The SCADA-Mate R1 Renewal program is needed to address the safety, reliability and operational issues associated with malfunctioning SCADA-Mate R1 switches. Mitigating the safety issues related to operating the switch requires additional switching procedures that usually involve further isolating more of the feeder circuit and, as a result, forcing more customers to experience an outage. This not only negatively affects reliability for the customers, but further complicates how switching operations are done to resolve a fault causing an outage. These issues will be discussed in greater detail below.

E6.8.3.1 Program Drivers

The trigger and secondary drivers of the SCADA-Mate R1 Switch Renewal program are outlined in Table 3.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ SCADA-Mate R1 switches do not operate as intended; therefore, the functionality in switching operations is significantly diminished. ƒ The R1 switches cannot be used as a physical open point to isolate a feeder when performing field work. ƒ Outages on feeders connected by R1 switches affect a larger number of customers, as crews have to create the open isolation point at the next load break switch.
Secondary Drivers	**Reasoning**
Safety	ƒ Due to corrosion of the internal components, the interrupter switch and interrupter indicator on the SCADA-Mate R1 have previously malfunctioned and are considered unsafe for operation due to the risk of a arcing and flashover while manually opening an energized switch. ƒ The interrupter switch has previously closed on its own, re-energizing the circuit while crews were operating the equipment, and the indicator has misrepresented the operating state to the control room.

Failure Risk	ƒ SCADA-Mate R1 switches present an increased failure risk because of the suspension of maintenance on these switches (due to the safety risks associated with working with them) and their susceptibility to corrosion build-up. ƒ Failure of this equipment results in the loss of remote functionality, which prolongs the duration of outages by making it more difficult to locate faults and restore power to customers.

(i) Safe Operation of the Switch

One of the main functions of the SCADA-Mate switch is to enable crews to create an open isolation point on the circuit in order to safely perform work on the feeder downstream. When using a SCADA-Mate switch for this purpose, the switch needs to provide a visible open air-gap, as shown in Figure 3, to ensure the circuit is physically open and to safeguard against any interrupter malfunction or user error in the field or control room that could cause the switch to close and re-energize the circuit while employees are working on it.

FIGURE 3: SCADA-MATE VISIBLE AIR-GAP ISOLATION

Before crews create the visible air-gap, a number of steps must be taken to confirm that the switch interrupter is in the open position, and that the primary circuit downstream of the switch is isolated: 1) the interrupters have to be opened, 2) crews have to visually confirm the open position of the interrupter indicator, and 3) the control room must confirm that the switch is open. Once these precautions are satisfied, crews can physically open the hinged disconnect switches

and create the visible air-gap required to safely work on the feeder. This is done by using a hot stick to engage the disconnect operating lever to rotate the disconnecting switches into open position. If for some reason the interrupters are closed and primary circuit is energized while crews are performing this task, the disconnect switch would arc and create a flashover, damaging the switch and posing a safety risk to employees as well as members of the public within close proximity.

(ii) Incidents of Switch Malfunction

In 2008, two incidents of SCADA-Mate R1 switches malfunctioning were reported by Toronto Hydro's field crews (see Appendix A). During routine maintenance, the interrupters unexpectedly closed, energizing the circuit while the crew was physically opening the switches. This created an electrical arc, which caused damage to the switches, led to outages on the feeder and posed a serious safety hazard for employees.

After the incidents, Toronto Hydro noted that the local mechanical switch indicator did not correspond with the SCADA switch status indicators in the control room. The switch state in the control room read that the switch was open, while the interrupter in the field indicated that it was closed. Conflicting information between the control room and the actual conditions in the field is problematic because it impairs the ability of field crews to make reliable and safe decisions when operating the equipment.

In 2011, three similar incidents were reported, causing Toronto Hydro to suspend all work activities involving SCADA-Mate R1 switches. The details of these incidents were communicated to Toronto Hydro crews through internal safety bulletins, as disclosed in section Appendix A.

Following the 2008 and 2011 incidents, Toronto Hydro conducted a joint investigation with the manufacturer, S&C Electric Ltd., to determine why the R1 switches malfunctioned. The conclusion of the investigation was that that the failures were caused by corrosion of the internal components of the equipment (see Figures 5 and 6). Corrosion was attributed to the design of the breather hole, located at the rear of the motor (Figure 7), which allows moisture to condense and water to collect. As seen in Figure 7, the source of the corrosion is only visible when the switch is disassembled. Since corrosion occurs internally, there are no visual indicators to determine which switches are damaged to the point where a malfunction could occur (see Figure 6 below). As a result, following its investigation and using an abundance of caution, Toronto Hydro concluded that the safest course of action would be to assume that all SCADA-Mate R1 switches are defective and pose safety hazards.

Detailed discussion on the defect of SCADA-Mate R1 switches was provided in Phase 1 of the 2012-2014 IRM filing (EB-2012-0064: Tab 4, Schedule B8).

FIGURE 4: DEFECTIVE SCADA-MATE R1 SWITCH USED FOR INTERNAL INVESTIGATION

The photos below illustrate the components of a disassembled SCADA-Mate R1 switch that had failed.

FIGURE 5 : FIRST LAYER OF DISASSEMBLY OF THE FAILED SCADA-MATE R1 SWITCH

FIGURE 6: CORRODED COMPONENTS INSIDE THE MOTOR OPERATOR OF THE FAILED SCADA-MATE R1 SWITCH

FIGURE 7: BREATHER INSIDE THE MOTOR OPERATOR OF FAILED SCADA-MATE R1 SWITCH

Following the 2008 and 2011 incidents, Toronto Hydro determined that it is no longer safe to use the SCADA-Mate R1 switch to create an open isolation point when crews need to perform work on a feeder. Since this is the most common and efficient method to repair faults and restore customers, Toronto Hydro's operational abilities have been impaired. Not being able to use the SCADA-Mate switches means that the isolation open must be established at the next loadbreak switch. In some cases, the loadbreak switch may be at the station, resulting in an outage on the entire feeder. In other circumstances, where a SCADA-Mate R1 switch is tied to another feeder, isolation may necessarily extend to the other feeder as well, effectively resulting in an unplanned outage on an additional feeder. In short, not being able to use SCADA-Mate R1 switches to isolate and restore faulty feeders means that more customers will experience outages on a feeder than would otherwise be affected if the SCADA-Mate switch operated as intended.

The SCADA-Mate R1 switches can still be used to transfer load and reconfigure the feeder using the interrupters as long as a physical open point is not required. However, because these switches are considered defective and unsafe, Toronto Hydro crews have not performed maintenance on them since 2011. The lack of maintenance means that these switches have likely been experiencing accelerated degradation since 2011. For example, the maintenance lifecycle to replace the backup battery in the RTU is every three years. The backup battery is required to ensure that the SCADA-Mate is powered to communicate and operate when there is a power outage and its primary source of power is no longer there. It is assumed that the majority of the

batteries will have very little capacity, if any, to supply backup power to the RTU and switch during an outage by 2015 and beyond.

Toronto Hydro's intends to replace the remaining SCADA-Mate R1 switching units with the SCADA-Mate R2 switching unit, which is portrayed below in Figure 8.

FIGURE 8: SCADA-MATE R2 SWITCH

The R2 is a new model of SCADA-Mate switch, and it has been used in Toronto Hydro's overhead system since September of 2000. A key features of the SCADA-Mate R2 is that it comes equipped with an interlock mechanism that blocks the operation of the visible air-gap disconnect until the interrupters are opened. Unlike the R1 interlock that opens the interrupters when the disconnect switches are being opened, this mechanism blocks the disconnect switches from opening if the interrupter is closed. This feature eliminates the arc-flash hazard posed by the R1 model. In addition, the R2 switch allows crews to operate the interrupter switch remotely or on-site from the local push button.

Another important feature of the R2 model is the ventilation mechanism, which has extra drain holes and vents that prevent condensation and water build-up by allowing the water dissipate before it corrodes the motor operator's internal components. An additional feature associated with the R2 models is the ability to open and close the interrupters multiple times without a 120V supply or battery backup by building a charge through a built in pull ring. In comparison, the R1 switches only allow one interrupter operation in the absence of the 120V supply. The ability of the

R2 to operate without the 120V supply improves the operational flexibility and reliability of the switch.

Toronto Hydro expects this program to offer significant reliability benefits, as functioning SCADA-Mate switches serve a critical role in reducing the duration of outages. To illustrate, it typically takes a control room operator 30 minutes to locate and isolate a feeder fault and restore the unaffected portions of the feeder using the SCADA-Mate switching functionality. In the absence of SCADA-Mate, a field crew must be deployed to determine the location of the fault, manually isolate the faulted section, and restore the remaining feeder. On average, this task takes three hours to complete. In some cases, where a feeder has many R1 switches, crews may need to leave the entire feeder isolated, and install or utilize existing disconnect switches to minimize impacts to the customers.

The importance of maintaining control of trunk related outages is illustrated in Figure 10 by comparing the SAIDI impact of trunk related outages to lateral ones. The feeder consists of the trunk, which is the main section of the feeder that is connected to the substation that supplies it. The laterals branch off the trunk section of the feeder and are usually protected by fuses. The laterals almost exclusively supply the customers on the feeder. When an outage occurs, the lateral contains the fault by isolating with a fuse. When an outage occurs on the trunk it affects the entire feeder as the trunk supplies all the laterals. The SCADA-Mate switches are then required to isolate the fault on the trunk and resupply the remaining portion of the feeder. As a result, the duration of outages on feeder trunks are almost twice as long as the duration of outages on laterals; a trunk outage typically lasts 40 minutes while a lateral outages lasts 20. If a trunk related outage cannot be managed and restored via SCADA-Mate switches, the outage duration will increase throughout the system as crews will have to manually locate and isolate the fault while restoring the unaffected sections. Furthermore, if the crew has difficulty isolating the faulted section of the feeder because the available switches are SCADA-Mate R1 switches, they will have to move upstream to the next available loadbreak switch or install a disconnect switch themselves as an isolation point.

FIGURE 9: SYSTEM AVERAGE INTERRUPTION DURATION INDEX (SAIDI) COMPARISON BETWEEN TRUNK AND LATERALS

Functioning SCADA-Mate switches play an important role in the deployment of future technologies, such as feeder automation (see section E7.3 Feeder Automation) or other future technologies that may utilize the sensory capabilities and remote functionalities of this equipment. The switches generate efficiencies with respect to implementing future smart grid applications by utilizing the hardware of the SCADA-Mate switches. For example, by programming the controllers with Feeder Automation software and incorporating these switches into that solution, system restoration efforts would benefit and the operational workloads for the controller would decrease.

The R2 switch comes with a ratchet operation that allows the motor to wind the spring just short of its release point and hold it there until a switching operation is initiated. The interrupters can be operated remotely or on site from the local push button causing the motor to wind the spring past its release point and change the switch state. This allows the interrupter to be operated to an open or close position if the controller loses its 120V supply or battery backup. If field crews require to open the interrupter and the RTU controller had lost all power, the crew could still operate it using ratchet operation, which would then allow a safe method to open the disconnect switch.

E6.8.3.2 Asset Details

(i) Asset Lifecycle

With regular maintenance, the useful life of a SCADA-Mate switching unit is approximately 40 years. The majority of the SCADA-mate R1 switches targeted by this program were installed in the mid to late 1990's and have an average age of approximately 15 to 20 years. However, due to internal corrosion, the expected operational lifecycle of the R1 switching unit has been reduced to approximately less than half of what was expected. As such, Toronto Hydro is replacing these units due to their deterioration and their inability to function as required rather than because of their age.

Toronto Hydro expects that the malfunction rate will increase with respect to the remaining useful functions (i.e., interrupter usage for load transfers and sensory functions on the feeder) because maintenance activities can no longer be performed on these switches as mentioned earlier. Toronto Hydro anticipates that the first issue that will arise with respect to these switches is the depletion of the backup battery, as batteries have a replacement cycle of three years. By the time this program is deployed, the batteries will have not been replaced for four years, which means that any functionality will likely be lost if the switch loses its 120V power supply. The absence of battery power is problematic when a power outage occurs because the switch will go unpowered; if a fault occurs, the switch will not operate as needed.

(ii) Asset Failure Impacts

All SCADA-Mate R1 switches are considered defective and cannot be operated as intended. As a result, they do not have the capability to perform any load breaking operations, which means that Toronto Hydro must de-energize the circuit when it requires any isolation using SCADA-Mate R1 switches. The inability to operate SCADA-Mate R1's to isolate sections of the feeder during a fault impacts all customers associated with that section of feeder. The load breaking must be done at another location further upstream from the fault, causing more customers to experience an outage and for a longer duration than would otherwise be required. Figure 10 illustrates the situation where restoring a fault is more complicated due to the lack of an operating switch. The figure shows a simple feeder configuration where one of the switches is a SCADA-Mate R1 switch. When a fault occurs crews cannot create a physical air-gap using the disconnect switch on the SCADA-Mate R1 switch and have to deploy to the next location to create the open point. This causes an additional section of the feeder to be without power and, as a result, more customers experience an outage. While every feeder is configured differently, on average, a fault

could affect approximately a third of the feeder's load (typically about 5 MVA) and could affect approximately 1,000 customers.

FIGURE 10: OPERATIONAL DIFFICULTIES WITH SCADA-MATE R1 SWITCHES

Since crews cannot perform maintenance on SCADA-Mate R1 switches, component related failures are expected to increase, contributing to feeder outages where these switches are located, and impairing the remaining functionality of these switches (i.e., remote load transfers and sensory functions on the feeder). Along with not being able to use these switch locations to create an open air-gap, this could create issues with respect to sensing the status of the feeder and the ability to remotely operate the interrupter switches, particularly if there is a loss of supply due to battery depletion or further physical damage due to corrosion.

E6.8.4 Timing & Pacing of the Program

Following the OEB approval of the SCADA-Mate R1 capital investments, which were included as part of the Incremental Capital Module (ICM) within Toronto Hydro's 2012-2014 rate filing, Toronto Hydro commenced projects in 2013 designed to replace malfunctioning SCADA-Mate R1 switching units. To date, Toronto Hydro has replaced 90 R1 SCADA-Mate switches. Toronto Hydro proposes to replace all remaining R1 switching units from 2015 to 2017, with spending levels noted in the table below. Toronto Hydro is proposing an aggressive replacement program in order to reduce the duration of customer outages and address the known safety risks in a timely fashion. Due to the numerous safety, reliability and operational issues associated with SCADA-Mate R1 switches, Toronto Hydro cannot defer or delay this program.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	-	-	1.90	2.57	6.16	4.11	2.69	-	-

There is an increase in spending from 2014 to 2015 to accommodate carry-over projects from the 2012 to 2014 ICM program. Furthermore, the first two years of the program will address the highest priority and most urgent switches.

The replacement of switches must be performed in phases in order to mitigate the risks associated with practical considerations such as operational constraints, feeder loading restrictions, limited control room resources, and limited protection and control resources. Working in phases will allow the timely completion of this project given resource constraints.

E6.8.4.1 Ranking & Prioritization

The entire SCADA-Mate R1 switch population requires replacement as soon as possible. The ranking and prioritization of the replacement of the SCADA-Mate R1 switches is based on the following criteria:

- Switches on feeders near heavily contaminated areas and/or using obsolete RTU's
- Switches that are on feeders that have historically had outages on the feeder's trunk

SCADA-Mate R1 switches that are on feeders near heavily contaminated areas such as highways and arterial roads and that are using obsolete RTU's are at risk of being damaged due to excessive corrosion or failure of an unsupported obsolete RTU. Accordingly, these switches

were given highest priority. Next, Toronto Hydro plans to focus on switches that are on feeders that have historically experienced outages on the feeder's trunk as this is the main section of the feeder on which SCADA-Mate switches perform their switching operations. Toronto Hydro will address feeders with the highest number of outage events on the trunk first.

E6.8.5 Program Execution

As mentioned in section E6.8.4.1, the program must be executed in phases due to operational constraints, feeder loading restrictions, limited control room resources, and limited protection and control resources. To manage these constraints, Toronto Hydro plans to group the work by feeder in line with its prioritization scheme discussed in the previous section. Executing work in this manner will enable Toronto Hydro controllers to manage the work in an effective and efficient manner. Toronto Hydro will also create contingency plans in the event of outages. Where possible, Toronto Hydro will group switch replacements by geographic region in order to reduce travel times.

The construction execution process involves coordination with construction crews, the control room, and program and control (P&C) crews. Before any construction commences, the control room requires a feeder plan of the type of work involved and to ensure that customers will be supplied by alternative routes. The typical switch replacement process requires that the switch be isolated from the primary feeder circuit by connecting jumpers on the primary to bypass the switch, essentially creating a short circuit in parallel with the switch. The switches are then disconnected from the primary feeder and the switch is removed from the pole. The new switch is installed, programmed by the P&C crew and tested for operation on location and remotely from the control room. If the switch passes the testing phase, it is connected back to the primary feeder and the jumpers are disconnected.

If the RTU is obsolete (such as a MOSCAD RTU) or the radio unit requires upgrading to the new SD-9 radio, it will be replaced during the switch replacement. Replacing obsolete RTU units while the switch is being removed also allows the entire switch to be brought up to standard with the most recent RTU and radio at the same time, instead of using two separate construction schedules to replace each piece of equipment. At times during complete switch installations, poles will be replaced if necessary in order to avoid having to undertake additional construction at a later time. If the switch and the RTU require replacement, it is assumed that the pole will require replacement as well. It is also assumed that every location will require a new SD-9 radio since most switches are using an obsolete radio system.

E6.8.5.1 Program Risks

The main risks to completing this program are summarized below:

- Operational Constraints: The SCADA-Mate switches are located on the main portion of the feeder known as the trunk. If an alternate supply does not exist to supply all the customers on that feeder, then complex switching and temporary disconnect switch installations will be required to minimize outages associated with the work.

- Feeder Loading Restrictions: During the summer, feeders are running at capacity and transferring any load over to a feeder to accommodate work can increase the risk of an outage due to the over-loading of a feeder. In order to reduce this risk, certain program phases that affect areas that have lighter loads will be planned and executed in the summer.

- Limited Control Room Resources : There are limited control room resources available to accommodate the large number of planned outages associated with this program. This risk is mitigated by planning the work in geographical phases and trying to replace as many switches on a feeder as possible at the same time in order to reduce the number of planned outages required.

- Limited Protection and Control Resources: There are a limited number of protection and control resources available for commissioning and decommissioning of the SCADA-Mate switches. By keeping the work in a local area, Toronto Hydro will reduce the travel time associated with commissioning and will allow control room resources to focus on localized areas.

E6.8.6 Evaluation of Alternatives

E6.8.6.1 Quantification/Evaluation of Options

Toronto Hydro evaluated three options to address the problems associated with the SCADA-Mate R1 switches.

Option 1: Status Quo

The status quo option involves replacing R1 switches upon failure and continuing to use them in their limited capacity, such as for sensing and interrupter switch control. Toronto Hydro does not recommend maintaining the status quo for following reasons.

- Although R1 switches have some remaining functionality, they no longer provide Toronto Hydro with the full suite of services that Toronto Hydro requires to effectively manage and operate the distribution system. The limited functionality of the SCADA-Mate R1 switches prolongs the duration of outages and causes more customers to experience an outage than would otherwise be required if the SCADA-Mate switches functioned as designed.

- Since maintenance in not performed on the SCADA-Mate R1 switches (as it is classified as defective equipment), their rate of failure is expected to increase.

- Toronto Hydro expects that backup batteries will no longer function adequately by 2015 because they have not been replaced since 2011, and cannot be replaced due the safety hazards associated with this equipment. As mentioned earlier, the backup battery requires replacement every four years for to ensure adequate functionality. When there is an outage and the main 120 V supply is lost to the switch, RTU and communication systems require backup power from the battery. If there is no backup to the 120 V supply, the already limited functionality of SCADA-Mate switches will be impacted further.

- Replacing switches reactively would prolong the time that defective switches remain in service. Accordingly, the operational and safety issues related to these defective switches would remain and the risk of failure would increase due to a lack of maintenance.

Option 2: Install Retrofit Kit Provided by the Manufacturer

The second option is for the manufacturer to install a retrofit kit that will upgrade the SCADA-Mate R1 switch into an R2 switch. Toronto Hydro does not recommend this option for the following reasons:

- The retrofit kit can only be installed by the manufacturer at its facilities; therefore, this option requires the switch to be removed from the pole and to be delivered to the manufacturer. A replacement R2 switch from storage would have to be installed in place of the removed R1 that has been shipped for retrofitting. When the manufacturer returns the retrofitted switch, it would then be installed in another location. This process is costly and time consuming.

- The retrofit kit does not upgrade all the components of the switch; it only upgrades the motor operator to the R2 version. The motor operator is the source of where moisture and corrosion builds; however, if corrosion has spread to other parts of the unit, the switch will remain defective regardless of the retrofit.

The cost of retrofitting a switch is $3,600 less than the cost of replacing the switch. If further corrosion has occurred beyond the motor mechanism that is being replaced, the switch is deemed unsafe and would have to be scrapped, negating potential savings.

Option 3: Replace SCADA-Mate R1 Switches with New R2 Switches

The third option is to proactively replace the SCADA-Mate R1 switches with SCADA-Mate R2 switches. Toronto Hydro recommends this option because it addresses the safety, reliability and operational issues associated with the SCADA-Mate R1 switches and generates a net benefit of $100.66 million as explained below.

The cost of ownership (COO) and program net benefit (NPV) associated with the SCADA-Mate R1 Renewal program is further detailed in Table 5. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities in this program. The cost of ownership (COO) of a state reflects the risk of asset failure, including both direct and indirect costs; these costs include customer interruptions, emergency repairs, and asset replacements associated with a given state. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_N) state. Non-asset risks are further explained in Section D3.3. All of these factors combine

to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3.

When the difference in cost of ownership ($\hat{u}COO_1$) is compared to the associated program costs (PC_1) for the first of activities, SCADAMATE R1 Renewal produces a net benefit (NPV_1) value of $100.66 million, as shown in Tables 5 and 6.

TABLE 5: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	334.82
Non Asset Risk [NAR_E]	1023.04
Maintenance Cost [MC_E]	0
Additional Quantifiable Benefits [AQB_E]	0
Cost of Ownership of Existing Assets [COO_E]	1357.87

TABLE 6: SCADAMATE R1 REPLACEMENT BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: SCADAMATE R1 Replacement (N)	
Asset Risk [AR_N]	283.79
Non Asset Risk [NAR_N]	967.26
Maintenance Cost [MC_N]	0
Additional Quantifiable Benefits [AQB_N]	0
Cost of Ownership of New Assets [COO_N]	1251.05
Option 1: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	106.82
Program Cost [PC_1]	6.16
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	100.66

E6.8.7 2015 Project Details

Table 7 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved SCADA-Mate R1 Switches segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 7: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	CIR Projects
1.72	4.44

In total, the 2015 work program is targeting the replacement of 72 SCADA-Mate R1 switches. Table 8 lists all projects that will be partially or completely executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

E6.9 Network Vault Renewal

EQUIPMENT PLACEMENT IN NEWLY BUILT VAULT

E6.9.1 Summary

Program Description

The Network Vault Renewal program is a continuation of the network vault rebuild and decommissioning activities previously detailed in Phase 1 and 2 of Toronto Hydro's 2012-2014 ICM application. The projects that comprise this program are identical in nature to the jobs in the Network Vaults and Roofs segment approved by the OEB in EB-2012-00641.

The network vaults associated with the secondary network system were constructed in the 1950s and 1960s, mainly beneath the sidewalks in the busy downtown Toronto core. The function of the network vaults is to provide physical isolation from energized Toronto Hydro equipment. Today, there are many critical structural issues inherent with the condition of these assets, which must be addressed in order to mitigate (1) potential failure risks that can negatively impact the reliability and effective operation of Toronto Hydro's distribution system and (2) potential safety risks to the public and Toronto Hydro's crews.

The Network Vault Renewal program is designed to address these condition related issues when they can no longer be mitigated by routine maintenance. The function of the network vaults is to provide physical isolation from energized Toronto Hydro equipment. The vaults identified for

[1] EB-2012-0064, Tab 4, Schedule B9.

renewal in this program require one of the following three interventions during the 2015-2019 period.

(1) Toronto Hydro plans to decommission two vaults where load displacement has eliminated the need for the vaults.

(2) Toronto Hydro plans to rebuild 15 network vault roofs that have been identified as having severe structural deficiencies, but which are located on network vaults that are otherwise structurally sound.

(3) Toronto Hydro plans to rebuild 40 network vaults that have been identified as having severe structural deficiencies requiring a complete reconstruction. These vaults cannot be decommissioned, but require more extensive repairs beyond a vault roof replacement.

The anticipated benefits of the Network Vault Renewal program are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Helps ensure physical isolation from Toronto Hydro equipment for heavy pedestrian traffic ƒ Ensures safe and uninterrupted passage for pedestrians, as a deteriorated vault structure may need to be cordoned off, causing interruption in pedestrian traffic
Reliability	ƒ Reduction of failure risk; outages related to deteriorated network vaults can affect power supply to approximately 500 to 3000 customers ƒ New standards implemented to build two separate adjacent civil structures for vaults with two transformers will help safeguard against vault fires spreading from one transformer to the other
Safety	ƒ Helps safeguard the public and Toronto Hydro crews against tripping hazards ƒ Mitigation of slipping and falling hazards, especially in bad weather. ƒ Toronto Hydro vaults are designed as per "Canadian Highway Bridge Design Code" CSA-S6-06 CL-625 ONT Live Loading. During emergencies, a fire truck may be required to park over the sidewalk where the vault is located. In such a case, a badly deteriorated vault roof and structure may not be able to hold the load of a fire truck and thus compromise the emergency response team's ability to provide services
Efficiency	ƒ New standard galvanized beams used for roofs are expected to age at a slower rate than non-galvanized beams ƒ Fibreglass rebar is being investigated for use in 2015-2019 projects; this will help reduce the aging process due to corroding metal rebar

Program Drivers

The trigger and secondary drivers for Network Vault Renewal program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	Failure Risk	ƒ 80% of the vault roofs are over 25 years old. ƒ Over 60% of the vaults will be 60 years or older within 10 years. ƒ Accelerated aging of some vaults has been observed ƒ Poor vault condition is expected to contribute to the poor condition of electrical assets housed inside the vault, impacting reliability of distribution system
Secondary Drivers	Safety	ƒ Risk of tripping and slipping to the public and Toronto Hydro employees

Preferred Alternative

Toronto Hydro evaluated the following alternatives for addressing the assets in this program:

(1) Continue with routine maintenance repairs until such time that reactive replacement is required, typically after a structural failure.

(2) Renew the network vaults which are in poor condition before there is a structural failure.

Option II is the preferred alternative as it reduces the risk of injury to the public and Toronto Hydro employees, while also reducing the risk to system reliability due to asset failure.

The completion of the first year of activities in this program will result in an avoided estimated risk cost (ARC) of $4.63 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.9.7).

Timing and Pacing

Toronto Hydro invested $17.02 million in network vault renewals between 2010 and 2013. The investment level for 2014 is forecasted to be $0.93 million, which is lower than previous and future amounts due to resource constraints. The amount and pace of future spending is based on

need that was evaluated using the ACA and additional civil assessments. Thus, Toronto Hydro plans to rehabilitate 57 of the highest risk vaults during this planning horizon.

Table C provides historical and projected program spending.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	1.69	0.87	3.65	10.81	0.93	3.95	10.37	10.29	10.25	10.24

Through its workforce staffing strategy (Exhibit 4A, Tab 4, Schedule 3), Toronto Hydro is working to ensure that the required resources are available to carry out a pace in 2016-2019 that is equivalent to what was achieved in 2013. Renewing at this pace will allow Toronto Hydro to address many of the vaults that require near-term proactive action given the utility's limited resources to perform this complex work. Given the relatively slow pace of vault rehabilitation relative to the age of the asset population, Toronto Hydro plans to continue to implement a rigorous network vault maintenance program to patch up deficiencies appearing in the increasing number of aging network vaults. This maintenance program includes inspection of network vault structures every six months and the issuance of work orders for required patch work to fix deficiencies.

E6.9.2 Program Description

The Network Vault Renewal program is a continuation of the network vault rebuild and decommissioning activities previously detailed in Phase 1 and 2 of Toronto Hydro's 2012-2014 ICM application. The projects that comprise this program are identical in nature to the jobs in the Network Vaults and Roofs segment approved by the OEB in EB-2012-0064.

The network vaults associated with the secondary network system were constructed in the 1950s and 1960s, mainly beneath the sidewalks in the busy downtown Toronto core. Today, there are many critical structural issues inherent with the condition of these assets, which must be addressed in order to mitigate (1) potential failure risks that can negatively impact the reliability and effective operation of Toronto Hydro's distribution system and (2) potential safety risks to the public and Toronto Hydro's crews

Toronto Hydro works to ensure that customers are not only supplied reliable electricity, but are also provided physical isolation from energized Toronto Hydro equipment. This is especially important in dense downtown core areas where pedestrian traffic can be heavy and many people rely on safe passage to make their way from one destination to another. If a vault roof or structure fails, it is highly likely to disrupt the pedestrian traffic resulting from rerouting of the walkway, which can be very challenging in busy downtown core areas. Degradation of these vaults can expose customers to hazards, such as tripping or more critical safety risks as further explained in section E6.9.3.

As vaults are inspected each year, maintenance to the civil structure is typically performed as needed to fix small problems and to further extend the life of a vault. However, once a vault reaches the point where there are major structural failures and maintenance can no longer sufficiently address the problem, Toronto Hydro considers one of three different options:

(1) Decommissioning the vault

(2) Rebuilding the vault roof

(3) Rebuilding the entire vault

Toronto Hydro also considers evolving customer needs and system requirements when choosing the best intervention for any given vault location.

With the 2015-2019 Network Vault Renewal program, Toronto Hydro plans to eliminate immediate structural vault deficiencies of 57 high risk vaults identified through Toronto Hydro's Asset Condition Assessment (ACA) process as being in "poor" or "very poor" condition. In

addition to the ACA process, Toronto Hydro carries out civil assessments wherein a civil engineer visually inspects the network vault roof and walls to recommend whether a roof or whole vault rebuild is required (see section E6.9.3.5 for additional details).

The 2015 to 2019 program includes decommissioning two vaults, rebuilding 15 vault roofs and completely rebuilding 40 vaults. Figure 1 shows the various projects forecasted to be completed during this timeframe. The estimated total cost of this program over 2015-2019 period is $45.1 million.

FIGURE 1: LOCATIONS OF NETWORK VAULT RENEWAL PROJECTS 2015-2019

The following subsections describe each of the three network vault intervention options in additional detail.

E6.9.2.1 Network Vault Decommissioning

Toronto Hydro plans to decommission two network vaults between 2015 and 2019 where load displacement has eliminated the need for the vaults. This will remove any structural deficiencies associated with these vaults and any corresponding system reliability or safety issues for both Toronto Hydro crews and pedestrians.

Load displacement on the original secondary network system is largely due to development in the downtown area. When buildings in the city are redeveloped, the low voltage network connection is typically no longer a viable option for the customer. This is because redeveloped or new buildings usually have a customer-owned substation inside the building, with a supply configuration that is either 'dual radial' or 'spot network'. If Toronto Hydro no longer requires the secondary network system capacity from a specific vault, that vault can be decommissioned. The typical cost to decommission a vault is approximately $50,000 and it takes approximately one month to perform the work. Decommissioning a network vault involves removing the network transformer and protectors within the vault, along with primary and/or secondary cables. The empty vault is then backfilled with gravel, and the sidewalk overtop is rebuilt. Figure 2 below shows a vault in the process of being decommissioned.

FIGURE 2: IN-PROGRESS VAULT DECOMMISSIONING

E6.9.2.2 Network Vault Roof Rebuild

Toronto Hydro plans to rebuild 15 network vault roofs between 2015 and 2019 that have been identified as having severe structural deficiencies (see section E6.9.3 for additional details), but which are located on network vaults that are otherwise structurally sound. A network vault roof rebuild is not as complex as a complete vault rebuild, but replacement or re-arrangement of the secondary and primary cables within the vault is still required. This involves the removal of the existing damaged roof and replacement with a new vault roof.

Rebuilding the network vault roof can take between three and nine months to perform because (1) a temporary roof (refer to Figures 3, 4 and 5 below) must be constructed to protect the vault equipment, cables and fuse panels, (2) work restrictions prevent work during peak pedestrian times, and (3) extensive precautions are required due to work safely around live electrical equipment. The work also involves removing any Asbestos-Insulated Lead-Covered (AILC) secondary cable and Paper-Insulated Lead-Covered (PILC) primary cables, installing new primary and secondary cables, rebuilding the actual vault roof and rebuilding the adjoining sidewalk. New standard galvanized beams are also used to hold the roof slabs in place, which help reduce the rate of corrosion caused by seepage of salty water. The typical cost of rebuilding a vault roof is approximately $250,000.

While the overall network vault has a useful life of 60 years, network vault roofs must be rebuilt more frequently because of their relatively modest useful life of 25 years. The useful life for a vault roof is shorter because it undergoes significantly more stress from pedestrian traffic, snowplows and salting.

Figure 3 shows a vault roof during a rebuild process. The roof is in the process of being demolished while a temporary roof is put in place to cover the electrical assets housed inside the vault. Figures 4 and 5 show a new roof in the rebuilding phase and a completed vault roof.

FIGURE 3: TEMPORARY ROOF BEFORE NEW ROOF IS BUILT

FIGURE 4: TEMPORARY ROOF BEFORE NEW ROOF IS BUILT

FIGURE 5: COMPLETED VAULT ROOF

E6.9.2.3 Network Vault Rebuild

Toronto Hydro plans to rebuild 40 network vaults that have been identified as having severe structural deficiencies requiring a complete reconstruction. These vaults cannot be decommissioned, but require more extensive repairs beyond a vault roof replacement.

A complete rebuild or relocation of defective network vaults in some cases requires rebuilding the neighbouring cable chamber, installing new ducts and replacing both the primary cables and secondary grid cables. Also, in order to maintain power to customers during a vault rebuild, Toronto Hydro must install additional secondary cables from the network grid or add additional temporary transformers in an adjacent vault.

In some cases, the vaults will be rebuilt in the original location and existing auxiliary civil infrastructure will be maintained. In other cases, a new vault, along with auxiliary civil infrastructure, will be constructed in a new location, and the old vault will be decommissioned. In general, Toronto Hydro will replace the existing network units with new network units at the time of a full vault rebuild. This is done to avoid the planning inefficiencies inherent in returning to the same site for unit replacement at a later date. Older network vaults typically contain aging network units; however, to ensure that asset value is maximized, Toronto Hydro assesses the

remaining useful life of the removed network units and keeps a number of units with useful life remaining on hand for use in reactive replacement scenarios.

The rebuilt vaults are redesigned according to current design and construction standards. For example, Toronto Hydro currently uses galvanized steel I-beams instead of regular steel to support the vault roof, which addresses the problem of rapid corrosion caused by sidewalk salt exposure. Toronto Hydro has also updated its standards to rebuild vaults originally containing two transformers as two separate, adjacent civil structures. This will help mitigate the risk of a potential fire damaging all equipment within the vault, as a potential fire from one side will not be able to affect equipment on the other side. Furthermore, in an effort to continuously improve standards to extend the useful life of the assets, Toronto Hydro plans to investigate the use of fiberglass rebar to further enhance the vault roof and walls structure. This new material standard for vaults is expected to address problems with rebar corroding rapidly from salt exposure. Furthermore, reduction in corrosion of rebar will reduce the cost of maintenance and increase safety for Toronto Hydro crews. The investigation for this standard should conclude by the end of 2014 and the new standard is tentatively planned for deployment in 2015 to 2019 projects. The ventilation grade of vaults will also be redesigned to meet the latest applicable by-laws.

