take down conductors. The connecting conductors provide two counteracting forces to stabilize the pole. If a conductor goes down, there is an imbalance in forces that is pulling the pole to one side. If the pole is rotted, there is a further risk of the pole breaking or falling over. This creates a risk of safety to the public and crews when working. Crews take specific safety measures to stabilize the pole when they are working on it but the risk to the public can still exist as this failure can occur at the time of the fault. This risk is further increased when there is additional distribution equipment attached to the top of the pole.

Non-stand equipment on the overhead system, including aging porcelain insulators and arrestors, can also contribute to fault occurrences as they are prone to cracking and flashovers. For underground rear lot circuits (which are predominately direct-buried), fault identification and repair efforts are further complicated by the need to dig out the cable, often exacerbated by the encroachment of fences and other structures onto the easement. The use of T-splices to split the underground distribution circuits, as opposed to the standard switchgear and switching transformers, makes it even more difficult to assess which branch of the splice is faulted. When underground cables are split like this and are radial, the customers downstream of the fault could be out until the cable fault is repaired, where a looped system could restore the customers with a few switching operations on site while the field crew repairs the fault.

By converting the rear lot plant to an underground front lot, Toronto Hydro can effectively eliminate the access, safety, and reliability risks associated with the rear lot plant, providing a modern, safe and accessible system for the customers in these areas.

E6.6.3.2 Asset Details

(i) Asset Lifecycle

The rear lot system consists of many assets that are non-standard or have exceeded their useful lives. Approximately one-third of all critical assets comprising the rear lot infrastructure, such as transformers and switches, are beyond their useful lives and are at risk of failure. The majority of poles have feathering on their tops, indicating rot, while many also have extensive cracking, which compromises a pole's ability to support the attached distribution equipment (see Figure 19). Non-standard equipment like porcelain arrestors and insulators are prone to failure.

FIGURE 19: POLE WITH EXTENSIVE CRACKING AND FEATHERING

Figures 20 and 21 show the replacement demographics for rear lot overhead transformers and switches relative to their optimal intervention timing (also known as economic end-of-life criteria, as determined by the Feeder Investment Model (FIM), which is further explained in Section D3.1.2.1.) As seen in these figures, many of the assets should already have been replaced as they are past their economic end-of-life criteria. Figure 20 shows that there are 568 transformers

at or past their economic optimal replacement time (this asset has a typical useful life of 40 years). Figure 21 shows there are 479 switches at or past their economic optimal replacement timing (this asset has a typical useful life of 50 years).

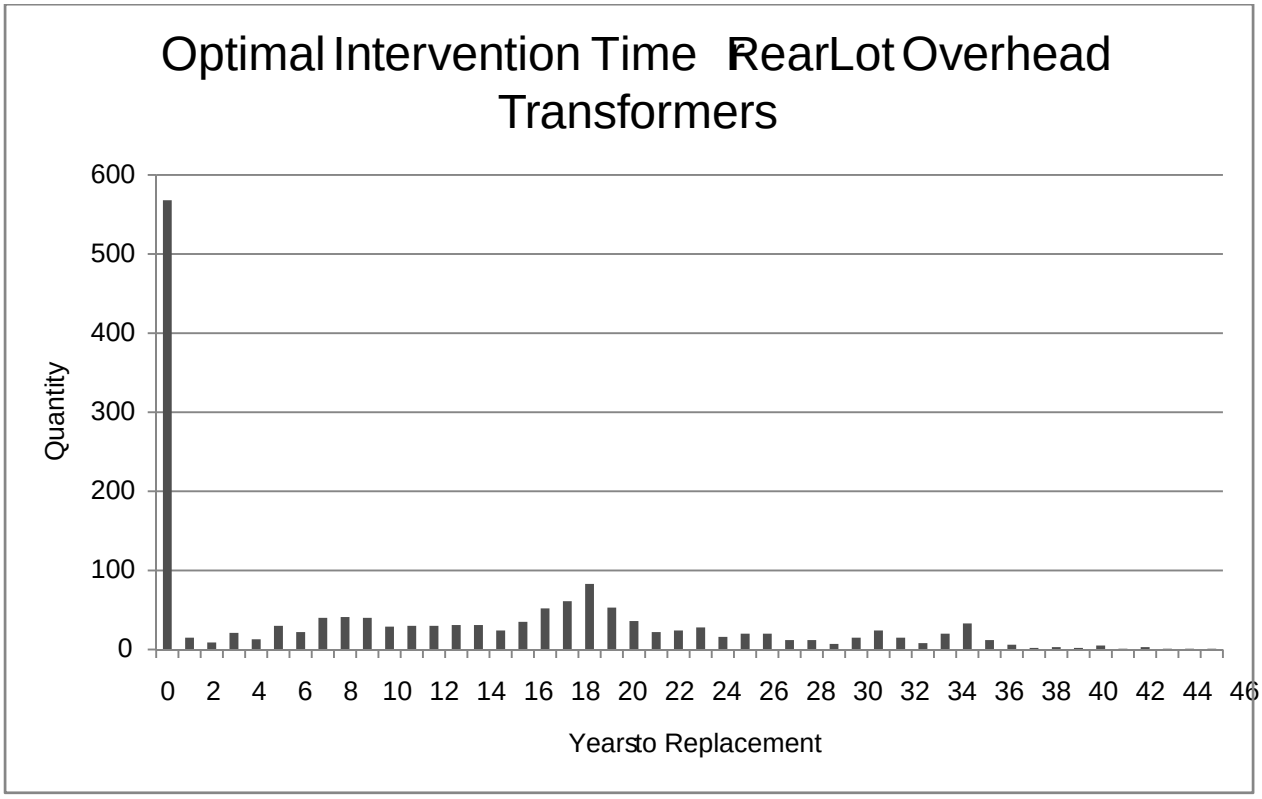

FIGURE 20: OPTIMAL INTERVENTION TIME – REAR LOT OVERHEAD TRANSFORMERS

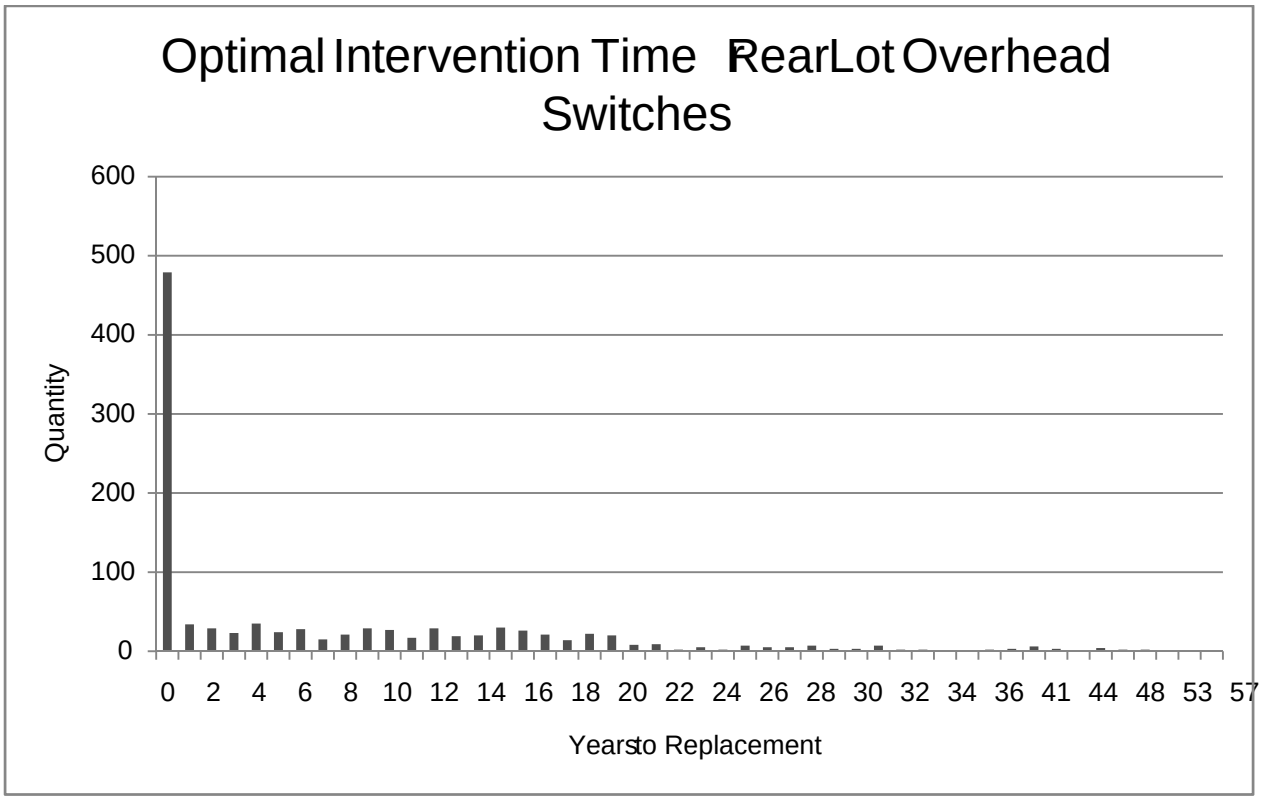

FIGURE 21: OPTIMAL INTERVENTION TIME – REAR LOT OVERHEAD SWITCHES

(ii) Asset Failure Impacts

The rear lot system targeted by this program exclusively supplies residential properties. The failure of individual rear lot assets tends to impact a small number of customers (as the feeders are small) but can result in lengthy outage durations. Rear lot system outages, on average, are almost twice as long as outages associated with other Toronto Hydro connection configurations. Most residential customers can tolerate a few short outages a year, particularly when the outages occur during non-critical times of use. However, when outages are lengthy, sometimes lasting for days, customers are understandably frustrated, particularly when faced with multiple lengthy outages in a single year. The combination of asset age, condition, and non-standard equipment provides an expected trend that failures are expected to increase in the rear lot if there is no replacement.

E6.6.4 Timing & Pacing of the Program

The Rear Lot Conversion program is a continuation of the existing rear lot program that began in 2007 and will continue beyond 2019. As per the table below, Toronto Hydro is expecting to spend an average of $12 million per year over the 2015-2019 period.

TABLE 7: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	6.88	16.6	17.5	23.8	22.7	17.05	8.06	10.3	10.3	13.6

Rear Lot Conversion projects are resource intensive, relatively complex and require a steady, moderate pace of construction. The amounts shown in the table above represent the amount of investment required to maintain a reasonable level of service and to prevent an excessive backlog of work from accumulating. Deferral of the program to 2020 would create a larger backlog of increasingly critical rear lot projects, since equipment will continue to age and failure risks to increase. This backlog could become difficult to manage and could contribute to the deterioration of system performance and safety. By undertaking this program using the schedule provided, Toronto Hydro anticipates that growing operational, reliability and safety risks will be mitigated.

E6.6.4.1 Ranking & Prioritization

The prioritization of work in the Rear Lot Conversion program is based on asset reliability, equipment condition, and coordination with planned city road work. Areas experiencing poor reliability are targeted first. As well, the condition of assets is taken into account to help determine the probability of future outages and the risks of delaying conversion work.

A critical consideration taken into account when choosing areas to target is city road work moratoriums. Once a moratorium is in place, Toronto Hydro is unable to undertake the underground work required and conversion can be delayed for five years or more. For this reason, high priority projects need to occur as soon as possible or risk being deferred for five years. A medium-priority project may also need to occur soon or risk becoming a high priority project during the five year road moratorium.

E6.6.6 Program Execution

Several of the areas that are targeted for rear lot conversion contain multiple supply feeders and, in some cases, multiple substations. This interconnection of feeders enables load shifting and the ability to resupply another area under contingency. Due to the complexity of these interconnections, the conversion of large areas can be complicated and requires dividing the area into multiple phases.

Each phase is divided into civil and electrical construction elements. Construction of the civil infrastructure to house the underground primary, secondary and service infrastructure is performed first, followed by electrical infrastructure construction.

During civil construction, concrete encased ducts are installed to protect the new underground cables. The civil work also establishes transformer pads, where the transformers will be installed, and tapboxes where connections will be made to service lines that will supply the residences. The electrical infrastructure consists of transformers, switchgear, and cable routed through the new ducts. Service lines are routed in between homes and connected to the customer's meter. The old rear lot electrical plant that previously supplied the residences is then removed from the rear lot. Once one phase of a project is completed, the next is undertaken and so on, until all phases in a particular neighbourhood are completed.

Depending on the size of the project, a project phase can be typically completed within a year for civil infrastructure installing and another year for electrical infrastructure installation along with the old electrical plant's removal.