The typical cost for rebuilding a vault, including both civil and electrical work, is approximately $1 million, which includes the average costs for both civil and electrical plant replacement in adjacent network vaults. Depending on the complexity of the job, Toronto Hydro estimates that it will take between 18 and 24 months to complete a vault rebuild job (refer to section E6.9.6 for additional details). Figure 6 illustrates a fully rebuilt vault.

FIGURE 6: COMPLETELY REBUILT VAULT

Table 2 summarizes the number of assets forecasted for replacement during the 2015-2019 period.

TABLE 1: ASSETS TO BE RENEWED

Assets (Units)	2015	2016	2017	2018	2019	Total
Vaults	6	9	9	9	9	42
Roofs	4	2	2	3	4	15
UG Network Units	11	18	17	20	20	86

The Network Vault Renewal program delivers customer value in a number of ways, including improved reliability, safety and efficiency. A summary of these program benefits is provided in Table 3.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Ensures physical isolation from Toronto Hydro equipment for heavy pedestrian traffic ƒ Ensures safe and uninterrupted passage for pedestrians, as a deteriorated vault structure may need to be cordoned off, causing interruption in pedestrian traffic ƒ The completion of the first year of activities in this program will result in an avoided estimated risk cost (ARC) of $4.63 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.9.7).
Reliability	ƒ Structurally sound network vaults provide protection against physical damage to electrical equipment ƒ Reduction of failure risk; outages related to deteriorated network vaults can affect power supply to approximately 500 to 3000 customers ƒ New standards implemented to build two separate adjacent civil structures for vaults with two transformers will help safeguard against vault fires spreading from one transformer to the other
Safety	ƒ Helps safeguard the public and Toronto Hydro crews against tripping hazards ƒ Mitigation of slipping and falling hazards, especially in bad weather. ƒ Safer environment for Toronto Hydro crews working inside the network vaults, specifically from falling debris. ƒ Toronto Hydro vaults are designed as per 'Canadian Highway Bridge Design Code' CSA-S6-06 CL-625 ONT Live Loading. During emergencies, a fire truck may be required to park over the sidewalk where the vault is located. In such a case, a badly deteriorated vault roof and structure may not be able to hold the load of a fire truck and thus compromise the emergency response team's ability to provide services
Efficiency	ƒ New standard galvanized beams used for roofs are expected to age at a slower rate than non-galvanized beams ƒ Fibreglass rebar is under investigation, which Toronto Hydro anticipates using 2015-2019 projects; this will help reduce the aging process due to corroding metal rebar ƒ Avoided high costs of emergency repairs

E6.9.3 Why the Program is Needed

Network vaults are a critical part of Toronto Hydro's secondary network system, especially in the downtown core. The vaults house various types of underground equipment, including network unit(s), automatic transfer switches (ATS), reverse power breakers (RPB) and compact radial design (CRD) assets. Most of these vaults were built nearly 50 to 60 years ago and, in certain cases, network vaults have reached an unacceptably low level of physical integrity. These

conditions increase the risk of structural failure, which may cause network equipment to fail and may pose an increased risk of injury to the public and Toronto Hydro employees.

E6.9.3.1 Program Drivers

Toronto Hydro has classified the continuing Network Vault Renewal program as a System Renewal activity because the assets being addressed require immediate replacement due to age and condition. Failure risk is therefore identified as the trigger driver, with safety as a secondary driver. Table 3 explains the drivers in further detail.

TABLE 3: PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	Failure Risk	ƒ 80% of the vault roofs are over 25 years old. ƒ Over 60% of the vaults will be 60 years or older within 10 years. ƒ Accelerated aging of some vaults has been observed ƒ Poor vault condition is expected to contribute to the poor condition of electrical assets housed inside the vault, impacting reliability of distribution system ƒ At risk electrical assets include critical secondary network equipment, e.g. ATS, RPB, CRD, cable, etc.
Secondary Drivers	Safety	ƒ Risk of tripping and slipping to the public and Toronto Hydro employees ƒ Falling debris hazard for workers inside vaults

The structural deficiencies of the vaults that Toronto Hydro continues to address through this program are mainly caused by old age and the adverse environment. Over 80% of vault roofs have reached the end of their expected useful lifespan of 25 years. In addition, over 60% of the vault civil structures will have reached the end of their expected useful lifespan of 60 years within 10 years. As well, the ACA suggests that some vaults have been aging at an accelerated pace and require repairs even though they have yet to reach their expected end-of-life age of 60 years. These vaults are generally located in high pedestrian areas under sidewalks in the downtown core that are excessively salted in the winter to melt ice and snow. When melted, this salted water drains into the vaults, corroding and damaging the vault structure.

A network vault provides the necessary foundation for the assets contained within; a poor condition vault is expected to contribute to the poor condition of electrical assets housed inside the vault (e.g., network units, ATS, RBP, CRD assets, cables, etc.). Therefore, poor structural

condition of the vaults may lead to failure of the electrical equipment housed inside the vault, causing prolonged power outages and severely impacting the reliability of the distribution system.

Some commonly found structural deficiencies caused by asset aging and environmental factors are explained below in the following sections.

(i) Exposed Roof Rebar

Exposed roof rebar weakens the vault's roof structure and can potentially lead to the collapse of the entire network vault roof, which may damage the equipment in the vault and may pose a risk to pedestrian and Toronto Hydro crew safety, as they could suffer injuries by tripping on the crumbling or depressed vault roof. Furthermore the workers inside the vaults could face hazard from falling debris. Figure 7 shows exposed rebar on the inside of a network vault roof.

FIGURE 7: ROOF EXPOSED REBAR

(ii) Exposed Wall Rebar

The walls within a network vault are critical to the load bearing capability of the entire vault. Corrosion of the rebar within these walls significantly weakens the structural integrity of the vault as a whole. Over time, corrosion can result in the collapse of the vault walls, which may damage

the electrical assets contained within, causing a power outage and costly repairs. Figure 8 shows an example of a network vault wall with exposed rebar.

FIGURE 8: NETWORK VAULT WALL WITH EXPOSED REBAR

(iii) Corroded I-Beams

The I-beam is the major support structure for the vault roof. In addition to age, environmental factors can accelerate the corrosion of an I-beam, e.g., salt used to melt snow that seeps through the roof. This could lead to a failure of the I-beam, which may result in the complete collapse of the roof. Figure 9 below shows a heavily corroded I-beam.

FIGURE 9: CORRODED I-BEAMS

(iv) Cracked roof

A cracked roof can result in water leaking into the vault. This can accelerate the degradation of rebar and I-beams and may also lead to rusting, contamination and degradation of the electrical assets inside. Leaking water may also increase the risk of catastrophic failure of critical electrical assets such as network units. (A network unit consists of a protector and transformer, where the protector works like an automatic breaker.) If this equipment is damaged, the supply to the customer may be disrupted. In addition, pedestrians may trip and fall due to the uneven surface caused by the cracks. These risks are further illustrated in Figure 10 below.

FIGURE 10: CRACKED ROOF

(v) Cracked Wall

When a network vault wall develops cracks it increases the likelihood of water entering the vault, which may ultimately result in vault flooding, thus potentially causing a short circuit and overall outage to the secondary network system. Figure 11 illustrates a typical crack found inside a Toronto Hydro vault.

FIGURE 11: CRACKED WALL

Deferring the proposed vault and vault roof rebuild activities will likely increase the risk of structural failure that can lead to catastrophic failure of the network assets contained within the vault, ultimately leading to power outages in the downtown core.

E6.9.3.2 Asset Details

(i) Asset Lifecycle

In addition to tracking the age of its assets, Toronto Hydro analyzes the useful life of network vaults through its Asset Condition Assessment (ACA) program and additional physical inspections by civil engineers. The ACA uses inspection data to determine the condition of an asset and to drive replacement of that asset at the optimal time. The ACA for network vaults classifies vaults requiring major civil rebuilding as "very poor" or "poor". Along with ACA results, civil assessment reports have been used to prioritize vaults that require partial or complete rehabilitation. Civil assessments are carried out in addition to the ACA process by a certified civil engineer. During the assessments, a civil engineer physically conducts a visual inspection of the network vault roof and walls and comments on the extent of damage and deterioration to all parts of the vault structure. Based on these comments, the engineer recommends a roof or whole vault rebuild. When a project scope is issued, a copy of this report is attached with the package.

The replacement of a network vault may take up to 24 months to complete because of the complexity of rebuilding civil and electrical infrastructure in the downtown core. This long project timeframe necessarily means that planning for network vault rehabilitation must begin well in advance of execution.

Currently, Toronto Hydro has 1,067 network vaults in the downtown core supplying the network system. Figure 12 shows the age distribution of all network vaults with reference to the useful life of both the overall vault and the roof. While a vast majority of vaults have reached or are quickly approaching their expected end-of-life age (60% will have reached end-of-life within ten years or less), a majority (80%) of network vault roofs are already well past the vault roof expected life of 25 years and in need of a rebuild. The ACA also suggests that some vaults have been aging at an accelerated pace and require repairs even though they have yet to reach their expected end-of-life of 60 years.

Toronto Hydro plans to address six per cent of all existing network vaults between 2015 and 2019.

FIGURE 12: DISTRIBUTION OF NETWORK VAULTS

(ii) Asset Failure Impacts

As described in section E6.9.3.1, there are several failure modes and deficiencies that may lead to structural failure leading to failure of the equipment inside the vault. These failure modes are classified as exposed roof rebar, exposed wall rebar, corroded I-beams, cracked roof and cracked walls. Such damage to the network vaults is likely to negatively affect the performance of the electrical equipment contained inside, potentially contributing to a catastrophic failure of the network assets contained within the vaults and thereby causing a power outage in the downtown core. Such a power outage could impact between 500 customers (5 MVA) for smaller network grids, up to 3,000 customers (50 MVA) for the large network grids in the downtown core, and can last between several hours to a few days, depending on the location and which network distribution system is impacted by an outage. The cost of repairing the vaults under reactive circumstances – which must typically occur on weekends and during the night – are much higher than planning and performing the work during regular hours. It is also important to note that damage to equipment as a result of vault failures is often extensive (as in the case of vault fires,

for example), and tends to result in incremental costs beyond regular costs related strictly to the restoration of power.

Furthermore, deteriorated vaults may cause safety issues for the public as well as Toronto Hydro crews. Toronto Hydro values the safety of its customers and employees and takes its responsibility to ensure public safety around distribution plant very seriously. Poor condition network vaults must be rebuilt in a timely manner to avoid risk of failure and mitigate safety hazard to employees and the public.

Because these vaults are beneath sidewalks in the busy downtown core, any failure in the vault structure could cause a person to trip and fall, potentially onto hazardous areas. In addition, the risk of injury increases even more in the presence of rain and snow. To properly address this issue and maintain a high standard of safety for the customer, Toronto Hydro must address deteriorated vaults through the vault renewal program. Table 4 shows some of the potential safety risks that could occur due to deterioration of network vault structures.

TABLE 4: SAFETY RISK & DESCRIPTIONS

Safety Risk	Description
Tripping	A deteriorated vault roof may lead to tripping, which could cause injury to members of the public or Toronto Hydro crews.
Slipping	A deteriorated vault roof may lead to slipping, especially in bad weather, which could cause injury to the public or Toronto Hydro crews.
Falling	Tripping or slipping could cause a person to fall, which may result in more severe injury.
Falling Debris	Toronto Hydro crews working inside the vault may encounter falling debris from the deteriorated roof or walls of a given vault. This could lead to serious injury, especially when working near live equipment.
Fire	Poor condition of vaults can be a contributing factor to catastrophic failures such as vault fires.

The reliability of the Toronto Hydro network vaults civil structure is not only critical for the equipment housed inside the vaults but also for the safety of public and Toronto Hydro employees. For example if a vault roof is not replaced in time, later removing it to replace faulty equipment can cause it to collapse and thereby make it more dangerous and challenging for the crew to replace the equipment. In this scenario, the feeder providing power supply to the failed equipment will be turned off for longer periods of time, which will increase the risk of an outage to

the customers fed by that feeder. In order to maintain reliable service to the relevant customers, it is imperative that these assets be renewed before they fail.

Figures 13 and 14 below show the structural failure of a vault located in front of a bus shelter near a major intersection in North York (March 2010). To make this location safe, the hole in the vault roof was covered temporarily by a piece of plywood, and surrounded by pylons. This step was taken on an emergency basis until the location could be permanently fixed. This failure resulted in disruption to daily commuter traffic in the vicinity of the station and presented a potential safety hazard to pedestrians.

FIGURE 13: STRUCTURAL FAILURE OF VAULT LOCATED NEAR LAWRENCE/YONGE ST FRONT OF A BUS SHELTER, WITH PLYWOOD TEMPORARILY COVERING THE HOLE IN SIDEWALK

FIGURE 14: STRUCTURAL FAILURE OF VAULT LOCATED NEAR LAWRENCE/YONGE STREET, AS SEEN FROM WITHIN THE VAULT CHAMBER

Figure 15 below shows a network vault at another busy intersection downtown (April 2010) where a large piece of concrete has fallen off the vault wall. This was caused by a structural deficiency as a result of old age, as well as salt and water entering the vault through cracks in the vault roof and side walls. Falling concrete has the potential to cause damage to the electrical equipment resulting in power interruptions and creates a potential safety hazard for Toronto Hydro crews working inside the vault.

FIGURE 15: PHOTO OF A LARGE PORTION OF CONCRETE DETACHED FROM VAULT WALL KING/YONGE STREET

Figure 16 illustrates the failure of a vault roof located in a busy downtown area. The edges of the concrete roof cracked and fell into the vault. It was determined that both the beams and roof slabs had deteriorated due to old age and salt usage on the sidewalk during winter. As this failure occurred in a busy area with a large amount of pedestrian traffic, it posed a potential safety risk to the public.

FIGURE 16: PHOTO OF A VAULT ROOF COLLAPSED DUE TO FAILED SUPPORTING BEAM

E6.9.4 Timing & Pacing of the Program

As per the table below, the total cost of this program over the 2015-2019 period is $45.10 million.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending ($Million)					Future Spending ($Million)				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	1.69	0.87	3.65	10.81	0.93	3.95	10.37	10.29	10.25	10.24

Prior to 2010, Toronto Hydro replaced network vaults on a reactive basis. In 2010, Toronto Hydro established a proactive network vault renewal program in order to deal with the growing backlog of network vaults reaching end-of-life. Toronto Hydro expects 60% of the total population of 1,067 vaults will have reached their end-of-life during 2015 to 2019 period. To manage the reliability and safety risks associated with the high number of end-of-life vaults and vault roofs, Toronto Hydro must maintain a steady pace of proactive vault rehabilitations, complimented by an efficient maintenance program, during the forecast period and beyond.

Toronto Hydro invested $17.02 million in network vault renewals between 2010 and 2013. The investment level for 2014 is forecasted to be $0.93 million, which is lower than previous and future amounts due to resource constraints. The amount and pace of future spending is based on need that was evaluated using the ACA and additional civil assessments. Toronto Hydro plans to rehabilitate 57 of the highest risk vaults during the planning horizon. This includes decommissioning two vaults, rebuilding 15 vault roofs and completely rebuilding 40 vaults.

Through its workforce staffing strategy (Exhibit 4A, Tab 4, Schedule 3), Toronto Hydro is working to ensure that the required resources are available to carry out a pace in 2016-2019 that is equivalent to what was achieved in 2013. Renewing at this pace will allow Toronto Hydro to address many of the vaults that require near-term proactive action given the utility's limited resources to perform this complex work. Given the relatively slow pace of vault rehabilitation relative to the age of the asset population, Toronto Hydro will continue to implement a rigorous network vault maintenance program to patch up deficiencies appearing in the increasing number of aging network vaults. This maintenance program includes inspection of network vault structures every six months and the issuance of work orders for required patch work to fix deficiencies.

E6.9.4.1 Ranking & Prioritization

Toronto Hydro considers several factors when determining the sequencing of work within the Network Vault Renewal program. Some factors may be considered before others depending on the situation. However, generally, asset condition, municipal planning and customer type are considered as primary prioritization criteria. These factors are described as follows:

- Asset Condition and Safety: Asset age and condition are both determining factors when prioritizing network vault rehabilitation projects. Deterioration of a network vault poses potential safety risks to the public and Toronto Hydro employees, and can negatively affect system reliability and customer satisfaction.

- Municipal Planning: City of Toronto moratoriums are another important consideration. Specific moratoriums may already be in effect or will come in to effect during the planning and execution period of 2015 to 2019. These are generally road moratoriums where a newly paved road is not allowed to be repaved for a set period of time. Toronto Hydro coordinates with the city to obtain permits in order to perform vault rebuilds and a permit may or may not be granted based on the existing moratoriums. Toronto Hydro works with

the City to anticipate moratoriums so that projects can be appropriately advanced or deferred in coordination with pending roadwork.

- Customer Type: The type of customer is also an important factor in prioritizing projects. For example, if the customer is a hospital, that would likely result in the project being given higher priority.

E6.9.5 Program Execution

A network vault renewal project may involve decommissioning a vault, rebuilding a roof or rebuilding a whole vault. The process of decommissioning and roof rebuilding has been described in sections E6.9.2.1 and E6.9.2.2 respectively. Execution of a vault rebuild project is a more complex process that can take up to 24 months from start to finish and requires resources with specialized skills. The planning stages of the project include coordination with the city, obtaining construction permits, scheduling outages, allocating extra distribution capacity to handle contingency situations and maintaining uninterrupted supply to the customers fed from the vault being rebuilt.

Another important consideration is to ensure that the work is scheduled so that during the summer peak months vault rehabilitation work does not compromise the Toronto Hydro grid. The utility has specific summer restrictions, where operations is notified to ensure that certain feeders are flagged as at risk for being overloaded in case of a contingency situation during peak hours or summer days.

The construction process itself is complex and requires the mitigation of risks to worker and pedestrian safety while Toronto Hydro carries out construction. Figures 17 through to 22 illustrate the process of rebuilding the vault and demonstrate the complexity of the project execution in the construction phase.

Figure 17 below shows a construction crew demolishing the roof and walls. It should be noted that in many cases, as shown below, the secondary cables supplying the customers remain connected during construction of the new vault and must be protected to ensure uninterrupted supply. This requires extra caution and time to demolish and reconstruct the vault.

FIGURE 17: VAULT ROOF & WALLS BEING DEMOLISHED

Furthermore, Figure 18 below shows the new rebar framing being installed to serve as the base for the grout used to form the vault's wall and roof. Special care must be taken when installing and aligning the framing to ensure that walls and roofs are built to the design specification and hence are structurally sound. Any duct banks connected to the vault walls must also be maintained.

FIGURE 18: REBAR FRAMING FOR NEW WALLS AND ROOF

In Figure 19 below, the grouting process is illustrated, where grout is a mixture of water, cement, sand and gravel. This is another critical step in the construction process where the crew must ensure that the rebar framing is filled with grout uniformly without air pockets. If this is not done properly, it can result in unforeseen structural deficiencies.

FIGURE 19: GROUTING FOR VAULT WALLS AND ROOF

Fully cured walls and parts of the roof are shown in Figure 20 below. The crews have removed the wooden framing and the vault is prepared for the transformers and auxiliary equipment to be installed.

FIGURE 20: FINISHED WALLS & PARTIALLY COMPLETED ROOF

Figure 21 below shows the network unit (transformer mounted with network protector) being placed in the vault. A crane is used to lift and lower the equipment in the vault. The crane blocks one or two lanes on the adjacent roadway.

FIGURE 21: PLACEMENT OF EQUIPMENT IN THE NEWLY BUILT VAULT

Lastly, the following pictures illustrate a completely rebuilt vault, with the area surrounding the vault fully restored.

FIGURE 22: COMPLETELY REBUILT VAULT

E6.9.5.1 Proposed Work Plan

Table 6 below shows the number of different projects planned for completion during the 2015-2019 period. Further details on 2015 projects can be found in section E6.9.8.

TABLE 6: 2015-2019 LONG TERM PLAN

Year	Vault Decommissioning	Vault Roof Rebuild	Vault Rebuild
2015	2	4	4
2016	0	2	9
2017	0	2	9
2018	0	3	9
2019	0	4	9

E6.9.5.2 Program Risks

Throughout the program planning and execution process, a number of implementation risks are considered. Some of these risks can be mitigated during the planning phase of the project and others can impact the project at later stages. Some of the risks include:

- Moratoriums: As noted earlier, and although existing moratoriums by the City of Toronto are considered when planning for the vault renewal projects, it is possible that new moratoriums are introduced after the planning has been completed. This can result in delays to the work. To mitigate this risk, Toronto Hydro continuously receives information about moratoriums from the city. This helps Toronto Hydro better plan and execute projects within the allotted window before or after the moratorium.

- Summer Restrictions: Toronto Hydro imposes switching restrictions on certain feeders during the summer months when peak load demand is highest. In other words, the switching off of any restricted feeders may cause overloading on other vaults in the distribution grid during summer peaks and these feeders therefore cannot be turned off for any planned work or operations. If the vault being planned for rebuild is fed from one of the restricted feeders, then the work can only be conducted in the off-peak times and this may hinder the execution of a given project. Toronto Hydro's Load Demand program for 2015-2019 (Section E5.4 of the DSP) is intended to help mitigate these risks by enhancing the grid so that feeder restrictions during the summer peak times are minimized.

- Metrolinx Subway Expansion: Projects such as the expansion of the subway system in Toronto are especially challenging to plan for, as these projects have a dynamic decision making process which can take decades to conclude. When such large projects are in the execution phase, the City or Metrolinx may impose a moratorium to suspend all planned capital work until critical phases of subway expansion projects are completed. In

addition, relocation of Toronto Hydro assets in order to accommodate construction of the subway may have consequences for how a vault rebuild has been planned and designed by Toronto Hydro. To mitigate this risk, Toronto Hydro communicates with Metrolinx throughout the year to ensure that the impact of development work by Metrolinx on the Toronto Hydro projects is minimal.

Toronto Hydro has considered each of these program risks when developing the five-year plan for network vault renewals.

E6.9.6 Evaluation of Alternatives

E6.9.6.1 Quantification/Evaluation of Options

There are two ways that Toronto Hydro can address poor condition network vaults going forward. The first option is to maintain the network vaults in the current known conditions and the second option is to proceed with rebuilding the network vaults prior to failure. Both of these options are discussed below in further detail.

(i) Status Quo

Under the status quo option, Toronto Hydro would continue to maintain the network vaults in their current state. Maintenance of the vaults involves structural patching up of the roof, wall(s) and/or floor as triggered by network vault inspections conducted two times a year. Because the vaults proposed for renewal are in "poor" to "very poor" condition, maintaining rather than rebuilding will inevitably increase the risk of structural failure, which may lead to failure of the equipment housed inside the vaults. Furthermore, the safety issues such as tripping and falling, for both the public and Toronto Hydro crews, may become more likely. Toronto Hydro will be required to resolve these issues reactively, incurring higher costs and unplanned interruptions of supply to the customers.

(ii) Renew Network Vaults

Toronto Hydro's program to proactively renew the highest risk network vaults, which are in "poor" to "very poor" condition, will reduce the risk of injury to the public and Toronto Hydro crews and the risk to system performance due to asset failure. The replacement of the network vaults in the first year of the program will result in an avoided estimated risk cost (ARC) of $4.63 million, as detailed in Table 7. This value represents the avoided cost of executing the first year of activities

as scheduled as opposed to deferring these activities until 2020. The ARC is representative of the economic prudence of executing the activities within the program when compared to the programs' associated capital costs, taking into account the risk costs to the customer due to power outages. These avoided costs include quantified risks, taking into account the assets' probability of failure, and multiplying this by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. A positive ARC value is indicative of a reduction in impacts due to outages to customers through the renewal of the assets within this program. Further detail on the ARC approach is provided in Section D3.3. These investments will also result in long term benefits for the civil structures of the vaults as well as the equipment housed inside them. Such benefits include longer expected life for the civil structure of the vault as well as the electrical equipment by using improved standards and materials.

TABLE 7: BCE RESULTS

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$ 5.04
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$ 0.41
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - NET_COST(First Year of Activity))]	$ 4.63

E6.9.7 2015 Projects

Table 8 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

- previously filed projects that appeared as jobs in the OEB approved Network Vaults and Roofs segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and
- projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 8: 2015 PROGRAM COST

Years	2015 CAPEX ($M)	
	ICM Projects	CIR Projects
CAPEX	3.48	0.47

Table 9 lists all projects that are expected to be partially or completely executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 9: 2015 PROJECTS

Estimate Number	Project Name	Total Project Cost	Start Date	Project Type (ICM or CIR)
X12263	X12263 Vault Loc#Z0005, Rebuild Vault Roof Danforth/Coxwell	$179,643	2015	ICM
X12289	X12289 New Vault - Adelaide St. West Loc #4412	$606,108	2015	ICM
X12830	X12830 Loc#4432 vault rebuild 2013	$1,227,692	2015	ICM

X14602	X14602 - Abandon vaults 4325 and 4330 Ph2 (civil)	$102,822	2015	CIR

The following map shows the locations of all Network Vault Renewal projects planned for 2015. Further details are provided for the 2015 projects in the following subsections.

FIGURE 23: LOCATIONS OF NETWORK VAULT RENEWAL PROJECTS 2015

E6.9.7.1 X12263 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X12263 Vault Loc#Z0005, Rebuild Vault Roof Danforth/Coxwell

Project Number: X12263 (ICM)

Project Year: 2015

Estimated Cost: $179,643

(i) Objective

This project rebuilds the roof for vault location Z0005, located at a very busy downtown intersection near a bus stop. Completion of this project will help improve the asset condition and greatly reduce safety risk to the public and Toronto Hydro crew.

(ii) Scope of Work

TABLE 10: X12263 SCOPE OF WORK DETAILS

District Neighborhood	DANFORTH AVE. & COXWELL AVE.
Station(s)	MAIN
Feeder(s)	A736M, A738M

TABLE 11: X12263 ASSETS REPLACED

Assets (Units)	2015
Roof	1

(iii) Justification & Benefits

Vault Z0005 is located at a busy downtown intersection of Danforth Ave. and Coxwell Ave. This vault is part of the sidewalk next to a bus station and hence exposed to very high volume of pedestrian traffic. Due to its location, the roof receives large quantities of salt in the winter; there is deterioration of the roof and I-beams that hold the roof slab in place.

Inspection of this location shows that large parts of concrete slabs of the roof have been destroyed and replaced by asphalt. Cracks at the bottom of the slabs are also visible and the I-

beams have severe corrosion requiring replacement. The figure below shows some instances of damage to the roof at this location.

FIGURE 24: DAMAGED ROOF SLAPS WITH CRACKS AND CORRODED I-BEAMS

Based on this information, the roof of vault Z0005 must be rebuilt to alleviate reliability and safety risks.

E6.9.7.2 X12289 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X12289 Loc #4412, Complete Vault Rebuild - Adelaide St. West

Project Number: X12289 (ICM)

Project Year: 2015

Estimated Cost: $606,108

(i) Objective

Vault at location 4412, located near Adelaide St. W. and Yonge St., has been assessed as severely damaged, raising reliability and potential safety concerns. Hence, by executing this project, Toronto Hydro plans to wholly rebuild this vault to minimize these concerns.

(ii) Scope of Work

TABLE 12: X12289 SCOPE OF WORK DETAILS

District Neighborhood	ADELAIDE ST. W. & YONGE ST.
Station(s)	GEORGE & DUKE
Feeder(s)	A4010 GD, A4610 GD

TABLE 13: X12289 ASSETS REPLACED

Assets (Units)	2015
Vault	1
UGN/W Units	2

(iii) Justification & Benefits

This is a 58 year old vault located at 11 Adelaide St. W. (intersection of Adelaide St. W. and Yonge St.) on a sidewalk. This is a busy downtown area with high pedestrian traffic.

The roof of the vault is covered by stone pavement and is in reasonably good condition. However, inspections show that the walls of the vault have severely deteriorated. This damage includes spalled concrete caused by age and exposure to salt and moisture. Furthermore the rebar of the

walls is exposed and rusted. Such damage may lead to failure of the structure causing damage to the electrical equipment and may compromise the safety of the public and Toronto Hydro crew. The figure below shows the severely deteriorated walls of this vault.

FIGURE 25: DAMAGED WALLS WITH SPALLING AND CORRODED REBAR

Considering the information above, this vault must be fully rebuilt to restore the integrity of the structure and maintain high reliability as well as minimizing safety risks to the public and Toronto Hydro crew posed by poor condition of the vault.

E6.9.7.3 X12830 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X12830 Loc#4432 vault rebuild

Project Number: X12830 (ICM)

Project Year: 2015

Estimated Cost: $1,227,692

(i) Objective

Vault 4432, located at the north east corner of King St. W. and John St., has damaged walls and a moderate level of deterioration on the roof. Completion of this project will rehabilitate this vault completely to help mitigate the risk its current condition poses to reliability and safety in this busy downtown area.

(ii) Scope of Work

TABLE 14: X12830 SCOPE OF WORK DETAILS

District Neighborhood	KING ST. & JOHN ST.
Station(s)	WINDSOR
Feeder(s)	A62 WR, A66 WR

TABLE 15: X142830 ASSETS REPLACED

Assets (Units)	2015
Vault	1
UGN/W Units	2

(iii) Justification & Benefits

Located in downtown Toronto, this vault is part of a busy sidewalk and also serves as a cover for isolation of electrical equipment from pedestrians. This vault has reached the end of its life as it is over 60 years old.

Furthermore, the inspection of the vault shows that its roof has deteriorated moderately with some patches of asphalt having been applied to repair the damage. However, the walls show clear signs of aging with cracks and spalled concrete. This vault poses a high risk of failure. Figures below show the extent of deterioration to the roof as well as walls of this vault.

FIGURE 26: REPAIRED ROOF AND LARGE CRACK IN THE WALL OF THE VAULT

FIGURE 27: SEVERE SPALLING OF CONCRETE AND EXPOSED RUSTED REBAR IN THE WALLS OF THE VAULT

The condition of this vault warrants a full rebuild. The risks posed to system reliability and to the safety of the public and Toronto Hydro crews will be mitigated by rebuilding this vault completely.

E6.9.7.4 X13692 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X13692 P13 Vault 4731 - Rebuild Roof

Project Number: X13692 (ICM)

Project Year: 2015

Estimated Cost: $178,605

(i) Objective

This project will rebuild the severely deteriorated roof of vault 4731.

(ii) Scope of Work

TABLE 16: X13692 SCOPE OF WORK DETAILS

District Neighborhood	OVERLEA BLVD & THORNCLIFFE PARK DR.
Station(s)	LEASIDE
Feeder(s)	A16L, A17L

TABLE 17: X13692 ASSETS REPLACED

Assets (Units)	2015
Roof	1

(iii) Justification & Benefits

This vault is located in the Thorncliffe area of Toronto, in the eastern part of the downtown core. Inspection of this vault show that the roof is in very poor condition. The roof has heavy damage to the seals around the slabs and wide cracks in the perimeter walls. In addition, wide cracks and large spalling areas are present at the bottom of slabs indicating advanced corrosion of rebar. Some I-beams are also heavily damaged by corrosion and degraded beyond repair. The figure below shows the deterioration of the vault roof.

FIGURE 28: SEVERELY CORRODED I-BEAM AND CRACKS IN THE ROOF SLAB

The condition of the vault roof presents a serious risk to the reliability of the system as well as to the safety of the public and Toronto Hydro crews. Therefore, the roof must be completely rehabilitated.

E6.9.7.5 X14591 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X14591 Vault Roof Rebuild, Loc 4830

Project Number: X14591

Project Year: 2015

Estimated Cost: $168,677

(i) Objective

To rebuild the roof of vault 4830 in order to minimize the tripping hazards and risk of failure.

(ii) Scope of Work

TABLE 18: X14591 SCOPE OF WORK DETAILS

District Neighborhood	QUEEN ST. E. & VICTORIA ST.
Station(s)	GEORGE & DUKE
Feeder(s)	A4-13 GD, A4-19 GD

TABLE 19: X14591 ASSETS REPLACED

Assets (Units)	2015
Roof	1

(iii) Justification & Benefits

This vault is located near Queen St. E. and Victoria St. with high volumes of pedestrian traffic. The inspection report for this vault shows that there is a tripping hazard because of the corrosion of the vents and deformations of concrete slabs. There is also risk of leakage from the roof cracks and corroded seals causing further corrosion of rebar, I-beams and the electrical equipment housed inside the vault. The figure below shows deteriorated roof and rusted rebar of the roof structure.

FIGURE 29: DETERIORATED ROOF (TRIPPING HAZARD) AND EXPOSED REBAR WITH CORROSION

Based on this information the roof of this vault must be rebuilt. Completion of this project is expected to result in a safe roof structure for both the equipment in the vault and the public.

E6.9.7.6 X14592 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X14592 Vault Rebuild, Loc 4210

Project Number: X14592 (ICM)

Project Year: 2015

Estimated Cost: $500,951

(i) Objective

To improve the reliability of the distribution system and increase the safety of the public and Toronto Hydro crew by rebuilding vault 4210 located in the busy downtown core of Toronto.

(ii) Scope of Work

TABLE 20: X14592 SCOPE OF WORK DETAILS

District Neighborhood	ADELAIDE ST. W & YONGE ST.
Station(s)	TERAULEY
Feeder(s)	A-B4-1A, A-B6-1A

TABLE 21: X14592 ASSETS REPLACED

Assets (Units)	2015
Vault	1
UGN/W Units	2

(iii) Justification & Benefits

This vault under a sidewalk is located at the intersection of Adelaide St. and Yonge St., which are two major arterial roads of Toronto with very high volume of pedestrian traffic. This area of the downtown core has an extensive distribution network of which vault 4210 is a part.

The vault is over 65 years old and the inspection shows that there is severe damage to the roof and walls. The roof has severe damage to the perimeter wall with one I-beam corroded beyond repair. Similarly, the walls of the vault show signs of aging with spalled concrete, corroded rebar

and cracks. The figure below shows some instances of damage to this vault. A full rebuild of the vault is required.

FIGURE 30: DAMAGE AND CRACKS ALL AROUND ROOF PERIMETER WALL. WALL WITH CRACKS AND EXPOSED CORRODED REBAR

E6.9.7.7 X14597 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X14597 Vault Rebuild, Loc 4258

Project Number: X14597 (ICM)

Project Year: 2015

Estimated Cost: $620,069

(i) Objective

To rebuild the aging vault 4258 completely, in order to minimize the risk of damage to electrical equipment inside and safety hazards posed to the public and Toronto Hydro crews.

(ii) Scope of Work

TABLE 22: X14597 SCOPE OF WORK DETAILS

District Neighborhood	ISABELLA ST. & YONGE ST.
Station(s)	CHARLES
Feeder(s)	A7 5 CS, A7 7 CS

TABLE 23: X14597 ASSETS REPLACED

Assets (Units)	2015
Vault	1
UGN/W Units	2

(iii) Justification & Benefits

Located at the busy intersection of Isabella St. and Yonge St., this vault is over 70 years old and is due for a complete rebuild. Records indicate that holes and cracks in the roof have been filled with asphalt and the steel I-beams have been affected by corrosion. Similarly, the walls of the vault have large cracks and corroded and exposed rebar. There is also spalling areas on the walls. Based on this information the vault structure is in a condition that poses a risk to system

reliability and to public and Toronto Hydro crew safety. The figure below shows some instances of the effect of aging.