E6.6.6.1 Proposed Work Plan

Toronto Hydro's long term plan for the 2015-2019 period is to convert the rear lots of neighbourhoods that are supplied by the stations in Table 8.

TABLE 8: 2015-2019 LONG TERM PLAN

Year	Station
2015	Mill MS
2015	Dalegrove MS
2015	Warden TS
2016	Mill MS
2016	Dalegrove MS
2016	Warden TS
2016	Chaplin MS

Year	Station
2017	Mill MS
2017	Dalegrove MS
2017	Chaplin MS
2018	Mill MS
2018	Neilson MS
2018	Longfield MS
2019	Mill MS
2019	Longfield MS
2019	Ravensbourne MS

The neighbourhood of Markland Wood is supplied by Mill MS and Neilson MS; the work in this neighbourhood is expected to take approximately five years to complete. The Thorncrest neighbourhood is large and is supplied by Dalegrove MS, Longfield MS and Ravensbourne MS. During the 2015-2019 timeframe, work in the Thorncrest neighbourhood is planned to be conducted adjacent to the work performed from 2012 to 2014. The neighbourhood of Clonmore is supplied by one feeder from Warden TS while the neighbourhood of Forest Hill is supplied by two feeders from Chaplin MS and will complete the rear lot work from this area.

The projects listed above are divided into multiple civil and electrical phases to allow for the steady staging of the project so that each phase is completed in a given year (i.e., civil completed the first year, followed by electrical installation and old electrical plant removal the next year).

E6.6.6.2 Program Risks

A risk to the program is the imposition of a minimum five-year moratorium on new road work in an area where Toronto Hydro intends on performing rear lot conversion work. Toronto Hydro will mitigate this risk by working closely with the City of Toronto on planned road work by participating in utility coordination council meetings. In the event that planned City of Toronto work puts program completion at risk, Toronto Hydro will negotiate with the city to coordinate a construction schedule that is acceptable to all parties and stakeholders involved.

Customer care is a significant aspect of risk mitigation during the planning and execution phases of rear lot projects, which by nature are relatively intrusive and involve the installation of new assets on customer properties. Toronto Hydro maintains extensive and proactive customer communication and provides an opportunity for customer's to voice their concerns and to work with the designer to determine asset locations that best align to customer preferences.

E6.6.7 Evaluation of Alternatives

E6.6.7.1 Quantification/Evaluation of Options

Option 1: Maintain status quo and make reactive replacements

This option proposes to maintain the rear lot distribution system and repair it reactively. This option will address equipment issues as a feeder fails and involves regular maintenance work to mitigate any critical risks. However, this option does not address the safety, reliability, and access issues that are inherent to the system.

Option 2: Rebuild rear lot distribution to ensure it meets current safety regulations

This option proposes to rebuild the rear lot distribution in the rear to replace the aging and non-standard equipment that is currently in use. Measures should be taken to ensure that identified safety issues are addressed. This would involve installing new poles, transformers and conductors to meet overhead requirements. For underground equipment, trenching the owners' yard for ducts and then re-sodding the yards would be required. As well, extensive tree trimming, and in some cases tree clearing, may be required in heavy vegetation areas.

This option could reduce the number of outages experienced; however, it does not address access issues and may involve potentially unsafe work environments for Toronto Hydro crew members. Furthermore, fault locating and repairing will remain a lengthy and difficult procedure, and customers will continue to experience long outages when they occur. In addition, the minimum clearance will not be met in certain areas of the system. In summary, while a renewal program in the rear lot will improve the equipment, it will not address the operational, safety and reliability issues that are associated with the rear lot. Many of the current issues would reoccur years later, making the investment's benefits temporary. In addition, since it is difficult to undertake construction in the winter months, most of the construction would have to take place in the summer, disrupting customer's enjoyment of their backyards.

Option 3: Replace rear lot distribution with overhead front lot distribution

This option involves replacing the rear lot distribution system with an overhead front lot distribution system. All 4.16 kV equipment is removed from the rear lot and the customers will be

supplied from a 27.6 kV feeder from the overhead front lot. Service conductors will have to be inserted in between property lines to access the meter base located at the back of the houses.

This option is not favourable to customers as it harms the aesthetic value of the front lots in their neighbourhoods. Also, in many areas, large trees would need to be cut down to accommodate a pole line running along the street. Furthermore, because communication lines are typically supplied through the rear, there will be an abundance of overhead lines in the neighbourhoods. Customers are often concerned about the affect this will have on their neighbourhood and their property values and could issue complaints, causing the projects to be postponed or redesigned, ultimately increasing the cost and duration of the projects.

Option 4: Replace rear lot distribution with underground front lot distribution

Under this option, the rear lot distribution would be removed and the customers would be supplied by a 27.6 kV front lot underground service. The service cables would be supplied underground between the customers' properties and connect to the meter base located at the back of the house. This would maintain the aesthetics of the customer's front lot and neighbourhood.

This option is preferred because it mitigates accessibility and safety issues and addresses aging and non-standard equipment that could degrade reliability and exacerbate other issues. Furthermore, this option improves reliability by moving the equipment underground in heavily treed areas. This will reduce interference related faults associated with tree and animal contacts and adverse weather related outages.

The cost of ownership (COO) and program net benefit (NPV) associated with the Rear Lot Conversion program is further detailed in Figure 9. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities in this program. The cost of ownership (COO) of a state reflects the risk of asset failure including both direct and indirect costs. These costs include the costs of customer interruptions, emergency repairs and asset replacements associated with current and new state designs. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_N) state. Non-asset risks are further explained in Section D3.3. Costs for related maintenance activities are also included for both states. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3.

The difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first year of activities. Where civil work is included in the first year activities, the cost and the benefits of the electrical phase are also included in the analysis. Rear Lot Conversion program produces an NPV of $5.71 million, as shown in Figure 10 and Figure 11.

E6.6.9 2015 Project Details

Table 11 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved Rear Lot Construction segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

E6.6.9.1 Livingston Guildwood Project Description

Investment Category: System Renewal

Program: Rear Lot Conversion

Project Title: Livingston Guildwood Rear Lot Conversion

Project Number: E11382 (ICM), E11382 (ICM)

Project Year: 2015

Estimated Cost: $4.32 Million

(i) Objective

The objective of this project is to improve the reliability in the Livingston Guildwood area by converting the rear lot distribution system to an underground front lot distribution system. This project will convert the following 4.16 kV rear lot feeders to 27.6 kV front lot underground: GGF1, and GEF2 from Livingston Guildwood MS and Galloway Dearhamwoods MS. This project will replace the overhead and underground rear lot facilities by installing new concrete-encased front lot ducts. This job will continue the work from phase 1 and will install the remaining civil and electrical infrastructure for this area. Once this work is completed the entire neighbourhood will be fully converted.

(ii) Scope of Work

E6.6.9.1 Markland Wood Project Description

Investment Category: System Renewal

Program: Rear Lot Conversion

Project Title: Markland Wood Rear Lot Conversion

Project Number: W11726 (ICM), W15203, W15210, W15211

Project Year: 2015

Estimated Cost: $5.44 Million

(i) Objective

The objective of this project is to improve the reliability in the Markland Woods area by converting the rear lot distribution system to an underground front lot distribution system. This project will convert the following 4.16 kV rear lot feeders to 27.6 kV front lot underground: ETLFF1, ETLFF2, ETLFF3, ETLF4, and ETBAF1 from Mill MS and Neilson MS. This project will replace the overhead and underground rear lot facilities by installing new concrete-encased front lot ducts. This job is continuing the work that was approved in 2014 by installing the electrical infrastructure in the civil infrastructure installed in 2014. It will continue the conversion by beginning the construction of new civil infrastructure in a new area of this neighbourhood. This work will continue in this neighbourhood to fully convert within the next five years.

(ii) Scope of Work

Reliability	• Area experiences long duration outages • Feeder consistently experiencing outages
Other (i.e., moratorium, etc)	• Upcoming moratorium on select streets • Aging substation proposing decommissioning

(iii) Justification & Benefits

This work continues the electrical work of the approved civil work from the 2014 EDR. This area has been subjected to a number of lengthy outages. Some of the more notable outages was an underground cable fault on direct buried cable that took 18.9 hours to correct and damage caused by adverse weather that took 44.7 hours. This work will eliminate the operational, safety and reliability risks that have been described in this narrative by resupplying the customers from an underground front lot system and removing the aging rear lot equipment.

E6.6.9.2 Thorncrest Project Description

Investment Category: System Renewal

Program: Rear Lot Conversion

Project Title: Thorncrest Rear Lot Conversion

Project Number: W15561, W15562

Project Year: 2015

Estimated Cost: $4.42 million

(i) Objective

The objective of this project is to convert the rear lot distribution system, in the neighbourhood of Thorncrest, to an underground front lot distribution system. This project will convert the following 4.16kV rear lot feeder to 27.6kV front lot feeder: ETRAF1, ETRAF2, and ETBHF1 from Thornton MS and Longfield MS. This work will replace the overhead rear lot facilities by installing aluminum TRXLPE-insulated cable in new concrete-encased front lot ducts and associated equipment. A new pole line will be installed along Princess Margaret Blvd to supply the adjacent rear lot neighbourhoods. This project will install new civil infrastructure this year and will install the electrical infrastructure the following year. Further conversion of this area will continue through the next five years.

(ii) Scope of Work

Other (i.e., moratorium, etc)	ƒ Aging substation proposing decommissioning

(iii) Justification & Benefits

This work continues the expansion work from the 2014 EDR by introducing a new phase for conversion in this neighbourhood. Over the last five years there have been 11 faults in the rear lot in this part of the system. This work will eliminate the operational, safety and reliability risks that have been described in this narrative by resupplying the customers from an underground front lot system and removing the aging rear lot equipment.

E6.6.9.3 Clonmore Project Description

Investment Category: System Renewal

Program: Rear Lot Conversion

Project Title: Clonmore Rear Lot Conversion

Project Number: E15563, E15568

Project Year: 2015

Estimated Cost: $2.86 million

(i) Objective

The objective of this project is to convert the rear lot distribution system, in the neighbourhood of Clonmore, to an underground front lot distribution system. This work will replace the overhead rear lot facilities by installing aluminum TRXLPE-insulated cable in new concrete-encased front lot ducts and associated equipment. This project will start with installing the civil infrastructure in 2015 and will complete the neighbourhood the following year, 2016, with the installation of the electrical infrastructure and removal of the rear lot plant.

APPENDIX 1: TORONTO HYDRO'S MINIMUM CLEARANCE STANDARDS

E6.7 Box Construction Conversion

TYPICAL BOX CONSTRUCTION

E6.7.1 Summary

Program Description

The Box Construction Conversion program is a continuation of activities previously described in Phase 1 and 2 of Toronto Hydro's 2012-2014 ICM application. The projects that comprise this program are identical in nature to the jobs that constituted the OEB approved Box Construction segment in EB-2012-0064[1].

Box construction is a type of legacy 4.16 kV overhead construction that was used within the former (pre-amalgamation) City of Toronto. Due to a number of reliability, safety and load capacity issues, Toronto Hydro no longer uses box construction for new capital projects. To address these issues for legacy installations, this style of construction will be replaced with 13.8 kV or 27.6 kV overhead feeders.

[1] EB-2012-0064, Tab 4, Schedule B5.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Clearance issues with new or redeveloped buildings near box construction primary feeders can result in additional costs for connecting customers. These costs will typically be unnecessary following conversion to 13.8kV/27.6kV infrastructure. ƒ 13.8kV/27.6kV feeders can better accommodate larger customer connections in the downtown area
Reliability	ƒ Average outage duration for 13.8 kV overhead feeders is lower than for 4 kV box construction feeders ƒ Impact of major storm events is less on 13.8 kV overhead feeders when compared to 4 kV box construction feeders
Safety	ƒ Less congestion at top of 13.8kV/27.6kV poles reduces risk of electrical contact ƒ Greater accessibility with bucket trucks on 13.8kV/27.6kV overhead feeders allows for safer work practices ƒ 13.8kV/27.6kV overhead feeders adhere to clearances outlined in EUSR 129 ƒ Removal of legacy equipment such as shielded primary cable and Positect switches eliminates the safety issues associated with this equipment
Efficiency	ƒ 13.8 kV overhead feeders have three times the capacity of box construction feeders ƒ Line losses are lower on 13.8 kV and 27.6 kV feeders ƒ Program projects are prioritized to avoid renewal of end-of-life legacy 4.16 kV stations equipment where possible
Other	ƒ Avoid procurement issues associated with some box construction equipment

Program Drivers

The trigger driver for this program is Functional Obsolescence, due to the safety, capacity, procurement and reliability issues associated with this legacy construction. The trigger and secondary drivers for this program are summarized in Table ii.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Legacy overhead construction standard no longer used for new capital projects ƒ High number of assets past useful life ƒ Skill set for maintaining/troubleshooting box construction is diminishing ƒ Procurement issues with legacy equipment
Secondary Drivers	**Reasoning**
Safety	ƒ System complexity (multiple circuits through same area) ƒ Accessibility issues with bucket trucks ƒ Proper working clearances are often unattainable ƒ Equipment built to legacy construction standards creates additional safety risks
Efficiency	ƒ Line losses are higher than 13.8kV/27.6kV overhead distribution, with a correspondingly higher carbon footprint.
Reliability	ƒ Average outage duration of box construction feeders is greater than that of 13.8kV feeders ƒ Impact of major storms shown to be greater on box construction feeders when compared to 13.8kV overhead feeders in downtown core

Preferred Alternative

The Box Construction Conversion program analyzed and evaluated the following options:

(1) Replace the aged, legacy box construction with new box construction

(2) Convert the aged, legacy box construction to new 13.8 kV or 27.6 kV Infrastructure

Option II is the preferred option as it allows necessary working clearances, capacity to accommodate future load requests and higher overall system reliability. Option I would likely also has the disadvantage of forcing Toronto Hydro to continue investing in and maintaining stations assets at the 4 kV municipal stations that supply existing box construction feeders. Many of these stations are lightly loaded and avoided costs could be realized by decommissioning the stations following load conversion as part of the Box Construction program.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $22.44 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.7.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.64 million, confirming the economic prudence of the investments (see Section E6.7.7).