FIGURE 31: CORRODED VAULT ROOF I-BEAMS AND DETERIORATED WALLS EXPOSED CORRODED REBAR

The optimal way of addressing the structural deficiencies and the safety risks posed to the public and Toronto Hydro crews is to rebuild this vault completely.

E6.9.7.8 X14587 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: Network Vault Roof Rebuild - LOC4872 A48H

Project Number: X14587

Project Year: 2015

Estimated Cost: $169,326

(i) Objective

This project rebuilds the roof of vault 4872. The newly built roof will minimize the safety risks to the public and Toronto Hydro crews.

(ii) Scope of Work

TABLE 24: X14587 SCOPE OF WORK DETAILS

District Neighborhood	ST. CLAIR AVE. E & YONGE ST.
Station(s)	HIGH LEVEL
Feeder(s)	A4-48 H

TABLE 25: X14587 ASSETS REPLACED

Assets (Units)	2015
Roof	1

(iii) Justification & Benefits

Records indicate that the roof of this vault has deteriorated beyond repair and must be rebuilt. There is heavy damage to concrete of the slabs and perimeter wall. This includes spalled concrete and heavy cracking in the perimeter wall of the roof. These conditions are a tripping hazard and there is a risk of failure that could damage the equipment inside the vault. The figure below shows damage on the vault roof.

FIGURE 32: DAMAGED ROOF PERIMETER WALL AND SLABS

E6.9.7.9 X14682 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X14682 - Abandon vaults 4325 and 4330 Ph1 (Elec)

Project Number: X14682

Project Year: 2015

Estimated Cost: $198,007

(i) Objective

To transfer electrical loads from the lightly loaded vaults 4325 and 4330 to the neighboring vaults fed by Windsor West (WR-W). Execution of this project will complete phase 1 of the project and mainly consists of electrical work.

(ii) Scope of Work

TABLE 26: X14682 SCOPE OF WORK DETAILS

District Neighborhood	SIMCOE ST. & DUNDAS ST. W.
Station(s)	CECIL AND WINDSOR
Feeder(s)	A5-50 CE, A5-51 CE, A6-51 WR, A6-52 WR

TABLE 27: X14682 ASSETS REPLACED

Assets (Units)	2015
No assets replaced	

(iii) Justification & Benefits

Located in the busy part of downtown Toronto, vaults 4325 and 4330 are over 79 and 65 years old respectively. This age is well past the end-of-life for vault structures of 60 years. Records show that the CE (Cecil) network along Simcoe St. is now very lightly loaded where these vaults are located. Extending the neighboring WR-W network north and picking up the load on the south end of CE (Cecil) network on Simcoe St. will allow Toronto Hydro to abandon vaults 4325 and 4330. Project X14602 (described in following subsection) will be executed to abandon these

vaults following completion of X14682. This project will result in better utilization of distribution network capacity and will provide service to customers from more structurally reliable vaults.

E6.9.7.9 X14602 Project Description

Investment Category: System Renewal

Program: Network Vault Renewal

Project Title: X14602 - Abandon vaults 4325 and 4330 Ph2 (civil)

Project Number: X14602

Project Year: 2015

Estimated Cost: $102,822

(i) Objective

To abandon vaults 4325 and 4330 as the load served by these vaults will be transferred to the neighboring network with the completion of X14682. Execution of this project will mainly consist of civil work.

(ii) Scope of Work

TABLE 28: X14602 SCOPE OF WORK DETAILS

District Neighborhood	SIMCOE ST. & DUNDAS ST. W.
Station(s)	CEL CIL
Feeder(s)	A5 50 CE, A5 51 CE

TABLE 29: X14602 ASSETS REPLACED

Assets (Units)	2015
Vault	2
UGN/W Units	3

(iii) Justification & Benefits

Vaults 4325 and 4330 are reported to be in severely deteriorated condition with ages of 79 and 65 years respectively. These vaults are located in an area with a high volume of pedestrian traffic and pose a safety risk to the public and Toronto Hydro crews and a risk to distribution system reliability.

The inspection report for vault 4325 indicates that the roof and walls are severely deteriorated with a severe crack in the west wall and corroded I-beams. The roof on the north side is severely damaged. Similarly, inspection report for 4330 shows that the vault roof is severely damaged with corroded I-beams and cracked slabs. The pictures below show the severity of the damage on both vaults.

FIGURE 33: DETERIORATED ROOF AND CRACKED WALL

FIGURE 34: DETERIORATED ROOF WITH SEVERELY CORRODED I-BEAMS

Rehabilitation of these vaults is projected to cost over $1 million. The optimal course of action is abandonment, given the change in loading conditions in the area..

This project is planned for completion once the electrical work has been completed as part of X14, during which the load served by these vaults will be transferred to the neighboring distribution network.

E6.10 Network Unit Renewal

VAULT FIRE EVENT

E6.10.1 Summary

Program Description

Toronto Hydro's Network Unit Renewal (NUR) program addresses obsolete and deteriorated Network Units that are at risk of failure. These Network Units have experienced degradation such that they are in poor condition and may not operate correctly going forward. Toronto Hydro plans to replace 240 Network Units during the 2015 to 2019 period. The Network Units to be replaced are classified as Fibertop Network Units (see Figure 1) and Semi-Dust-Type Network Units (see Figure 2).

The proactive replacement of certain Fibertop Network Units is an activity that was previously presented to the Ontario Energy Board (OEB) and approved in the Fibertop Network Units segment of Toronto Hydro's 2012-2014 ICM rates application[1]. The Network Unit Renewal program will complete the removal of Fibertop Network Units from the system.

Toronto Hydro plans to replace old and obsolete Network Units with modern Submersible Network Units first introduced in 2003.

The anticipated benefits of the Network Unit Renewal (NUR) program are as follows:

[1] EB-2012-0064, Tab 4, Schedule B10.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigation of reliability and safety risks for customers in the downtown area.
Reliability	ƒ Reduces the number of failures, including catastrophic failures that would otherwise impact the system.
Safety	ƒ Removing Fibertop Network Units are expected to reduce the risk of vault fires and explosions that could harm Toronto Hydro employees and the general public.
Efficiency	ƒ The Submersible Network Unit comes equipped with sensors that monitor the transformer and protector. These sensors allow controllers in Toronto Hydro's control room the ability to remotely view real time statuses such as flooding, temperature and loading.
Environmental	ƒ Leaking Network Units are expected to be replaced as part of this program and their vaults will be cleaned thoroughly prior to the installation of new Network Units.

Program Drivers

The trigger and secondary drivers for Network Unit Renewal (NUR) program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Primary Driver	Reasoning
Failure Risk	ƒ Network Units addressed by the program are aging and exhibit various signs of deterioration (i.e. protector contamination, corrosion, leaking oil, etc). ƒ Deterioration of Network Units leads to a heightened risk of failure that can have widespread and prolonged outage impacts.
Secondary Driver	**Reasoning**
Safety	ƒ A fire-related failure incident can expose Toronto Hydro employees and the general public to significant safety risks.

Preferred Alternative

Toronto Hydro considered the following alternatives for addressing aging and deteriorated Network Units.

(1) Continue to maintain existing deteriorated Fibertops and Semi-Dust-Type Network Units and replace each unit upon failure

(2) Address safety risks associated with deteriorating Network Units and improve the reliability and efficiency of the network system proactively.

Option II is the preferred alternative because it reduces the risk of injury to the public and Toronto Hydro employees, while also reducing the risk to system reliability due to asset failure.

The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $7.11 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.10.7).

Timing and Pacing

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	1.69	0.87	3.65	10.81	0.93	3.95	10.37	10.29	10.25	10.24

Toronto Hydro has approximately 1,892 Network Units in the distribution system. As is further discussed in Section D2 the expected useful life of a network unit is 30 years. In order to maintain an asset base that is within the expected useful life, Toronto Hydro plans to continue making replacements throughout the 2015 to 2019 period. Prior to 2012, Toronto Hydro executed Fibertop Network Unit replacements as part of wider network unit replacement initiative that included other types of heavily degraded end-of-life Network Units. The overall pace at which Network Units were replaced was about 50 units per year; Toronto Hydro will continue with this pace throughout the 2015 to 2019 period.

E6.10.2 Program Description

Toronto Hydro's Network Unit Renewal (NUR) program addresses obsolete and deteriorated Network Units that are at risk of failure. These Network Units have experienced degradation such that they are in poor condition and may not operate correctly going forward. Toronto Hydro plans to replace 240 Network Units during the 2015 to 2019 period. Table 1 shows the number of units forecasted for replacement each year during this period. The Network Units to be replaced are classified as Fibertop Network Units (see Figure 1) and Semi-Dust-Type Network Units (see Figure 2).

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Network Unit (Transformer and Protector)	40	50	50	50	50	240

Network Units are comprised of both a network transformer and a network protector. At least two Network Units are connected together to form a grid. For reliability purposes, customers connected to this grid receive supply from multiple sources. The network protector opens and isolates the secondary side of the circuit from the supply side should a fault be detected. This important action prevents reverse current flowing from the low-voltage secondary network grid, feeding the fault on the supply side of the circuit. If the protector fails to operate, the fault will continue to be fed, damaging the equipment.

Fibertop Network Units

Fibertop Network Units are designed such that their secondary terminals are placed directly on top of the protector component (see Figure 1). This design allows debris and salt to accumulate, which can cause tracking between phases that can lead to a vault fire. These units are also susceptible to failure due to flooding; the case of the protector is not water tight and, in locations where flooding occurs, water can damage the internal mechanism of the network protector component. Fibertop Network Units are also the oldest type of Network Units in the system and were most recently installed in the early 1970s. Many of these units are corroding and in some cases have started to leak oil. The `

FIGURE 1: FIBERTOP NETWORK UNIT (TRANSFORMER AND PROTECTOR), RIGHT: TOP OF PROTECTOR COMPONENT

Semi-Dust-Type Network Units

Semi-Dust-Type Network Units (see Figure 2) are the second oldest type of network unit currently in service. This second generation of network unit was installed from 1970 to 2003. These units have a raised secondary bus as seen in Figure 2. This connection point is raised off the top of the protector component, which reduces the chance of tracking between phases. Like the Fibertop Network Units, the casing on the Semi-Dust-Type units is not water tight and, due to their location, some are at risk of being flooded. Over time, flooding can cause corrosion to the structure and operating mechanism of the network unit.

Many of the oldest Semi-Dust-Type units are in need of replacement due to corrosion and severe rust – characteristics that can also lead to oil leaking from the transformer tank. All of the Semi-Dust-Type Network Units addressed by this program have been inspected and have been identified as having reached their end-of-life.

FIGURE 2: SEMI-DUST-TYPE NETWORK UNIT (TRANSFORMER AND PROTECTOR), RIGHT: PROTECTOR COMPONENT

Replacement Solution: Submersible Network Units

Old and obsolete Network Units are expected to be replaced with modern submersible Network Units first introduced in 2003. Submersible Network Units addresses many of the issues that contribute to the deterioration and failure of the older units; they feature a raised secondary bus bar (as illustrated in Figure 3) that reduces the chances of inter-phase tracking. The case of the protector component is also water tight, preventing flooding. In all, these features reduce the risk of a catastrophic failure of the network unit. The new units also feature sensors that provide enhanced load monitoring capabilities for controllers and better visibility into the conditions of the equipment inside the network vault.

FIGURE 3: SUBMERSIBLE NETWORK UNIT (TRANSFORMER AND PROTECTOR)

The total cost of the program, over the 2015 to 2019 period is $34.38 million. Figure 4 shows the geographic location of each replacement that will be taking place in 2015 in red and projects for 2016 – 2019 in grey. The replacements will predominantly occur in the downtown region of Toronto. The prioritization of projects is discussed in E6.10.4.1.

FIGURE 4: MAP OF NETWORK UNITS TO BE REPLACED

The anticipated benefits of this program are summarized in the table below.

TABLE 2: PROGRAM BENEFITS

Customer Value	ƒ Mitigation of significant potential reliability and safety risks for customers in the downtown area. ƒ The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $7.11 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.10.7).
Reliability	ƒ Reduces the number of failures, including catastrophic failures that would otherwise be more likely to occur.
Safety	ƒ Removing Fibertop Network Units is expected to reduce the risk of vault fires and potential explosions that could

	harm Toronto Hydro employees and the general public.
Efficiency	ƒ The Submersible Network Unit comes equipped with sensors that monitor the transformer and protector. These sensors allow controllers in Toronto Hydro's control room the ability to remotely view real time statuses such as flooding, temperature and loading.
Environmental	ƒ Leaking Network Units will be replaced as part of this program and their vaults will be cleaned thoroughly prior to the installation of new Network Units.

E6.10.3 Why the Program is Needed

E6.10.3.1 Program Drivers

Table 3 explains the primary and secondary drivers of the NUR program. Toronto Hydro has classified the NUR program as a System Renewal initiative, with a primary driver of failure risk.

TABLE 3: PROGRAM DRIVERS

Primary Driver	Reasoning
Failure Risk	ƒ Network Units addressed by the program are aging and exhibit various signs of deterioration (i.e. protector contamination, corrosion, leaking oil, etc). ƒ Deterioration of Network Units leads to a heightened risk of failure that can have widespread and prolonged outage impacts.
Secondary Driver	**Reasoning**
Safety	ƒ A fire-related failure incident may expose Toronto Hydro employees and the general public to significant safety risks.

The objective of the NUR program is to mitigate the failure and safety risks associated with the catastrophic failure of aging and obsolete Network Units. A catastrophic failure is defined as an event, such as a vault fire or transformer failure, that requires the station bus to be dropped, affecting several feeders in order to isolate the affected vault. Fibertop Network Units are at risk of failure because they have deteriorate and because of their inherent design issues. Semi-Dust-Type Network Units are at risk of failure because they have deteriorated over time.

Certain design aspects of Fibertop Network Units create an elevated risk of fires and explosions (although Semi-Dust Type Network Units are also susceptible to fires). The top of the protector component on the Fibertop Network Unit, where interconnections are made to the secondary grid,

is susceptible to moisture and contamination (refer to Figure 1). The interconnections are spaced very closely together and allow for leaves and other debris to collect between contacts. This design flaw increases the probability of a short-circuit between phases (i.e., inter-phase tracking) occurring across these connections, which can potentially ignite a vault fire. Vault fires have occurred at a rate of one per year over the last five years and generally have a significant impact on reliability and safety of customers and Toronto Hydro staff.

Vault fires caused by Fibertop Network Units can jeopardize the safety of Toronto Hydro employees, fire fighters, and the general public, partly due to the fact that these assets are often located in high traffic pedestrian areas. In addition, these assets are often connected to the secondary grid using asbestos-insulated lead-covered (AILC) secondary cables. If these cables are involved in a vault fire, they can pose a potential health risk to Toronto Hydro crews during cleanup efforts and nearby pedestrians because asbestos fibers can be released into the air. To address the health risks, the AILC cables require a specialized cleanup crew to removed burned cable, which can increase restoration times. Finally, the structural integrity of the network vault may become compromised as a result of a fire, increasing the overall costs of repair. This was the case in a recent vault fire at 95 St. Clair Ave West in January 2013, further details of which can be found in section E6.10.3.2 (ii).

In addition to the risks of fires and explosions, Fibertop and Semi-Dust-Type Network Units are at risk of oil leakage. In some cases, oil leakage has resulted in low oil levels, which has, in turn, exposed the internal windings. Exposed internal windings can lead to internal failure of the Network Unit. These failures can negatively impact the reliability of the system by causing four- to eight-hour outages while the equipment is replaced.

As well, both types of underground network vaults are prone to flooding. Fibertop and Semi-Dust-Type Network Units are susceptible to failure as a result of a flood in the vault because the ventilation fins that allow the equipment to cool-off also permit water to penetrate the unit. Over time, water contact can cause equipment to corrode and ultimately fail to operate (i.e., fail to open), creating a dangerous back-feed of electricity to parts of the system that are either unintentionally grounded because of a fault or intentionally grounded as part of planned feeder work. Toronto Hydro's current network protector standard uses a submersible protector case to prevent flooding of components inside the case. Additional details of a back-feed incident caused by flooding are provided in Section E6.14.3.2.

E6.10.3.2 Asset Details

(i) Asset Lifecycle

Fibertops are the oldest type of network unit in Toronto Hydro's system, having last been installed in the early 1970s. At a minimum 40 years of age, these units are well past their effective useful life of 30 years, and show signs of wear and tear. With respect to Semi-Dust-Type units, although the majority of replacements are for assets between the ages of 30 and 50, Toronto Hydro is planning on replacing some units that are less than 30 years old, but are in locations that are prone to flooding.

Figure 5 provides demographic information for both Fibertop and Semi-Dust-Type Network Units that are scheduled to be replaced under the NUR program. In general, the Network Units continue to deteriorate as they age. In addition to taking into account the age of assets, inspections were conducted to identify and prioritize corroded and leaking units, which can lead to incidents such as transformer failure, fires, and explosions. As well, Toronto Hydro studied the location of assets to determine which are susceptible to flooding. In short, assets that are at risk of failure are scheduled to be replaced under this program.

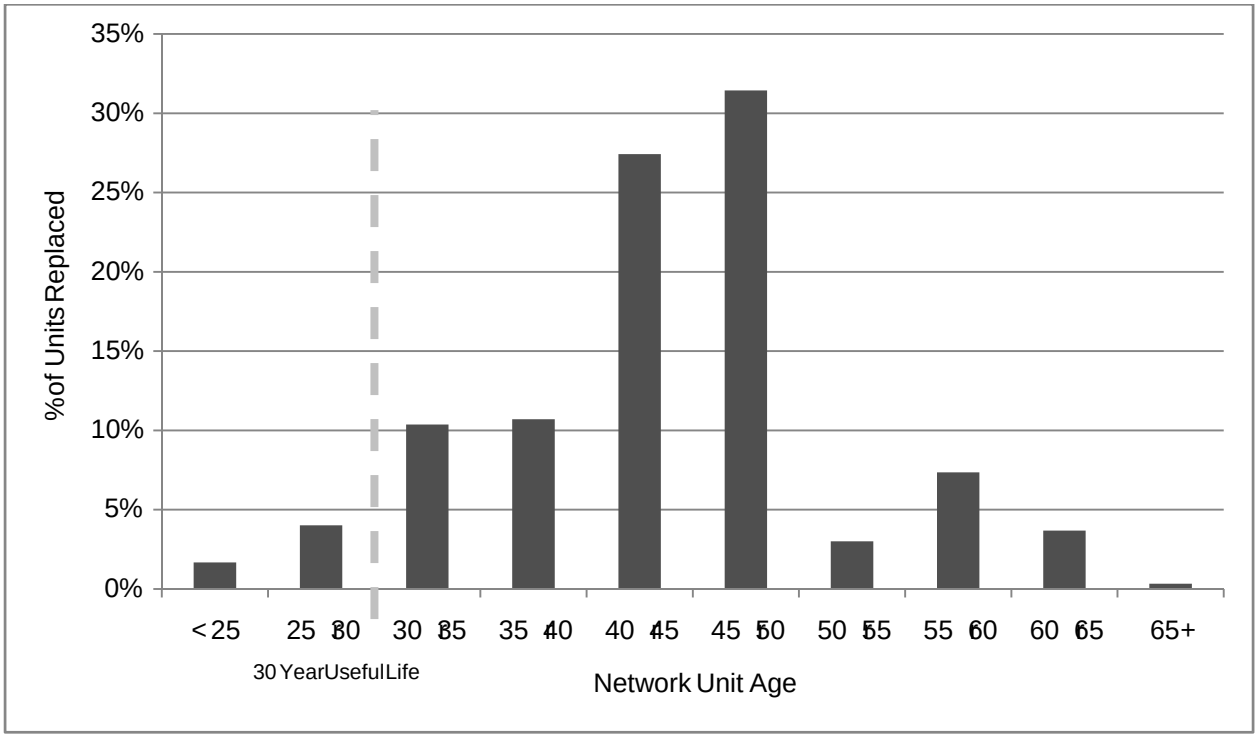

FIGURE 5: NETWORK UNIT RENEWAL - PLANNED REPLACEMENT DEMOGRAPHIC

(ii) Asset Failure Impacts

The failure of assets scheduled to be replaced under this program can negatively impact both the reliability of power supply and the safety of the public.

With respect to reliability issues, approximately 5,000 customers are directly connected to Network Units that will be replaced; they include office buildings, other medium sized commercial buildings and residential customers. These customers are exposed to both catastrophic failures and localized failures than only impact one feeder.

During a network vault fire, the fire department requires that the network grid be dropped. This can impact anywhere between three to six feeders, which means that a few city blocks may be without power for up to four hours while the affected equipment is isolated. After the grid is brought back online, the affected vault and connected customers are usually left without power until the Network Units are replaced, which can take up to an additional 12 hours.

The most recent fire took place on January 28, 2013 at 95 St. Clair Avenue West. The fire was a result of a catastrophic failure of a Network Unit. This fire caused damage to all of the equipment located in the vault, leading to a 49-hour outage for customers in the building. Feeders A53H and A54H were dropped during the outage and both feeds were out until the affected vault could be isolated. In total, this outage affected over 16 high-rise buildings. Certain customers experienced a power outage lasting about an hour, such as Upper Canada College, The Avenue (condominium) and the High Level Pumping Station. Toronto Hydro restored their power by switching to a standby supply on a feeder that was unaffected by the vault fire. In contrast, other customers were left without power for 16 hours; these customers experienced a prolonged outage until the affected vault could be safely isolated and power restored to both supply feeders. Once the debris and equipment was removed from the vault, a new temporary transformer was installed to restore power to all of 95 St. Clair Avenue West.

FIGURE 6: VAULT FIRE EVENT

The fire caused extensive damage; equipment in the vault needed to be entirely replaced and the network vault's civil structure was damaged. As seen in the photos below, the entire civil structure had to be rebuilt before the equipment could be restored. The process of designing and rebuilding the vault took just over one year and, during this time, 95 St Clair Avenue West was supplied by only one of its original feeders, with no ability to be switched to a standby supply in case of a failure or fault. If the building's supply feeder had failed, the customer would have likely experienced another extended service interruption of up to 12 hours.

FIGURE 7: AFTERMATH OF VAULT FIRE EVENT

In the case of localized network failures, some customers connected to the network may not be affected at all. However, dual radial customers, such as large downtown buildings, that are connected to the affected feeder will experience an interruption. Typically, outages on the primary feeder can leave four to five customers without power until they are switched over to their alternate supply, which can take up to 1.5 hours.

A localized network unit failure occurred on August 20, 2013 when a network unit failed to open on reverse current. Customers on feeder A40GD, the primary feeder for this network unit, had to be transferred to their standby supply. After inspecting the unit, crews discovered that the network unit failed because water damage had caused the protector mechanism to malfunction. The corrosion caused by the water damage is visible in the picture below on the right.

FIGURE 8: CORRODED NETWORK UNIT REMOVED FROM VAULT 4080

In addition to reliability issues, the public is put at risk if Network Units are allowed to fail. A catastrophic failure can cause explosions and fires, which pose a potential risk to members of the public. This issue is compounded by the fact Network Units are typically located under pedestrian sidewalks. Figure 9 is a picture of a network vault located under a pedestrian sidewalk.

FIGURE 9: SIDEWALK NETWORK VAULT

E6.10.4 Timing & Pacing of the Program

In order to mitigate the risks outlined in Section E6.13.3, investment is necessary to replace the remaining Fibertop Network Units and to begin addressing Semi-Dust-Type Network Units that are in poor condition or otherwise vulnerable to flooding. The pace of spending under the NUR program is provided in Table 4.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	7.26	4.43	5.07	7.30	3.58	5.18	7.36	7.30	7.28	7.26

Toronto Hydro has approximately 1,892 Network Units in the distribution system. As is further discussed in Section D2 the expected useful life of a network unit is 30 years. In order to maintain an asset base that is within the expected useful life, Toronto Hydro will continue to make

replacements throughout the 2015 to 2019 period. Prior to 2012, Toronto Hydro executed Fibertop Network Unit replacements as part of wider network unit replacement initiative that included other types of heavily degraded end-of-life Network Units. The overall pace at which Network Units were replaced was about 50 units per year; Toronto Hydro plans to continue with this pace throughout the 2015 to 2019 period.

In the early stages of the NUR program, Toronto Hydro will focus on the ongoing replacement of Fibertop Network Units because these pose the most immediate risk of failure. Only 120-140 Fibertop Network Units remain in the system and all will be replaced from 2015 to 2017.

Following replacement of all Fibertop Network Units, Toronto Hydro will begin to replace Semi-Dust-Type Network Units that are degraded, beyond their useful life and at risk of flooding. These activities will continue beyond 2019.

E6.10.4.1 Ranking & Prioritization

The replacement of Network Units has been prioritized based on the following factors:

- Fibertop Protectors Design Flaw – All Fibertop network units will be replaced at the beginning of the NUR program. These units pose the highest risk of failure to the system (refer to section E6.13.3).
- Asset Condition – The asset condition data collected from inspections conducted three times per year is used to determine replacement priority within specific asset classes. Severely deteriorated assets are given the highest priority. Projects can be reprioritized if an urgent/critical need is discovered.
- Flooding – Network Units located in areas that are prone to flooding and have non-submersible equipment will be prioritized to prevent failures.
- Risk – The Feeder Investment Model (FIM) uses asset condition and customer impact to determine optimal intervention time; this information is used to further prioritize the replacement schedule.
- Efficiency - Network units that are fed from the same feeder will be grouped together so as to replace several Network Units at the same time. This allows for more efficient use of resources.

E6.10.5 Program Execution

Over the past five years, Toronto Hydro has undertaken replacements that are similar in nature to the work to be performed under the NUR program. That experience has provided valuable insight on how to optimize the processes and resources to properly support this program.

The projects under the NUR program have been structured so that multiple network units on the same feeder can be replaced together, which maximizes the efficiency of each switching event required to take the primary feeder offline. Using this approach, the amount of time customers are reliant on only one source of supply is minimized.

Each replacement involves similar steps. First the Network Unit is isolated from the system by scheduling the primary feeder to be taken offline and grounded. Next, Toronto Hydro will remove connections to the Primary Feeder and Secondary Network. The Network Unit is then removed from the vault using a crane, and if it is in a sidewalk location the roof slab is removed to allow access to the underground unit. The new Network Unit is then placed in the same footprint of the old unit. Afterwards, the primary cable is re-terminated and the secondary network connections are reinstalled. Finally, the primary feeder is re-energized and the Network Unit will begin supplying power to the Secondary Network.

E6.10.5.1 Program Risks

Toronto Hydro's control room may restrict the replacement of certain Network Units during the summer months because their feeders will not be able to be taken out of service due to operational constraints. Another program risk is that must be managed is the fact that the removal of a Network Unit may cause the remaining Network Units to experience overloads. Toronto Hydro will manage these risks by scheduling the replacement of Network Units outside of the peak summer months where possible.

E6.10.6 Evaluation of Alternatives

E6.10.6.1 Quantification/ Evaluation of Options

Two alternatives were considered to address the issues generated by Network Units. Each alternative was evaluated using a net present value (NPV) calculation.

(i) Maintain status quo

In maintaining the status quo, Toronto Hydro would continue to maintain existing deteriorated Fibertops and Semi-Dust-Type Network Units and replace each unit upon failure. By maintaining the status quo, the multitude of issues discussed throughout the narrative would persist.

(ii) Replace deteriorated Network Units

By proceeding with the NUR program, Toronto Hydro plans to address safety risks associated with deteriorating Network Units and will improve the reliability and efficiency of the network system.

The replacement of Network Units in the first year of the program is expected to result in an avoided estimated risk cost (ARC) of $7.11 million, as detailed in Table 5. This value represents the avoided cost from executing the first year of activities in the year scheduled, as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the probability of failure of the assets, and multiplies this figure by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. Further details on the ARC approach is provided in Section D3.3.

TABLE 5: AVOIDED RISK COST BUSINESS CASE EVALUATION ($ MILLIONS)

Business Case Element	Cost
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$7.72
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$0.61
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$7.11

E6.10.7 2015 Project Details

Table 6 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved Fibertop Network Units segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 6: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	CIR Projects
4.33	0.86

Table 7 lists all projects that are planned to be partially or completely executed as part of the 2015 work program. Note that the table shows total costs for each program. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 7: 2015 PROJECTS

E6.11 Legacy Network Equipment Renewal (ATS & RPB)

NEW EQUIPMENT INSTALLED IN UNDERGROUND VAULT

E6.11.1 Summary

Program Description

The Legacy Network Equipment Renewal program is a continuation of the activities previously described in the OEB approved Automatic Transfer Switches (ATS) and Reverse Power Breakers (RPB) segment within the Incremental Capital Module (ICM) as part of Toronto Hydro's 2012-2014 rate filing[1]. ATS and RPB assets are functionally obsolete, as they are no longer supported by the original manufacturer and no spare parts are produced or available. These issues prevent Toronto Hydro from supporting these assets through the utility's maintenance practices and policies.

These assets are installed within the secondary network system and are used to supply medium-sized customers that require a reliable power supply, such as schools, supermarkets, and seniors' homes. ATS units typically fail due to a malfunction of the control electronics. When the control electronics fail, the unit either continuously switches back and forth between supplies, or

[1] EB-2012-0064, Tab 4, Schedule B11.

simply fails to perform the switching operation. Similarly, RPB failures are typically associated with failure of the circuit breaker to open due to malfunction of the controls electronics. Flooding of underground vaults is a contributing factor to such equipment failures. Water and contaminants corrode metals, which results in the rusting of equipment and other potential damage. Contact with water can damage sensitive electronics within the equipment while water and contaminants entering the equipment can cause electrical arcing and faults, potentially leading to catastrophic failures. The failure of ATS and RPB units can have extensive negative impacts on the reliability of the system and on the service provided to Toronto Hydro's customers, as further described in section E6.11.3.2.

Toronto Hydro plans to continue replacing ATS & RPB assets in order to mitigate their elevated failure risk. Toronto Hydro plans to replace 21 high priority legacy ATS and RPB units between 2015 and 2019 with standard equipment.

The anticipated benefits of the Network Vault Renewal program are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigate vault fires that result in potential damages to adjacent properties, risk of injuries and environmental issues such as oil spills and cleanup activities ƒ Reduce customer interruptions resulting from asset failure.
Reliability	ƒ Mitigate potential equipment failure and system outages ƒ Improve outage restoration time
Safety	ƒ Mitigate the risk of vault fires and catastrophic failure events ƒ Mitigate potential risk of injuries to the public and crews
Efficiency	ƒ Increase operational efficiencies due to automation ƒ Improve maintenance and service support ƒ Improved availability of spare parts for equipment repair ƒ Reduction in inventory cost

Program Drivers

The trigger and secondary drivers for the Legacy Network Equipment Renewal program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Non-submersible equipment legacy network equipment is prone to rusting and failure ƒ Spare parts no longer available for the assets address by this program ƒ Lack of spare parts precludes maintenance as an alternative for extending the life of the assets over the long-term
Secondary Drivers	**Reasoning**
Failure Risk	ƒ ATS failure can cause multiple brief power outages and power quality problems for customers. ƒ When an ATS fails to open, the customer can experience an outage until Toronto Hydro crews are notified to investigate the nature of the outage and address the problem. ƒ RPB failure can cause transformers overheat and fail, which ultimately causes the standby feeder breaker at the station to operate. As a consequence, customers that are fed by affected feeders will experience an outage. ƒ ATS and RPB asset related outages typically affect between 50-100 customers for the duration of one to four hours. ƒ Flooded vaults can cause non-submersible equipment to short-circuit, resulting in overheating and failure. In some cases, a catastrophic failure may occur, which could result in equipment and property damage.
Safety	ƒ Catastrophic failure due to ATS and RPB equipment can cause a vault fire ƒ Potential risk of injuries to customers and crews

Preferred Alternative

Toronto Hydro evaluated the following options for addressing obsolete and deteriorate ATS and RPB units.

(1) Continue to operate the ATS and RPB units as is, and replace them reactively upon failure.

(2) Replace ATS and RPB units in the form of like-for-like replacement

(3) Replace these assets with new, standard network equipment

Option III is the preferred alternative because it allows Toronto Hydro to continue to supply its customers reliably and mitigates the safety risks outlined in this narrative. This option is also the most cost-effective for Toronto Hydro's customers.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $0.55 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.11.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.098 million, confirming the economic prudence of the investments (see Section E6.11.7).

Timing and Pacing

Table C provides historical and projected program spending.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.39	0.03	0.09	1.60	0.25	0.45	0.98	1.14	0.91	1.14

Under this program, 21 high priority ATS and RPB locations are planned for replacement from 2015 to 2019 at a total cost of $4.6 million. An average of four ATS or RPB locations will be targeted annually, which is based on the severity of the asset condition and Toronto Hydro's forecasted resource availability.

E6.11.2 Program Description

The Legacy Network Equipment Renewal program is a continuation of the activities previously described in the OEB approved Automatic Transfer Switches (ATS) and Reverse Power Breakers (RPB) segment within the Incremental Capital Module (ICM) as part of Toronto Hydro's 2012-2014 rate filing.

ATS and RPB are types of network equipment installed within the secondary network system and are used to supply medium-sized customers that require a reliable power supply, such as schools, supermarkets, and long term care homes. An ATS automatically switches a customer to a designated standby feeder in the event the primary feeder fails, helping deliver reliable power supply to the customer. Similarly, an RPB automatically isolates a faulted primary feeder in the event of a feeder outage, which isolates faulted components and prevents potentially dangerous back-feed conditions.

ATS and RPB assets are functionally obsolete, as they are no longer supported by the original manufacturer and no spare parts are produced or available. These issues prevent Toronto Hydro from supporting these assets through the utility's maintenance practices and policies. Figure 1 and Figure 2 are images of typical ATS and RPB units housed in underground vaults.

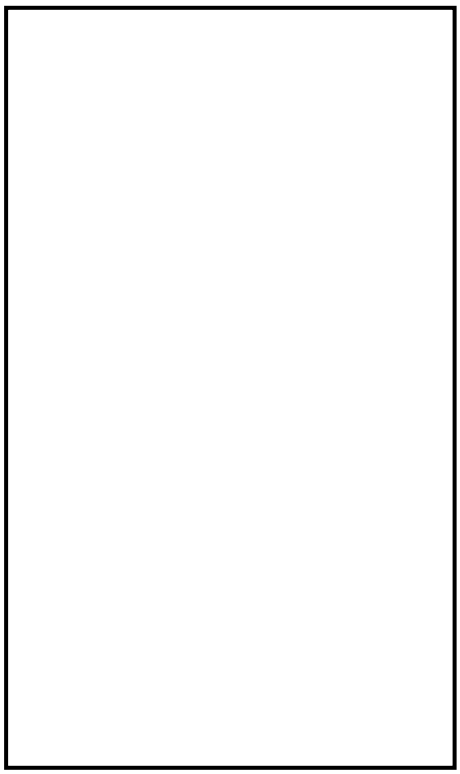

FIGURE 1: ATS UNIT (EXISTING NON-SUBMERSIBLE EQUIPMENT)

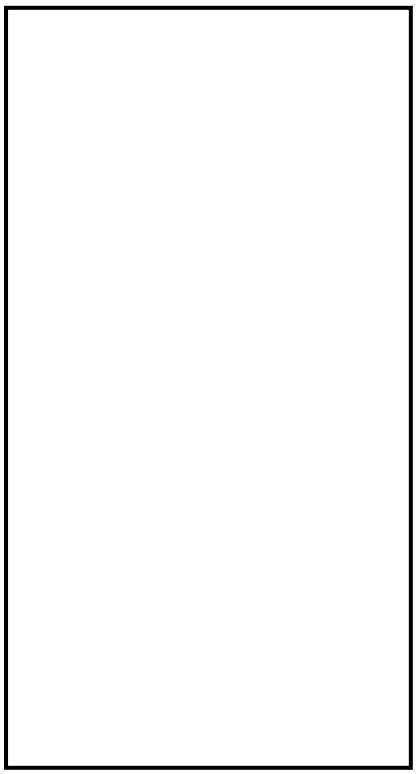

FIGURE 2: RPB UNIT (EXISTING NON-SUBMERSIBLE EQUIPMENT)

ATS units typically fail due to a malfunction of the control electronics. When the control electronics fail, the unit either continuously switches back and forth between supplies, or simply fails to perform the switching operation. Similarly, RPB failures are typically associated with failure of the circuit breaker to open due to malfunction of the controls electronics. Flooding of underground vaults is a contributing factor to such equipment failures. Water and contaminants corrode metals, which results in the rusting of equipment and other potential damage. Contact with water can damage sensitive electronics within the equipment while water and contaminants entering the equipment can cause electrical arcing and faults, potentially leading to catastrophic failures. The failure of ATS and RPB units can have extensive negative impacts on the reliability of the system and on the service provided to Toronto Hydro's customers, as further described in section E6.11.3.2.

As part of its 2012-2014 rate filing, Toronto Hydro developed a proactive ATS & RPB replacement program within the Incremental Capital Module to specifically target ATS and RPB assets identified as being in Very Poor or Poor condition (see section E6.11.3 for details). Toronto

Hydro plans to continue proactively replacing these obsolete assets with equipment that aligns with its current engineering standards during the 2015 to 2019 planning period.

Toronto Hydro plans to replace 21 high priority legacy ATS and RPB units between 2015 and 2019 with standard Toronto Hydro equipment. The anticipated annual breakdown of units replaced is shown in the following Table 1.

TABLE 1: ASSETS TO BE REPLACED

Assets (Vault Locations)	2015	2016	2017	2018	2019	Total
ATS	3	2	3	2	3	13
RPB	0	2	2	2	2	8

The total cost of the Legacy Network Equipment program is forecast to be $4.6 million from 2015 to 2019. Figure 3 shows a map of all the ATS and RPB assets Toronto Hydro proposes to proactively replace in 2015. Replacement priority is primarily determined based on asset condition. A detailed discussion of the prioritization of work within this program appears in Section E6.11.4.1.

FIGURE 3: MAP OF ATS AND RPB ASSET LOCATIONS (2015- 2019 REPLACEMENT)

Replacement Alternatives

In terms of assets to be installed in place of the legacy network equipment, Toronto Hydro considers several alternatives. The recommended course of action for each location is ultimately decided on a case-by-case basis, as each customer's solution will depend on various circumstances, such as the existing infrastructure type and size, system voltage requirements and customer loading. Toronto Hydro plans to replace legacy network equipment with one of the following standard alternatives depending on the specific circumstances:

(1) Stand alone network protectors,

(2) Network transformer units, or

(3) 600 A manual secondary switches.

A detailed description of each of these asset types is provided in the following subsections.

E6.11.2.2 Stand Alone Network Protectors (SANP)

The preferred solution for the replacement of ATS and RPB units is Stand Alone Network Protectors (SANPs), shown in Figure 4. This option is applicable to 120/208 V and 240/416 V vaults (i.e., two of the three secondary voltages).

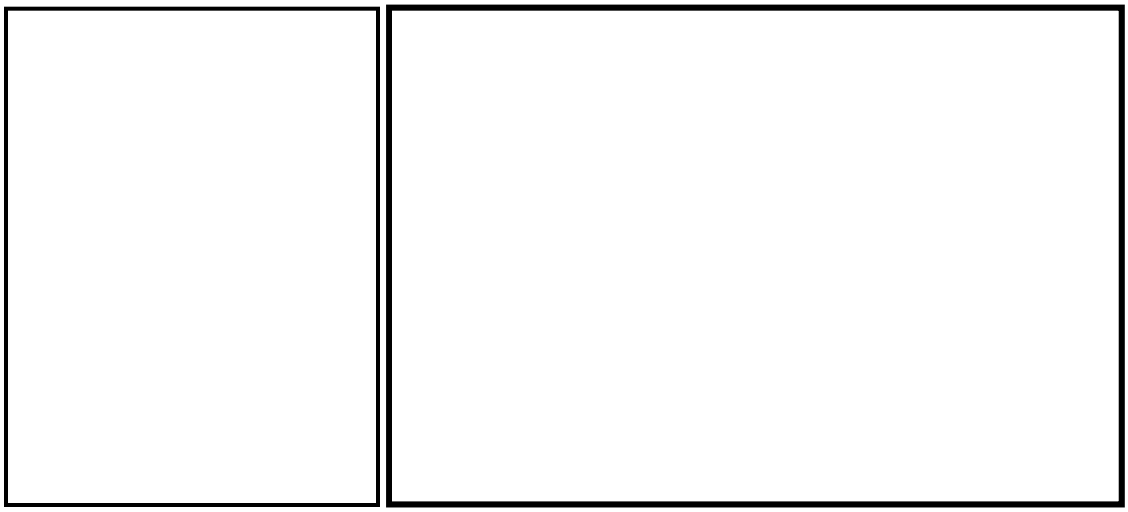

FIGURE 4: STAND-ALONE NETWORK PROTECTOR (SUBMERSIBLE EQUIPMENT)

The SANP provides the system with dual redundancy at the transformers and switches level and automatically performs feeder switching, both of which are not provided by either ATS or RPB assets. The feasibility of this option is conditional on customer load, customer service voltage, physical dimensions of existing civil infrastructure, and the condition of existing transformers. For example, when the physical dimensions of the civil infrastructure and the loading of the customer do not permit the use of SANP, the network unit option (described below) will be used instead. Although SANPs have a slightly larger footprint than existing ATS equipment, SANPs fit into most existing customer vaults except for larger sized customers. Toronto Hydro expects that this option will generally provide customers with improved quality of service with limited momentary interruptions from unplanned feeder outages as compared to the existing ATS and RPB assets.

Installing two SANPs and removing the ATS or RPB equipment typically costs $145,000 per location. In situations where the transformers are also in need of replacement, the replacement cost is typically $330,000 per location.

E6.11.2.3 Network Unit

Another alternative for ATS and RPB replacement is the installation of two standard network units, as shown in Figure 5. This option is only applicable to a secondary voltage of 120/208 V and large customers requiring 500 kVA transformation or greater. Standard network units can fit into almost all existing customer vaults. The reliability improvements associated with this option are expected to be the same as those provided by the use of SANPs. With this option, Toronto Hydro expects that customers will generally experience improved service quality with limited momentary interruptions from unplanned feeder outages in comparison to existing ATS and RPB assets. The network unit option provides the system with dual redundancy at the transformers and switches level and automatically performs feeder switching – functions that are not provided by either ATS or RPB assets. The average cost of this option is $230,000 per location.

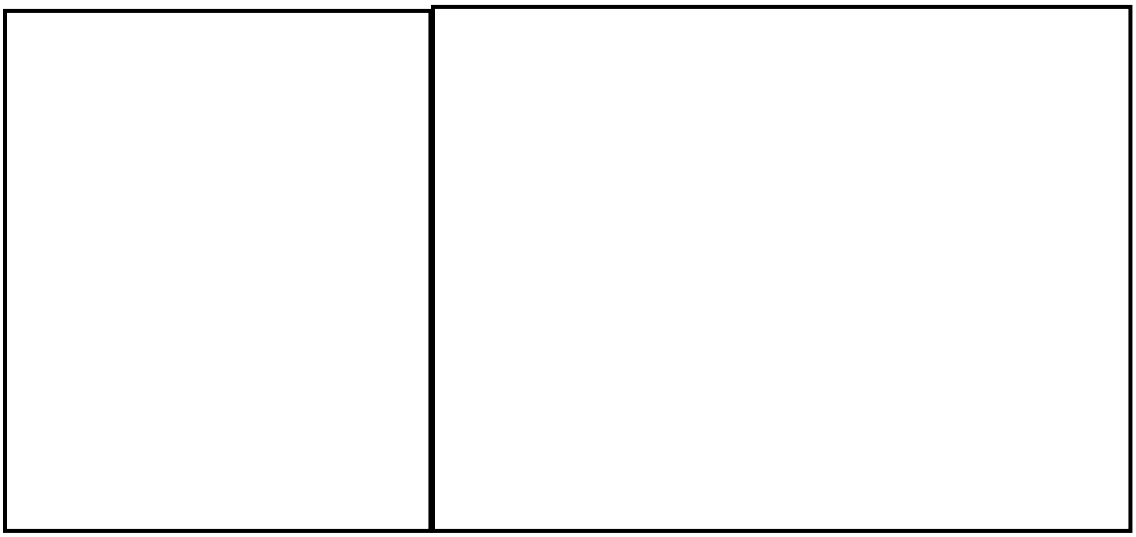

FIGURE 5: NETWORK VAULT (SUBMERSIBLE OR NON-SUBMERSIBLE EQUIPMENT)

E6.11.2.1 600A Manual Secondary Switch

Another option for the replacement of ATS or RPB units are modified 600 A Manual Secondary Switches, shown in Figure 6 below. This switching equipment is compact and will fit into virtually all existing customer vaults, but is limited to smaller customers with a service size no greater than 600 A. This option is applicable for secondary voltages of 120/208 V, 240/416 V and 347/600 V (i.e., all three secondary voltages). It is least preferable to use 600 A Manual Secondary Switches because manual switching is required. As a result, customers could experience inferior operating characteristics due to service restoration delays following unplanned feeder interruptions. The time required to perform the manual switching operation would typically take one to four and a half hours.

The cost of using a 600A Manual Secondary Switches is between $80,000 and $200,000 depending on the condition of the existing transformers and is applicable for secondary voltages of 120/208 V, 240/416 V and 347/600 V (i.e., all three secondary voltages).

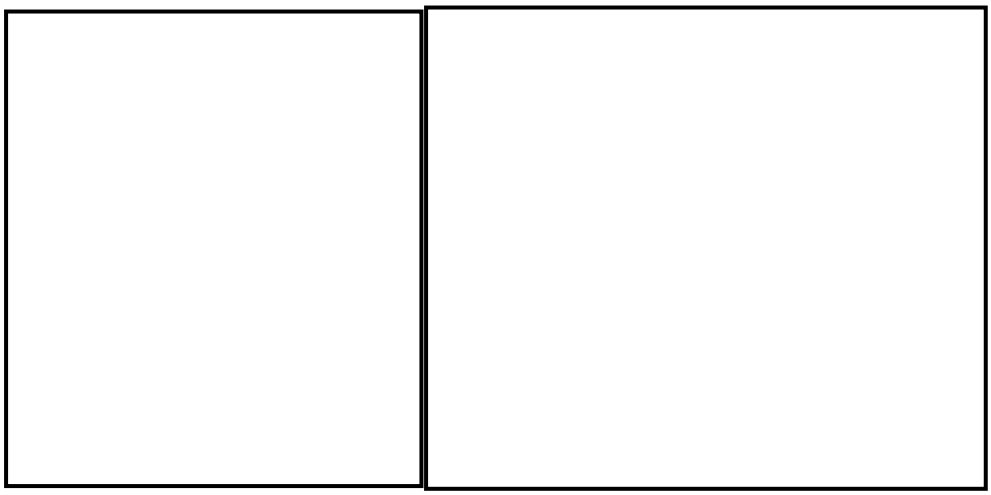

FIGURE 6: MODIFIED TTC VAULT (NON-SUBMERSIBLE EQUIPMENT)

For all three replacement options, existing electrical and civil infrastructure will be utilized wherever feasible; vaults and transformers in good condition will be left in service in order to make the most prudent and cost effective investments in the system. Details of individual unit location assessments and description of work is available in Section E6.11.8.

By replacing the legacy types of network equipment with equipment that aligns to Toronto Hydro's current standards, Toronto Hydro will realize program benefits outlined in Table 2.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigate vault fires that may result in damage to adjacent properties, risk of injuries and environmental issues such as oil spills and cleanup activities ƒ Reduce customer interruptions resulting from asset failure. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $0.55 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.11.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.098 million, confirming the economic prudence of the investments (see Section E6.11.7).
Reliability	ƒ Mitigate potential equipment failure and system outages ƒ Improve outage restoration time
Safety	ƒ Mitigate the risk of vault fires and catastrophic failure events ƒ Avoid potential risk of injuries to customers and crews
Efficiency	ƒ Increase operational efficiencies due to automation ƒ Improve maintenance and service support ƒ Improved availability of spare parts for equipment repair ƒ Reduction in inventory cost

E6.11.3 Why the Program is Needed

ATS and RPBs are types of legacy network equipment that are obsolete, in poor condition, and prone to failure due to various factors such as water penetration, exposure to heavy debris and contamination, which results in equipment rusting and control electronics failure. The penetration of water damages sensitive electronics within the equipment while water and contaminants entering the equipment can cause electrical arcing and faults, which may lead to catastrophic failures. In the years leading up to the 2012-2014 IRM period, Toronto Hydro began experiencing an increasing number of ATS and RPB unit failures. This led Toronto Hydro to replace these units on a less effective, more costly reactive basis. In 2008 and 2009, Toronto Hydro replaced one to two ATS units reactively due to equipment failure. In 2010, the number of ATS units rose to thirteen. Similarly, in both 2011 and 2012, nine ATS units were replaced reactively. As part of its 2012-2014 rate filing, Toronto Hydro established a new program to proactively replace nine ATS & RPB units in 2013, which were identified as being in Very Poor and Poor condition. Despite the execution of this program, an additional six assets failed during this time period and had to be

replaced reactively. Due to these continued failures, Toronto Hydro must carry this proactive replacement program forward during the 2015 to 2019 period.

E6.11.3.1 Program Drivers

The following table summarizes the drivers of the Legacy Network Equipment Renewal program. The trigger driver of this program is functional obsolescence.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Non-submersible equipment legacy network equipment is prone to rusting and failure ƒ Spare parts no longer available for the assets address by this program ƒ Lack of spare parts precludes maintenance as an alternative for extending the life of the assets over the long-term
Secondary Driver	**Reasoning**
Failure Risk	ƒ ATS failure can cause multiple brief power outages and power quality problems for customers. ƒ When an ATS fails to open, the customer can experience an outage until Toronto Hydro crews are notified to investigate the nature of the outage and address the problem. ƒ RPB failure can cause transformers overheat and fail, which ultimately causes the standby feeder breaker at the station to operate. As a consequence, customers that are fed by affected feeders will experience an outage. ƒ ATS and RPB asset related outages typically affect between 50-100 customers for the duration of one to four hours. ƒ Flooded vaults can cause non-submersible equipment to short-circuit, resulting in overheating and failure. In some cases, a catastrophic failure may occur, which could result in equipment and property damage.
Safety	ƒ Catastrophic failure due to ATS and RPB equipment can cause a vault fire ƒ Potential risk of injuries to customers and crews

(i) Functional Obsolescence

Both ATS and RPB units are non-submersible equipment types operated in harsh environments. These units are typically exposed to dirt, debris and water, often resulting in the corrosion of the

non-submersible enclosures and damage of the control electronics, as seen in Figures 7 to 9. Toronto Hydro considers ATS and RPB units to be functionally obsolete equipment designs due to the equipment enclosure's inability to prevent moisture ingress, which subsequently leads to equipment failure.

FIGURE 7: WATER, DEBRIS AND CONTAMINATION IN A VAULT

FIGURE 8: RUSTING AT BASE AND FOOTING OF ATS UNIT

FIGURE 9: RUSTING ON EQUIPMENT SURFACE

Another factor contributing to the functional obsolescence of these assets is that the manufacturer no longer supports this specific type of equipment. Spare parts are unavailable for equipment repairs, making it difficult for Toronto Hydro to achieve alignment with current maintenance and inspection practices. Going forward, the lack of spare parts precludes long-term maintenance as a viable option to extend the service life of the assets. For these reasons, this legacy network equipment no longer meets Toronto Hydro's standards.

(ii) Failure Risk

In the event of a system fault, failed or defective ATS and RPB units may not operate as intended, and in some instances catastrophic failures can occur, examples of which are described in section E6.14.3.2. There are many instances when ATSs have reportedly failed to transfer customers to the standby feeder after the normal feeder supplying customers became faulted. As well, Toronto Hydro has documented several instances of RPB units failing to properly isolate a fault as the RPB breaker failed to open. RPB malfunction can prolong equipment

exposure to large amounts of fault current, damaging equipment such as cables and transformers that are fed on common feeders. This damage can lead to vault fires and catastrophic failures.

Since 2010, Toronto Hydro has averaged 12 ATS or RPB replacements per year due to equipment deficiencies and equipment failures. Over 20% of the combined population of ATS and RPBs are known to be rusted or have failed to operate in the field and are considered high priority for replacement. There are currently a total of 21 ATS and RPB vault locations in need of replacement due to equipment rusting and potential failures as described in section E6.11.3.2.

(iii) Safety

Failing ATS and RPB assets can potentially put the safety of the public and Toronto Hydro employees at risk. In some incidences, catastrophic failure of ATS and RPB assets has resulted in damage to related equipment leading to vault fires that can harm individuals in proximity to the vault. The inherent safety risk of vault fires is heightened by the fact that these assets are generally located in populated downtown areas, as described in Section E6.11.3.2.

E.2 Asset Details

(i) Asset Lifecycle

Toronto Hydro plans to address 13 vault locations with ATS units and eight vault locations with RPB units over the 2015-2019 period. The typical useful life of an ATS unit is 40 years. As shown in Figure 10, of the 34 ATS units currently in service, over 32% will be in operation past their useful lives by 2015, with additional units reaching end-of-life within the 2015-2019 period.

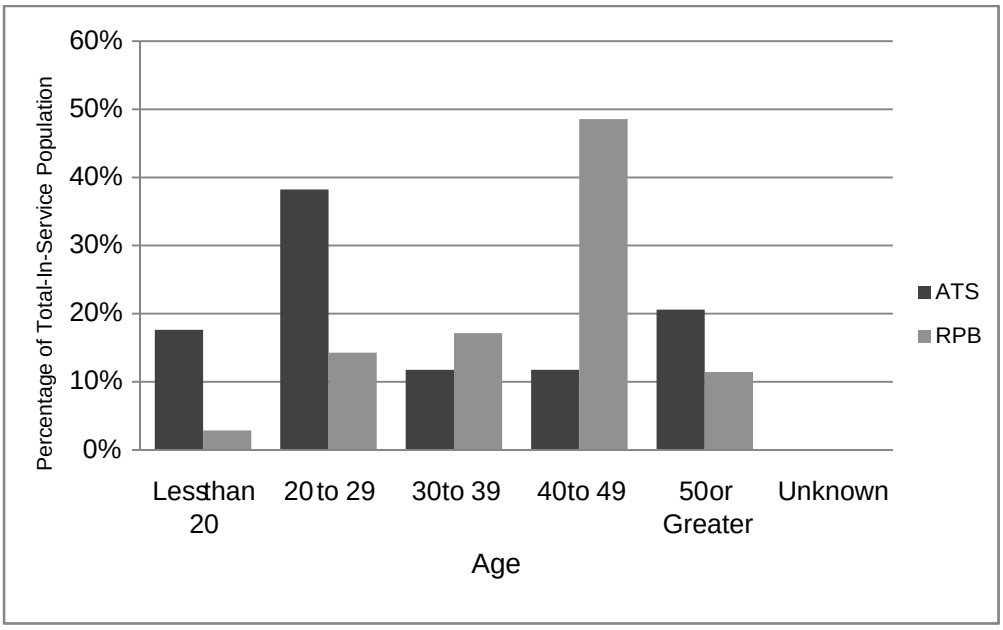

FIGURE 10: ASSET AGE DISTRIBUTION BY 2015

Annual inspections play an important role in identifying ATS and RPB units that are exposed to severe rusting conditions, as well as units that are currently malfunctioning. Of the 34 ATS vault locations and 70 RPB vault locations currently in service, 21 locations (i.e., 20%) are experiencing rusting conditions or were malfunctioning due to contact with debris, contaminants and water, which can damage control electronics. Figure 11 shows the number of ATS and RPB vault locations that are in need of replacement due to the aforementioned problems. The broad age distribution of the assets in need of replacement illustrates the fact that these assets were not designed to withstand exposure to the given environmental and operating conditions.

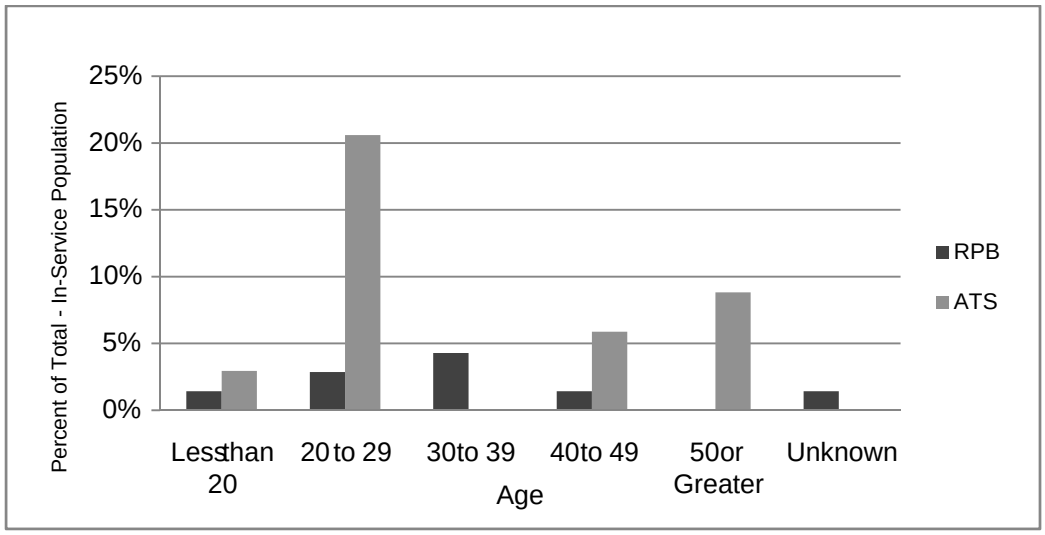

FIGURE 11: LEGACY NETWORK ASSETS IN NEED OF REPLACEMENT

There is an increasing rate of failure of legacy network assets, which is reflected in the increasing trend in reactive equipment replacements shown in Figure 12. Toronto Hydro has been replacing a large number of ATSs and RPBs since 2010. From 2010 to 2013, an annual average of 12 legacy network equipment locations required ATS or RPB replacement due to equipment deficiencies and equipment failures.

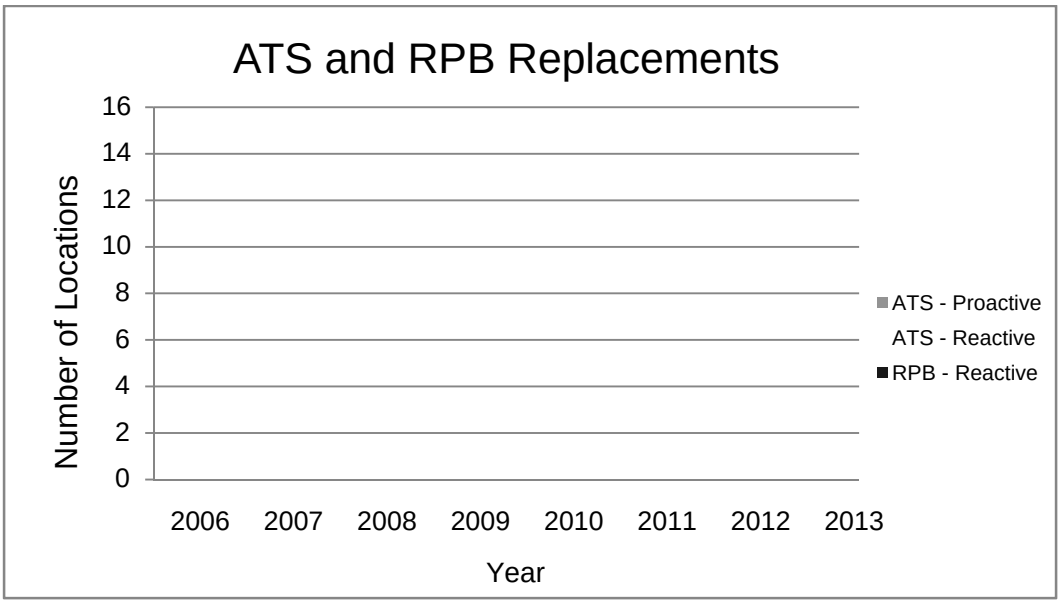

FIGURE 12: ATS & RPB REACTIVE REPLACEMENTS

(ii) Asset Failure Impacts

When an ATS fails, it may continuously transfer back and forth between supplies, causing customers to experience multiple brief power outages and power quality problems. When an ATS fails to open, the customer will experience an outage until Toronto Hydro crews are notified to investigate the nature of the outage and address the problem.

When an RPB fails to open, both supplies are connected to the customer, leading to a back-feed current that continues to feed the faulted part of the system. As a result, the transformers overheat and fail, which ultimately causes the standby feeder breaker at the station to operate. As a consequence, customers that are fed by affected feeders will experience an outage. ATS and RPB asset related outages typically affect between 50-100 customers for the duration of one to four hours.

In flooded vaults, when water reaches a certain level, equipment will short-circuit, resulting in overheating and failure. In some cases, a catastrophic failure may occur, which could result in equipment/property damage and significant safety risks to the public and Toronto Hydro employees. Previously recorded incidences of catastrophic failure are detailed below.

Failure at 33 Princess Street on January 16, 2012

An ATS unit failed on January 16, 2012 at approximately 1:25 pm, igniting a vault fire near Front and Sherbourne and two feeders, A14GD and A15GD. This fire was contained within the ATS vault; however, the fire damaged the primary cables on both feeders as well as the two distribution transformers supplying 33 Princess Street. The feeders were isolated at the station and power was promptly restored to most customers. Approximately 460 students from George Brown College, 50 seniors from a nearby retirement home, Fifty children from a daycare, and customers from 246 The Esplanade were evacuated because of this incident. Two large customers (Esplanade Development Corp and King James Place) supplied solely from feeders A14GD and A15GD also experienced extended outages. Some were left without power until approximately 2:00 pm the following day. Figures 13 to 15 illustrate the extensive equipment damage caused the fire.

FIGURE 13: THE FIRE DEPARTMENT PUTTING OUT THE FIRE AT 33 PRINCESS ST. (PHOTO TAKEN JANUARY 16, 2012)

FIGURE 14: DAMAGES FROM ATS EQUIPMENT FAILURE AT 33 PRINCESS ST. (PHOTO TAKEN JANUARY 17, 2012)

FIGURE 15: LOCATION REPLACED WITH TRANSFORMERS AND ATS AFTER THE FIRE. (PHOTO TAKEN JANUARY 23, 2012)

Failure at 50 Marlborough Court on January 10, 2010

On January 10, 2010 a malfunctioning RPB in a vault near Yonge and Davenport with a history of flooding failed to open. The RPB failure allowed a back-feed of electricity into a primary fault, which damaged the transformers within the RPB vault, caused a catastrophic failure at another vault location (CTY), and damaged equipment in nearby vaults. Figures 16 to 19 below show the damaged transformers with overheated cables and burned oil discharge from the pressure relief valves. This incident resulted in ten hours of interruption to the associated network grid and over 26 hours of interruption to 50 Marlborough Avenue, impacting over 3,000 residential and large commercial customers in the downtown core (along roads such as Bloor St., Davenport Rd.,

Avenue Rd. and Yonge St.). One Toronto Hydro crew member suffered minor injuries related to the fault that occurred within the vault.

FIGURE 16: RPB UNITS FOLLOWING FAILURE AT 50 MARLBOROUGH (PHOTOS TAKEN JANUARY 10, 2010)

FIGURE 17: DAMAGE AT 50 MARLBOROUGH. (PHOTOS TAKEN JANUARY 10, 2010)

FIGURE 18: EQUIPMENT DAMAGE AT CUSTOMER (CTY) DUE TO RPB FAILURE

E6.11.4 Timing & Pacing of the Program

Under this program, 21 high priority ATS and RPB locations are planned for replacement from 2015 to 2019 at a total cost of $4.6 million. An average of four ATS or RPB locations will be targeted annually, which is based on the severity of the asset condition and Toronto Hydro's forecasted resource availability. Historical and future spending is outlined in Table 4.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.39	0.03	0.09	1.60	0.25	0.45	0.98	1.14	0.91	1.14

Historically, Toronto Hydro has replaced ATS and RPB equipment on a reactive basis, which has resulted in greater interruption costs to customers, higher per-unit replacement costs, and lower reliability for customers. As described in Section E6.11.3.2, Toronto Hydro has transitioned to a proactive replacement program to reflect the age and condition of these assets.

It is prudent that ATS and RPB assets be replaced in a timely matter to avoid asset failure, as the number of failures has increased in recent years. The five-year schedule was established to address equipment that is considered high priority due to permanent degradation issues such as oil leaks and rusting, equipment with a history of malfunctioning and equipment in locations that are exposed to heavy contamination, flooding and/or dampness in the vaults.

E6.11.4.1 Ranking & Prioritization

The sequencing of work within the Legacy Network Equipment program is determined based on several factors. These include:

- Inspection Results: Annual inspections play an important role in identifying ATS and RPB units that are exposed to severe rusting conditions, as well as units that are currently malfunctioning. Failure of these assets is largely due to the wear and tear of the mechanical operating mechanism, corrosion of the equipment and electronics malfunction due to water damage. Inspection records of ATS and RPB assets are considered key information to be evaluated for prioritization of work.

- Failure Risk and Impact: Equipment failure is associated with varying risks. ATS and RPB failure can result in one to four hours of customer outages, equipment and property damages and/or the risk of a catastrophic failure or a vault fire. The Legacy Network Equipment Renewal program gives priority to locations with higher failure risks such as rusted equipment enclosure and previous flooded locations.

- Reliability: Assets that are malfunctioning, have major deficiencies, or are being exposed to poor environmental conditions are deemed to be at higher risks of failing. In turn, asset failures can affect system reliability. The Legacy Network Equipment Renewal program considers reliability concerns associated with system performance when establishing work priorities.

- Asset Age: The sequencing of work takes into account an asset's useful life. Assets operating well past industry projected useful life are considered high risk in terms of potential failures.

- Coordination: To achieve greater efficiency, equipment fed from the same Toronto Hydro feeders in the region is coordinated in terms of replacement schedule and sequencing. This approach is intended to reduce disruption of supply and to provide continuous power to customers wherever possible. Reduced disruption to feeders translates into fewer outages for customers, and improved project efficiencies.

Assets in poor condition are prone to failure and are a safety and reliability concern to Toronto Hydro and its customers, especially considering to the potential for catastrophic failures like the ones described in Section E6.11.3.2. Equipment that is heavily rusted and that has a history of water penetration is ranked as high-priority for asset replacement due to greater risk of failure.

Accordingly, asset condition and failure risk are the primary factors considered in determining which ATS and RPB units need to be replaced first.

E6.11.5 Program Execution

Project execution begins with a portion of the legacy assets being removed from the vault as shown in Figure 19 and Figure 20. Toronto Hydro generally maintains service to the customers using the remaining legacy assets until new standard network equipment is installed, at which point the newly installed equipment will be used to re-service the customer. The remaining legacy assets are then removed from the system. The process of equipment removal and installation is performed by certified power cable persons (CPCP) with over five years of specialized training. The process is shown from Figures 21 to 24.

FIGURE 19: REMOVING ATS EQUIPMENT IN UNDERGROUND VAULT

FIGURE 20: OLD EQUIPMENT REMOVED BY CRANE

FIGURE 21: CRANING NEW EQUIPMENT TO BE INSTALLED

FIGURE 22: LOWERING NEW EQUIPMENT TO BE INSTALLED

FIGURE 23: NEW EQUIPMENT INSTALLED IN UNDERGROUND VAULT

FIGURE 24: NEW EQUIPMENT INSTALLED IN UNDERGROUND VAULT

Due to access and space limitations, a crane is used to remove and install equipment. When equipment is placed into position, cables are installed, terminated, racked into position, and then the system is tested prior to supplying the customer with power. Upon job completion, the vault roof is placed back into position and the location is restored to its original condition.

E6.11.5.1 Proposed Work Plan

The long term plan addresses 21 vault locations from 2015 to 2019 as outlined in Table 5, averaging four locations annually.

TABLE 5: 2015-2019 LONG TERM PLAN

Year	Asset	Location
2015	ATS	4268
2015	ATS	D9016
2015	ATS	4914
2016	ATS	2 locations
2016	RPB	2 locations

E6.11.5.2 Program Risks

The challenges of operating in central Toronto – including access to vaults situated in high traffic sidewalks/laneways and the inherent difficulties of switching in the downtown core due to high loading conditions in summer – could potentially impact the pace of ATS and RPB replacements. Toronto Hydro's resource planning teams will coordinate and plan projects so that they are implemented in spring and fall seasons to account for switching complications. As well, Toronto Hydro plans to communicate with customers to create an agreeable timeline in accordance with system priorities.

The integrity of the civil structure at each vault location is reviewed in the planning and design stages of the project and may impact the project completion timeline. When safety deficiencies such as weak structural integrity of customer-owned vaults are identified, as shown in Figure 25, the customer will be made aware through a Customer Advice Form (CAF) at least a year in advance of the actual replacement of ATS and RPB units. This helps ensure that customers are given adequate advanced notice to address the civil work that needs to be carried out in relation to customer-owned vaults. Safety-related concerns such as major structural problems or trip hazards must be addressed either prior to the commencement of work or as part of the work being performed by Toronto Hydro crews. The work specified in a CAF may involve the rebuild of the vault roof or the entire vault depending on the condition of the site, in order to protect the safety of individuals, as well as Toronto Hydro and customer assets.

FIGURE 25: CIVIL STRUCTURE PROBLEMS

E6.11.6 Evaluation of Alternatives

E6.11.6.1 Quantification/ Evaluation of Options

(i) Status Quo

Maintaining the status quo entails continuing to operate the ATS and RPB units as is, and replacing them reactively upon failure. While failure rates have increased substantially in recent years, manufacturer support and spare parts are not available. Accordingly, Toronto Hydro forecasts that maintaining the status quo will negatively affect system reliability and will pose potential safety risks to customers as well as Toronto Hydro personnel. As such, this option is not recommended.

(ii) Like-for-Like Replacement

Non-standard equipment is required in order to replace ATS and RPB units in the form of like-for-like replacement. The use of non-standard equipment can be very expensive due to high

engineering, training, maintenance, manufacturing and inventory costs spread over a relatively small number of assets. In addition, when custom equipment is purchased, availability of spare parts and support is limited. As such, this option is not recommended.

(iii) Replacement with Standard Equipment

Replacing legacy network equipment with standard network equipment allows Toronto Hydro to continue to supply its customers reliably and mitigates the safety risks outlined in this narrative. Pursuant to the analysis below, this option is also the most cost-effective for Toronto Hydro's customers. Standard Toronto Hydro network equipment such as 600 A secondary manual switches, stand alone network protectors and network transformer units can be used to replace legacy network equipment as described in Section E6.11.2. The cost of this option is $70,000 to $300,000 per location depending on the existing infrastructure in place.