Timing and Pacing

The table below provides the estimated costs of the program for the 2015-2019 period. Given the current schedule, Toronto Hydro plans to address 65% of all box construction by the end of 2019. The conversion of all box construction feeders is expected to be complete by 2026.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	5.7	7.1	0.84	13.8	23.3	16.8	20.7	21.1	21.6	22.7

Ideally, due to the age and condition of existing box construction feeders, Toronto Hydro would convert all remaining box construction in the 2015-2019 period. However, converting all remaining box construction feeders over this time period is not feasible from an engineering perspective due a number of system constraints, including limited availability of certain feeders and the need to first upgrade certain Hydro One Networks Inc. (HONI) station equipment housed in Toronto Hydro transmission stations (TS).

E6.7.2 Program Description

The Box Construction Conversion program is a continuation of activities previously described in Phase 1 and 2 of Toronto Hydro's 2012-2014 ICM application. The projects that comprise this program are identical in nature to the jobs that constituted the OEB approved Box Construction segment in EB-2012-0064.

Box construction is a type of legacy 4.16 kV overhead construction that was used within the former (pre-amalgamation) City of Toronto and still exists in some areas of the city. Figure 1 shows a typical box construction installation. Due to a number of reliability, safety and load capacity issues, Toronto Hydro no longer uses box construction for new capital projects, rendering it a functionally obsolete standard. These issues are further described in Section E6.7.5.

FIGURE 1: TYPICAL BOX CONSTRUCTION

Toronto Hydro plans to address all of the issues related to box construction described in Section E6.7.5 through a proactive program that replaces these feeders with current standard 13.8 kV or 27.6 kV overhead construction. Figure 2 shows the conversion from highly concentrated cables in box construction to the less congested 13.8 kV or 27.6 kV overhead standards. The reduction in complexity and congestion at the top of the poles is apparent. Figure 3 illustrates another variation on the current 13.8 kV overhead construction standard.

FIGURE 2: ACTUAL CONVERSION PROJECT COMPLETED IN 2013 IN THE BYRON AVE. AND DANFORTH AVE. AREA. THE PHOTOGRAPH ON THE LEFT SHOWS THE 4.16 KV BOX CONSTRUCTION FEEDER PRIOR TO CONVERSION. THE COMPLETED PROJECT IS SHOWN IN THE PHOTOGRAPH ON THE RIGHT, WHERE ALL 4 KV BOX CONSTRUCTION HAS BEEN REMOVED AND REPLACED WITH A CURRENT CONSTRUCTION STANDARD 13.8 KV OH FEEDER.

FIGURE 3: TYPICAL CURRENT CONSTRUCTION STANDARD 13.8 KV OVERHEAD FEEDER

Toronto Hydro's Box Construction Conversion program targets all 4.16 kV box construction feeders. Toronto Hydro's objective is to replace the 4.16 kV box construction infrastructure with standard 13.8 kV or 27.6 kV overhead feeders and decommission associated 4.16 kV stations by 2026. Figure 4 shows a map of all box construction feeders in Toronto.

FIGURE 4: MAP OF ALL BOX CONSTRUCTION F EEDERS SLATED FOR CONVERSION THROUGH 2026

Total costs for the Box Construction Conversion program are estimated to be $103.1 million over the period of 2015 to 2019. Figure 5 shows a map of box construction feeders that Toronto Hydro will convert over this period.

FIGURE 5: MAP OF PROPOSED FEEDER CONVERSIONS FOR 2015-2019

The following table summarizes the number of assets that Toronto Hydro plans to replace over the 2015-2019 program by asset class.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
OH Transformer	183	381	86	175	77	902
OH Switch	154	301	70	176	85	786
Poles	377	780	277	255	117	1,806
UG Switch	0	0	0	6	0	6
UG Transformer	20	27	9	52	17	125
OH Conductor (km)	23.5	46.2	11.4	24.4	11.5	117.1
UG Cable (km)	6.0	10.4	1.5	5.8	1.4	25.0

IC

Toronto Hydro evaluated the proposed program against the status-quo alternative of maintaining and replacing (on a like-for-life basis) the equipment used in box construction, and determined that proactive conversion is the best alternative. Table 2 summarizes the benefits associated with the Box Construction Conversion program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Clearance issues with new or redeveloped buildings near box construction primary feeders can result in additional costs for connecting customers. These costs will typically be unnecessary following conversion to 13.8kV/27.6kV infrastructure. ƒ 13.8kV/27.6kV feeders can better accommodate larger customer connections in the downtown area ƒ Aesthetic improvements ƒ The difference in the cost of ownership between existing and renewed assets (ΔCOO) for the first year of the program is $22.44 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.7.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.64 million, confirming the economic prudence of the investments (see Section E6.7.7).
Reliability	ƒ Average outage duration for 13.8 kV overhead feeders is lower than for 4 kV box construction feeders ƒ Impact of major storm events is less on 13.8 kV overhead feeders when compared to 4 kV box construction feeders
Safety	ƒ Less congestion at top of 13.8kV/27.6kV poles reduces risk of electrical contact ƒ Greater accessibility with bucket trucks on 13.8kV/27.6kV overhead feeders allows for safer work practices ƒ 13.8kV/27.6kV overhead feeders adhere to clearances outlined in EUSR 129 ƒ Removal of legacy equipment such as shielded primary cable and Positect switches eliminates the safety issues associated with this equipment
Efficiency	ƒ 13.8 kV overhead feeders have three times the capacity of box construction feeders ƒ Line losses are lower on 13.8 kV and 27.6 kV feeders ƒ Program projects are prioritized to avoid renewal of end-of-life legacy 4.16 kV stations equipment where possible
Other	ƒ Avoid procurement issues associated with some box construction equipment

E6.7.3 Why the Program is Needed

The Box Construction Conversion program is required to eliminate the reliability, efficiency and safety risks associated with the functionally obsolete box construction feeder design.

E6.7.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for replacing box construction. Box construction replacement is a System Renewal initiative with a trigger driver of functional obsolescence.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Legacy overhead construction standard no longer used for new capital projects ƒ High number of assets past useful life ƒ Skill set for maintaining/troubleshooting box construction is diminishing ƒ Procurement issues with legacy equipment
Secondary Drivers	**Reasoning**
Safety	ƒ System complexity (multiple circuits through same area) ƒ Accessibility issues with bucket trucks ƒ Proper working clearances are often unattainable ƒ Equipment built to legacy construction standards creates additional safety risks
Efficiency	ƒ Line losses are higher than 13.8 kV/27.6 kV overhead distribution, with a correspondingly higher carbon footprint.
Reliability	ƒ Average outage duration of box construction feeders is greater than that of 13.8 kV feeders ƒ Impact of major storms shown to be greater on box construction feeders when compared to 13.8 kV overhead feeders in downtown core

Functional Obsolescence

- Box construction is a 4 kV legacy overhead construction standard that Toronto Hydro no longer uses for new capital projects. This design is considered functionally obsolete due to a number of safety, load capacity, procurement and reliability issues that render it undesirable for new projects. In addition to these design deficiencies, a high number of

box construction assets are past their useful lives (see Section E6.7.3.2 (i) for further details) and are likely to fail in the near future, leading to more frequent and extended outages on these feeders. Maintaining aging box construction could become more challenging in the future as experienced employees retire and the number of skilled resources with box construction knowledge and experience diminishes. Each of these issues is discussed in detail in the following subsections.

- Some legacy equipment associated with box construction is difficult to procure due to a limited number of suppliers or, in a few cases, no supplier. For example, only one North American supplier currently manufactures shielded primary cable. Since this cable is a 'non-stock, non-standard' item for the supplier, a lengthy 12-week lead time and a minimum quantity of 3000 metres is required for each order. Another example is Positect switches, which are no longer available from the manufacturer.

- Box construction's status as both a unique and functionally obsolete design creates additional pressures in terms of resource availability. In the past, when 4.16 kV box construction feeders were the standard design for overhead distribution, crews had continuous experience working on them. Now, because new employees work on 4.16 kV box construction feeders on an infrequent, "as-needed" basis and the older generation of employees is retiring, fewer employees have skills and experience related to this design.

Safety

- Unlike typical standard 13.8 kV/27.6 kV overhead circuits, box construction poles typically support multiple live circuits in a more congested and tightly packed configuration relative to current overhead construction standards, which increases the potential risk of electrical contact for crews.

- Some box construction circuits cannot be accessed with bucket trucks – the industry-wide practice for overhead pole maintenance – due to the physical arrangement of the feeders running through a single box pole. Power Line Workers must climb these poles, which increases the potential safety risk for Toronto Hydro employees. These additional safety risks include injury from the additional physical exertion from climbing, a more severe falling hazard when compared to the use of a bucket truck and increased risk of electrical contact due to the inability to use the insulated aerial boom and bucket liner found on bucket trucks.

- In certain box construction work scenarios, Toronto Hydro crews working in close proximity to the lines can have difficulty conforming to the working clearances defined in Electrical Utilities Safety Rules (EUSR) #129. The required 15 cm air gap between people/tools and energized conductors cannot always be achieved.

Some equipment associated with box construction was designed and installed before Toronto Hydro adopted current safe work practices. One example of this is the 'Positect' switch, an obsolete type of fused switch originally designed to be operated by hand that puts field crews in the arc flash zone of the switch. While a stick was developed to operate 'Positect' switches from a distance, operation of this switch with the stick is inefficient when compared to operating it by hand.

Efficiency

Delivering electricity at a primary voltage of 4.16 kV (as is the case with box construction) is less energy efficient when compared to 13.8 kV feeders. The line losses associated with a 4.16 kV system are approximately nine times higher than those of 13.8 kV lines. Efficiency savings can be realized from converting from 4 kV to 13.8 kV, as detailed in Section E6.7.7 Evaluation of Alternatives.

Reliability

The 4.16 kV box construction configuration has also contributed substantially to outages for Toronto Hydro's customers relative to the comparable 13.8 kV and 27.6 kV standards. Historically, outage duration on 4.16 kV box construction feeders has been significantly worse than that of other overhead configurations. Table 4 compares the historical reliability of box construction feeders to standard 13.8 kV overhead feeders in the former (pre-amalgamation) City of Toronto. Total customer hours interrupted (CHI) for box construction feeders is considerably higher (1.65 hours) than on the 13.8 kV system (1.26 hours), despite the fact that total customers interrupted (CI) is approximately equal between the two systems, (Both systems are also approximately 625 circuit kilometers in length.)