The cost of ownership (COO) and program net benefit (NPV) associated with Legacy Network Equipment Renewal program is further detailed in Table 6. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities in this program. The COO of a state reflects the risk of asset failure including both direct and indirect costs. These costs include customer interruptions, emergency repairs, and asset replacements associated with a given design. For further details on the COO approach, please refer to Section D3.3.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$0.70
Non Asset Risk [NAR_E]	$0
Maintenance Cost [MC_E]	$0
Additional Quantifiable Benefits [AQB_E]	$0
Cost of Ownership of Existing Assets [COO_E]	$0.70

When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Legacy Network Equipment Renewal program produces a NPV of $0.098 million, as shown in Table 7. As the net present value is positive, this means that the benefits of executing the work outweigh the capital expenditures and the work is therefore economically prudent. A positive NPV shows a net reduction in risk when factoring in impacts to customers due to power interruptions.

TABLE 7: STANDARDIZED REPLACEMENT BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 2: Replacement with Standard Equipment (N)	
Asset Risk [AR_N]	$0.16
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0
Additional Quantifiable Benefits [AQB_N]	$0
Cost of Ownership of New Assets [COO_N]	$0.16
Option 2: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	$0.55
Program Cost [PC_1]	$0.45
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	$0.098

E6.11.7 2015 Project Details

Table 8 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

- previously filed projects that appeared as jobs in the OEB approved ATS and RPB segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and
- projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 8: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	CIR Projects
0.26	0.19

Table 9 lists all projects that are planned for partial or complete execution as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 9: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Start Date	Project Type (ICM or CIR)
X12953	X12953, ATS Replacement, Loc 4268	$255,693	2015	ICM
X14520	X14520, ATS Replacement, Loc 4914	$138,042	2015	CIR
X14521	X14521, ATS Replacement, Loc D9016	$54,123	2015	CIR

The following subsections provide details for each of the 2015 projects listed in the table above.

E6.11.7.1 X12953 Project Description

Investment Category: System Renewal

Program: Legacy Network Equipment Renewal

Project Title: X12953, ATS Replacement, Loc 4268

Project Number: X12953 (ICM)

Project Year: 2015

Estimated Cost: $255,693

(i) Objective

The purpose is to replace ATS equipment located at 1130 Bloor St. W. with network equipment.

(ii) Scope of Work

TABLE 10: X12953 SCOPE OF WORK DETAILS

District Neighborhood	BLOOR DAVENPORT VILLAGE
Station(s)	DUFFERIN
Feeder(s)	A41 DN, A89 DN

TABLE 11: X12953 ASSETS REPLACED

Assets (Units)	2015
ATS	1
Transformers	2

(iii) Justification & Benefits

This ATS equipment in location 4268 was installed in 1963. Maintenance inspection records identified that the base of the ATS unit is rusting. This is due to a wet underground vault located beneath pedestrian walkways that is heavily salted. Rusting of the enclosure and water penetration often leads to equipment failure as described in detail in section E6.11.2. Replacing the non-submersible ATS equipment in poor condition with network equipment that is designed to be submersible in water and to be operated under harsh environments will mitigate impending failures and ensure the safe and reliable operation of the grid.

E6.11.7.2 X14520 Project Description

Investment Category: System Renewal

Program: Legacy Network Equipment Renewal

Project Title: X14520, ATS Replacement, Loc 4914

Project Number: X14520

Project Year: 2015

Estimated Cost: $138,042

(i) Objective

The purpose of this project is to replace ATS equipment located adjacent to 1537 Davenport.

(ii) Scope of Work

TABLE 12: X14520 SCOPE OF WORK DETAILS

District Neighborhood	CARLETON VILLAGE
Station(s)	WILTSHIRE
Feeder(s)	A2-25 kV, A3-39 kV

TABLE 13: X14520 ASSETS REPLACED

Assets (Units)	2015
ATS	1
Transformers	2

(iii) Justification & Benefits

Maintenance inspection records identified that the ATS unit in location 4914 is rusting. The footing of the unit has been rusting badly since 2010. This is an indication of a wet underground vault. Due to rusting of the enclosure and water penetration, the ATS unit malfunctioned and failed to perform the feeder transfer operation. Delaying the ATS unit replacement at location 4914 would risk failure and safety issues as detailed in sections E6.11.3.1.

As discussed in sections E6.11.2, the equipment cannot be serviced and spare parts are no longer available. Replacing the non-submersible ATS equipment with network equipment that is

designed to be submersible in water and to be operated under harsh environments will mitigate impending failures and ensure the safe and reliable operation of the grid.

E6.11.7.2 X14521 Project Description

Investment Categories: System Renewal

Program: Legacy Network Equipment Renewal

Project Title: X14521, ATS Replacement, Loc D9016

Project Number: X14521

Project Year: 2015

Estimated Cost: $54,123

(i) Objective

The purpose of this project is to replace ATS equipment located on the east side of Brant St. and south of Richmond St. W.

(ii) Scope of Work

TABLE 14: X14521 SCOPE OF WORK DETAILS

District Neighborhood	FASHION DISTRICT
Station(s)	WINDSOR
Feeder(s)	A6-64 M WR, A6-69 M WR

TABLE 15: X14521 ASSETS REPLACED

Assets (Units)	2015
ATS	1

(iii) Justification & Benefits

Maintenance inspection records identified that the ATS unit in location D9016 is rusting. Although the ATS unit was installed in 1993 and has been in service for a short duration, it is heavily rusted. The unit has signs of surface rust and the footings have been heavily rusted since 2010.

The equipment cannot be serviced or repaired and is in need of replacement as rusting of the enclosure and water penetration often leads to equipment failure. Replacing the non-submersible ATS equipment in poor condition with network equipment that is designed to be submersible in

water and to be operated under harsh environments will mitigate impending failures and ensure the safe and reliable operation of the grid.

E6.12 Network Circuit Reconfiguration

SWITCH AND FUSE UNITS

E6.12.1 Summary

Program Description

The Network Circuit Reconfiguration program addresses the functionally obsolete design of the existing secondary network distribution system in certain areas of Toronto. This program is made up of the following two initiatives:

(1) Enhancement of secondary network grid flexibility: Toronto Hydro plans to upgrade the secondary grid by splitting large grids into more robust spot vaults and enhanced mini-grids, each with fewer primary feeders. The objective of this initiative is to minimize customer interruptions, improve planning and operational flexibility, enhance the ability of the network system to operate under extreme events and, most importantly, to prevent the secondary network distribution system from becoming functionally obsolete in the face of incremental changes that have been made to the distribution system over time. (In particular, the network system was designed for pure network loads and not the mixed network and radial loads that exist today. Enhancement of secondary network grid flexibility is necessary to adapt to this new standard.)

(2) 600 V network distribution initiative: Toronto Hydro plans to supplement existing 433Y/250V and 216Y/125V network equipment with new 600Y/347V network equipment in order to prevent the secondary network distribution system from becoming obsolete in light of changing customer needs. (In particular, the need for reliable supply to customers with significantly greater building heights than the network system was originally designed to accommodate).

The anticipated benefits of the Network Circuit Reconfiguration program are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Following major equipment failures, fewer customers will be dropped, fewer customers will be required to reduce load and customers will experience shorter outages. ƒ Eliminates customer outages due to special switching requirements in some locations. ƒ Improves Toronto Hydro's ability to meet the service needs of new customers through new service supply options.
Reliability	ƒ Improved ability to operate networks under multiple contingency events. ƒ Forecast two-thirds reduction in load interruptions during second contingency events. ƒ Eliminates special operating restrictions that interrupt a second feeder following a failure on specific feeders. ƒ Permits station to station feeder ties to improve reliability as part of the Downtown Contingency program.
Safety	ƒ Minimizes hazardous manual switching activities following major equipment failures. ƒ Reduced loss of supply to life support equipment. ƒ Eliminates hazardous Sachsenwerk switch and fuse units in four locations.
Efficiency	ƒ Improves the productivity of power system controllers and system response crews. ƒ Removes special operating procedures at four locations.
Other	ƒ Reconfigured network feeders can be tied to feeders from other stations as part of the Downtown Contingency program. ƒ Improved ability to transfer loads.

Program Drivers

The trigger and secondary drivers for the Network Circuit Reconfiguration program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ The network system was designed for pure network loads and not the mixed network and radial loads that exist today. Enhancement of secondary network grid flexibility is necessary to adapt to this new standard. ƒ The network system is becoming functionally obsolete due to its inability to supply new classes of customers, while at the same time existing classes of customers are dwindling. The 600 V network distribution initiative is necessary in order to allow the secondary network distribution system to operate as needed for new classes of customers.
Secondary Drivers	**Reasoning**
Reliability	ƒ The secondary network system was originally designed to withstand first contingency operation; however, multiple contingency events are now a common occurrence, which result in widespread outages. ƒ Although the network system was originally designed to allow faulted equipment to burn clear, present operating practices often require Toronto Hydro to cut all power, resulting in widespread customer outages. ƒ Operating restrictions on existing hazardous Sachsenwerk switch and fuse units reduce the reliability of power supply.
System Efficiency	ƒ Network Circuit Reconfiguration will relieve power system controller workload during multiple contingency events and reduce the need for system response crews to perform load relief and restoration tasks.
Safety	ƒ Sachsenwerk loadbreak switches in use pose safety hazards.

Preferred Alternative

Toronto Hydro considered the following alternatives for preventing the functional obsolescence of the network system.

(1) Allow the network system reliability to degrade as new customer loads are added, radial and network loads are mixed on the same feeders and operating practices are continuously modified to meet safety requirements.

(2) Implement the Network Circuit Reconfiguration program to ensure long term load growth and system flexibility needs are met.

The current operational constraints within the existing network circuit configuration create one to two complete network interruptions each year following multiple contingency network outages. Without Network Circuit Reconfiguration, Toronto Hydro expects that network system reliability continue to degrade as new customer loads are added, radial and network loads are mixed on the same feeders and operating practices are modified to enhance safety and satisfy new requirements. The utility also expects that the secondary network distribution system will continue to become functionally obsolete and will not be able to meet customers' changing needs. Also, by maintaining the status quo, existing 600 V switch and fuse units that use Sachsenwerk switches and that require switching restrictions will remain in place, negatively impacting system reliability and safety. For these reasons, Option II is preferred.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $3.08 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.12.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.77 million, confirming the economic prudence of the investments (see Section E6.12.7).

Timing and Pacing

The Network Circuit Reconfiguration program addresses issues that have been developing over the past few decades and that are expected to continue to worsen. Toronto Hydro plans to start this program during the 2015 to 2019 period in order to begin clearing a growing backlog of required investments, but anticipates work to continue beyond 2019. Table C provides historical and projected program spending.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending

E6.12.2 Program Description

The Network Circuit Reconfiguration program addresses the functionally obsolete design of the existing secondary network distribution system in certain areas of Toronto. This program is made up of the following two initiatives, which are further discussed in the following sections:

(1) Enhancement of secondary network grid flexibility, and

(2) 600 V network distribution initiative.

Both the enhancement of secondary network grid flexibility and 600 V network distribution initiative projects proposed for the 2015 to 2019 timeframe are illustrated in Figure 1 below. The total cost of the program for the 2015 to 2019 period is estimated to be $9.14 million. As this is a long-term planned renewal program, Toronto Hydro expects to continue reconfiguring the secondary network distribution system beyond 2019.

FIGURE 1: NETWORK CIRCUIT RECONFIGURATION PROJECT MAP

E6.12.2.1 Enhancement of Secondary Network Grid Flexibility

The enhancement of secondary network grid flexibility addresses the major components of the secondary network system, including secondary grids, network transformers and primary feeders. Toronto Hydro plans to upgrade the secondary grid by splitting large grids into more robust spot vaults and enhanced mini-grids, each with fewer primary feeders. The goal is to minimize customer interruptions, improve planning and operational flexibility, enhance the ability of the network system to operate under extreme events and, most importantly, to prevent the secondary network distribution system from becoming functionally obsolete in the face of incremental changes that have been made to the distribution system over time. Pressures facing the existing network system are discussed in detail in section E6.12.3.

Secondary network distribution systems behave very differently than other common distribution systems and have unique and demanding operating requirements. In order to understand how the network system works and why the Network Circuit Reconfiguration program is necessary, an introductory outline of the secondary network distribution systems follows.

Secondary Network Distribution Systems

The secondary network distribution system is unique in that it utilizes multiple transformers connected to multiple feeders to simultaneously supply several customers through an interconnected secondary grid. Figure 2 illustrates how a simple network system is connected. The key component to making this system work is the network protector. The network protector automatically connects and disconnects individual transformers from the secondary grid to compensate for primary feeder switching and equipment failures. Secondary network systems are, by this means, able to provide uninterrupted service to customers even if one or more components in the grid fail.

Network vaults are either configured as grid vaults or spot vaults. In grid vaults, secondary grid cables are tied to cables of neighbouring vaults, as illustrated in Figure 2. A mini-grid is an area in which a few network vaults are tied together, but the group is not tied to the rest of the grid. In spot vaults, the secondary grid cables are not connected to any neighbouring vaults. Spot vaults always contain two or more network transformers and are needed when either the secondary voltage is different than neighbouring vaults or when it is not practical to interconnect the secondary cables with other vaults.

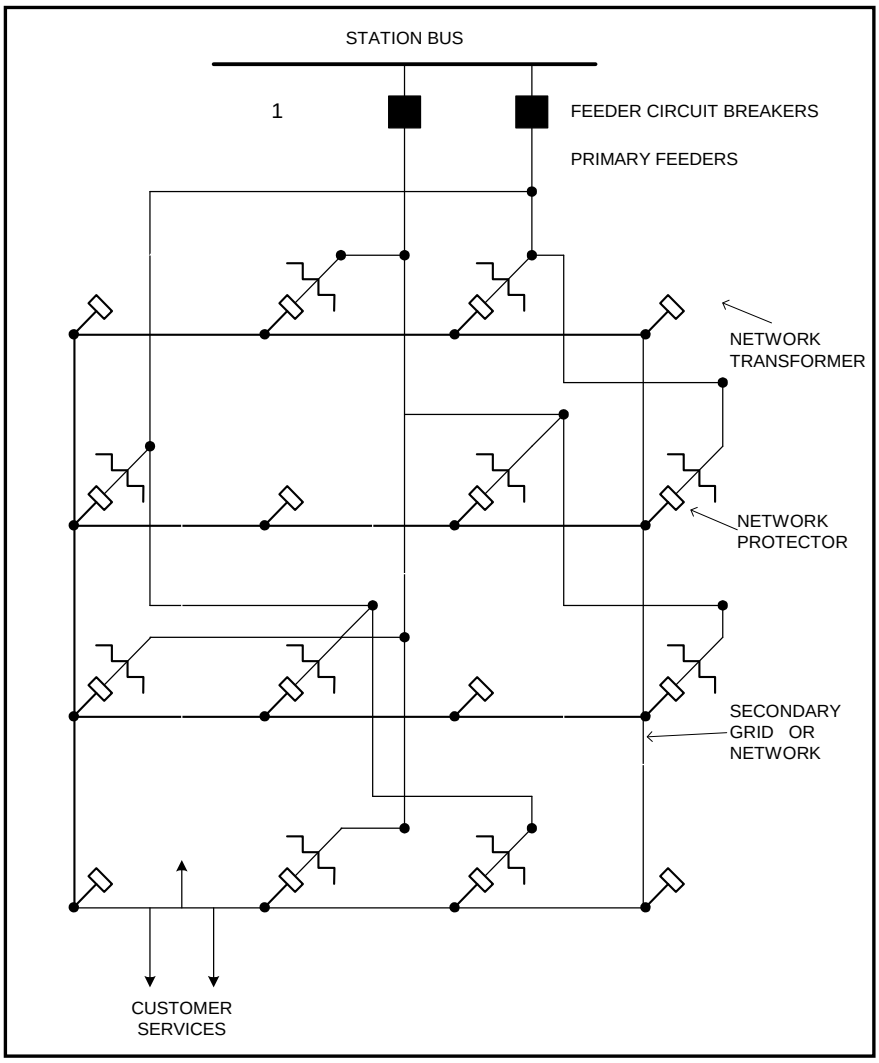

FIGURE 2: BASIC SECONDARY NETWORK DISTRIBUTION SYSTEM

Contingency Events and the Evolution of the Network System

Toronto Hydro's network system is designed to operate under first contingency conditions, meaning that any one primary feeder, transformer, or other critical piece of equipment can be put out of service without causing a service interruption to customers. A second contingency occurs when any two primary feeders, transformers, or other critical pieces of equipment are out of service. Although the system is not designed to operate under second or higher multiple contingency conditions, they can sometimes be sustained for short periods of time. When second or multiple contingency conditions arise, the situation as a whole must be evaluated and if it is

determined that the network is unable to sustain the event, the entire network grid must be dropped.

In order to assess whether a system can operate reliably under first contingency conditions, network systems are modeled, taking into account primary cables, transformers, secondary grids and customer loads, and simulations are conducted. These assessments are typically conducted whenever major changes are made to a network. Over the years, Toronto Hydro has had to make many small, urgent, reactive changes in order to add load to existing customers, add new customers, transfer customers and modify primary feeders without the opportunity to evaluate the net effect..

In addition to the modifications mentioned above, Toronto Hydro has made changes to its safety and operating practices, which has also considerably impacted the network's ability to sustain outages. When Toronto Hydro originally developed the network system, it was designed to sustain equipment outages for a single day without exceeding the thermal limits of the equipment remaining in service. Today's planned feeder outages typically last three days, which result in higher equipment peak temperatures and an accelerated loss of life for equipment. Another issue is that the secondary network distribution system was not originally designed to allow network primary feeders to mix with radial primary feeders. However, at the present time, network and radial loads are mixed on the same feeders and the network grids have not been reconfigured to reflect this new reality.

Proposed Changes to the Network System

Toronto Hydro plans to reconfigure large network grids so that either: (a) sufficient grid flexibility is introduced to enable the sustainment of multiple contingency events, or (b) sufficient customer loads are automatically dropped during multiple contingency events to allow the remainder of the grids to continue operating properly. Examples of how these objectives can be achieved and the impact that they would each have on the network system follow.

As a starting point, Figures 3 through 5 provide an example of a mini-grid consisting of three vaults that each contain two network transformers. This mini-grid is able to operate under first contingency conditions but not under second contingencies. Second contingency events result in transformer overloads that require intervention by the power system controllers to identify the problem and drop the mini-grid. If the overloading problem is not identified and corrected in time, it could result in equipment failure and widespread customer interruptions.

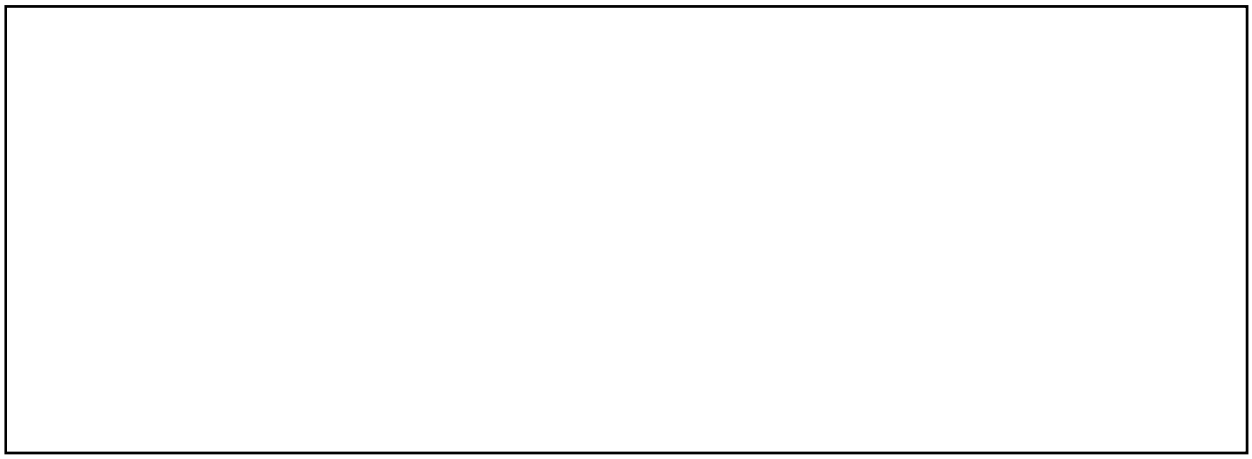

FIGURE 3: EXISTING NETWORK CONFIGURATION (1 OF 3)

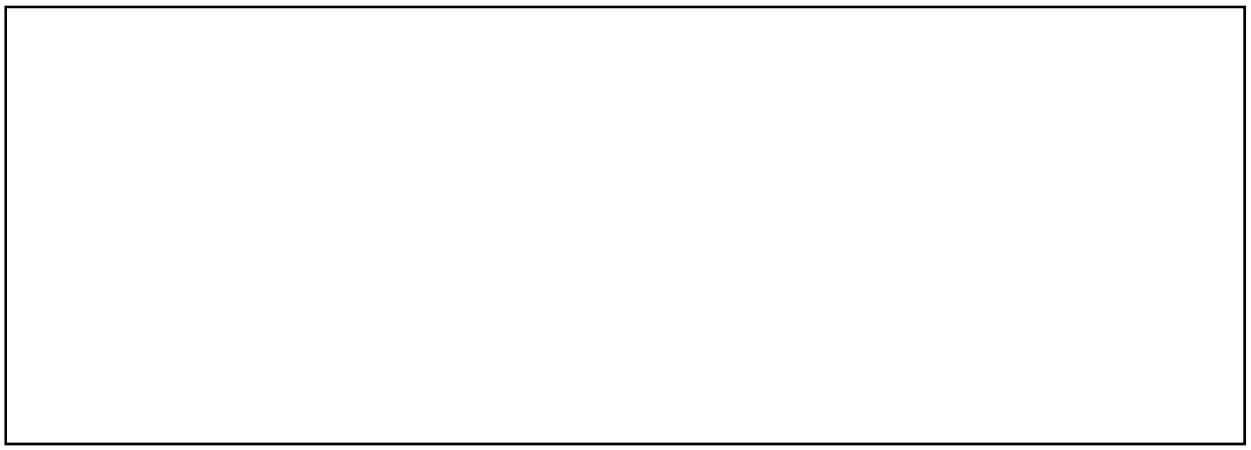

FIGURE 4: EXISTING NETWORK CONFIGURATION (2 OF 3)

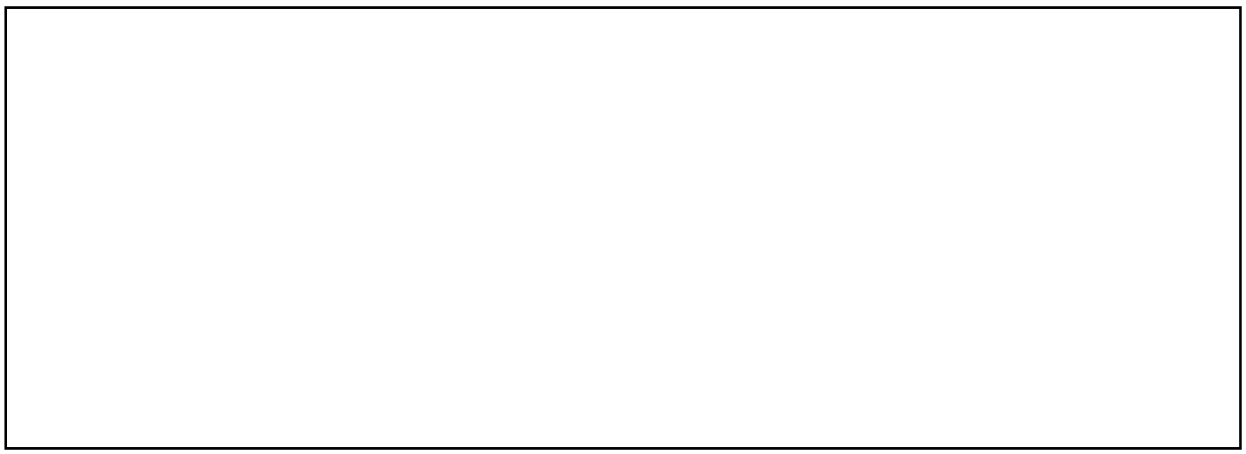

FIGURE 5: EXISTING NETWORK CONFIGURATION (3 OF 3)

The Network Circuit Reconfiguration program uses a number of different options to address the problems and risks associated with multiple contingency events, including:

(1) splitting grid into spot vaults,

(2) splitting grid into enhanced mini-grids,

(3) upsizing transformers, and

(4) primary feeder changes.

These four options are listed in order of increasing benefit, i.e. option four is generally superior to option 1 in terms of reducing the number of customers dropped and equipment damages during second or third contingencies.

Splitting grid into spot vaults

Figures 6 and 7 below illustrate converting a network grid into spot vaults. This option solves overload problems under second contingency events that could result in equipment failure, and eliminates the need for power system controller intervention during these events. On the downside, up to two-thirds of customer loads would automatically dropped during second and third contingency events.

FIGURE 6: FIGURE E6.12-6: SPLITTING GRID INTO SPOT VAULTS (1 OF 2)

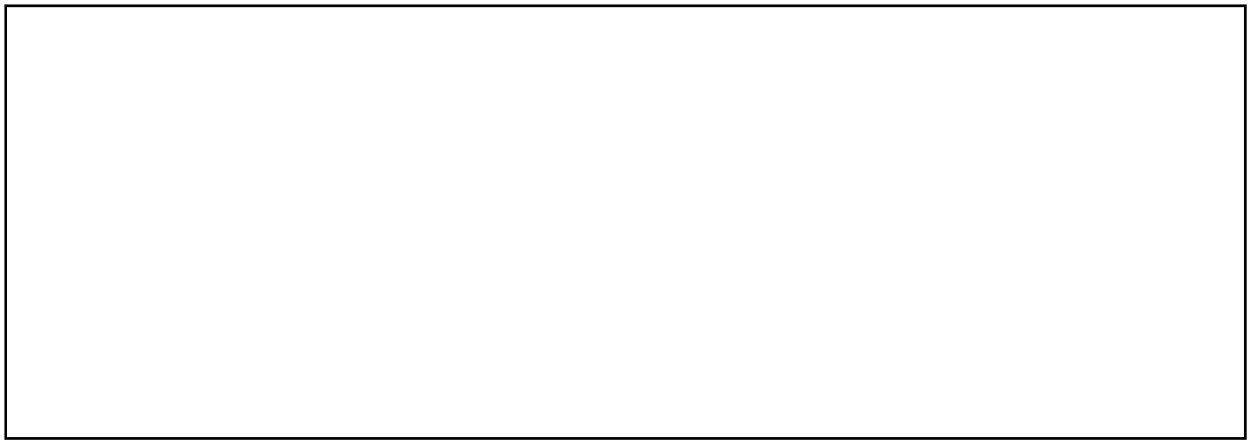

FIGURE 7: SPLITTING GRID INTO SPOT VAULTS (2 OF 2)

Splitting grid into enhanced mini-grids

Figures 8 and 9 below illustrate the second option of dividing a large grid into smaller enhanced mini-grids and spot vaults. This option is able to better sustain customer loads under multiple contingency events than what is possible using the first option. However, a third contingency would still result in a serious transformer overload and require prompt action by the power system controllers to identify the problem and drop the load on the grid.

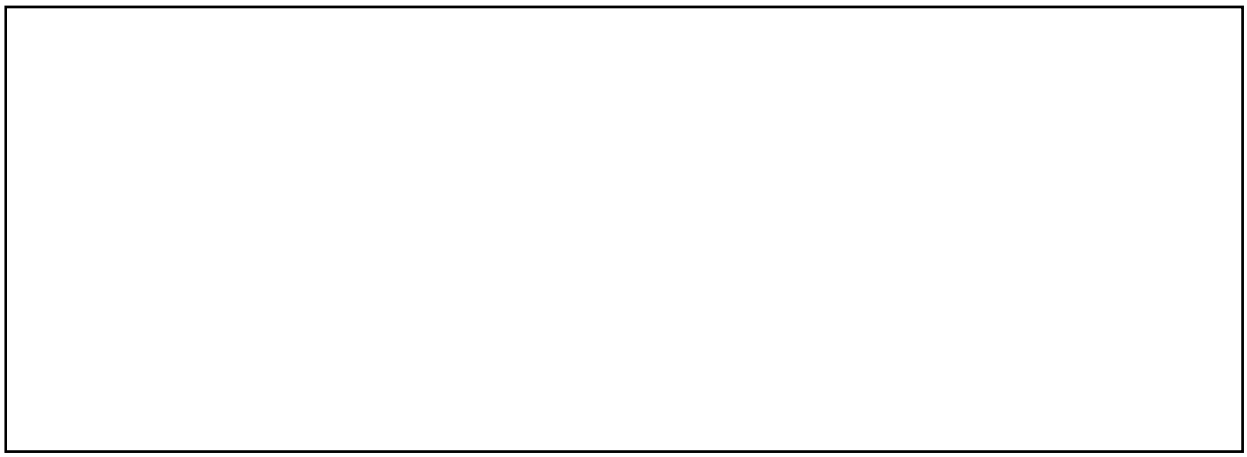

FIGURE 8: SPLITTING GRID INTO ENHANCED MINI-GRIDS (1 OF 2)

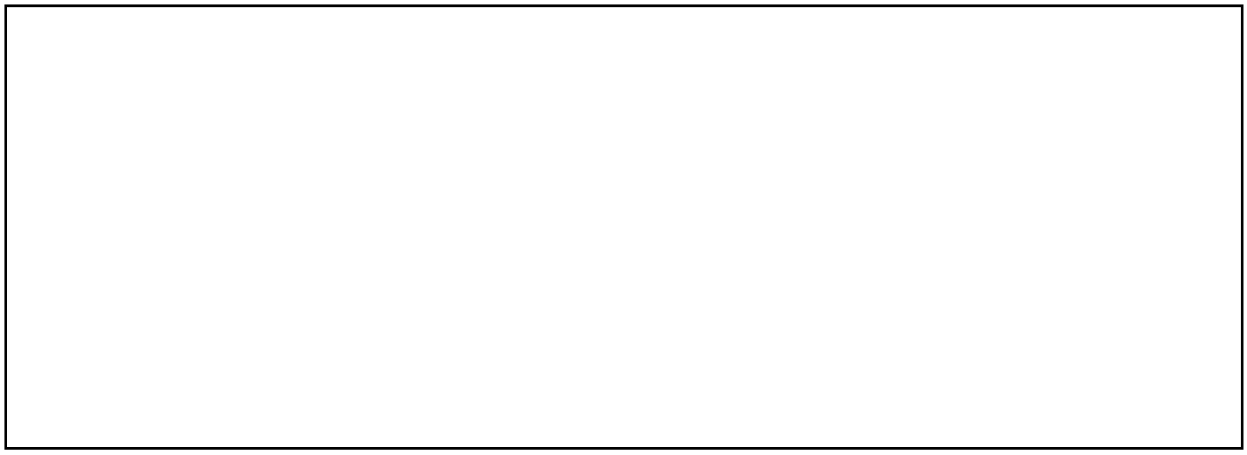

FIGURE 9: SPLITTING GRID INTO ENHANCED MINI-GRIDS (2 OF 2)

Upsizing transformers

Another option to enhance the grid is to upsize transformers where necessary to sustain continuous first contingency and limited second contingency conditions. Figures 10 and 11 below illustrate this third option.

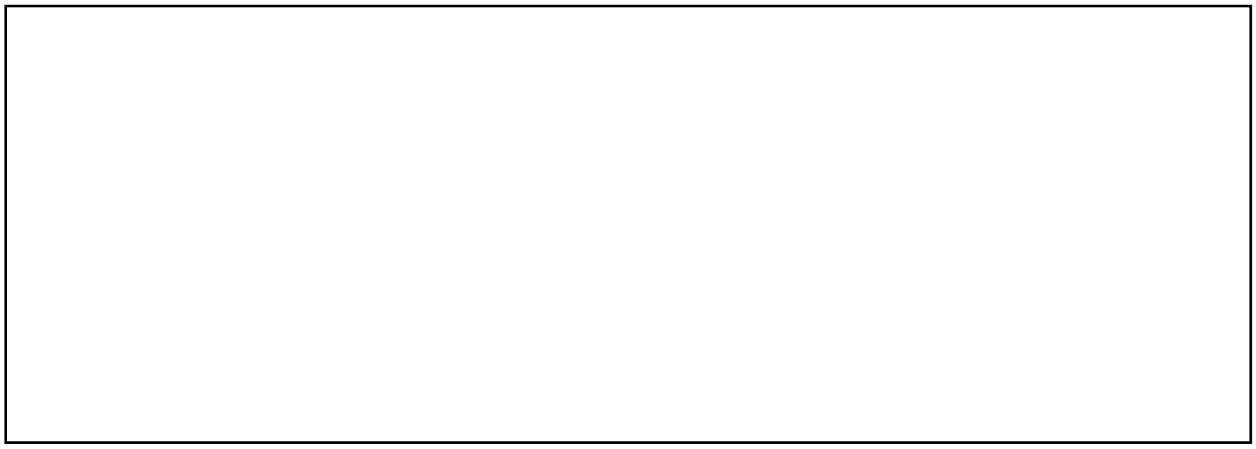

FIGURE 10: UPSIZING TRANSFORMERS (1 OF 2)

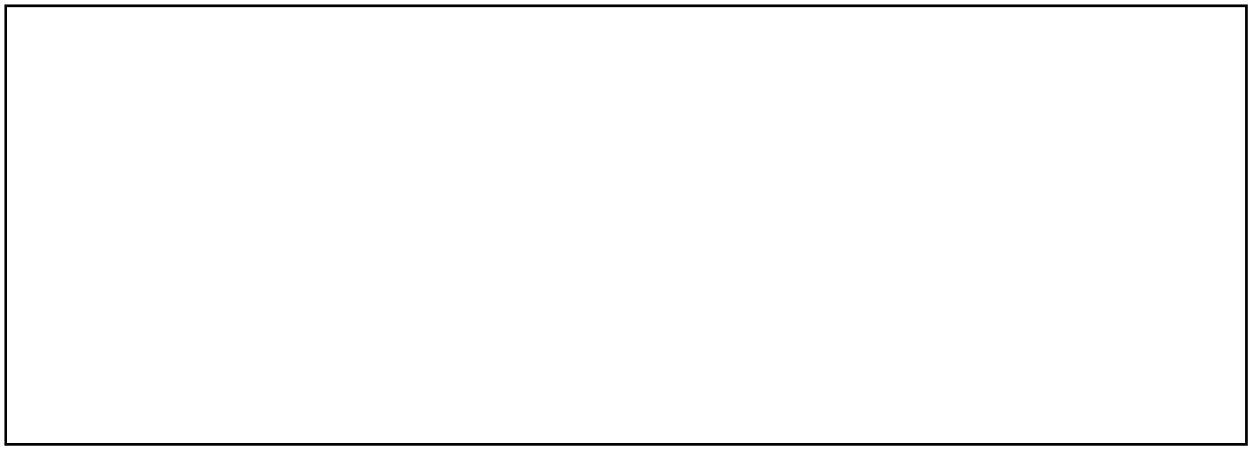

FIGURE 11: UPSIZING TRANSFORMERS (2 OF 2)

The option allows all customer loads to be sustained during any second contingency condition; however, a third contingency would still result in a serious transformer overloads and would require prompt action by the power system controllers to identify the problem and drop the load on the grid.

Primary feeder changes

A fourth option is to change primary feeder connections where necessary to sustain continuous first contingency and limited second contingency conditions. Figures 12 and 13 below use the same network grid to show how this can be implemented.

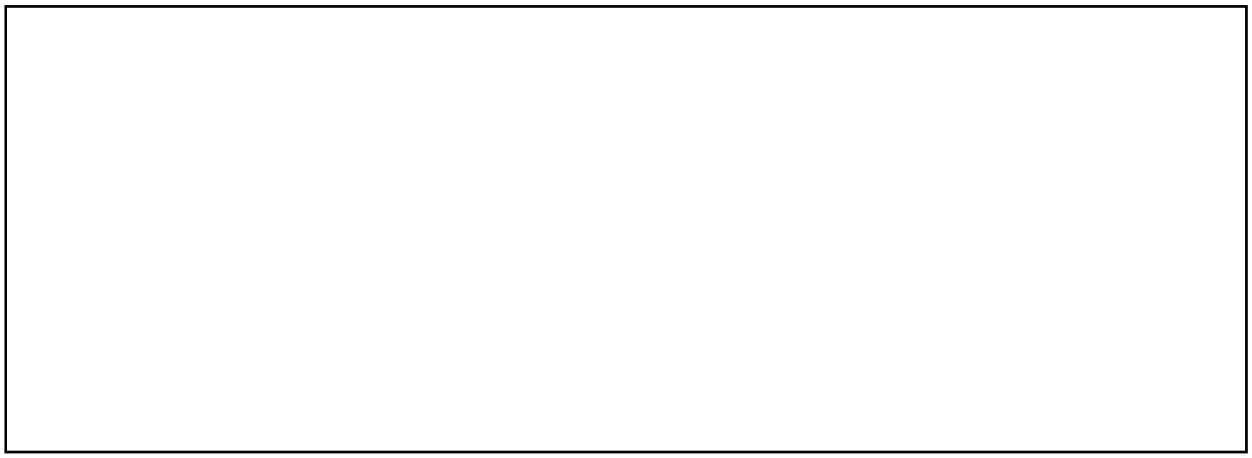

FIGURE 12: PRIMARY FEEDER CHANGES (1 OF 2)

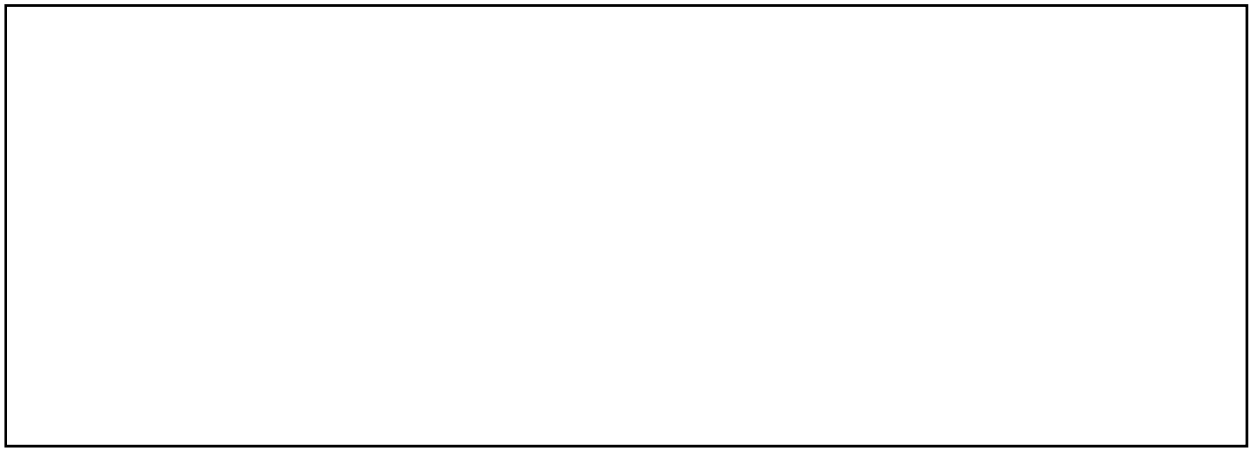

FIGURE 13: PRIMARY FEEDER CHANGES (2 OF 2)

All customer loads would be sustained during any second contingency condition and some third contingencies. However, certain third contingency conditions would result in serious transformer overloads and would require prompt action by the power system controllers to identify the problem and drop the load on the grid.

Summary

While the options above are generally listed in order of increasing benefit, this order of merit varies depending upon the circumstances of each individual network. In other words, each of the

above options may be the optimal solution in a particular circumstance, and each reconfigured network will typically use a combination of these options. For example, combining primary feeder changes with transformer upsizing would allow customer loads to be sustained during any third contingency condition. The optimal combination will maximize the reliability of power supply for customers under multiple contingency events and greatly simplify the problems that the power system controllers must deal with during the same events.

When an entire network must be dropped, up to 50 MVA of customers are interrupted. Currently, the entire network is typically dropped for four hours, with smaller portions dropped for 12 to 24 hours. As a result of the enhancement of secondary network grid flexibility, the impact of outages will decrease. While the amount of improvement will vary substantially from network area to network area, the amount of customer load dropped on a typical six feeder network grid would be reduced by approximately two-thirds.

Since reconfigured network areas are expected to require much less effort to restore widespread service interruptions, emergency response resources will be freed up and can be redirected to restore other, longer outages. Although the number of customers experiencing longer outages may not be dramatically reduced as a result of this initiative, the duration of outages will drop.

Finally, Network Circuit Reconfiguration is a prerequisite for Downtown Contingency station-to-station feeder ties (refer to section E7.7 for details on the Downtown Contingency program). The proposed work under the enhancement of secondary network grid flexibility initiative will permit further service reliability improvements that the Downtown Contingency station-to station program has to offer.

The network reconfiguration projects proposed for the 2015 to 2019 timeframe are illustrated in Figure 2. Network reconfiguration projects were selected to include areas both east and west of Yonge Street in order to balance labour requirements. Particular networks were selected because they are relatively small and simple, and can be quickly and efficiently reconfigured to improve reliability. An additional benefit of this small-scale approach is that Toronto Hydro expects to gain useful experience on how to manage issues and problems with respect to network reconfiguration; later, Toronto Hydro will apply its learnings to other, more challenging networks.

E6.12.2.2 600 V Network Distribution Initiative

The 600 V network distribution initiative proposes to supplement existing 433Y/250V and 216Y/125V network equipment with new 600Y/347V network equipment in order to prevent the

secondary network distribution system from becoming obsolete in light of changing customer needs.

The 600 V initiative will develop and introduce new network distribution equipment as a standard option for future installations. Four locations are included in this initiative in 2016:

- X15511 - Replace Equipment at location PCS with 600Y/347V NW Equipment
- X16148 – Replace Equipment at location CTS with 600Y/347V NW Equipment
- X16149 – Replace Equipment at location DHC with 600Y/347V NW Equipment
- X16150 – Replace Equipment at location ECE with 600Y/347V NW Equipment

Currently, Toronto Hydro supplies network customers with either 433Y/250V or 216Y/125V network equipment.

433Y/250V

Distribution equipment rated 433Y/250V is rarely used in new installations because it is obsolete, difficult to acquire and is no longer supported by Toronto Hydro for new customer installations. Accordingly, 433Y/250V has essentially been superseded by 600Y/347V.

216Y/125V

While equipment rated 216Y/125V is still considered current, it is constrained by a practical building height limit of approximately 25 stories due to excessive voltage drop within the building. As such, upper floors of tall buildings would not be able to maintain voltage at utilization points in accordance with minimum acceptable levels. Consequently, downtown redevelopments above 25 stories cannot be connected to the network system using this technology, and must therefore use less reliable radial distribution equipment. The 600 V network distribution initiative will provide a highly reliable alternative for customers in highrise buildings. Distribution equipment is readily available at 600Y/347V and the practical building height limit at this voltage is about 70 stories. This increased height limit accommodates most network area redevelopment projects.

Sachsenwerk Switch

In addition to new network customers, several existing customers are already supplied by hazardous Sachsenwerk switch and fuse locations at 600Y/347V. Please refer to Section E6.12.3.1 for further details of these locations. Most of these locations have relatively large vaults that are candidates for 600 V network equipment. The 600 V network distribution initiative will replace four of these switches with 600 V network equipment in 2016, while the remainder of the locations will be addressed as part of the Underground Legacy Infrastructure program (Section E6.3).

Introduction of 600 V

The use of 600 V network distribution equipment is an evolutionary development to the lower voltage secondary network equipment that is currently used by Toronto Hydro. In incorporating the new network equipment into the system, Toronto Hydro will take into account the unique maintenance and operating requirements that arise out of the use of higher voltages. In particular, to ensure safe operations, Toronto Hydro must plan for the new design and operating constraints associated with greater arc flash energy levels. Toronto Hydro plans to address these constraints by introducing a number of useful features, including: a submersible case; current limiting fuses (as opposed to alloy type fuses used in lower voltage submersible protectors); arc flash isolating upper links to permit protector overhaul without customer interruption; and network automation to allow remote monitoring and control of the protectors from the control center. A composite photo rendering of these features of the proposed protector is illustrated in Figure 14.

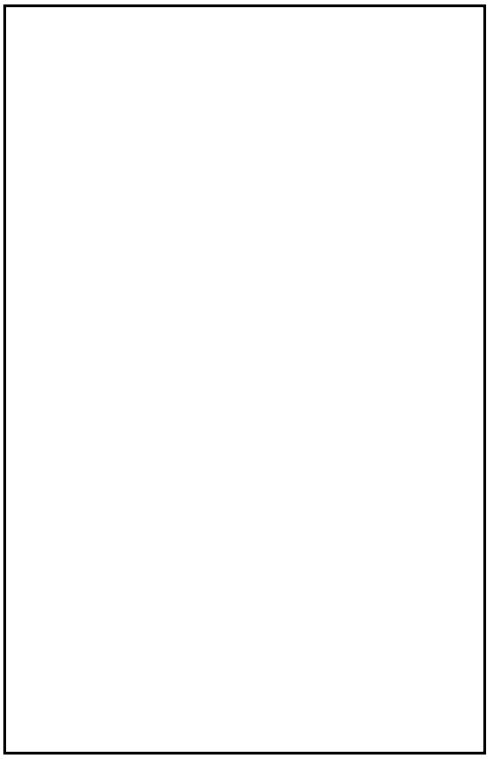

FIGURE 14: COMPOSITE PHOTO RENDERING OF PROPOSED 600V NETWORK PROTECTOR

Another proposed 600 V network feature is the use of transformers of up to 2500 kVA rating, compared to 1000 kVA maximum at 216Y/125V and 2000 kVA at 433Y/250V. These transformers are associated with lower losses than existing lower voltage units, which should generally enable Toronto Hydro to retrofit them so that they can be placed into existing vault structures. The reuse of existing vault structures would be desirable in the case of an existing building being refurbished, or where an underutilized sidewalk vault is repurposed to feed a new building.

Toronto Hydro plans to use multiple single unit vaults when new vaults are required in order to prevent the failure of one network unit damaging other units. This design will improve the reliability of power supply for customers that are fed from the vault and for the network grid as a whole, which would otherwise be exposed to a multiple contingency event. The first four 600 V network installations will reuse existing vaults that currently contain Sachsenwerk switchgear. (Saschenwerk switch and fuse units are a type of legacy underground equipment used to provide certain customers with a dual radial supply; these switches are planned for replacement during 2015-2019 as part of the Underground Legacy Infrastructure program (E6.3)).

The layout, primary cabling and secondary cabling of a typical 600 V network vault is illustrated in Figure 15. This layout is representative of one that would is planned for all four Sachsenwerk switchgear vault projects. In this example, two network units are installed in the vault.

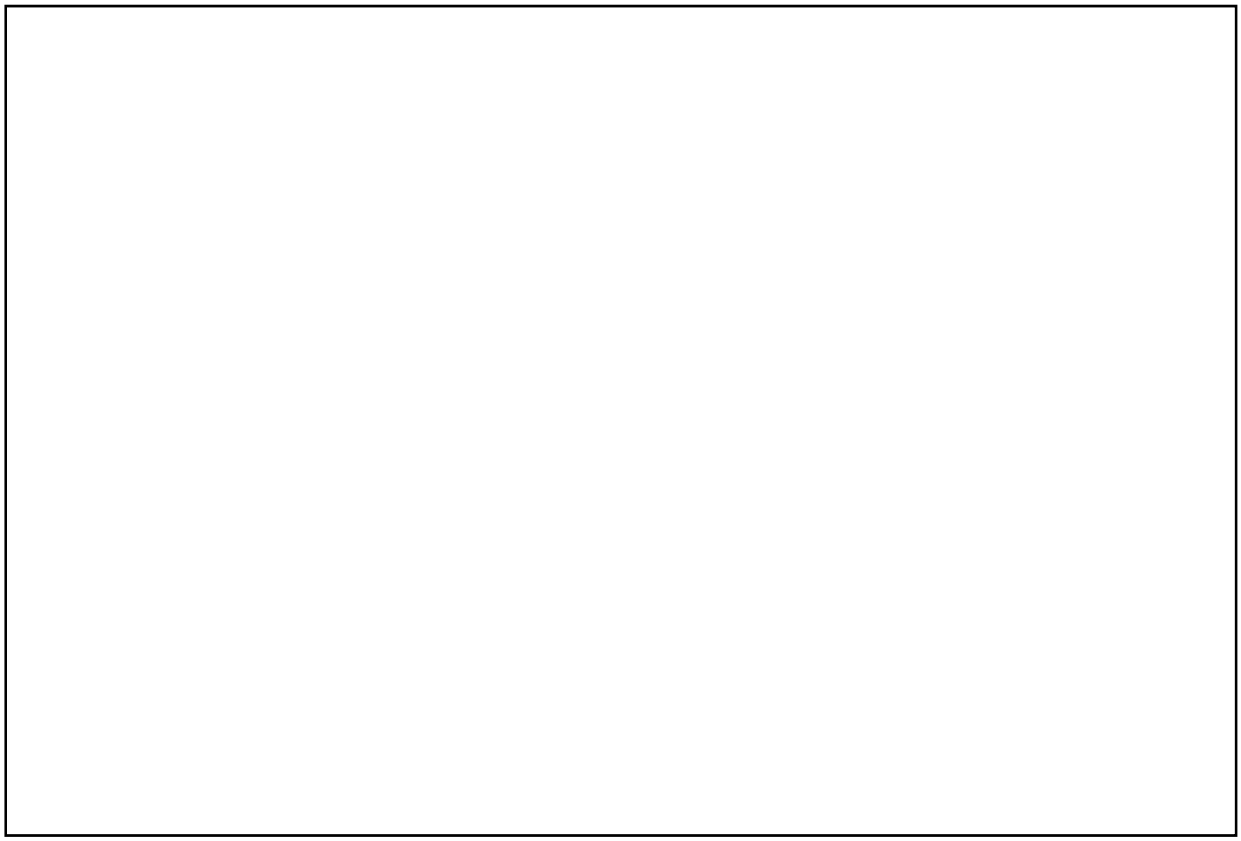

FIGURE 15: LAYOUT OF TYPICAL 600V NETWORK VAULT

The 600 V network distribution initiative involves the replacement of eight switchgear and four transformers with eight new network units as illustrated in Table 1 below.

TABLE 1: ASSETS TO BE ADDED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
UG Transformers		8				8

The benefits of the Network Circuit Reconfiguration program include increased customer value along with improvements to reliability, efficiency and safety. A summary of these anticipated benefits is provided in Table 2 below.

TABLE 2: PROGRAM BENEFITS

Customer Value	ƒ Following major equipment failures, fewer customers will be dropped, fewer customers will be required to reduce load and customers will experience shorter outages. ƒ Eliminates customer outages due to special switching requirements in some locations. ƒ Improves Toronto Hydro's ability to meet the service needs of new customers through new service supply options. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $3.08 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.12.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.77 million, confirming the economic prudence of the investments (see Section E6.12.7).
Reliability	ƒ Improved ability to operate networks under multiple contingency events. ƒ Two-thirds reduction in load interruptions during second contingency events. ƒ Eliminates special operating restrictions that interrupt a second feeder following a failure on specific feeders. ƒ Permits station to station feeder ties to improve reliability as part of the Downtown Contingency program.
Safety	ƒ Minimizes potentially hazardous manual switching activities following major equipment failures. ƒ Eliminates hazardous Sachsenwerk switch and fuse units in four locations.
Efficiency	ƒ Improves the productivity of power system controllers and system response crews. ƒ Removes special operating procedures at four locations.
Other	ƒ Reconfigured network feeders can be tied to feeders from other stations as part of the Downtown Contingency program. ƒ Improved ability to transfer loads.

E6.12.3 Why the Program is Needed

The main driver for the Network Circuit Reconfiguration program is Functional Obsolescence, which is a result of urgent, incremental changes being made to the system and the evolution of

operative practices to accommodate new customers. Other secondary drivers include Reliability, System Efficiency, and Safety.

E6.12.3.1 Program Drivers

Table 4 presents the primary and secondary drivers for Network Circuit Reconfiguration, which is considered a System Renewal initiative because the primary driver is Functional Obsolescence.

TABLE 3: PROGRAM DRIVERS

Primary Driver	Reasoning
Functional Obsolescence	ƒ The network system was designed for pure network loads and not the mixed network and radial loads that exist today. Enhancement of secondary network grid flexibility is necessary to adapt to this new standard. ƒ The network system is becoming functionally obsolete due to its inability to supply new classes of customers, while at the same time existing classes of customers are dwindling. The 600 V network distribution initiative is necessary in order to allow the secondary network distribution system to operate as needed for new classes of customers.
Secondary Drivers	**Reasoning**
Reliability	ƒ The secondary network system was originally designed to withstand first contingency operation; however, multiple contingency events are now a common occurrence, which result in widespread outages. ƒ Although the network system was originally designed to allow faulted equipment to burn clear, present operating practices often require Toronto Hydro to cut all power, resulting in widespread customer outages. ƒ Operating restrictions on existing hazardous Sachsenwerk switch and fuse units reduce the reliability of power supply.
System Efficiency	ƒ Network Circuit Reconfiguration will relieve power system controller workload during multiple contingency events and reduce the need for system response crews to perform load relief and restoration tasks.
Safety	ƒ Sachsenwerk loadbreak switches in use pose safety hazards.

(i) Functional Obsolescence

The primary driver for the Network Circuit Reconfiguration program is Functional Obsolescence. The network grid has not been adjusted to account for incremental modifications that were made to the network to accommodate new customers, which reduces its ability to operate under multiple contingency conditions. As well, Functional Obsolescence is an issue because changes

to operating practices now force multiple contingency events, which the system was not originally designed to manage.

Mixing of Different Types of Loads

The secondary network distribution system was originally designed and constructed when network primary feeders were not mixed with radial primary feeders. Since then, network and radial loads have been mixed on the same feeders, raising the following issues:

(1) Network feeders are designed with high loading factors, which is acceptable because when a primary feeder is out of service, loads automatically get redistributed across all of the other network feeders. However, radial feeders must be designed with low loading factors because radial loads are either entirely on the normal feeder, or entirely on the standby feeder. As a result, when radial loads are connected to network feeders, the loading margins needed to operate the network under multiple contingency events quickly disappear.

(2) Radial customer work often requires feeders to be de-energized for extended periods of time. Network equipment, on the other hand, is designed to operate with overloads that can only be sustained for short periods of time when a feeder is out. As a result, radial loads tend to erode the margins required to operate networks. This can be a serious problem during multiple contingency events.

The problems mentioned above are having an increasingly negative impact on Toronto Hydro's ability to manage the secondary network distribution system. For example, 54 network feeders could not undergo planned interruptions during the summer of 2014, in order to avoid cable and equipment overloads. Enhancement of secondary network grid flexibility is required in order to compensate for the present practice of mixing network and radial loads on the same feeders.

Downtown Redevelopment Customers and Existing Customers Declining

The network system is also becoming functionally obsolete due to existing network equipment being unsuitable for use with new classes of downtown redevelopment customers, while at the same time, the number of existing network customers is dwindling. Figure 16 below illustrates the recent drop in network load as a percentage of total downtown loads. Over the past seven years, the network portion of downtown loads has dropped by more than 25%.

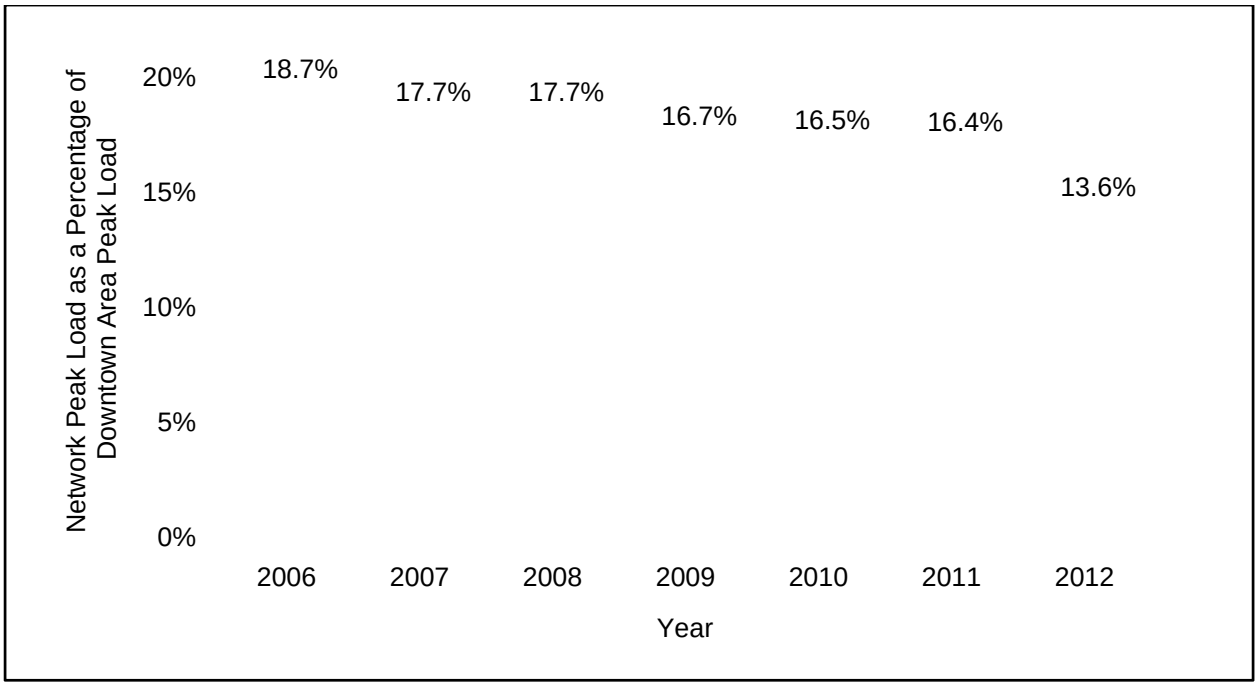

FIGURE 16: NETWORK PEAK LOAD TO TORONTO DOWNTOWN AREA PEAK LOAD

Total load carried by the network system has dropped over the last seven years from 307.8 MVA down to 243.5 MVA. This represents a decrease of almost 21% and is shown in Table 4 below:

TABLE 4: NETWORK SYSTEM & TORONTO DOWNTOWN AREA SYSTEM PEAK LOADS

Year	2006	2007	2008	2009	2010	2011	2012
Toronto Downtown Area System Peak Load (MVA) (a)	1,648	1,705	1,684	1,663	1,701	1,694	1,789
NWK System Load (MVA) (b)	307.8	301.3	298.8	278.1	280.6	277.3	243.5
Ratio (b/a)	18.68%	17.67%	17.74%	16.72%	16.50%	16.37%	13.61%

The decreasing percentage of total downtown peak load supplied by the network, combined with continually decreasing network loads, demonstrates that the existing network system no longer provides suitable connection services for customers and as a result, is becoming obsolete. There are three major reasons for this trend.

(1) High-rise redevelopment of network areas . New developments in the downtown area are generally made up of office and condominium buildings that are 35 stories or higher. These redevelopments are rapidly replacing existing buildings that are generally two to four stories high and that are supplied by secondary network distribution. As such, the redevelopment represents a very significant demographic switch from when the network system was first constructed. Given that existing 216Y/125V network equipment has a practical height limitation of about 25 stories, it is unable to supply the majority of new construction. As a result, new redevelopments have to depend on the less reliable 13.8 kV radial distribution option. In addition, the existing network infrastructure is generally not suitable for reuse with radial distribution, so costly new construction is often required to supply new customers.

(2) Customer updating of electrical equipment . Existing mid-rise buildings that use electrical equipment at their end-of-life often replace obsolete 433Y/250V equipment with modern 600Y/347V equipment. Seeing as Toronto Hydro does not currently possess 600Y/347V network option, customers are forced to depend on the less reliable 13.8 kV radial distribution option.

(3) Network customer supply size limit . Toronto Hydro is no longer offering new customers 433Y/250V network service. The service size limit for new 216Y/125V network customers is 750 kVA. Since new high-rise customers typically have a demand of 2500 kVA or more, they must connect to the 13.8 kV radial distribution option, which does not have the same reliability benefits as the network system.

All of the issues described above can be resolved by Toronto Hydro offering a 600Y/347V network option to customers with increased service size limitations. The high-rise redevelopment of network areas limit is resolved by the practical building height limit at 600Y/347V being about 70 stories; the customer updating of electrical equipment issue is resolved by providing service at the customers' desired voltage; and the network customer supply size limit is resolved by offering multi-MVA supply sizes.

To summarize, this program is needed so that Toronto Hydro can sustain the network system and continue to offer new customers the highly reliable secondary network distribution system as a supply option. Should this work not proceed, downtown customers' reliability may suffer. The 600 V network distribution initiative is necessary so that the secondary network distribution system maintains its relevance and performance.

(ii) Reliability

Reliability is an important secondary driver of the program. The secondary network distribution system has experienced reduced reliability in the past few decades. System reliability has been impacted by changes that were made to operating practices that force multiple contingency interruptions, and by incremental modifications that were made to the network in order to accommodate new customers, which reduces its ability to operate under multiple contingency conditions. The Network Circuit Reconfiguration program is intended to restore network reliability to original design levels.

Evolving Operating Practices

The secondary network system was originally designed to burn clear faults and self-isolate damaged equipment; meaning that that most failures of network transformers and primary and secondary cabling do not result in customer interruptions. Virtually all failures of primary and secondary cabling are cleared without requiring intervention from the power system controllers and without interruption to network customers. However, a small number of transformer failures result in vault fires.

The fire department's current practice is to require that Toronto Hydro immediately cut all power supplies into the vault as a first step in fighting the fire. As a consequence, multiple network primary feeders must be tripped, which leaves insufficient remaining contingency capacity to sustain the network grid. As a result, entire network grids, with as much as 50 MVA of customer loads, often must be dropped, causing widespread and long outages. Assuming a typical residential customer load of 4 kVA, this 50 MVA interruption represents 12,500 residential customers.

By reconfiguring the network grids into spot vaults and enhanced mini-grids, the need to drop entire network areas can be greatly reduced or eliminated. These reconfigured grids will be able to better sustain the majority of loads; only small portions of customers will experience outages. Overall network reliability can thereby be substantially improved.

For a typical six primary feeder network, a second contingency failure incident entails dropping about 30 MVA of load for four hours. A reconfigured network grid should be able to sustain a second contingency incident without requiring the entire network to be dropped. The reconfigured network should, by design, shed sufficient load under second contingency conditions to allow the remainder of the grid to continue to operate. This should typically result in only about 10 MVA of

load being dropped, a two-thirds reduction in interrupted load. This reliability enhancement is illustrated in Figure 17 below.

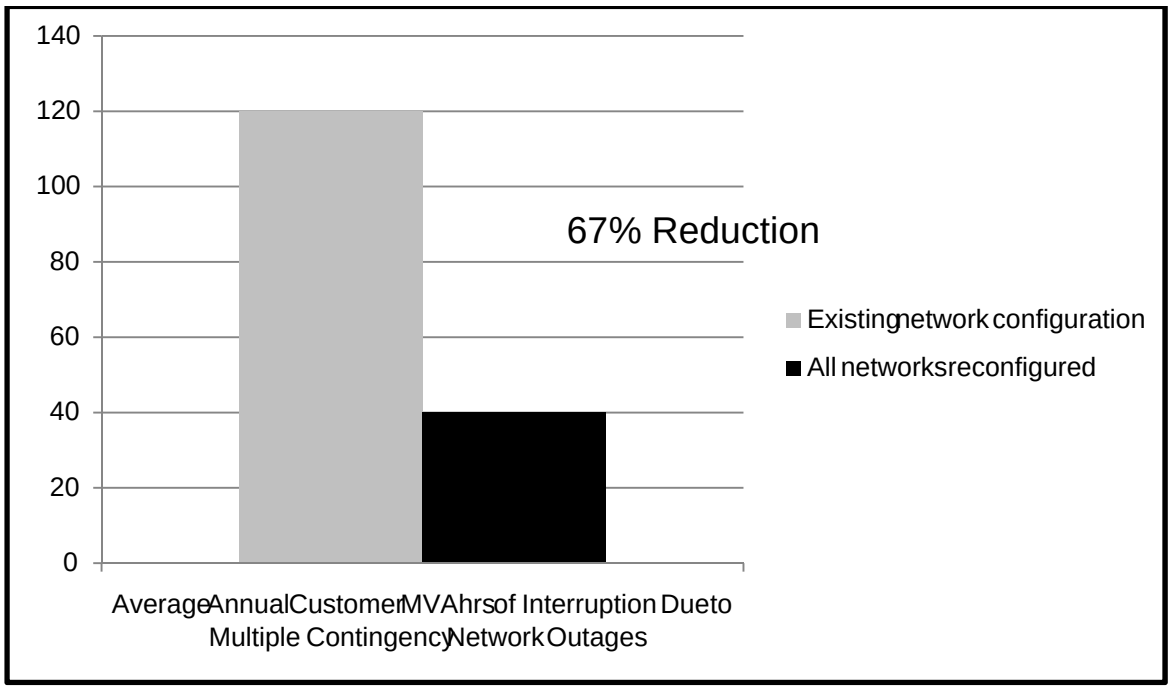

FIGURE 17: RELIABILITY IMPROVEMENT FROM NETWORK CIRCUIT RECONFIGURATION

Multiple Contingency

Multiple contingency operation of the network system imposes daunting requirements on operating personnel. First, a network expert must analyze the grid, identify critical overload conditions and propose customer load reductions and necessary reactive tasks all within restrictive time limits. Should such an expert not be immediately available at the control center, the power system controllers may be forced to drop the entire grid in order to prevent a network cascade failure. A network cascade failure would likely result in the loss of up to 50 MVA of customer load for at least 24 hours.

Second, once the necessary reactive switching and load reduction tasks are identified, system response crews must perform this work, and customers need to reduce their loads within the identified time limitations. Reconfigured networks will generally be able to continue operating under multiple contingency events by automatically shedding unsustainable loads, relieving

power system controller workload and reducing the need for system response crews to perform reactive load relief and restoration tasks.

Secondary Interconnections

Another shortcoming of the existing network configuration is that it is not practical to provide network feeders with station-to-station feeder ties. The large number of secondary interconnections means that network feeders must be energized simultaneously rather than one at a time. This causes two significant problems:

(1) The entire alternate station bus that would pick-up the network experiencing a station loss-of-supply incident must be dropped. This would cause unacceptable widespread outages to customers that would otherwise not experience an outage.

(2) The subsequent requirement to simultaneously pick-up both the emergency transferred network load and the original alternate station bus loads would almost certainly exceed the cold load pick-up capabilities of the station bus.

Reconfigured network grids will permit station-to-station feeder ties to be picked-up one at a time. These grids are therefore compatible with the Downtown Contingency program (see Section E7.7), and thereby permit further reliability improvements.

Downtown Developments and the Sachsenwerk Switch

Many new downtown developments require 347/600V services. However, at the present time, all available options involve the use of dual radial distribution equipment, which do not provide reliable service to customers. Accordingly, the development and use of 600Y/347V secondary network distribution equipment will significantly enhance customer reliability.

In addition, operating restrictions are currently in place on the hazardous Sachsenwerk switch and fuse units, which results in unnecessary customer interruptions following feeder failures. The replacement of these switches through the 600 V network distribution initiative will eliminate the operating restrictions and improve service reliability on the associated feeders.

Toronto Hydro plans to replace four locations containing eight Sachsenwerk switch and fuse units with 600Y/347 V network equipment in 2016. The age of these Sachsenwerk units vary between 25 and 27 years and are detailed in Figure 18 below.

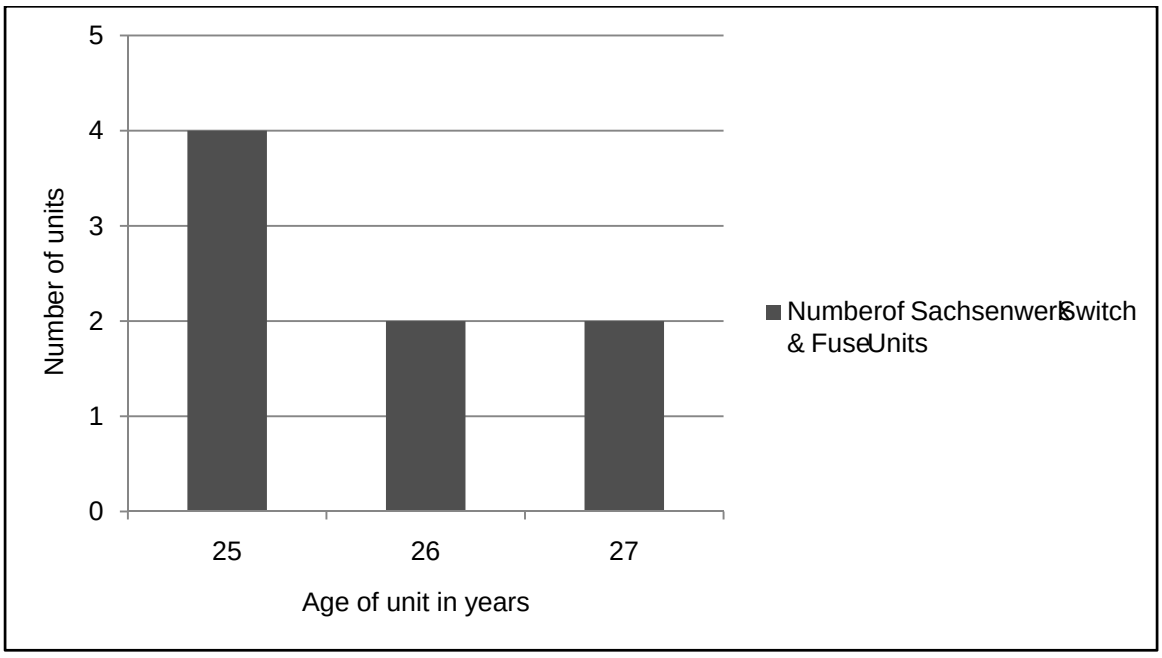

FIGURE 18: AGE OF SACHSENWERK SWITCH AND FUSE UNITS TO BE REPLACED IN 2016

The Sachsenwerk switch and fuse units must be replaced, as they are no longer manufactured and serviced, and can pose serious hazards (as described below).