TABLE 4: AVERAGE OUTAGE DURATION (DATA 2000-2012)

	4.16 kV Overhead Box Construction	13.8 kV Overhead Construction
Total CI	142,023	149,613
Total CHI	234,491	188,813
Average Outage Duration	1.65 hours	1.26 hours

Major storm events have also been shown to have a larger impact on box construction feeders when compared to other overhead distribution configurations. On October 29th and 30th of 2012, the City of Toronto endured a powerful storm from Hurricane Sandy, causing several extended outages across the city. Figure 6 illustrates the total customer hours interrupted (CHI) and customers interrupted (CI) on overhead feeders in the downtown area during the storm:

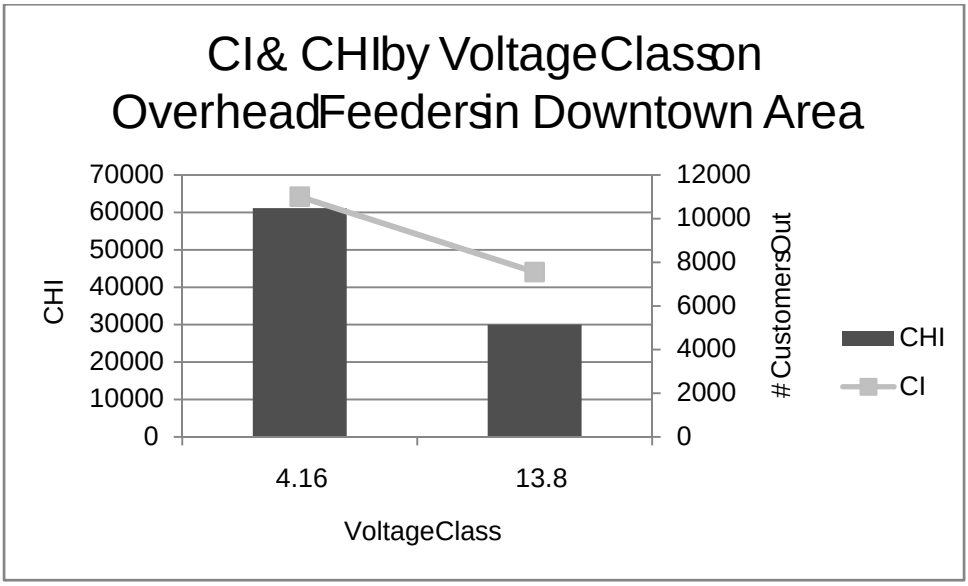

FIGURE 6: CI & CHI BY VOLTAGE CLASS ON OVERHEAD FEEDERS IN DOWNTOWN AREA DURING HURRICANE SANDY

The outage impact in terms of customer-hours interrupted was twice as high on 4.16 kV box construction circuits compared to standard 13.8 kV circuits. Factors contributing to outages and outage durations on box construction circuits include the following:

- Box construction assets are generally old and in poor condition; they are less able to withstand strong winds and contact from trees during storms compared to 13.8 kV overhead feeders in the downtown area.
- There are a limited number of field crews familiar with 4.16 kV box construction feeders, which contributes to delays in restoring power.

Figure 7 breaks down the areas impacted by the storm, sorted by station:

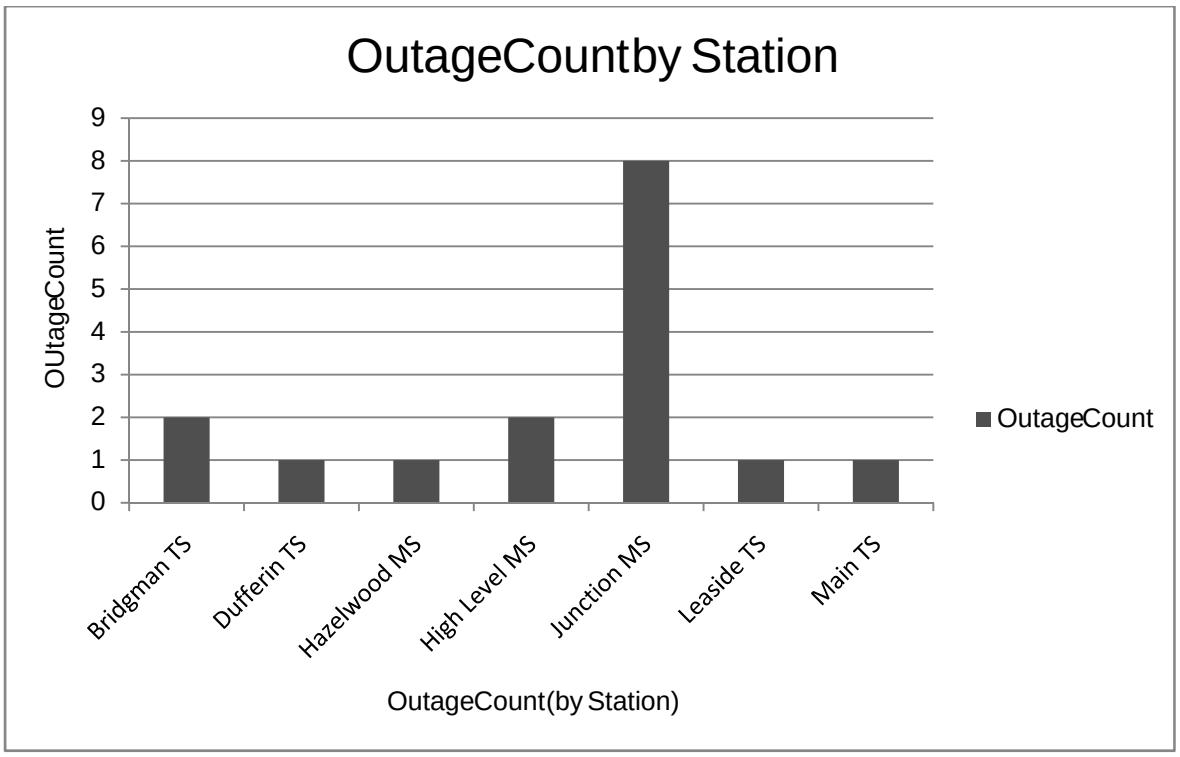

FIGURE 7: OUTAGE COUNT BY STATION IN DOWNTOWN AREA DURING HURRICANE SANDY

Junction MS, High Level MS and Hazelwood MS are stations that supply 4.16 kV box construction feeders (note: Hazelwood MS supplied only two distribution feeders at the time). The transformer stations (TS) shown serve the same areas but do not supply any box construction feeders. The figure shows that (i) Junction MS, which supplies a number of aging box construction feeders, experienced by far the most outages and (ii) 11 outages occurred on feeders from the three stations supplying box construction while only five outages occurred on feeders from the four transformer stations (TS) in the same area.

Reliability measures for box construction feeders in the 2015-2019 conversion program are summarized in Table 5.

TABLE 5: HISTORICAL RELIABILITY FOR FEEDERS PROPOSED FOR CONVERSION

	2007	2008	2009	2010	2011	2012
Customer Hours Interrupted	24,469	26,465	52,139	23,218	31,665	35,298
Customers Interrupted	31,824	29,314	37,696	22,802	21,765	19,671
Average Outage Duration (hours)	0.77	0.90	1.38	1.02	1.45	1.79

Figure 8 to Figure 11 illustrate customers interrupted (CI), customer hours interrupted (CHI), system average interruption frequency index (SAIFI) and system average interruption duration index (SAIDI) for feeders proposed for conversion.

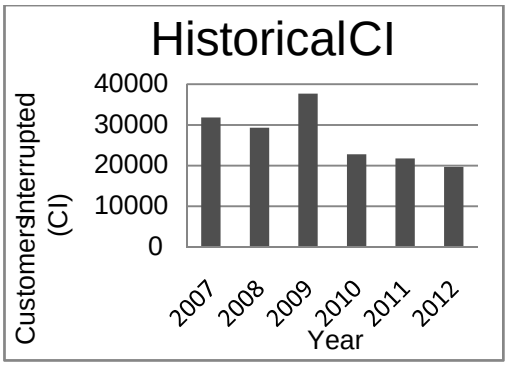

FIGURE 8: HISTORICAL CI FOR FEEDERS PROPOSED FOR CONVERSION

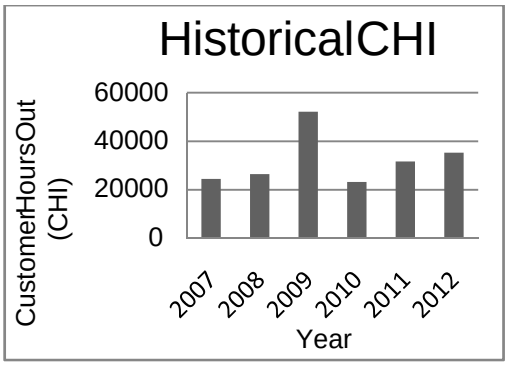

FIGURE 10: HISTORICAL CHI FOR FEEDERS PROPOSED FOR CONVERSION

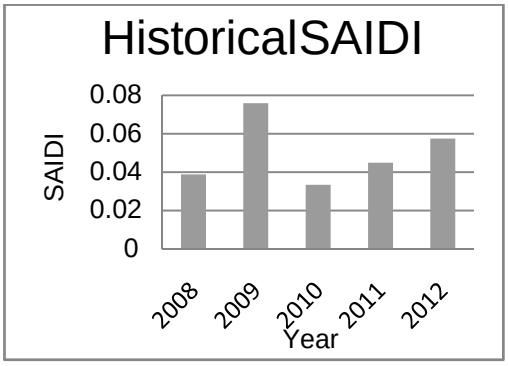

FIGURE 9: HISTORICAL SAIDI FOR FEEDERS PROPOSED FOR CONVERSION

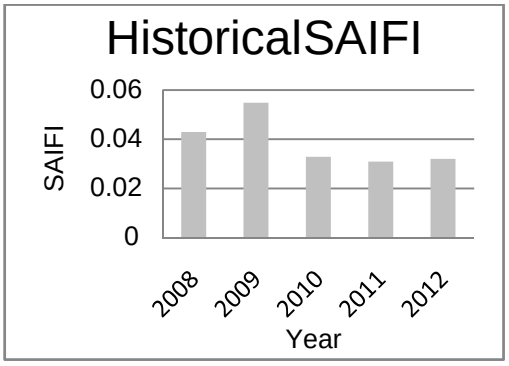

FIGURE 11: HISTORICAL SAIFI FOR FEEDERS PROPOSED FOR CONVERSION

Aging 4.16 kV Stations Assets

The 4.16 kV station assets that supply 4.16 kV box construction feeders are aging and in some cases require replacement in the near future. Rather than invest in legacy station equipment under the Station Switchgear Renewal (section E6.14), Station Power Transformer Renewal (section E6.15) or the Station Circuit Breaker Renewal (section E6.16) programs, Toronto Hydro's preferred alternative is to convert all 4.16 kV load from these stations to current standard 13.8 kV or 27.6 kV construction. This enables Toronto Hydro to eventually decommission the stations.

Load Capacity

Load capacity of 4.16 kV box construction feeders (3 MVA) is less than a third of the capacity of 13.8 kV overhead feeders (10 MVA). These feeders are not as flexible in accommodating new large customers or renewable generation suppliers. Toronto Hydro must connect these larger customers using alternative means, such as running a new feeder or extending an existing feeder to a given location, which requires additional time and Toronto Hydro resources. In these scenarios, the customer is also responsible for the additional connection costs, which are reflected in their Offer to Connect (OTC) agreement. Conversion to standard 13.8 kV or 27.6 kV feeders will help to mitigate such costs for future customers.

Clearance Issues

Clearance issues are also prevalent with 4.16 kV overhead box construction feeders. As per Canadian Standards Association (CSA) and Toronto Hydro standards, the clearance between overhead primary conductors and buildings must be greater than three meters. In many cases, as buildings are replaced, rebuilt or refurbished, they are being located closer to or even right against the lot lines, which compromises the line clearances previously achievable. Similar complications can arise from building restorations due to the temporary scaffolding required. In many instances, the three metre clearance cannot exist between the lot line and the closest primary conductor on the overhead box pole because of the large area that the box occupies at the top of the pole. In these situations, extensive planning must be done to isolate the conductors while maintaining safe and reliable supply to customers in the area. There is also a financial impact to customers, as the customer requesting the work is responsible for the cost of isolating the feeders that impede the required clearance. As standard 13.8 kV and 27.6 kV overhead feeders occupy a smaller area at the top of any given pole, the issues and costs related to the isolation of box construction feeders can ultimately be avoided in many cases with timely

conversion. Figure 12 shows some examples of recent property development activities and their interference with the existing box construction plant.

FIGURE 12: INSTANCES OF REQUIRED RECONFIGURATION

Conclusion: Need for a Proactive Replacement Program

Toronto Hydro could elect to maintain and repair box construction wherever it currently exists during the 2015-2019 period. However, due to the high number of assets past their useful lives on these feeders (as seen in Figures 13 to 16 below), the utility anticipates that this status quo option would result in worsening reliability and avoidable maintenance costs from associated 4.16 kV MS's that could otherwise be decommissioned. Also, the safety and operational issues outlined in Section E6.7.5.4 would remain.

In contrast, Toronto Hydro's preferred alternative, i.e., the planned conversion program, will convert 44 outdated 4.16 kV box construction feeders to current standard 13.8 kV or 27.6 kV feeders between 2015 and 2019.

E6.7.3.2 Asset Details

(i) Asset Lifecycle

Figures 13 to 16 illustrate the asset age profiles for overhead transformers, underground transformers, overhead switches and poles on box construction feeders. The areas highlighted in red approximate the number of assets considered past useful life. Over one-quarter of overhead transformers (Figure 14) are 35 years or older, which exceeds the useful life of this asset class. In addition, roughly another one-quarter of overhead transformers are between 25-34 years of age

and will soon be reaching the end of their 35 year lifecycle. Toronto Hydro plans to address overhead transformers reaching end-of-life within the 2015-2026 period to mitigate outage duration and frequency for customers and to improve safety and efficiency. A similar pattern is seen with underground transformers, where over half of the current assets are 35 years or older (Figure 15).

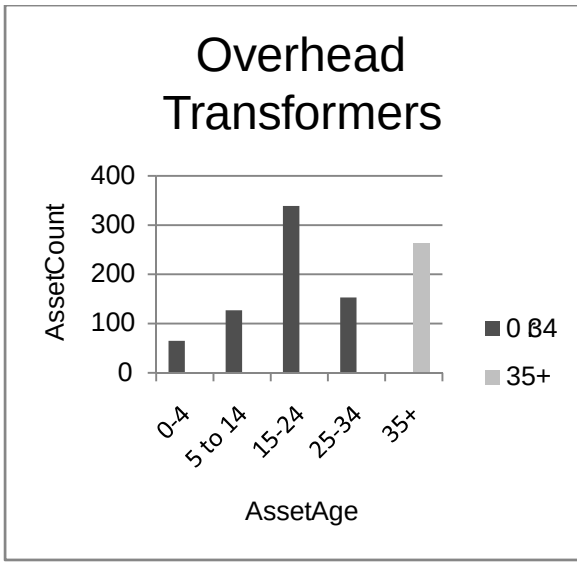

FIGURE 13: ASSET COUNT BY AGE GROUP FOR OVERHEAD TRANSFORMERS FOUND ON BOX CONSTRUCTION FEEDERS SCHEDULED FOR REPLACEMENT IN 2015-2019

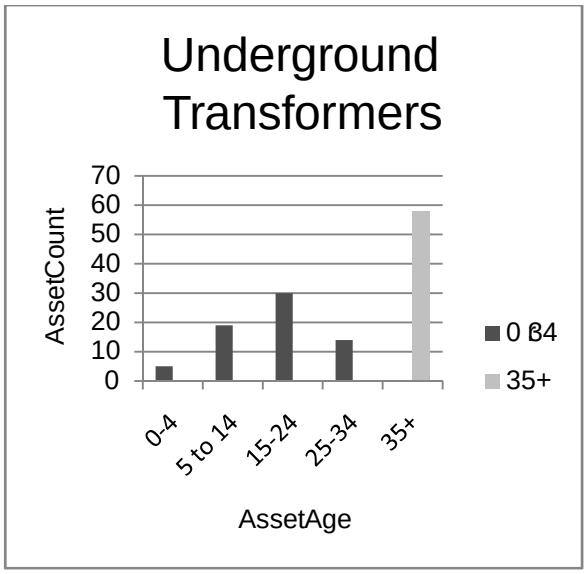

FIGURE 14: ASSET COUNT BY AGE GROUP FOR UNDERGROUND TRANSFORMERS FOUND ON BOX CONSTRUCTION FEEDERS SCHEDULED FOR REPLACEMENT IN 2015-2019

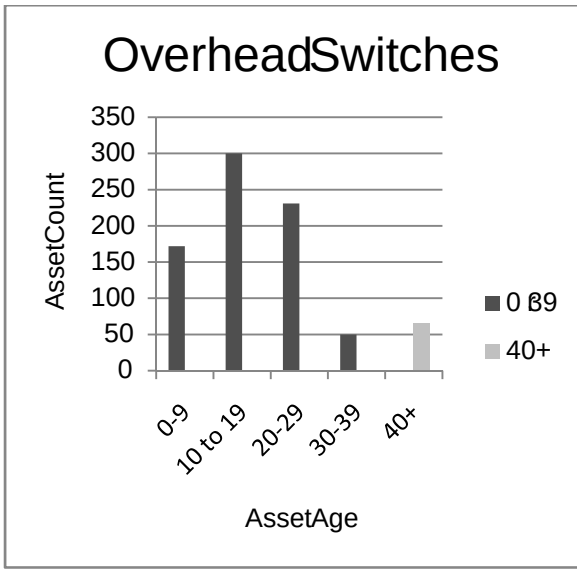

FIGURE 15: ASSET COUNT BY AGE GROUP FOR OVERHEAD SWITCHES FOUND ON BOX CONSTRUCTION FEEDERS SCHEDULED FOR REPLACEMENT IN 2015-2019

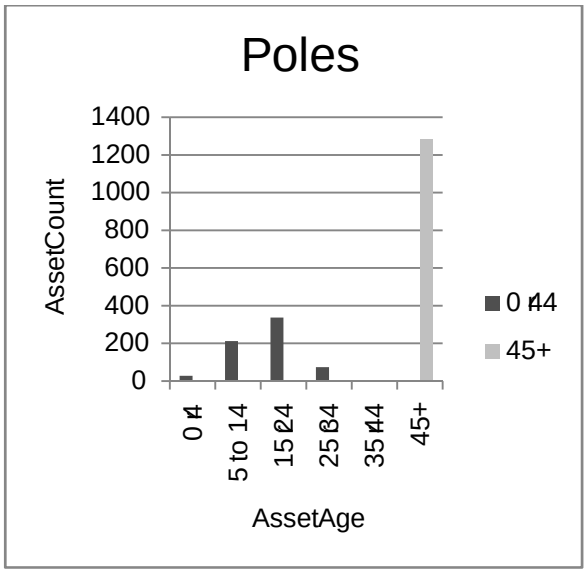

FIGURE 16: ASSET COUNT AGE GROUP FOR POLES FOUND ON BOX CONSTRUCTION FEEDERS SCHEDULED FOR REPLACEMENT IN 2015-2019

The majority of poles associated with the box construction are beyond useful life Figure 16), which raises failure risks and safety concerns for customers and crew workers. Overall, Figure 13 through Figure 16 show that approximately forty percent of box construction assets are past their useful lives and in need of replacement in order to mitigate failures, outages and safety risks.

(ii) Asset Failure Impacts

Depending on the failure mode and type of fault, there will be varying impacts on customers. However, Table 4 shows that on average, outage duration on 4.16 kV box construction feeders is considerably longer than on 13.8 kV overhead feeders. Figure 17 shows the cumulative number of customers per year who will be converted to standard 13.8 kV or 27.6 kV circuits as part of the ongoing Box Construction Conversion program. Figure 17 is a result of the criteria used to determine the order of conversion for these feeders; where possible, feeders from more lightly loaded stations are considered for conversion prior to the ones from heavily loaded stations. This approach allows those stations to be removed from service more quickly, thereby avoiding the associated future maintenance and asset replacement costs sooner.

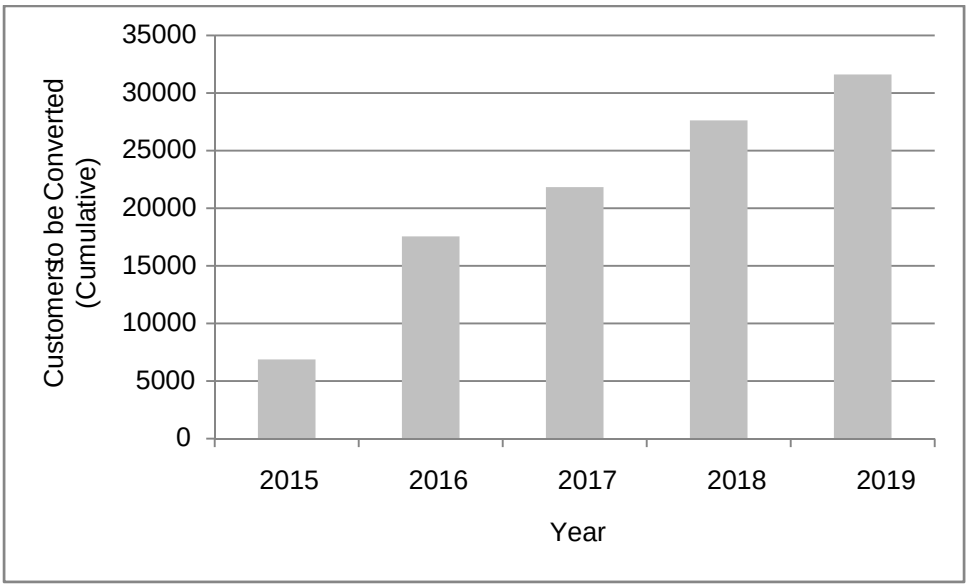

FIGURE 17: CUSTOMERS TO BE CONVERTED PER YEAR

E6.7.4 Timing & Pacing of the Program

Toronto Hydro plans to address all of the issues associated with 4.16 kV box construction feeders through a proactive program to convert these feeders to standard 13.8 kV or 27.6 kV overhead construction. The table below provides the estimated costs of the program for the 2015-2019 period. Given the current schedule, Toronto Hydro plans to address 65% of all box construction by the end of 2019. The conversion of all box construction feeders is expected to be complete by 2026.

TABLE 6: HISTORICAL AND FORECASTED SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	5.7	7.1	0.84	13.8	23.3	16.8	20.7	21.1	21.6	22.7

Ideally, Toronto Hydro would convert all remaining box construction in the 2015-2019 period. However, converting all remaining box construction feeders over this time period is not feasible from an engineering perspective due a number of system constraints, including limited availability of certain feeders and the need to first upgrade certain Hydro One Networks Inc. (HONI) station equipment housed in Toronto Hydro transmission stations (TS):

- Availability of 13.8 kV or 4-wire (with neutral) feeders: Three-phase overhead feeders require a fourth neutral cable to accommodate single-phase load (fed from a low-impedance 4-wire bus), but not all 13.8 kV feeders are '4-wire' (e.g., underground 13.8 kV feeders can be either 3-wire or 4-wire). Only those 4.16 kV box construction feeders that have either 13.8 kV 4-wire feeders or a 4-wire bus at a station in their vicinity can be converted to 13.8 kV overhead feeders. In addition, the available 13.8 kV overhead feeders must have sufficient capacity to accommodate the existing 4.16 kV load, which is not always the case.

- Some HONI-owned station equipment in Toronto Hydro transmission stations (TS) requires upgrades: Station equipment, such as transformers, switchgear and busses, must be upgraded to accommodate a future 4-wire bus for 4.16 kV box construction conversion jobs. For example, Highlevel TS must have its high-impedance 3-wire 13.8 kV bus/transformer/switchgear upgraded to a low-impedance 4-wire bus to accommodate 4.16 kV conversion jobs at Highlevel MS. Therefore, stations like Highlevel MS have not been targeted for conversion in the 2015-2019 timeframe.

E6.7.4.1 Ranking & Prioritization

Toronto Hydro considers several factors when determining the sequencing of work within the Box Construction Conversion program. These include:

- Asset condition and age – Toronto Hydro's sequencing of planned work accounts for the risk of failure by considering which assets are in poor condition and past useful life. Assets prone to failure have a higher impact on customer service, satisfaction and reliability.

- Proximity to 13.8 kV 4-wire bus with capacity – Feeders that are especially far from the nearest available 4-wire bus with available capacity can encounter significant engineering challenges requiring additional planning and coordination to develop a feasible alternative supply. High Level MS is an example of a heavily loaded MS that has no 4-wire bus in its vicinity. An upgrade of the High Level TS 13.8 kV 3-wire bus to a 4-wire bus is required accommodate conversion projects in this area.

- Avoiding replacing legacy 4.16 kV station assets – Coordination with stations investment programs is a factor when prioritizing work, specifically the switchgear, power transformer and circuit breaker replacement programs. Stations that are targeted for decommissioning within the Box Construction Conversion program can potentially be part of station renewal efforts, and coordination is done to avoid the scenario of replacing station assets in one program that are targeted for decommissioning in another. Conversely, station assets that have been recently replaced have a lower replacement priority. An example of such a station is Sherbourne MS, where a station transformer was recently replaced in 2010. Accordingly, box construction conversion for this station's feeders is not scheduled until later in the conversion period (currently 2024).

- Reliability – An important prioritization criterion for many System Renewal and System Service investments is feeder reliability. All other prioritization factors being equal, Toronto Hydro intends to address the poorest performing feeders first.