Flashovers in Saschenwerk Units

Presently four locations in downtown Toronto are supplied from hazardous dual-radial switch and fuse vaults with 600Y/347V transformers. These particular switch and fuse units use Sachsenwerk load break switches that periodically fail to engage properly during open and close operations, resulting in flashover that causes the station breaker to open, and presents a hazard to the switch operator. As a result, Toronto Hydro has introduced operating restrictions to manage this risk. Further discussion of Sachsenwerk switch and fuse units can be found in Section E6.3 Underground Legacy Infrastructure.

In order to reduce the risk of flashovers occurring in Saschenwerk units during switching operations, they are only operated in paralleling operations that do not make or break loads. This means that even if a Saschenwerk switch malfunctions during its operation, it will not cause a hazardous flashover. During most normal switching operations, customers will not experience service interruptions. However, during emergency switching operations, customer service is impacted. For example, if one feeder goes out on fault, the second feeder will be interrupted prior to operating the Sachsenwerk switches. The result is a second contingency event that likely results in a number of otherwise unnecessary customer interruptions.

The 600 V network distribution initiative will replace the equipment in four of these Sachsenwerk switch and fuse locations, which will eliminate unnecessary customer interruptions. Furthermore, the provision of secondary network distribution equipment will provide additional customer reliability improvements over alternative dual-radial equipment.

Subway Transformers

In addition to the Sachsenwerk switch and fuse units, Toronto Hydro plans to replace related 600Y/347 V subway transformers. Subway transformers are designed for use in underground applications; however, they are not compatible with network equipment and therefore must also be replaced.

The age of these subway transformers vary between 25 and 27 years as shown in Figure 19 below. Subway transformers have a useful life of 35 years and the transformers removed from service will have their condition reassessed. If the subway transformers are evaluated to be in good condition, they will be retained for reuse in other parts of the system, rather than scrapped.

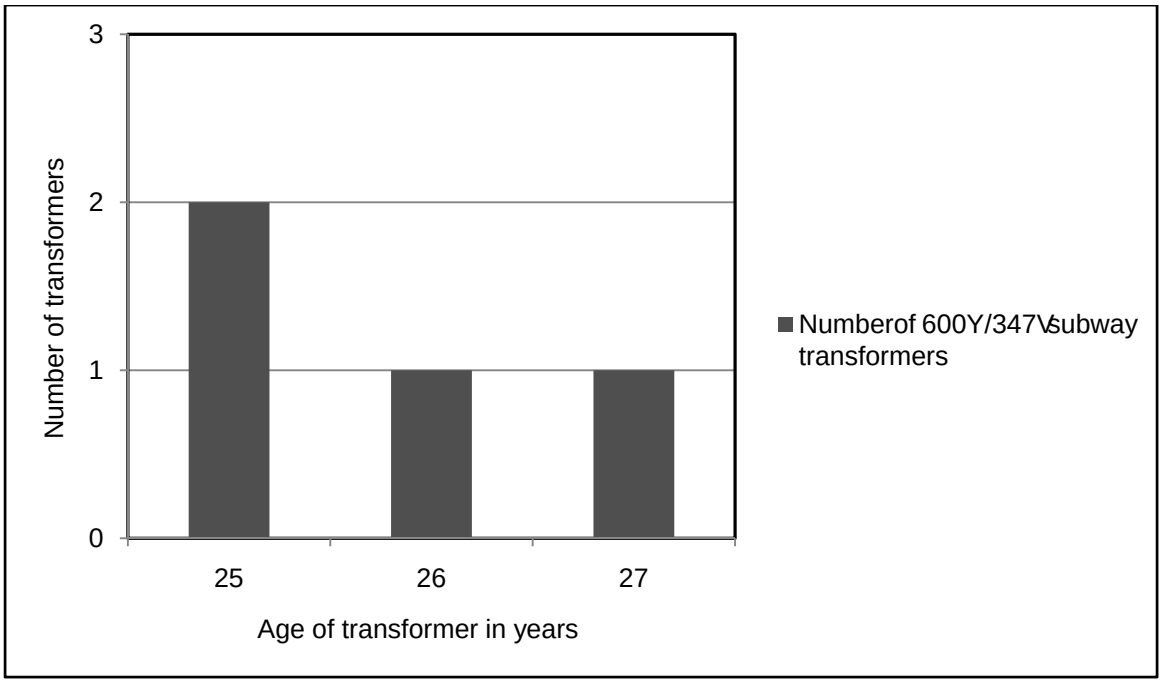

FIGURE 19: AGE OF SUBWAY TRANSFORMERS TO BE REPLACED IN 2016

Reach of the Secondary Network Distribution System

The secondary network distribution system represents 13.6% of the downtown Toronto peak load, or 243.5 out of 1789 MVA. Although it is Toronto's most reliable distribution system, when a major secondary network equipment failure occurs, the impact is widespread. Often entire station switchgear, with up to 50 MVA of customer load, equivalent to approximately 12,500 residential customers, must be interrupted following such events. These widespread service interruptions average about four hours in length, with some customers being interrupted for 12 to 24 hours. The resulting customer interruption costs are significant. Assuming an average of two four-hour interruptions of 30 MVA each year, the average annual customer interruption cost for entire networks being dropped is estimated to be $2.7 million. Refer to section D3.1 for customer interruption cost evaluation.

In recent years, such events have typically occurred once to twice each year. A recent example of a failure in a single location causing widespread customers interruptions took place on September 3, 2012. This incident transpired after a customer accidentally dug into buswork directly supplied from four transformer network vault locations at 4384 St Clair Avenue West. In order to isolate this customer fault, Toronto Hydro had to interrupt the entire High Level St. Clair

network. In all, Toronto Hydro was required to interrupt 41 MVA of load for 109 minutes, affecting 3,073 customers, including Upper Canada College, Hyatt Hotel, the Royal Ontario Museum, adjacent TTC stations, and Bishop Strachan School. If the network supply in this area had been reconfigured, this fault would likely have automatically cleared without requiring interruption of the entire network. Photos from this incident are included in Figure 20 below.

FIGURE 20: SEPTEMBER 3, 2012 INCIDENT AT LOC 4384

Reconfiguring Networks

In addition to ongoing efforts with respect to Fibertop Network Unit replacements (refer to Section E.6.10), Toronto Hydro can further reduce service outages by reconfiguring networks to minimize the number of feeders that must be interrupted following multiple contingency events. With an average of six feeders per network, a typical second contingency incident would leave four feeders in service; typically reducing the number of customer and load interrupted by

approximately two-thirds. This benefit would apply to both network and radial supplied customers fed from these network feeders, and may exceed 33 MVA of load that otherwise would be interrupted. The benefits of particular reconfiguration changes are illustrated in the Figures of Section E6.12.2.1.

The three network reconfiguration projects forming part of this program impact the services of 2,038 customers, many of which are large customers. Total load on the three networks is 50.6 MVA, which represents the equivalent of 12,600 residential customers of 4 kVA load each.

(iii) System Efficiency

Another secondary driver of the program is System Efficiency. The network system in Toronto was designed to handle first contingency operation. Under any first contingency event, power system controllers at the control center do not need to take any action to ensure continued reliable supply to network customers. Multiple contingency events, however, require immediate action by power system controllers and system response crews. Often, only minutes are available to take effective action in order to prevent a cascading failure of network grids.

Network Circuit Reconfiguration will generally allow a network to sustain a second contingency incident without requiring the entire network to be dropped. The reconfigured network should, by design, shed sufficient load under second contingency conditions to allow the remainder of the grid to continue to operate. Since almost all network emergencies involve only first and second contingency outages, this will result in an efficiency improvement within system control.

In addition, most multiple contingency network emergencies require the power system controllers and system response crews to spend hours conducting switching operations to stabilize the network and restore as many customers as possible. As a result, work to isolate and repair failed equipment may be delayed until this work is completed. Network Circuit Reconfiguration will reduce the workload required to stabilize the network and restore customers. This should allow restoration work to begin at the earliest opportunity and thereby minimize the time required to restore the network to normal operation.

The 600 V network distribution initiative will also eliminate the switching restrictions presently imposed on four existing 600 V switch and fuse locations with Sachsenwerk switches. Presently these switches may only be operated under conditions that do not make or break load. As a result, following the failure of a feeder supplying a customer fed from one of these vaults, the power system controllers must arrange an interruption to the second feeder supplying the vault.

This planned second contingency outage involves extra switching operations and service interruptions to some customers that would otherwise not require outages. It also greatly extends the duration of the outage to the customer supplied by the vault. The 600 V network project will eliminate the hazardous equipment and remove the switching restrictions on the associated feeders.

An additional benefit to the power system controllers is the automatic switching of network equipment following feeder outages compared to the manual switching required by dual radial equipment. Network supplied customers do not require power system controller intervention to restore power following feeder failures.

(iv) Safety

Safety is an additional secondary driver for this program. Some existing 347/600 V supplied customers are fed from Toronto Hydro vault equipment utilizing 13.8 kV Sachsenwerk loadbreak switches. Since these switches have been identified as being hazardous to operators, Toronto Hydro has imposed operating restrictions to maintain safety.

Safety is an issue because the switch operating mechanism on a Sachsenwerk switch and fuse unit uses spring action to rapidly snap open and close when operated in order to safely interrupt the 13.8 kV arc. At times, Toronto Hydro has found that the over-center spring does not engage properly and the switch slowly operates under the direct motion of the operating handle. As a result, the switch could draw an arc for an excessive length of time and fault to ground. This flash-over poses a serious risk of injury to the switch operator

A detailed discussion of Sachsenwerk switch and fuse units can be found in Section E6.3 Underground Legacy Infrastructure.

As part of the 600 V network distribution initiative, Toronto Hydro plans to remove this hazardous equipment from four locations where 600 V secondary network distribution equipment was determined to be the most suitable replacement equipment. The remaining Sachsenwerk Loadbreak switch locations are not suitable for 600 V network equipment and will have alternative equipment installed as detailed in Section E6.3 Underground Legacy Infrastructure. Photos of this equipment are included in Figures 21 and 22 below.

FIGURE 21: PHOTO A SHOWS THE SACHSENWERK SWITCH REMOVED FROM ITS CABINET, PHOTO B SHOWS THE SWITCH AND FUSE UNITS (NOTE SEPARATE COMPARTMENTS FOR EACH) AND THE SWITCH HANDLE BEING OPERATED, EXTERNAL DOOR IS OPEN.

FIGURE 22: PHOTOS OF SWITCH COMPARTMENTS FROM LOCATION MDH (LEFT) AND LOCATION GWD (RIGHT) AFTER FLASH-OVER INCIDENTS

The Network Circuit Reconfiguration program will reduce the number of manual switching operations performed by field staff. As these manual switching operations potentially expose the operator to high energy flashovers, they pose the highest risk of all activities performed by field staff. The Network Circuit Reconfiguration program will therefore positively impact worker safety.

Another important consideration is life-support customers. Life-support equipment generally has battery back-up that can last no more than a few hours during a service interruption. Long outages therefore increase the risk that life-support equipment could be compromised. Toronto Hydro keeps track of known life-support customers. However, there is a high likelihood that additional life-support customers unknown to Toronto Hydro exist. These customers could face serious consequences from a prolonged service interruption. The Network Circuit Reconfiguration program will reduce the likelihood of secondary network distribution supplied life-support customers experiencing outages by two-thirds, and also reduce the duration of outages when they do occur.

(v) Other Benefits

The Downtown Contingency program provides ties between feeders originating from different stations, and provides an alternate source of supply for customers should the normal supply station experience a major outage. Network feeders are presently not suitable candidates for such station to station feeder ties because the substantial cross connection of secondary cables between network transformers supplied by a number of different feeders makes it difficult to pick up loads in manageable pieces.

Currently, two possibilities exist for re-energizing a network; (1) all at once and (2) feeder by feeder. In order to pick-up a network all at once, the station switchgear at the transformer station must first be dropped. Next, all of the station to station feeder ties must be closed and finally, the station switchgear picked up. The cold load pick-up requirement of two complete switchgears will exceed the capability of the Hydro One Networks Inc. (HONI) supply and trip out the HONI circuit breakers. Therefore this is not a viable option.

The alternative option requires the feeder ties to be closed one at a time. Although this resolves the station cold load pick-up problem, it creates a multiple contingency problem for the network, with a significant risk of creating a cascade failure. In order to avoid the risk of cascade failure, detailed loading analysis and unusual and elaborate switching is required. The risks and effort associated with this solution are considered to be sufficiently excessive as to make this a non-viable option.

Network Circuit Reconfiguration projects enable the transfer of loads via station to station feeder ties, one at a time, with mitigated risk of cascade failure. Therefore reconfigured networks become suitable candidates for inclusion in the Downtown Contingency program. The Network

Circuit Reconfiguration program is both an enabler and prerequisite for inclusion of network feeders in the Downtown Contingency program.

E6.12.4 Timing & Pacing of the Program

Although the Network Circuit Reconfiguration program has only recently been established, it addresses issues that have been developing over the past few decades and that will continue to worsen going forward. Toronto Hydro plans to start this program during the 2015 to 2019 period in order to begin clearing a growing backlog of required investments, but anticipates work to continue beyond 2019.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0	2.30	2.29	2.28	2.27

In 2015, Toronto Hydro plans to do the preliminary engineering work necessary for projects to take place in subsequent years. In 2016, Toronto Hydro plans to address three of the 45 secondary distribution networks through enhancement of secondary network grid flexibility projects. As a foundation for the more complex projects planned for the following years, Toronto Hydro must first undertake these three basic projects. This enhancement work is required before the primary feeders of a network can be equipped with ties to feeders from another station as part of the Downtown Contingency program (E7.7). Eventually, the Network Circuit Reconfiguration and the Downtown Contingency programs will be coordinated to achieve implementation efficiencies.

Also, by utilizing this staggered schedule, Toronto Hydro can develop safe work practices and operating procedures and ensure the proper staff training prior to the commencement of construction. This approach requires the first years' projects to be executable without requiring changes to established work practices.

Toronto Hydro plans to implement the 600 V network distribution initiative in four locations that are currently served by hazardous dual-radial switch and fuse gears. These particular locations have operating restrictions in place and are targeted for prompt replacement. The timing of this portion of the program allows for development of new 600 V network distribution equipment prior to the first field installations in 2016. Figure 3 in the Program Description section includes a map identifying these project locations.

E6.12.4.1 Ranking & Prioritization

Virtually all networks in the downtown area require Network Circuit Reconfiguration in order to address multiple contingency operation and customer service reliability issues. The challenges, however, vary dramatically from one network to the other. In order to minimize program execution risk, networks will initially be ranked and prioritized by those posing the fewest difficulties and allowing for the most immediate completion timelines.

The 600 V network distribution initiative portion of this program is considered high priority because the four projects address serious safety and reliability risks associated with Sachsenwerk switch and fuse gear in four existing vault locations. All four locations pose the same risks and are therefore assigned the same ranking and prioritization.

E6.12.5 Program Execution

As explained in Section E6.12.2.2, there are generally multiple alternative options available to reconfigure a network. During the planning phase, various secondary network areas will be reviewed to determine what difficulties each present and afterwards, a priority sequence for execution will be established. Once a particular secondary network has been selected for reconfiguration, its weaknesses will be identified and a final state established. Various alternatives will be evaluated and the options with the highest benefit to cost ratio will be designed and implemented.

Construction work on individual jobs may include network transformer installation and replacement, primary cable installation and transfers, secondary cable installations, removals and transfers and civil construction and rebuild. The civil construction element poses execution risk because some civil rebuild requirements may not be able to be identified prior to beginning electrical construction.

The 600 V portion of the program requires Toronto Hydro to develop and install new equipment in four locations containing Sachsenwerk loadbreak switches with known safety and operational concerns. Given that new equipment is going to be developed, there is an elevated risk of delay during execution due to possible technical challenges in developing the new 600 V network equipment taking longer to resolve than anticipated.

E6.12.5.1 Proposed Work Plan

The first year of the Network Circuit Reconfiguration program, 2015, will focus on preliminary engineering work, to allow projects to be executed in following years. Seven projects are scheduled to be executed in 2016; three are enhancement of secondary network grid flexibility projects and four are 600 V network distribution initiative projects. Projects will continue in 2017 and subsequent years.

E6.12.5.2 Program Risks

The Network Circuit Reconfiguration program is subject to the usual risks facing downtown underground programs and projects.

Structures at the End of their Useful Lives

Since the program may involve the installation of additional cabling within existing cable chambers and duct structures, there is the possibility that the required structures will be at the end of their useful lives and may require replacement before the planned work can be executed. This would necessitate scope and timing changes to some projects. However, as identified in section E6.12.2.2, there are usually multiple options to reconfigure a network. Should the optimal design require civil structure replacement, an alternative that still provides the required reliability and operational improvements, but that does not require civil structure replacement, can likely be found. The design would be revised accordingly to mitigate the cost and timing impacts.

Switching Restrictions

Many downtown network feeders have summer switching restrictions. As such, the months available to execute work on these network feeders would be limited, which would impact the scheduling and timing of work. This risk can be mitigated by scheduling projects so that construction on restricted feeders is performed outside of the restriction period.

Customer-Owned Civil Structures

There may be unforeseen condition or access problems with some customer-owned civil structures. In these situations, the customer may have to perform civil rebuild work as a precursor to Toronto Hydro commencing its activities, causing project delays. This risk can be mitigated by fully inspecting all civil plants prior to finalizing the design, and introducing lead times for customer civil design and construction activities in the project schedule.

Develop New Equipment

Another program risk is that there may be difficulties associated with developing new 600 V network equipment that complies with regulations and/or maintenance and operating constraints. The ability to comply with arc flash requirements is one such risk. In addition, unanticipated problems may arise in connection with developing new designs to address performance requirements. These risks may delay the program or increase its cost. However, these issues are mitigating by the fact that Toronto Hydro plans on beginning the development of 600 V network equipment in 2014 so that sufficient time is available to resolve equipment related problems prior to construction commencing in 2016.

E6.12.6 Evaluation of Alternatives

E6.12.6.1 Quantification/ Evaluation of Options

(i) Option 1: Status Quo

The current operational constraints within the existing network circuit configuration create one to two complete network interruptions each year following multiple contingency network outages. Without Network Circuit Reconfiguration, network system reliability is expected to continue to degrade as new customer loads are added, radial and network loads are mixed on the same feeders and operating practices are modified to enhance safety and satisfy new requirements. The secondary network distribution system is expected to be less able to meet customers' changing needs. Also, by maintaining the status quo, existing 600 V switch and fuse units that use Sachsenwerk switches and that require switching restrictions will remain in place, negatively impacting system reliability and safety.

(ii) Option 2: Network Circuit Re configuration – Proposed Program

By implementing the Network Circuit Reconfiguration program, several benefits discussed throughout this narrative will be produced, some of which are not monetized in the calculations below, including:

- Service reliability improvements and the elimination of safety risks through the replacement of the 600 V switch and fuse units that use Sachsenwerk switches with new 600 V network equipment.

- Operating efficiencies gained by the ability to reduce the amount of load that needs to be dropped following multiple contingency events by approximately two-thirds.

In terms of quantifiable benefits, assuming an average of two four-hour interruptions of 30 MVA each year, Toronto Hydro expects to avoid about $1.8 million in customer interruption costs annually from being able to reduce the amount of load that needs to be dropped following multiple contingency events.

The cost of ownership (COO) and program net benefit (NPV) associated with Network Circuit Reconfiguration is further detailed in Tables 6 and 7. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of activities in the program. The COO of a state reflects the risk of asset failure, including both direct and indirect costs; these costs incorporate customer interruptions, emergency repairs and asset replacements associated with each design. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Network Circuit Reconfiguration program produces a NPV value of $0.77 million, as shown in Tables 6 and 7.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$5.97
Non Asset Risk [NAR_E]	$0
Maintenance Cost [MC_E]	$0
Additional Quantifiable Benefits [AQB_E]	$0
Cost of Ownership of Existing Assets [COO_E]	$5.97

TABLE 7: NETWORK RECONFIGURATION BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: Network Reconfiguration	
Asset Risk [AR_N]	$2.89
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0
Additional Quantifiable Benefits [AQB_N]	$0
Cost of Ownership of New Assets (Network Reconfiguration) [COO_N]	$2.89
Option 1: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	$3.08
Program Cost [PC_1]	$2.30
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	$0.77

E6.13 Switchgear Renewal

E6.13.1 Summary

Program Description

Toronto Hydro's Switchgear Renewal program is a continuation of the switchgear replacement work undertaken in recent years. The program involves proactive replacement of obsolete and aging switchgear - the majority of which are past their useful lives of 50 years - with modern technology. Specifically, this program continues the work indentified as part of the Municipal Station Switchgear and Transformer Station Switchgear segments filed as part of the Incremental Capital Module (ICM) in Toronto Hydro's 2012-2014 IRM/ICM filing, which resulted in approval to proceed with replacement of four obsolete municipal station (MS) switchgear and four transformer station (TS) switchgear between 2012 and 2014[1]. Toronto Hydro plans to replace nine MS switchgear and 11 TS switchgear during the 2015-2019 planning horizon.

The anticipated benefits of this program are summarized in Table A below.

[1] EBr2012r0064, Tab 4, Schedules B13.1 and B13.2.

TABLE A: PROGRAM BENEFITS

Customer Value	ƒ Reduce the risk of switchgear failure, which can negatively affect service to a large number of customers.
Reliability	ƒ Reduce the risk of RTU failure and avoid potential prolonged station related outages ƒ Enable substations without SCADA connection to monitor and control feeder loading
Efficiency	ƒ Enable remote troubleshooting and switching capabilities at existing substations without SCADA connection, which are expected to result in labor cost savings by eliminating the need for station crews to go on-site to identify problems and perform manual switching ƒ Automatic switching capability will help achieve maintenance efficiency through the effective streamlining of functions, reducing the need for maintenance crews. ƒ Efficiency achieved through lower maintenance costs associated with vacuum circuit breakers as compared to existing air-blast, air-magnetic and oil circuit breakers
Safety	ƒ Enhance safety by replacing the existing non-arc resistant switchgear design with type C arc resistant design ƒ Mitigate the following risks associated with legacy circuit breakers by replacing them with vacuum circuit breaker: o Risk of a catastrophic failure due to presence of oil in oil breakers o Formation of non-friable asbestos due to degradation of arc chutes in air-magnetic breakers

Program Drivers

The Switchgear Renewal program is driven by the safety and reliability risk associated with non-arc proof legacy switchgear, as well as the obsolescence of the Remote Terminal Units (RTU's) currently installed with these legacy assets. These assets are therefore considered functionally obsolete. Table B summarizes the trigger and secondary drivers of the program.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Replacement parts for legacy breakers and obsolete RTUs and their associated communication channels are no longer available from the original manufacturer ƒ Design features of these obsolete switchgear do not adhere to Toronto Hydro's current practice for new switchgear design installations ƒ High number of assets are past their useful lives
Secondary Drivers	**Reasoning**
Reliability	ƒ Switchgear failure affects a large number of customers and has

	reactive costs
Safety	***f*** Arc-flash during switchgear failure can result in a catastrophic failure resulting in excessive damage to the equipment, surroundings and any personnel in the nearby vicinity *f* Consequences of a switchgear failure can be catastrophic due to presence of flammable oil in oil circuit breakers *f* Presence of non-friable asbestos in degrading arc-chutes of air-magnetic circuit breaker can be hazardous if those components are pulverized or damaged during a switchgear failure

Preferred Alternative

Toronto Hydro evaluated four alternatives to address the issues posed by functionally obsolete switchgear units.

(1) Reactive replacement of switchgear upon failure

(2) During failure of a 4.16 kV switchgear, the load from that failed switchgear can be transferred to an adjacent station bus as a temporary solution to minimize the impact of the failure.

(3) Converting the existing 4.16 kV load to 27.6 kV and decommissioning switchgear, where possible

(4) Replacing obsolete switchgears with metal clad enclosure, arc resistant design, and vacuum circuit breakers.

Option 4 is the preferred alternative because it addresses the obsolescence of the existing switchgear units and alleviates the associated reliability and safety risks in the most cost-effective manner. A complete analysis of the above options can be found in Section E6.13.7.

The completion of the first year of activities in this program will result in an avoided estimated risk cost (ARC) of $28.5 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.13.7).

Timing and Pacing

Toronto Hydro plans to replace three to four switchgears every year from 2015 through 2019. As detailed in Table C below, the total cost of this program is $106.2 million.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	14.9	12.9	11.6	7.9	24.6	11.9	18.9	25.5	27.6	22.4

Toronto Hydro plans to replace three to four switchgears every year from 2015 through 2019. The labour resources used for switchgear replacement are shared with other station renewal programs, including the Power Transformer Renewal program (E6.14), the Circuit Breaker Renewal program (E6.15) and the Station Control & Monitoring program (E6.16). In order to accommodate work involved in all of these important programs, Toronto Hydro must balance its resource availability to target a certain number of switchgears every year. All other things being equal, Toronto Hydro schedules the replacement of switchgears based on their age and condition. However, the schedule of the switchgear replacement is also planned in co-ordination with other station asset renewal activities, wherever possible. The strategy is to schedule all station renewal activities such as switchgear replacement, transformer replacement, circuit breaker replacement or RTU system replacement in the same year to efficiently utilize all available resources. Planning to replace both the assets at the same station in the same year allows control room to minimize planned station outages, resulting in cost savings, reduction in station downtime and increased work efficiency.

E6.13.2 Program Description

Toronto Hydro's Switchgear Renewal program is a continuation of the switchgear replacement work undertaken in recent years. The program involves proactive replacement of obsolete and aging switchgear - the majority of which are past their useful lives of 50 years - with modern technology. Specifically, this program continues the work indentified as part of the Municipal Station Switchgear and Transformer Station Switchgear segments filed as part of the Incremental Capital Module (ICM) in Toronto Hydro's 2012-2014 ICM rate-setting application[2], which resulted in approval to proceed with replacement of four obsolete MS switchgear and four TS switchgear between 2012 and 2014.

The purpose of this program is to proactively replace and modernize Toronto Hydro's aging and obsolete switchgear population. Switchgear are a critical link in the distribution system. Each switchgear supplies a very large number of customers, and an outage due to equipment failure could have severe consequences. This is especially true for TS switchgear, which supply areas that do not typically have provisions to transfer load to a back up bus or station. While switchgear are generally reliable, a significant and growing percent of Toronto Hydro's switchgear assets are beyond end-of-life, significantly increasing the risk of failure. Further to this, switchgear replacement projects are complex, require long lead times and may require the system to be in a contingency state for extended periods of time. Given these considerations, Toronto Hydro believes that a "run-to-failure" approach would create a number of unacceptable risks and would not be appropriate. The utility therefore plans to proactively replace its existing switchgear assets which are at end-of-life and employ obsolete technology, with modern equipment.

Located at a station, switchgear is an equipment assembly that is used to distribute power from a supply point to multiple individual feeders. It is generally comprised of an enclosure which is made up of a bus compartment and any number of cells. The individual cells contain disconnect switches, circuit breakers, instrumentation equipment and/or protection/control devices. There are two general categories of switchgear addressed as part of this program: transformer station (TS) switchgear and municipal station (MS) switchgear. Switchgear located at transformer stations (TS) operate at 13.8 kV and are supplied directly by HONI owned transformers. They generally supply a larger number of feeders compared to MS switchgear, and therefore are generally comprised of a larger number of cells. They also often house HONI's incoming circuit breakers, which connect the switchgear bus to the supplying transformer windings. Existing TS switchgear enclosures are either brick and mortar type, which utilize a brick structure with wooden doors or

[2] EBr2012r0064, Tab 4, Schedules B13.1 and B13.2.

non-arc resistant metal type. MS switchgear generally supply 3 feeders, although there are some exceptions. MS voltages range from 4.16 kV to 13.8 kV and utilize non-arc resistant metal enclosures. Some MS switchgear have been installed without SCADA systems to allow for remote monitoring and control of the equipment. Figures 1, 2 and 3 show a typical example of aging and obsolete non-arc resistant switchgear at Toronto Hydro's Carlaw TS, Windsor TS and Brimley Bernadine MS stations, respectively.

FIGURE 1: NON-ARC RESISTANT BRICK STRUCTURE TS SWITCHGEAR AT CARLAW TS

FIGURE 2: NON-ARC RESISTANT METAL-CLAD SWITCHGEAR WITH AIR MAGNETIC CIRCUIT BREAKERS AT WINDSOR TS

FIGURE 3: NON-ARC RESISTANT METAL-CLAD SWITCHGEAR AT BRIMLEY BERNADINE MS

Given the advanced age of Toronto Hydro's switchgear population, there are a number of obsolescence-related issued currently afflicting the population. These issues include:

Circuit Breakers

A key component of a switchgear lineup is the type and vintage of the circuit breakers. The legacy circuit breakers contained in older switchgear include oil breakers, air blast circuit breakers and air magnetic circuit breakers. These breaker types are obsolete and are associated with significant drawbacks (discussed in Section E6.13.3). Circuit breaker technology, which is differentiated based on the current interrupting medium, has evolved over the past several decades resulting in improvements to reliability, safety, operating cost and the environment. Modern vacuum breakers, such as those Toronto Hydro installs with new switchgear, offer several improvements over the legacy technology that is currently installed in the field (discussed

in Section E6.13.3). As is the case with most legacy equipment, maintenance costs are relatively high and spare parts are difficult to obtain.

Enclosures

The existing switchgear targeted as part of this program utilize non-arc resistant designs. Brick-and-mortar enclosures, which are used for some existing TS switchgear, use wooden doors and offer very little arc protection. Modern switchgear enclosures are specifically designed to safely handle an arc flash while minimizing the risk to nearby personnel and equipment.

SCADA

Some legacy MS switchgear were not designed or built with SCADA systems. SCADA systems are standard in modern distribution applications and allow for remote monitoring and control of equipment.

These factors and more are described in further detail in section E6.13.3.

Toronto Hydro plans to replace existing switchgear at MS and TS locations with “Type C,” arc-resistant switchgear design that features modern vacuum circuit breakers, modern SCADA integration, modern remote terminal units (RTU) for communication and microprocessor relays. Figure 4 shows this new Type C arc-resistant metal-clad switchgear.

FIGURE 4: NEW TYPE C ARC-RESISTANT METAL-CLAD SWITCHGEAR WITH VACUUM CIRCUIT BREAKERS

Arc-resistant switchgear are designed such that the energy generated by an internal arc is safety channeled in such a way as to prevent damage to equipment and people. When an arc fault occurs, the temperature increases and expands the air in the enclosure. This causes the pressure inside the enclosure to increase and can ultimately create a risk of an explosion. An explosion would not only severely damage the switchgear that experiences that fault, but also has the potential to cause collateral damage to nearby equipment and potential safety risks to any personnel who happen to be in the immediate area. The inability to proactively predict when arc faults may occur makes them more dangerous. The Type C arc-resistant design provides arc resistance from the front, sides and rear, and between compartments within the same cell or adjacent cells. The expanding hot gases are routed through a system of vents and flaps through the roof as shown in Figures 5 and 6.

FIGURE 5: FRONT VIEW OF THE ARC-RESISTANT METAL-CLAD SWITCHGEAR SHOWING THE EXPLOSION VENTS ON THE TOP

FIGURE 6: SIDE VIEW OF THE ARC-RESISTANT METAL-CLAD SWITCHGEAR SHOWING THE EXPLOSION VENTS

Switchgear replacement projects are complex and require a significant amount of planning and coordination. This is especially so for TS switchgear replacement projects, as they require coordination with HONI to replace their incoming circuit breakers and to connect the new switchgear to the supply transformers. To this end, Toronto Hydro is required to execute a Connection Cost Recovery Agreement (CCRA) outlining the scope of work and the capital contribution Toronto Hydro will pay to Hydro One Networks Inc. (HONI) to cover their costs. Additionally, significant work may be required at the transformer station building to prepare it for installation of the new switchgear. This could include reinforcing the floor or extending the building. At a high level, the scope of work for a TS switchgear replacement job involves the following:

(1) Coordinate with HONI to agree on their scope of work, schedule and costs.

(2) Prepare site.

(3) Purchase and install new switchgear.

(4) Coordinate with HONI to facilitate energization of the new switchgear.

(5) Transfer feeders from old switchgear to new switchgear

(6) Decommission the old switchgear.

If space is limited, load must be transferred to different stations by building new distribution infrastructure before the new switchgear can be installed. An MS switchgear replacement project involves many of the same steps, although no HONI coordination is required (as an MS is supplied by a Toronto Hydro distribution feeder) and site preparations are less likely to be as onerous given the smaller footprint and size of MS switchgear.

The estimated cost of the Switchgear Renewal Program for the 2015-2019 period is approximately $106.2 million. Table 1 summarizes the number of assets that are forecasted for replacement over the 2015 to 2019 period.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
TS Switchgear	0	3	2	2	2	9
MS Switchgear	3	4	2	1	1	11

Figure 7 shows a map of all the stations selected for switchgear replacement during this period.

FIGURE 7: MAP OF MS SWITCHGEAR REPLACEMENT LOCATIONS

A summary of the benefits associated with the Station Switchgear Renewal program is provided in Table 2.

TABLE 2: PROGRAM BENEFITS

Customer Value	***f*** Reduce the risk of switchgear failure, which can negatively affect service to a large number of customers. *f* The completion of the first year of activities in this program will result in an avoided estimated risk cost (ARC) of $28.5 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.13.7).
Reliability	*f* Reduce the risk of RTU failure and avoid potential prolonged station related outages *f* Enable substations without SCADA connection to monitor and control feeder loading

Efficiency	ƒ Enable remote troubleshooting and switching capabilities at existing substations without SCADA connection, which will likely result in labor cost savings by eliminating the need for station crews to go on-site to identify problems and perform manual switching ƒ Automatic switching capability will help achieve maintenance efficiency through the effective streamlining of functions, reducing the need for maintenance crews. ƒ Efficiency achieved through lower maintenance costs associated with vacuum circuit breakers as compared to existing air-blast, air-magnetic and oil circuit breakers
Safety	ƒ Enhance safety by replacing the existing non-arc resistant switchgear design with Type C arc resistant design ƒ Mitigate the following risks associated with legacy circuit breakers by replacing them with vacuum circuit breaker: o Risk of a catastrophic failure due to presence of oil in oil breakers o Formation of non-friable asbestos due to degradation of arc chutes in air-magnetic breakers

E6.13.3 Why the Program is Needed

The Switchgear Renewal Program is needed to minimize failure risk and address obsolescence issues associated with Toronto Hydro's aging switchgear population, a significant percentage of which has already exceeded its typical 50 year useful life. The existing switchgear utilizes obsolete technology such as brick and mortar built enclosures, non-arc resistant designs and legacy circuit breakers. Switchgears are high impact assets – failure has the potential to impact a large number of customers for an extended period of time. The deteriorating condition of aging units will eventually result in failure, a risk that increases each year.

Both TS and MS switchgear failures pose significant safety risks to Toronto Hydro personnel. Due to the non-arc-resistant design of some legacy switchgears, there is a high probability of explosion should an arc-flash occur during a switchgear failure. The consequence can be catastrophic if Toronto Hydro personnel are working in the vicinity. There are additional risks associated with the presence of flammable oil and non-friable asbestos in legacy circuit breakers. A summary of the risks associated with these obsolete technologies is contained in Table 3.