Asset condition/age, reliability and avoiding replacement of legacy 4.16 kV stations assets are all important prioritization criteria that are considered when ranking box construction projects. Proximity to a 13.8/27.6 kV 4-wire bus with capacity is a limiting factor for the order of project execution, as explained in the above points. Projects are conditional on whether there is sufficient

13.8/27.6 kV overhead infrastructure in the vicinity for conversion. Projects lacking this infrastructure will necessarily occur later in the program sequence.

The following table shows the order of forecasted decommissioning of stations that will be made possible in part by the execution of the Box Construction Conversion program.

TABLE 7: PROPOSED STATION LEVEL DECOMMISSIONING 2015-2026

Year	Station
2015	MILLWOOD MS
2016	MERTON MS
2016	QUEENSWAY MS
2017	DUFFERIN MS
2017	DUPONT MS

2026	ISLAND MS

E6.7.6 Program Execution

Toronto Hydro's proposed Box Construction Conversion program consists of multiple discrete projects over the 2015 through 2019 period. Detailed projects for the year 2015 are provided in Section E6.7.8. In a typical box construction conversion project, construction crews install new framed poles for 13.8 kV/27.6 kV overhead distribution in close proximity to the existing box construction poles. Next, crews install de-energized primary and secondary cable and pole-mounted transformers. Once the new circuit is energized, customers that were initially supplied from the box construction feeder(s) are transferred to the new service. After the entire load is transferred off of the box construction circuits in the area, the circuits are de-energized and the box construction infrastructure is physically removed. Figure 19 shows an example of an actual conversion project.

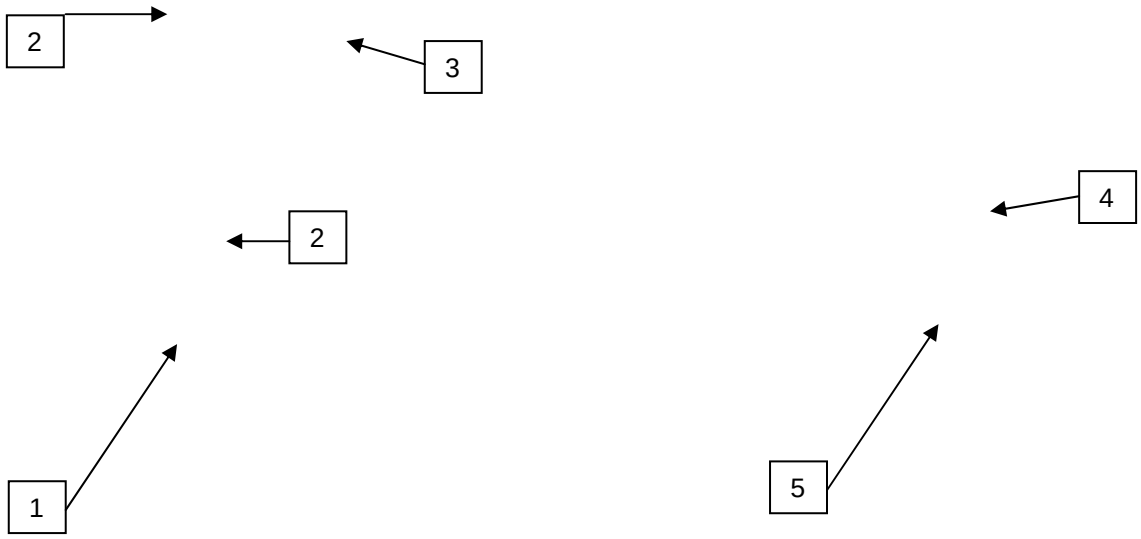

FIGURE 18: EXAMPLE OF BOX CONSTRUCTION CONVERSION JOB. (1) NEW POLES ARE INSTALLED IN CLOSE PROXIMITY TO EXISTING POLES. (2) NEW PRIMARY (TOP) AND SECONDARY CABLE (MIDDLE) INSTALLED (NOT ENERGIZED). (3) NOTE THAT CUSTOMERS STILL SUPPLIED FROM 4.16 KV BOX SERVICE, AND NOT NEW 13.8 KV/27.6 KV SERVICE. (4) CUSTOMERS ARE SWITCHED OVER TO NEW SERVICE. (5) ONCE ALL LOAD FROM CIRCUITS RUNNING THROUGH BOX POLES ARE DE-ENERGIZED, BOX CONSTRUCTION INFRASTRUCTURE (POLES, CIRCUITS, SWITCHES, TRANSFORMERS) CAN BE REMOVED.

The planned projects within the Box Construction Conversion program are occasionally broken into smaller "reactive" projects in order to make the most efficient use of Toronto Hydro resources. Toronto Hydro may proactively rebuild laterals of 4.16 kV box construction feeders in poor condition (identified by field crews) to 13.8 / 27.6 kV construction standards using reactive crew resources when they are not otherwise allocated to reactive work. Toronto Hydro would then continue to operate the lateral at 4.16 kV system voltage. When the eventual conversion of that feeder takes place, the poles and conductors on those laterals will already be prepared for the conversion, which allows the project to be completed in a more timely fashion. Another significant benefit of this approach is that the failure risks associated with poor condition 4.16 kV assets are eliminated in a more timely manner.

E6.7.6.1 Proposed Work Plan

The proposed work plan in the 2015-2019 period does not necessarily follow a station-by-station approach but rather indicates a milestone year when all load will be converted at a given station. Feeders proposed for conversion in the 2015-2019 period are summarized Table 8.

Issues may arise that are specific to certain conversions; however, current planning processes have not identified any major issues in years 2015-2019 other than the continued deterioration and aging of assets.

Ultimately, work proposed for 2016 to 2019 is of the same nature as work proposed from 2015. No major change in design standards or planning methodologies that could affect the work program are anticipated.

2019	B7DF	DEFOE MS

E6.7.6.2 Program Risks

The following are risks to program completion that Toronto Hydro considers when planning and executing box construction conversions.

- Timely third-party project completion: Some box construction conversion projects are contingent on the completion of HONI stations projects. For example, Toronto Hydro has scheduled a conversion project for Carlaw MS in 2015, but this project cannot start until a

new bus at Carlaw TS is commissioned. A significant delay of HONI's portion of the Carlaw TS expansion will necessarily lead to a delay in Toronto Hydro's box construction conversion project. To mitigate this risk, Toronto Hydro will work closely HONI to ensure that there is a mutually agreed project schedule.

E6.7.7 Evaluation of Alternatives

E6.7.7.1 Quantification/Evaluation of Options

In addition to the benefits outlined in section E6.7.3.1 , the value derived from the Box Construction Conversion program can be further quantified by examining the difference in cost of ownership between the existing box construction design that will be replaced and the new standardized 13.8 kV overhead design that will be installed. This difference in costs includes quantified risks, taking into account the probability of failure of the asset, and multiplying this by the direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs and replacement. The underlying methodology and processes associated with the business case results provided below are further explained within Section D3.1.

(i) Status Quo ("Like-for-Like" Replacement)

In the status quo scenario, Toronto Hydro would continue to maintain and repair box construction assets wherever they are currently found, and replace failed assets as needed. Due to the high number of box construction assets past their useful lives, Toronto Hydro anticipates that maintaining the status quo would result in additional avoidable maintenance costs and deteriorating reliability, as described in section E6.7.3.1. Also, the safety and operational issues outlined in Section E6.7.5.4 would remain.

The status quo options requires Toronto Hydro to manage the issues described above in a reactive and less efficient manner, delaying the decommissioning of some municipal stations (MS) or possibly preventing decommissioning of the MS altogether. The continued cost of ownership associated with the status quo option (COO_E) is highlighted in Table 9.

TABLE 9: COST OF OWNERSHIP OF EXISTING ASSETS / STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	15.38
Non Asset Risk [NAR_E]	58.22
Maintenance Cost [MC_E]	1.55
Additional Quantifiable Benefits [AQB_E]	0
Cost of Ownership of Existing Assets [COO_E]	75.15

(ii) Conversion to Standardized 13.8 kV or 27.6 kV Infrastructure

The cost of ownership (COO) and program net benefit (NPV) associated with box construction conversion is further detailed in Table 12. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities in this program. The cost of reflects the risk of asset failure for a given state, including both direct and indirect costs. These costs include customer interruptions, emergency repairs, and asset replacements associated with the given design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NARE) and proposed (NARN) state. Non-asset risks are further explained in Section D3.3. Costs in maintenance activities are also included for both states and any additional benefit that is associated with the program that is external to the asset and non-asset related risk evaluation is quantified for both the existing state (AQBE) and new state (AQBN). Note that, for this program, AQB corresponds to savings from line losses as a result of conversion projects. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3.

When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first year of activities, the box construction conversion produces a net present value (NPV) of $5.64 million, as shown in Table 10.

TABLE 10: BOX CONSTRUCTION CONVERSION BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 2: Conversion to Standardized 13.8 kV Feeders (N)	
Asset Risk [AR_N]	3.34
Non Asset Risk [NAR_N]	52.58
Maintenance Cost [MC_N]	0
Additional Quantifiable Benefits [AQB_N]	-3.21
Cost of Ownership of New Assets (Conversion to 13.8 kV) [COO_N]	52.72
Option 2: Project Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\Delta COO_1 = (COO_E - COO_N)$]	22.44
Program Cost [PC_1]	16.80
Program Net Benefit [$NPV_1 = (\Delta COO_1 - PC_1)$]	5.64

E6.7.8 2015 Project Details

Table 13 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved Box Construction segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 11: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	CIR Projects
5.98	10.82

Table 14 lists all projects that Toronto Hydro plans to partially or completely execute as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 12: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Start Date	Project Type

TOTAL		$16,796,984		

The following subsections provide additional details for all of the projects listed in the table above.

E6.7.8.10 X12129 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Merton-Millwood Conversion Phase 2 (B2MR, B3MD)

Project Number: X12129 (ICM)

Project Year: 2015

Estimated Cost: $1,972,609

(i) Objective

The objective of this job is to prepare Millwood MS feeder B3MD and Merton MS feeder B2MR for conversion from 4.16 kV to 13.8 kV for eventual decommissioning of Millwood MS and Merton MS. The main objective is to mitigate the safety concerns associated with working around energized box construction, which is found on feeders from both Millwood MS and Merton MS.

(ii) Scope of Work

TABLE 13: X12129 SCOPE OF WORK DETAILS

District Neighborhood	MOORE PARK
Station(s)	MERTON MS, MILLWOOD MS
Feeder(s)	B2MR, B3MD

Table 14 outlines the historical reliability of this feeder (Note: the majority of this project is for the conversion of B3MD).

Feeder CHI	0	0	0

The project is bounded by Bayview Avenue to the east, Mount Pleasant Avenue to the west, Millwood Road to the north and Merton Street to the south. Table 15 details the quantities and kilometers of assets to be replaced.

TABLE 15: X12129 ASSETS REPLACED

Assets (Units)	2015
OH Transformer	30
OH Switch	23
Poles	34
UG Switch	0
UG Transformer	5
OH Conductor (km)	3.2
UG Cable (km)	0.6

(iii) Justification & Benefits

This work will mitigate potential safety risks, improve reliability and, when conversion is complete, reduce line losses. Associated benefits of this project align to the program benefits and drivers outlined in sections E6.7.2 and E6.7.3. Furthermore, deferral of this project will likely delay plans to decommission Merton MS and Millwood MS.

E6.7.8.11 X12143 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Merton-Millwood Conversion Phase 3 (B1MR, M2MR)

Project Number: X12143 (ICM)

Project Year: 2015

Estimated Cost: $1,897,845

(i) Objective

The purpose of this project is to convert existing Merton MS feeders B1MR (complete) and B2MR (partial) load to 13.8 kV. This project is the third phase of a multi-phase project to convert the entire 4.16 kV load at Merton MS and Millwood MS to 13.8 kV with the objective of decommissioning both stations.

(ii) Scope of Work

TABLE 16: X12143 SCOPE OF WORK DETAILS

District Neighborhood	MOORE PARK
Station(s)	MERTON MS, MILLWOOD MS
Feeder(s)	B1MR, B2MR

Table 17 outlines the historical reliability of this feeder (note: the majority of this project is for the conversion of B1MR).

The project is bounded by Mount Pleasant Road to the east, Yonge Street to the west, Manor Road to the north and Davisville Avenue to the south. Table 18 details the quantities and kilometers of assets to be replaced.

TABLE 18: X12143 ASSETS REPLACED

Assets (Units)	2015
OH Transformer	30
OH Switch	20
Poles	48
UG Switch	0
UG Transformer	2
OH Conductor (km)	3.3
UG Cable (km)	0.8

(iii) Justification & Benefits

This work will mitigate potential safety risks, improve reliability and, when conversion is complete, reduce line losses. Associated benefits of this project align to the program benefits and drivers outlined in sections E6.7.2 and E6.7.3. Furthermore, deferral of this project will likely delay plans to decommission Merton MS and Millwood MS.

E6.7.8.9 X13003 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Convert 4kV Dupont B6DU to 13.8 kV – Civil only

Project Number: X13003 (ICM)

Project Year: 2015

Estimated Cost: $1,419,765

(i) Objective

In order to accommodate the electrical conversion work for feeder B6DU, X13003 must first proceed to install new civil infrastructure for the 13.8 kV feeder that will take on B6DU feeder's load. This project is Phase 1 of 2 (civil only).

(ii) Scope of Work

TABLE 19: X13003 SCOPE OF WORK DETAILS

District Neighborhood	CRISTIE-BITTS
Station(s)	DUPONT TMS
Feeder(s)	B6DU

Table 20 the historical reliability of feeder B6DU.

TABLE 20: HISTORICAL RELIABILITY – B6DU

HISTORICAL RELIABILITY PERFORMANCE – B6DU			
Reliability Metric	2011	2012	2013
Feeder CI	0	835	1
Feeder CHI	0	529	2

The project will take place along Dufferin Street, bounded by Davenport Road to the north and Dupont Street to the south. 4 kV assets will be replaced when conversion of 4 kV B6DU load occurs in a later project in 2016. As a result, there are no asset replacements shown for this project.

(iii) Justification & Benefits

Conversion of 4 kV Dupont MS feeders to the 13.8 kV system is required due to the aging station and distribution equipment, load growth, and obsolete distribution design configuration. The conversion will also improve supply reliability to customers as well as enhance work safety for crews. Furthermore, deferral of this project will likely delay plans to decommission Dupont MS.

E6.7.8.2 X13004 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Convert 4kV Dupont B4DU/B71DU to 13.8 kV - Phase 3 UG Electrical

Project Number: X13004

Project Year: 2015

Estimated Cost: $890,496

(i) Objective

The purpose of this project is to install new underground cable to allow for the conversion of legacy 4.16 kV box construction feeders B4DU and B71DU. The new underground cable will then be utilized to connect to a new overhead 13.8 kV line to be built in future phases. This project is the third phase of a multi-phase project to convert the B4DU and B71DU feeders at Dupont MS with the eventual objective of decommissioning this station.

(ii) Scope of Work

TABLE 21: X13004 SCOPE OF WORK DETAILS

District Neighborhood	ANNEX/ST CLAIR WEST
Station(s)	DUPONT MS
Feeder(s)	B4DU/B71DU

Table 22 outlines the historical reliability of this feeder.

TABLE 22: HISTORICAL RELIABILITY – B4DU AND B71DU

Reliability Metric	2011	2012	2013
Feeder CI	2577	0	1326
Feeder CHI	1572	0	884

The project is bounded by Christie Street to the east, Dufferin Street to the west, Davenport Road to the north and Dupont Street to the south. As this phase of the conversion plan only installs new cable, no assets are being replaced by this project.

(iii) Justification & Benefits

This project will allow for the conversion of 4.16 kV Dupont MS B-4-DU/B-71-DU feeders to 13.8 kV system in a later phase, and is the third phase of a multi-phase conversion plan which needs to take place before 4.16 kV Dupont MS can be decommissioned. Modernizing and upgrading the existing system will improve reliability and aesthetics, and reduce system losses and maintenance. Furthermore, deferral of this project will likely delay the later phases for the conversion of B4DU and B71DU feeders, as well as the eventual decommissioning of Dupont MS.

E6.7.8.3 X13164 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Voltage Conversion B2W/B1W phase 1

Project Number: X13164

Project Year: 2015

Estimated Cost: $1,234,184

(i) Objective

The purpose of this project is to convert the existing 4 kV Wiltshire MS B2W feeder and a portion of B1W feeder to the 13.8 kV system. This is the first phase of a multi-phase conversion plan to convert B2W and B1W feeders, as well as the eventual decommissioning of 4.16 kV Wiltshire MS.

(ii) Scope of Work

TABLE 23: X13164 SCOPE OF WORK DETAILS

Assets (Units)	2015
OH Transformer	19
OH Switch	11
Poles	30
UG Switch	0
UG Transformer	3
OH Conductor (km)	1.8
UG Cable (km)	1.2

(iii) Justification & Benefits

Modernizing and upgrading the existing system will improve reliability and aesthetics, and reduce system losses and maintenance. Deferral of this project will mean that all operational efficiency, safety and reliability issues discussed earlier in Section E6.7.3 will remain.

E6.7.8.4 X13173 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Convert 4kV Wiltshire MS B3W to 13.8 kV system

Project Number: X13173

Project Year: 2015

Estimated Cost: $1,317,019

(i) Objective

The purpose of this project is to convert the existing 4 kV Wiltshire B3W feeder to the 13.8 kV system and decommission the 4.16 kV B3W feeder. This project is a part of a multi-phase plan to convert the entire 4.16 kV load at Wiltshire MS with the objective of decommissioning this station.

(ii) Scope of Work

E6.7.8.5 X13174 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Convert 4kV Wiltshire MS B2W/B1W to 13.8 kV system - Phase 2

Project Number: X13174

Project Year: 2015

Estimated Cost: $1,559,904

(i) Objective

The purpose of this project is to convert the remaining portion of existing 4 kV Wiltshire B1W feeder to 13.8 kV overhead infrastructure. This project is the second phase of a multi-phase plan to convert the entire 4.16 kV load at Wiltshire MS with the objective of decommissioning this station.

(ii) Scope of Work

TABLE 29: SCOPE OF WORK DETAILS

Feeder CHI	1798	0	3272

The project is bounded by Wiltshire Avenue to the east, Osler Street to the west, St. Clair Avenue West to the north and Adrian Avenue to the south. Table 31 details the quantities and kilometers of assets to be replaced.

TABLE 31: X13174 ASSETS REPLACED

Assets (Units)	2015
OH Transformer	25
OH Switch	15
Poles	48
UG Switch	0
UG Transformer	0
OH Conductor (km)	2.3
UG Cable (km)	0.5

(iii) Justification & Benefits

The conversion of 4.16 kV Wiltshire MS B-1-W feeder to 13.8 kV system is the second phase of a multi-phase conversion plan which needs to take place before 4.16 kV Wiltshire MS can be decommissioned. Modernizing and upgrading the existing system will improve reliability and aesthetics, and reduce system losses and maintenance. Associated benefits of this project also align to the program benefits and drivers outlined in sections E6.7.2 and E6.7.3. Furthermore, deferral of this project will likely delay the eventual decommissioning of Wiltshire MS.

E6.7.8.12 X13693 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: KS MS VC 4-13.8 kV BC ph2 (Construct only)

Project Number: X13693 (ICM)

Project Year: 2015

Estimated Cost: $690,125

(i) Objective

This project will convert and pick-up existing 4 kV loads along B4KS feeder. This project is the second phase of a multi-phase project to decommission 4 kV Keele and St. Clair MS.

(ii) Scope of Work

TABLE 32: X13691 SCOPE OF WORK DETAILS

District Neighborhood	JUNCTION (STOCKYARDS)
Station(s)	KEELE AND ST CLAIR MS
Feeder(s)	B1KS, B4KS

Table 33 summarizes the historical reliability of these feeders (note: the majority of this project is for the conversion of B4KS).

Reliability Metric	2011	2012	2013
Feeder CI	1028	382	382
Feeder CHI	2512	89	598

The project is bounded by Cawthra Avenue to the east, Keele Street to the west, St. Clair Avenue to the north and Vine Avenue to the south. Table 34 details the quantities and kilometers of

assets to be replaced.

TABLE 34: X13693 ASSETS REPLACED

Assets (Units)	2015
OH Transformer	20
OH Switch	14
Poles	42
UG Switch	0
UG Transformer	6
OH Conductor (km)	2.4
UG Cable (km)	1.1

(iii) Justification & Benefits

Conversion of 4 kV Keele and St.Clair MS B-1-KS and B-4-KS feeders to 13.8kV/27.6kV systems is needed due to the current station's equipment conditions and loads, the adjacent station's loads and to maintain safe and reliable supply to customers. Deferral of this project will likely delay plans to decommission Keele and St. Clair MS.

E6.7.8.1 X14413 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Convert Dupont 4kV B4DU/B71DU- Ph 2 Decommission LOC2630

Project Number: X14413

Project Year: 2015

Estimated Cost: $183,815

(i) Objective

The purpose of this project is to resupply customer fed via LOC2630 then decommission LOC2630 fed via B4DU, including all cables and transformers. This project is the second phase of a multi-phase plan to convert feeders B4DU and B71DU, with the objective of decommissioning Dupont MS.

(ii) Scope of Work

TABLE 35: X14413 SCOPE OF WORK DETAILS

E6.7.8.6 X14444 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Convert 4kV B2HS to 13.8 kV overhead feeder

Project Number: X14444

Project Year: 2015

Estimated Cost: $2,331,130

(i) Objective

Convert 4 kV box construction feeder B2HS to 13.8 kV overhead infrastructure. This project is the first phase of a multi-phase conversion plan to convert the entire 4.16 kV load at Hammersmith MS with the objective of decommissioning this station.

(ii) Scope of Work

TABLE 38: X14444 SCOPE OF WORK DETAILS

District Neighborhood	BEACHES
Station(s)	HAMMERSMITH MS
Feeder(s)	B2HS

Table 39 outlines the historical reliability of this feeder.

TABLE 39: HISTORICAL RELIABILITY – B2HS

HISTORICAL RELIABILITY PERFORMANCE – B2W and B1W			
Reliability Metric	2011	2012	2013
Feeder CI	2437	0	0
Feeder CHI	6698	0	0

The project is bounded by Victoria Park Avenue to the east, Hammersmith Avenue to the west, Kingston Road to the north and Hubbard Avenue to the south. Table 40 details the quantities and kilometers of assets to be replaced.

TABLE 40: X14444 ASSETS REPLACED

Assets (Units)	2015
OH Transformer	31
OH Switch	24
Poles	92
UG Switch	0
UG Transformer	1
OH Conductor (km)	4.5
UG Cable (km)	0.1

(iii) Justification & Benefits

The conversion of 4.16 kV Hammersmith MS B-2-HS feeder to the 13.8 kV system is the first phase of a multi-phase conversion plan which must occur before 4.16 kV Hammersmith MS can be decommissioned. Furthermore, converting this feeder to 13.8 kV will reduce the load at this station enough to allow a station transformer in poor condition to be decommissioned, rather than replace it. Modernizing and upgrading the existing system will improve reliability and aesthetics, and reduce system losses and maintenance.

Deferral of this project will necessitate further maintenance of Hammersmith MS, and will also delay other conversion projects in this area that require X14444 to be completed.

E6.7.8.7 X15017 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Box conversion to 13.8 kV Elec Carlaw B4E B8E Phase 1

Project Number: X15017

Project Year: 2015

Estimated Cost: $1,540,556

(i) Objective

Convert 4 kV box construction feeder B4E and B8E to 13.8 kV overhead infrastructure. This project is the final phase of a multi-phase conversion plan to convert the entire 4.16 kV load at Carlaw MS with the objective of decommissioning this station.

(ii) Scope of Work

TABLE 41: X15017 SCOPE OF WORK DETAILS

District Neighborhood	LESLIEVILLE
Station(s)	CARLAW MS
Feeder(s)	B4E/B8E

Table 42 outlines the historical reliability of this feeder.

TABLE 42: HISTORICAL RELIABILITY – B4E AND B8E

HISTORICAL RELIABILITY PERFORMANCE – B4E and B8E			
Reliability Metric	2011	2012	2013
Feeder CI	0	0	0
Feeder CHI	0	0	0

The project is bounded by Kingston Road to the east, Booth Street to the west, Gerrard Street to the north and Queen Street East to the south. This project only installs 13.8 kV poles and overhead transformers. Assets will be replaced when conversion of 4 kV load occurs in a later project: X15281 (phase 2). As a result, there are no asset replacements shown for this project.

(iii) Justification & Benefits

The conversion of 4.16 kV Carlaw MS B-4-E/B-8-E feeder to the 13.8 kV system is the final phase of a multi-phase conversion plan that must occur before 4.16 kV Carlaw MS can be decommissioned. Furthermore, the bus supplying Carlaw MS (Carlaw TS A4-5E bus) requires replacement in 2018 and this conversion project must be executed prior the bus replacement. Deferral of this project will necessitate further maintenance of Carlaw MS, and will also delay other conversion projects in this area that require the completion of X15017. Modernizing and upgrading the existing system will improve reliability and aesthetics, and reduce system losses and maintenance.

E6.7.8.8 X15281 Project Description

Investment Category: System Renewal

Program: Box Construction Conversion

Project Title: Box conversion to 13.8 kV B4E/B8E (phase 2)

Project Number: X15281

Project Year: 2015

Estimated Cost: $1,759,530

(i) Objective

Convert 4 kV box construction feeder B4E and B8E to 13.8 kV overhead infrastructure. This project is the final phase of a multi-phase conversion plan to convert the entire 4.16 kV load at Carlaw MS with the objective of decommissioning this station.

(ii) Scope of Work

TABLE 43: X15281 SCOPE OF WORK DETAILS

District Neighborhood	LESLIEVILLE
Station(s)	CARLAW MS
Feeder(s)	B4E/B8E

Table 44 outlines the historical reliability of this feeder.

TABLE 44: HISTORICAL RELIABILITY – B4E AND B8E

HISTORICAL RELIABILITY PERFORMANCE – B4E and B8E			
Reliability Metric	2011	2012	2013
Feeder CI	0	0	0
Feeder CHI	0	0	0

The project is bounded by Kingston Road to the east, Booth Street to the west, Gerrard Street to the north and Queen Street East to the south. Table 45 details the quantities and kilometers of

assets to be replaced. This project utilizes the 13.8 kV poles and overhead transformers installed in project X15017 (phase 1) and takes on 4 kV load from B4E and B8E, and also removes all associated 4 kV assets.

TABLE 45: X15281 ASSETS REPLACED

Assets (Units)	2015
OH Transformer	67
OH Switch	41
Poles	77
UG Switch	0
UG Transformer	5
OH Conductor (km)	4.6
UG Cable (km)	1.4

(iii) Justification & Benefits

The conversion of 4.16 kV Carlaw MS B-4-E/B-8-E feeder to the 13.8 kV system is the final phase of a multi-phase conversion plan that must occur before 4.16 kV Carlaw MS can be decommissioned. Furthermore, the bus supplying Carlaw MS (Carlaw TS A4-5E bus) requires replacement in 2018 and this conversion project must be executed prior the bus replacement. Deferral of this project will likely delay plans to both decommission Carlaw MS and replace the aging A4-5E bus at Carlaw TS. Modernizing and upgrading the existing system will improve reliability and aesthetics, and reduce system losses and maintenance.

E6.8 SCADA-Mate R1 Switch Renewal

DEFECTIVE SCADA-MATE R1 SWITCH USED FOR INTERNAL INVESTIGATION

E6.8.1 Summary

Program Description

The SCADA-Mate R1 Switch Renewal program will complete the ongoing activities previously described in the Ontario Energy Board (OEB) approved SCADA-Mate R1 Switches segment in the Incremental Capital Module (ICM) as part of Toronto Hydro's 2012-2014 rate filing.[1]

The SCADA-Mate R1 Switch Renewal program targets the replacement of SCADA-Mate R1 switches which have proven to be defective. There have been three incidents of the switch operating unexpectedly when crews were establishing an open air-gap with the disconnect switch. In one case, this resulted in a flashover and a pole catching fire while a field worker was manually operating the disconnect switch underneath. It has been determined that corrosion of internal components, coupled with the design of the switch, caused the switch to operate unexpectedly. After determining that these switches posed a significant safety hazard (as discussed in section E6.8.3), Toronto Hydro began to replace the SCADA-Mate R1 switches in its system with new R2 switches in 2013.

[1] EB-2012-0064, Tab 4, Schedule B8.

The anticipated benefits of the SCADA-Mate R1 Switch Renewal program are as follows:

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Faster restoration of service from fully functioning SCADA-Mate switches
Reliability	ƒ Functioning SCADA-Mate switches reduce the duration of trunk related outages, helping to manage SAIDI impacts from interruptions, including during major storm events.
Safety	ƒ Eliminates the risk of switch closing on itself during air-gap disconnect ƒ Eliminates the risk of flashover during use ƒ Eliminates the status indicator malfunction discrepancy from field to control room
Efficiency	ƒ The ability to safely establish open air-gap reduces switching activities
Other	ƒ Functioning SCADA-Mate switches will play an essential role in the expansion of Toronto Hydro's Feeder Automation program (refer to section E7.3 for details) ƒ SCADA-Mate R2 switch can operate without power supply due to manual charge spring in motor mechanism.

Program Drivers

The trigger and secondary drivers for SCADA-Mate R1 Switch Renewal program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ SCADA-Mate R1 switches do not operate as intended; therefore, the functionality in switching operations is significantly diminished. ƒ The R1 switches cannot be used as a physical open point to isolate a feeder when performing field work. ƒ Outages on feeders connected by R1 switches affect a larger number of customers, as crews have to create the open isolation point at the next load break switch.
Secondary Drivers	**Reasoning**
Safety	ƒ Due to corrosion of the internal components, the interrupter switch and interrupter indicator on the SCADA-Mate R1 have previously malfunctioned and are considered unsafe for operation due to the risk of a arcing and flashover while manually opening an energized switch. ƒ The interrupter switch has previously closed on its own, re-energizing the circuit while crews were operating the equipment, and the indicator has misrepresented the operating state to the control room.

Failure Risk	ƒ SCADA-Mate R1 switches present an increased failure risk because of the suspension of maintenance on these switches (due to the safety risks associated with working with them) and their susceptibility to corrosion build-up. ƒ Failure of this equipment results in the loss of remote functionality, which prolongs the duration of outages by making it more difficult to locate faults and restore power to customers.

Preferred Alternative

Toronto Hydro evaluated the following alternatives for addressing the assets in this program:

I. Do nothing and replace on a reactive basis only, incurring the risk of equipment failures and potential safety concerns
II. Retrofit the R1 switches with a kit provided by the manufacturer, which would necessitate the removal of each switch from the field, transport to and from the manufacturers facilities, and re-installation after the retrofit is complete
III. Replace the R1 switches with new R2 switches

Option III is the preferred alternative because it addresses the safety, reliability and operational issues associated with the SCADA-Mate R1 switches in the most cost-effective manner.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $106.82 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.8.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $100.67 million, confirming the economic prudence of the investments (see Section E6.8.7).

Timing and Pacing

Under this SCADA-Mate R1 Switch Renewal program, Toronto Hydro proposes to replace all remaining R1 switching units from 2015 to 2017, with spending levels noted in Table C below. Toronto Hydro is proposing an aggressive replacement program in order to reduce the duration of customer outages and improve safety in a timely fashion. Due to the numerous safety, reliability and operational issues associated with SCADA-Mate R1 switches, Toronto Hydro cannot defer or delay this program

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	-	-	1.90	2.57	6.16	4.11	2.69	-	-

E6.8.2 Program Description

The SCADA-Mate R1 Switch Renewal program will complete the ongoing activities previously described in the OEB-approved SCADA-Mate R1 Switches segment in the Incremental Capital Module (ICM) as part of Toronto Hydro's 2012-2014 rate filing[2]. Toronto Hydro expects to complete the proactive replacement of all in-service SCADA-Mate R1 switches with R2 switches by 2017.

SCADA-Mate switches are overhead load interrupting switches that have the capability of being remotely operated from the control room. The sensory, control and communication functions of these devices provide significant advantages in managing Toronto Hydro's distribution system. For example, SCADA-Mates can detect a fault on a feeder and enable the control room to rapidly isolate the faulted area and restore power to the unaffected areas of the main feeder (also known as the feeder's trunk) by opening and closing the switches remotely. In addition, SCADA-Mate switching units enable Toronto Hydro field crews to create an open isolation point when work is required on a circuit. This is a required and important safety measure to help ensure that the equipment will not become energized while field crews are working on the faulted section of the feeder when restoring a fault in order to create a zone of work protection for the field crews working on the feeder.3

Figure 1 illustrates a typical SCADA-Mate switch configuration, which consists of the switch assembly and the remote terminal unit (RTU). The switch assembly physically connects to the primary conductors to open and close the circuit. SCADA-Mate switches are equipped with SF_6 (sulfur hexafluoride) interrupters that limit and contain any electrical arcing from the interrupter switches. The interrupter indicator on the side of the switch shows whether the switch is in the open or closed position. This allows live circuit making and breaking without exposing Toronto Hydro crews and the public to the risk of arcing and flashovers.

[2] EB-2012-0064, Tab 4, Schedule B8.
[3] Infrastructure Health and Safety Association, Electrical Utility Safety Rules, (Mississauga: Infrastructure Health and Safety Association, 2014) at Rule 114 (Safe Conditions for Work), Rule 115 (Work on Isolated Circuits), and Rule 126 (Switching Operations) ["EUSR"]

FIGURE 1: SCADA-MATE R1 SWITCH CONFIGURATION

The RTU and the interrupters enable the remote operation of the switches. The RTU houses the switch controller and communication electronics that process the information necessary to activate the hardware (i.e., the disconnect operating lever) connected to the switch. It also enables Toronto Hydro field crews to operate the switch on location when they need to create an open isolation point on the circuit.

SCADA-Mate R1 switches were predominately installed between 1993 and 2000. There have been three incidents of the switch operating unexpectedly when crews were establishing an open air-gap with the disconnect switch. The worst of these incidents resulted in a flashover and a pole catching fire while a field worker was manually operating the disconnect switch underneath. An investigation determined that moisture entered the switch and caused internal components to corrode. The corrosion, along with the design of the switch, caused the switch to operate unexpectedly. After determining that these switches posed a significant safety hazard (as discussed in section E6.8.3), Toronto Hydro began to replace the SCADA-Mate R1 switches in its system with new R2 switches in 2013.

To date, Toronto Hydro has replaced 90 switches, leaving 196 switches to be replaced throughout the overhead distribution system as shown in Figure 2 below.

FIGURE 2: MAP OF THE REMAINING SCADA-MATE R1 SWITCHES

Toronto Hydro plans to continue replacing the remaining R1 units with the newer R2 switching units. As explained in section E6.8.3, the design of the SCADA-Mate R2 mitigates the safety risks to field crews and the public associated with operating the SCADA-Mate R1 switches.

Toronto Hydro plans to replace the remaining SCADA-Mate R1 switches from 2015-2017 at a total estimated cost of $12.96 million. Table 1 summarizes the assets to be replaced within this program.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
R1 Switch	99	67	57	-	-	223
RTU	69	49	14	-	-	132

/C

This program provides customer value by reducing the duration and frequency of outages and by enabling Toronto Hydro to manage and operate the distribution system more effectively. SCADA-Mate switches are an important feature of the overhead distribution system as they enable the control room to locate a fault on the feeder, isolate the affected sections of the feeder and restore

the unaffected customers, typically within 30 minutes. Without this technology, Toronto Hydro would have to deploy field crews to address the problem, which could take up to three hours. Furthermore, functional SCADA-Mate switches enable Toronto Hydro to better analyze the outages on feeders and diagnose feeders that are experiencing an increase in feeder faults. Customers benefit from this important functionality of the SCADA-Mate switches in the long-term, as it enables Toronto Hydro to take proactive steps to monitor, assess and remedy reliability on particular feeders.

SCADA-Mate switches have been strategically installed at locations of the feeder that enable optimal remote intervention. When SCADA-Mates malfunction, crews are unable to operate these switches for restoration purposes as intended. As a result, more customers are affected by an outage than would otherwise be required. The SCADA-Mate R1 Switch Renewal program is expected to remedy this problem, by replacing the malfunctioning R1 switches with new R2 switches.

The ability to remotely locate a fault also generates efficiency gains and safety benefits. Toronto Hydro fuel consumption is lower as fewer trips are taken to locate a fault. In terms of safety, Toronto Hydro personnel are not required to perform manual switching under dangerous conditions as noted above.

Table 2 summarizes the expected program benefits associated with the SCADA-Mate R1 Switch Renewal program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Faster restoration of service from fully functioning SCADA-Mate switches ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $106.82 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.8.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $100.67 million, confirming the economic prudence of the investments (see Section E6.8.7).
Reliability	ƒ Functioning SCADA-Mate switches reduce the duration of trunk related outages, helping to manage SAIDI impacts from interruptions, including during major storm events.
Safety	ƒ Eliminates the risk of switch closing on itself during air-gap disconnect ƒ Eliminates the risk of flashover during use ƒ Eliminates the status indicator malfunction discrepancy from field to control room

Efficiency	ƒ The ability to safely establish open air-gap reduces switching activities ƒ Improves productivity by reducing the need to drive to and patrol the area where an issue is occurring and perform switching.
Other	ƒ Functioning SCADA-Mate switches will play an essential role in the expansion of Toronto Hydro's Feeder Automation program (refer to section E7.3 for details) ƒ SCADA-Mate R2 switch can operate without power supply due to manual charge spring in motor mechanism.

E6.8.3 Why the Program is Needed