TABLE 3: SUMMARY OF THE RISKS ASSOCIATED WITH THE OBSOLETE TECHNOLOGIES

Switchgear Components	Component Type	Risks
Switchgear Enclosure	Brick Enclosure	ƒ Non-arc resistant ƒ Obsolete
	Metal-clad Enclosure	ƒ Non-arc resistant ƒ Obsolete
Legacy Circuit Breakers	Air-Magnetic Circuit Breaker	ƒ Spare parts not available ƒ Arc-chutes degrade with usage ƒ Presence of non-friable asbestos in arc-chutes
	Air-Blast Circuit Breaker	ƒ Air-compressors are obsolete and spare parts are difficult to obtain ƒ Higher maintenance cost due to deteriorating air-compressors
	Oil Circuit Breaker	ƒ Fire hazard due to presence of flammable oil
Obsolete Control & Monitoring	Obsolete RTUs and Communication Channel	ƒ Spare parts not available ƒ Increasing failure rate
	No SCADA Connection	ƒ Technologically obsolete ƒ No automatic switching ƒ Customers suffer longer outages during a Switchgear failure

E6.13.3.1 Program Drivers

Table 4 presents the trigger and secondary drivers for replacing TS and MS switchgears. Toronto Hydro has classified switchgear renewal as a System Renewal initiative because the trigger driver is functional obsolescence.

TABLE 4: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Replacement parts for legacy breakers and obsolete RTUs and their associated communication channels are no longer available from the original manufacturer ƒ Design features of these obsolete switchgear do not adhere to Toronto Hydro's current practice for new switchgear design installations ƒ High number of assets are past their useful lives
Secondary Drivers	**Reasoning**

Reliability	*f*	Switchgear failure affects a large number of customers and has reactive costs
Safety	*f*	Arc-flash during switchgear failure can result in a catastrophic failure resulting in excessive damage to the equipment, surroundings and any personnel in the nearby vicinity
	f	Consequences of a switchgear failure can be catastrophic due to presence of flammable oil in oil circuit breakers
	f	Presence of non-friable asbestos in degrading arc-chutes of air-magnetic circuit breaker can be hazardous to Toronto Hydro personnel if they are pulverized or damaged during a switchgear failure

There are a number of underlying issues supporting the Program Drivers that will be addressed proactively by Toronto Hydro through execution of this program. These issues, the majority of which are due to asset age, are described in detail in the sections that follow. Toronto Hydro's primary concern is that a very large number of switchgear assets are past end of life (refer to section E16.6.3 for more details). While switchgear have been historically very reliable, at some point in time failures will begin to occur based on the advanced equipment age. Given the number of switchgear assets in Toronto Hydro's system, and the lead times and complexity associated with a switchgear replacement project, it will not be possible to deal with a large number of failure on a reactive basis without a significant impact on system reliability.

Functional Obsolescence of Circuit Breakers

As discussed earlier, circuit breaker technology is differentiated based on the medium used to interrupt current. Over the years, circuit breaker technology has evolved significantly resulting in significant advances in safety, operating cost, reliability and environmental impact. The circuit breakers installed in existing assets are one of three types:

(a) Oil circuit breakers, which use the dielectric properties of oil to extinguish the current. A primary risk associated with oil breakers is that if a failure occurs, there is a high risks of collateral damage to nearby equipment and personnel. Failures can lead to fires or explosions and pose a high risk of serious injury to personnel working in the vicinity, or to damaging nearby equipment. For this reason, oil breakers require regular maintenance to ensure their proper operation, which results in higher maintenance cost.

(b) Air blast circuit breakers, which use compressed air to extinguish current. Air blast circuit breakers require dedicated air compressor systems to maintain adequate air pressure.

When these systems fail, a circuit breaker is no longer able to interrupt a fault, which could lead to equipment damage and a large outage. Maintenance costs are higher due to the frequency at which inspections of the air compressors and associated air pipes are required. The supplied air must also be very dry, or there is a risk of condensation or ice forming on the insulators or contacts. In addition, the air compressors are themselves old, obsolete and spare parts for their repair are also difficult to obtain.

(c) Air-magnetic breakers, which utilize magnetic fields to stretch and ultimately extinguish the arc created by separation of the breaker contacts. The arc chutes in air magnetic breakers, which are used to quench the electrical arc, degrade with usage and are a safety risk due to the presence of non-friable asbestos. Non-friable asbestos can become a safety issue if they are disturbed or damaged during an arc-fault explosion and release asbestos fibers into the air, effectively turning non-friable into friable.

All of these legacy circuit breakers are past their individual end-of-lives, increasing the risk of failure. Additionally, in the majority of cases the original equipment manufacturer is no longer manufacturing these devices and good quality new spares are difficult to acquire. In many cases, spare parts are only custom manufactured when required, which is neither cost effective nor sustainable. Lastly, annualized maintenance costs are higher relative to modern vacuum breakers. Vacuum circuit breakers require less periodic maintenance in comparison to the legacy breakers currently in use. This is primarily because the current interruption in a vacuum breaker occurs in a sealed environment. The legacy circuit breakers have a maintenance cycle of 3-4 years whereas vacuum circuit breakers have a maintenance cycle of eight years. Efficiency savings due to vacuum breakers can be calculated in the form of a maintenance cost reduction. The cost reduction is shown in Table 5.

TABLE 5: COST REDUCTION OF USING A VACUUM CIRCUIT BREAKER

	Air-Magnetic Circuit Breaker	Air-Blast Circuit Breaker	Oil Circuit Breaker	Vacuum Circuit Breaker
Unit Maintenance Cost	$943	$1,415	$943	$943
Maintenance Cycle	4 Years	3 Years	4 Years	8 Years
Cost Reduction by installing Vacuum Circuit Breaker	**50%**	**75%**	**50%**	

To provide a better illustration of the maintenance savings realized as a result of switchgear modernization, Tables 6 and 7 show a sample comparison between an old and new switchgear

asset. For the purpose of this analysis, we have selected Windsor TS A5-6WR Switchgear, which will be in-service in 2017 and Brian Elinor MS T1 Switchgear, which will come in-service in 2016.

TABLE 6: BREAKER MAINTENANCE COST COMPARISON BETWEEN OLD AND NEW WINDSOR TS A5-6WR SWITCHGEAR

Windsor TS A5-6WR Switchgear		
Status	Existing	New
Number of Circuit Breakers	12	18 (This number is subject to change based on design decision)
Type of Breakers	Air-Blast	Vacuum
Maintenance Cost Over 8-Year Cycle	$45,280	$16,974
Savings	**$28,306**	

TABLE 7: BREAKER MAINTENANCE COST COMPARISON BETWEEN OLD AND NEW BRIAN ELINOR MS T1 SWITCHGEAR

Brian Elinor MS T1 Switchgear		
Status	Old	New
Number of Circuit Breakers	3	3
Type of Breakers	Air-Magnetic	Vacuum
Maintenance Cost Over 8-Year Cycle	$5,658	$2,829
Savings	**$2,829**	

Integration of Modern RTU and SCADA Systems at MS Switchgear

Certain existing MS switchgear do not currently have an integrated SCADA system or have a SCADA system with an obsolete remote terminal unit (RTU). Toronto Hydro has a program, Station Control and Monitoring, which aims to proactively address these stations where no switchgear work is planned. In parallel, Toronto Hydro plans to leverage the Switchgear Renewal Program to integrate SCADA and a modern RTU with the replacement switchgear. Therefore, for MS locations which do not already have SCADA, this program has the added benefits of additional control and monitoring capabilities.

The lack of a SCADA communication system can result in longer outage durations. Substations selected for the Switchgear Renewal Program either have no SCADA system or are equipped with obsolete Remote Terminal Units (RTU) and communication systems. These obsolete RTUs

and communication systems are past their useful lives of 22.5 years with no spare parts available for replacement. The impact of a switchgear failure in terms of outage duration with and without the presence of a SCADA system at the substation is 180 minutes and 30 minutes, respectively. This will minimize outage duration in case of a failure and improve system reliability.

For stations with no SCADA, operators in the control room are currently unable to control and monitor critical equipment at the substation. A failure will result in longer outages since manual switching is required to correct faults. Installation of a SCADA communication system at municipal stations alongside switchgear replacement will help operators to minimize outage impacts and improve overall system efficiency by automating many of the tasks such as problem troubleshooting and station equipment maintenance. Remote troubleshooting allows SCADA console operators to identify the exact location of the outage and perform automatic switching to isolate the outage. Task automation is expected to result in labour cost savings by preventing the need for station crews to go to site and perform lengthy inspections and manual switching.

Automatic switching capability achieved through SCADA system installation will also help improve maintenance efficiency by reducing maintenance crew hours to complete the same work through harmonization of tasks and elimination of redundancies. As a result, planned maintenance outages and certain related maintenance cost will likely decrease.

Arc-Flash Susceptibility and Other Legacy Safety Concerns

When designing and constructing new infrastructure, Toronto Hydro employs safety-by-design principles to minimize hazards and risks to staff. In recent years there has been a significant amount of focus within the electricity industry on arc-flash, which is essentially a flash of electricity released into the environment due to a short circuit failure. New switchgear are specifically designed to limit the risk to workers and nearby equipment should an arc flash occur.

Existing switchgear were not designed with this in mind. The non-arc resistant design of legacy switchgear makes it vulnerable to damage from internal arc faults. A non-arc resistant switchgear is not designed to safely channel out the electricity released during an internal arc fault, which causes a rapid rise in pressure in an enclosed compartment. The occurrence of an internal arc fault in non-arc resistant switchgear can result in an explosion, which poses a safety hazard to nearby personnel and equipment and a potentially serious crew safety risk. There are more dangerous effects of this phenomenon occurring. An internal arc-fault can result in the development of poisonous gases due to the vaporizing of metals and insulation materials. These

gases can be harmful to person(s) inhaling them. Moreover, the explosion due to the arc-flash can be very loud that it has a risk of causing hearing damage to anyone in the vicinity.

All switchgear compartments have a front and rear door to make them accessible. Figures 8, 9, and 10 show the front and rear door designs of the brick and metal-clad enclosure of the existing obsolete switchgears. Figure 8 shows a non-arc-resistant switchgear construction, which features a rear entry mesh door of brick enclosure switchgear. Similarly, Figure 9 shows a front entry mesh door of non-arc resistant metal-clad switchgear. When an arc fault occurs, flames and hot gases can escape through the mesh and ignite nearby materials.

FIGURE 8: REAR DOOR OF A NON-ARC RESISTANT, BRICK STRUCTURE SWITCHGEAR

FIGURE 9: FRONT DOOR OF A NON-ARC RESISTANT METAL-CLAD SWITCHGEAR

FIGURE 10: FRONT DOOR OF A NON-ARC RESISTANT BRICK STRUCTURE SWITCHGEAR

Figure 10 shows the front door of brick enclosure switchgear. As air temperature increases in an enclosed compartment of the switchgear, so does the pressure. Without arc-resistant protection, explosion due to the rapid pressure build-up within a switchgear compartment can project objects such as the metal or wooden doors.

Proper maintenance of switchgear is essential in preventing the equipment failures that cause interruption of power supply to customers. Maintenance work includes testing and cleaning of circuit breakers, relays, disconnect switches, voltage transformers and current transformers to ensure proper operation. However, maintaining these existing obsolete switchgear requires maintenance personnel to be exposed to live, high voltage parts of the switchgear. For example, during circuit breaker maintenance inside a switchgear, the circuit breaker is isolated and verified dead before the maintenance work beings. However, the adjacent breaker compartments still remain energized. If an arc-flash occurs at any of the adjacent breaker compartments, there is a potential risk of an explosion due to the non-arc resistant design of the switchgear. Maintenance

personnel wear appropriate Personal Protective Equipment (PPE) categories to perform the tasks. However, the PPE categories only provide protection for the effects of the heat, but they do not necessarily provide protection against other potential consequences of an explosion. Toronto Hydro has protocols in place to reduce the potential safety risks associated with this work; nevertheless, the exposure risk to live equipments or the destructive effect of an arc fault is a significant safety risk that can only be further mitigated through improved switchgear design. This safety risk is also mitigated through SCADA connection to the new switchgear at non-SCADA substations. Another example of a maintenance safety risk is the cable temperature monitoring, which is essential to the maintenance of the switchgear since excessive temperature can be an indication of problem with a connection. Currently, the temperatures are monitored using infra-red scanners by opening the rear door of the energized switchgear. However, this exposes the maintenance personnel to live equipments. The new switchgears are equipped with infrared viewing ports which allow maintenance personnel to monitor temperatures of the cable and bus connection points in the rear of the switchgear while it is energized and under load.

Lastly, another safety issue associated with brick enclosure switchgear is reduced clearance for operating equipment. Tasks such as maintenance or troubleshooting may require work in areas where live parts are exposed. Reduced clearance in brick enclosure switchgear exposes Toronto Hydro personnel to this potential risk.

Impact of Failure

Failure of a switchgear, at either municipal or transformer stations, has the potential to have a significant customer impact due to the number of customers supplied from a single asset. Figures 11 and 12 show the number of customers connected to the targeted municipal and transformer stations, respectively, who are would be impacted in the event of a switchgear failure.

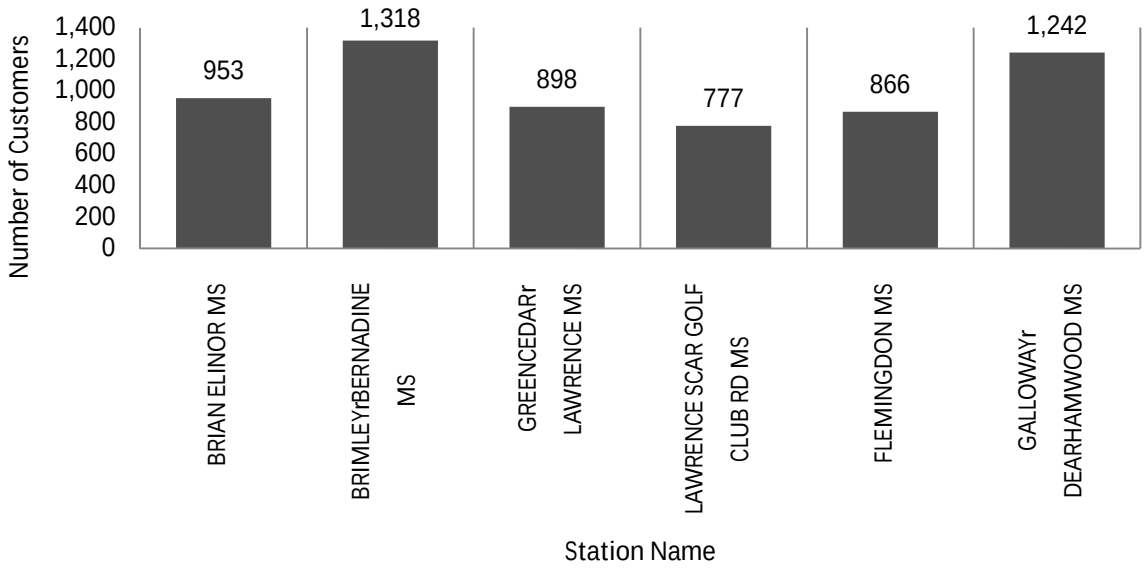

FIGURE 11: NUMBER OF CUSTOMERS SUPPLIED BY TARGETED MS SWITCHGEAR

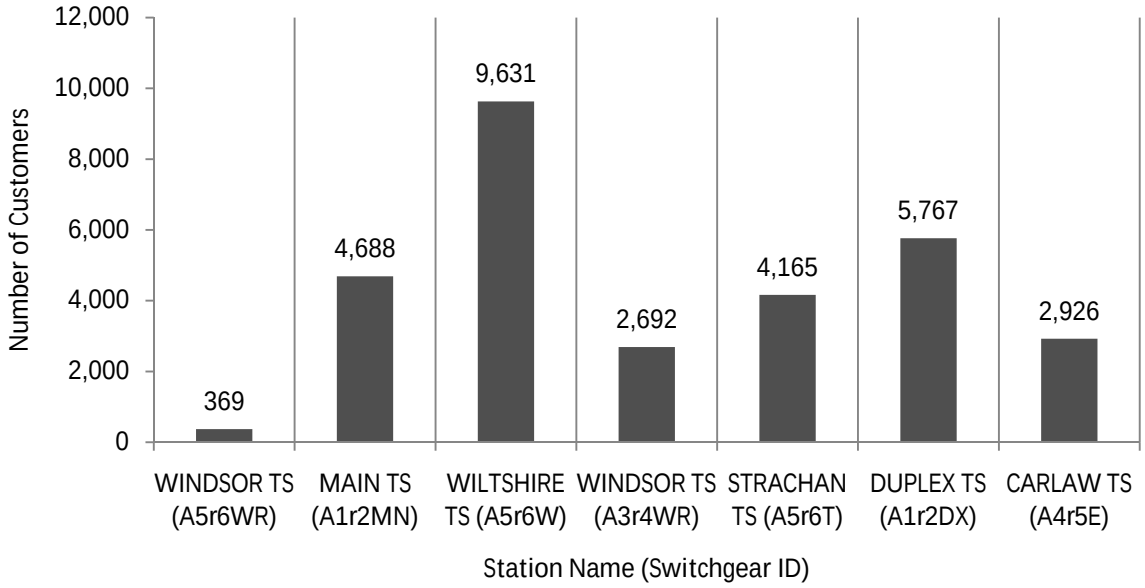

FIGURE 12: NUMBER OF CUSTOMERS SUPPLIED BY TARGETED TS SWITCHGEAR

The customer impact would be especially large in the event of a TS switchgear failure, as the 13.8 kV distribution system in the areas these switchgear are located does not have the provisions to enable load to be easily resupplied from an alternative sources. Thus, it is crucial that the switchgear be maintained, managed and operated in a reliable manner throughout its lifecycle. Given the advanced age of a large percentage of the existing switchgear population, the risk of failure is ostensibly increasing year over year. That, coupled with the complexity of a switchgear replacement project, makes it imperative that Toronto Hydro replace the oldest and poorest condition assets in a planned and proactive manner.

Given that a switchgear is made up of many different individual components, there are a number of different failure modes to be cognizant of. If a breaker fails to clear a fault, or becomes overloaded for some reason, then all equipment in the circuit will be subjected to extreme amounts of energy until an upstream breaker can sense and clear the overload. On the other hand, if a breaker fails to close, this means all downstream circuits that receive power from that feed point will not function. Additionally, over time, contaminants will build up on the internal insulators separating energized parts from grounded components. At some point, this contamination will likely lead to a flash, which in turn can cause an explosion or fire. These functional or catastrophic failures may severely damage or even destroy the switchgear itself and, in some cases, nearby equipment. It could also result in serious injury to Toronto Hydro personnel in the vicinity.

The purpose of switchgears is to connect and protect hundreds of feeders supplying thousands of customers. Switchgear faults and failures will typically have a high negative impact on both Toronto Hydro and its customers. The repair, replacement and clean-up costs associated with switchgear failure can be significant, and customers fed by the failed bus and feeders associated with the switchgear are likely to experience prolonged outage periods unless the circuit can be brought to service. Switchgears at municipal substations support the neighboring substations during contingency or during switchgear or transformer maintenance. If switchgear fails, there will be a cascading effect on the neighboring substations that back up its load by limiting their capability to handle additional load under second contingency. However, if switchgear at one MS fails and the contingent switchgear at another MS also fails, a significant outage could occur since the load of two switchgears cannot be backed up without experiencing capacity shortage and/or voltage drop problems. Toronto Hydro experienced a similar problem during a switchgear failure at Lesmil MS in 2007. When the Lesmil MS switchgear was out of service, switchgear at a neighboring substation, Don Mills MS, also failed. This resulted in a major outage where 700

customers were without power for almost 11 hours. The case is different for a TS switchgear failure, especially if the TS is located in a downtown location.

The switchgear addressed by this program are functionally obsolete due to a lack of spare parts and critical maintenance support, design features that do not adhere to Toronto Hydro's current design practice, and the increasing risk of failure due to switchgears reaching or surpassing end-of-life.

E6.13.3.2 Asset Details

(i) Asset Lifecycle

The expected useful life of switchgear is 50 years. Out of the 252 Toronto Hydro-owned switchgear, 44% are past their designed useful lives, as illustrated in Figure 13. In the absence of a switchgear renewal program, by 2019 this number will reach 62%.

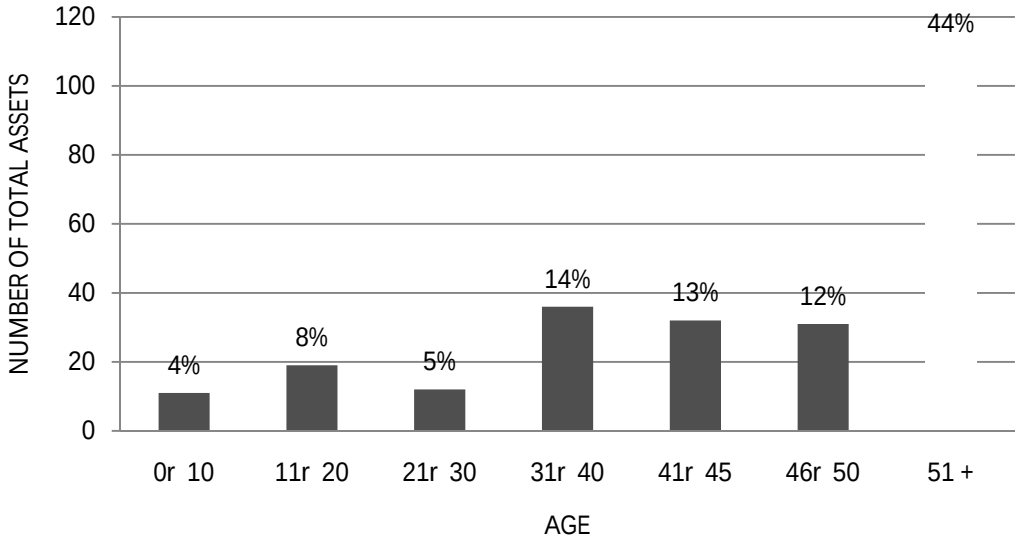

FIGURE 13: AGE DEMOGRAPHICS OF TORONTO HYDRO OWNED SWITCHGEAR

(ii) Asset Failure Impacts

Switchgears are high impact assets and the consequences of switchgear malfunctions are often catastrophic. Damage to the switchgear itself can be extremely expensive, but corollary damage and potential safety hazards to Toronto Hydro personnel and customers are an even greater risk.

The occurrence of an internal arc fault inside non-arc resistant design switchgear can have destructive effects. An incident might expel hot gases into the surrounding area and result in door/covers of the enclosures being blown out. Safety precautions and PPE may reduce the risk, but do not protect personnel from shrapnel and molten metal parts that may be projected as a result of a potential explosion.

Table 8 provides a list of switchgear failure experienced by Toronto Hydro in recent years, the duration of the resulting outage, and the number of customers affected.

TABLE 8: IMPACT OF AN INTERNAL ARC FAULT IN SWITCHGEAR AT TERAULEY TS

Year	Station Name	Failure Type	Outage Duration	Customers Affected
2001	Brimley Seminole MS	Switchgear Failure – Arcing Fault	3.6 Hours	3,908
2005	Walney MS	Switchgear Failure – Arcing Fault	15.8 Hours	339
2007	Glengrove TS	Switchgear Failure – Arcing Fault	5.5 Hours	4,971
2007	Terauley TS	Switchgear Failure – Arcing Fault	18 Hours	31,322
2008	Jane MS	Switchgear Failure – Busbar fault	2.7 Hours	1,754

One of the biggest incidents was the switchgear failure at Terauley TS in 2007. The arc fault at Terauley TS resulted in an explosion in the circuit breaker compartment and caused the front door to be removed from its mounts, as illustrated in Figure 14. No personnel were present at the time, but the explosion damaged surrounding equipment. A total of 31,322 customers suffered an outage for 18 hours as a result of this catastrophic failure.

FIGURE 14: IMPACT OF AN INTERNAL ARC FAULT IN SWITCHGEAR AT TERAULEY TS

All the switchgear currently proposed for replacement serve large numbers of customers (refer to Figures 11 and 12). Depending on the extent of the damage, a switchgear failure can result in prolonged customer outages. The outage duration and restoration times are much longer and more expensive for TS switchgears, since transformer stations do not have spare capacity to take load from an adjacent station during an emergency.

E6.13.4 Timing & Pacing of the Program

Toronto Hydro plans to replace eleven MS switchgears and nine TS switchgears at a total estimated cost of $106.2 million over the five year period from 2015 to 2019, as shown in Table A and Table 9.

TABLE 9: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
CAPEX ($M)	14.9	12.9	11.6	7.9	24.6	11.9	18.9	25.5	27.6	22.4

Table 9 also shows the historical spending associated with the Switchgear Renewal program. The Switchgear renewal program was planned to proactively replace and modernize these obsolete and aging assets. However, the historical spending does not reflect the original proposed plan. This can be attributed to the complex nature of the work, and the degree of external coordination (with HONI) required to execute a single project. In recent years, projects have been delayed due to the timing of funding approval from the OEB and unforeseen delays and complications associated with the HONI connection application process.

Every switchgear replacement job involves a set of unique circumstances which can impact project scope, cost and schedule. This includes the size of the switchgear, the need to reinforce, rebuild, expand or renovate a building, and operational complexity associated with transferring load from an old switchgear to a new switchgear. These factors are considered in the project planning phase, however it is an extremely challenging exercise to produce a highly accurate forecast of project requirements and cost. These difficulties result in a year-over-year spending profile that, despite a consistent number of planned units, appears to be somewhat erratic.

Spending from 2012 to 2014 was inconsistent due to a number of factors. Toronto Hydro received approval to replace four MS Switchgear and four TS Switchgear between the 2012 and 2014 period, whereas the utility's original plan was to replace ten MS Switchgear and four TS Switchgear from 2012 to 2014. Additionally, Toronto Hydro was not able to proceed with the work until mid-2013, which delayed the start of these projects as long lead items could not be procured. These delays also had a cascading effect and resulted in downstream impacts on resource allocation to the projects. Currently, the ICM approved projects are underway but behind schedule. In 2014, $24.6M is planned to be spent on these switchgear replacement projects. The cost is relatively high primarily due to the HONI payments associated with the switchgear replacement jobs done during the 2012 to 2014 period. Toronto Hydro plans to continue working on these projects and anticipates completion in 2015 and 2016.

Additional schedule delays have occurred as a result of complications with HONI coordination. For TS projects their support is required to purchase, install and commissioning their incoming breakers cells and to connect Toronto Hydro's new switchgear to their transformers. HONI's new

process requires Toronto Hydro to submit a connection application requesting HONI to perform an Engineering Study to identify the scope, costs and schedule necessary to connect their transformers to the new switchgear. Following that the study, both HONI and Toronto Hydro are required to enter in to a Connection and Cost Recovery Agreement (CCRA) for HONI to proceed with the design and construction of the incoming feeder cells. Introduction of this new process added additional time in the switchgear replacement projects, which pushed the in-service date of the TS Switchgear jobs to 2015 and 2016 Capital year.

As shown previously in Figure 13, 44% or approximately 110 of Toronto Hydro's existing switchgears will be past their useful lives of 50 years by 2015. Since switchgear is a high impact asset, the risk of executing this program on a reactive work basis is too high. In order to mitigate the risk of switchgear failure, Toronto Hydro plans to proactively replace this aging obsolete switchgear with metal-clad switchgear of Type C arc-resistant design, consisting of vacuum circuit breakers equipped with modern RTUs and communication media. All the TS Switchgear projects included in this program are large, complex and will be completed over multiple years. Each switchgear job is unique and is customized to meet the design needs and system constraints. This is a major contributing factor to the cost variation as shown in Table 10.

Toronto Hydro plans to replace three to four switchgears every year from 2015 through 2019. The labour resources used for switchgear replacement are shared with other station renewal programs, including the Power Transformer Renewal program (See E6.17), the Circuit Breaker Renewal program (See E6.18) and the Station Control & Monitoring program (See E6.19). In order to accommodate work involved in all of these important programs, Toronto Hydro must balance its resource availability to only target a certain number of switchgears every year. All other things being equal, Toronto Hydro schedules the replacement of switchgears based on their age and condition. However, the schedule of the switchgear replacement is also planned in co-ordination with other station asset renewal activities, wherever possible. The strategy is to schedule all station renewal activities such as switchgear replacement, transformer replacement, circuit breaker replacement or RTU system replacement in the same year to efficiently utilize all available resources. Planning to replace both the assets at the same station in the same year allows control room to minimize planned station outages, resulting in cost savings, reduction in station downtime and increased work efficiency.

E6.13.4.1 Ranking & Prioritization

Identifying switchgear assets for replacement is based on several factors, including asset condition, degree of equipment obsolescence, station criticality and whether the switchgear is

part of a substation targeted for voltage conversion. Since the impact of TS and MS switchgear failures are different, the replacement jobs for these respective switchgears are treated separately.

- **Asset condition and age** are determining factors in evaluating the failure probability of switchgear. Switchgear that is in poor condition and is past its useful life is given a higher priority for replacement. Any failure due to deteriorating condition will impact a large number of customers.

- The **obsolete** nature of the technologies used in legacy switchgear designs is another important factor in prioritization within the program. Ultimately, the relative seriousness of the safety risks that various obsolete technologies introduce is the overriding concern when ranking projects according to the level of obsolescence. Taking this factor into consideration, Toronto Hydro ranks the replacement of switchgear based on the following obsolete technologies:

    - Brick structure built enclosure
    - Non-arc resistant
    - Legacy Circuit Breakers
        - Oil Circuit Breaker
        - Air Magnetic Circuit Breaker
        - Air-Blast Circuit Breaker
    - No SCADA system or obsolete RTUs and Communication Channels
    - Brick structure built enclosure is the primary obsolescence factor since it is the oldest technology and poses the most risks in comparison to other obsolete technologies mentioned above. It is non-arc resistant by design, difficult to maintain, has high maintenance cost and also deteriorating due to age.

- The **criticality** of a station is determined by the number of customers connected to the bus and the load on the feeders. If a bus within a switchgear has feeders that are highly loaded and are connected to a large number of customers, the impact of a failure is naturally more severe.

- **Work coordination** with feeder investment groups is an additional factor when prioritizing work for MS switchgear replacement jobs. Many of the 4.16 kV municipal stations with aging obsolete switchgears, which are ideal for replacements, are targeted in the Box Construction Conversion program for decommissioning and thus will not be renewed.

E6.13.6 Program Execution

The execution of the Switchgear renewal program is outlined in detail section E6.13.8 Program Scopes and E6.13.6.1 Proposed Work Plan. A general description of work involved in MS and TS switchgear replacement is described below:

(i) MS Switchgear: Execution of Work

Station designers and engineers will prepare all necessary drawings and documents to purchase the new switchgear. Site or building upgrades are made as necessary. While the new switchgear is in the process of being delivered, the proposed switchgear is removed after the existing load from the bus is temporarily transferred to an adjacent substation. The new switchgear is then installed and commissioned along with the installation and commissioning of the communication system. Once the new switchgear is energized, the load from the adjacent station is transferred back to the new switchgear.

(ii) TS Switchgear: Execution of Work

In most TS switchgear replacement work, station designers and engineers design, procure, and purchase the new switchgear. Simultaneously, the site is prepared for the installation of the new switchgear, which could involve reinforcement of a floor, expansion of a building or other civil upgrades. However, there are cases such as Windsor TS A5-6WR Switchgear replacement, where the station does not have any additional space to install new switchgear. In that circumstance, Toronto Hydro would transfer the load from the targeted switchgear to a switchgear with spare capacity, and then remove the existing switchgear to prepare for the installation of the new switchgear. Once the new switchgear is delivered, it is installed, commissioned and tested. Toronto Hydro co-ordinates with HONI to purchase, install and commission the incoming feeder cells and configures the new bus. Following the completion of these tasks, the new switchgear is energized and the load from the existing obsolete switchgear bus is transferred to the new switchgear. The obsolete switchgear is then decommissioned.

E6.13.6.1 Proposed Work Plan

Table 10 shows the long term plan for the 2015-2019 periods being completed at select stations.

TABLE 10: 2015-2019 LONG TERM PLAN

Year	Bus	Station	Asset Age
2015	T1-T2SG	Porterfield MS	59
2015	T1-T2SG	Neilson Dr MS	61
2015	T1-T2SG	Thornton MS	60
2016	A6-7E	Carlaw TS	46
2016	A3-4W	Wiltshire TS	60
2016	A7-8T	Strachan TS	58
2016	T1-T2SG	Islington MS	59
2016	T1SG	Brian Elinor MS	59
2016	T1SG	Brimley Bernadine MS	54
2016	T1SG	Greencedar Lawrence MS	53
2017	A5-6DX	Duplex TS	39
2017	A5-6WR	Windsor TS	57
2017	1035TV	Scarborough Civic Centre (YMCA)	25
2017	T2SG	Lawrence Scarborough Golf Club MS	56
2018	A5-6W	Wiltshire TS	59
2018	A1-2MN	Main TS	57
2018	QYSG & QZSG	Flemingdon MS	52
2019	A3-4WR	Windsor TS	57
2019	A5-6T	Strachan TS	57
2019	T1SG	Galloway Dearhamwoods MS	54

E6.13.6.2 Program Risks

Space for transitioning switchgear is one risk associated with the switchgear renewal program. In some cases, substations do not have space available to install new switchgear. This issue is addressed via load transfer to adjacent stations, but is only feasible if the adjacent stations have enough spare capacity to take the load. Among the switchgear proposed for replacement, Windsor TS is the only station with no space available for new switchgear. Windsor TS A5-6WR switchgear replacement will be made possible due to the construction of Copeland TS. The A5-6WR bus will transfer the load to the new A1-2CL bus at Copeland TS and then be decommissioned to make space for the new switchgear.

Another program risk is scheduling of planned outages. Planned outages are required to transfer load between switchgears. However, scheduling planned outages at the desired time is not always possible because of its dependencies on factors like high load peak and emergency load restoration. Toronto Hydro's distribution grid has high load peak demand during summer and winter period. Hence, planned outages are not scheduled during these periods. This narrows down the window for planned outages to take place during spring and fall only. Furthermore, any emergency load restoration work during spring or fall takes precedence over planned outages for asset replacement. Thus, there is always the possibility of switchgear replacement work being delayed due to difficulty in scheduling a planned outage for load transfer.

E6.13.6.3 External Constraints

Toronto Hydro is required to co-ordinate with HONI for the installation and commissioning of the incoming feeder cells during switchgear replacement. This is a critical part of the switchgear replacement work. This dependency constrains Toronto Hydro from bringing switchgear to service until HONI completes their portion of the job. This risk is mitigated by coordinating with HONI to complete the work in phases with a planned schedule.

E6.13.7 Evaluation of Alternatives

E6.13.7.1 Quantification/Evaluation of Options

The alternatives for addressing the issues with functionally obsolete Switchgear at MS and TS are evaluated below:

(i) Status Quo

The status quo would have Toronto Hydro maintain a "run to failure" scenario, with replacement of existing switchgear only when failure occurs. Since all the selected assets are obsolete and majority of them are past their useful lives, Toronto Hydro would have to incur additional cost to maintain these assets. The associated safety and operational risks and issues detailed above would remain. The status quo would also only allow Toronto Hydro to defer this capital investment temporarily. However, the replacement will eventually be required on a reactive work basis, which will be more costly than replacing on a planned basis. Considering the safety concerns and the age of the assets, the impact of failure is high.

(ii) Load transfer to Adjacent Sub-stations

When 4.16 kV switchgear fails at a municipal station, the load from that failed switchgear bus can be transferred to an adjacent station bus to minimize outage duration. This contingency plan, however, is only a temporary solution. Over the long term, a voltage drop will become an issue especially if the load is transferred to a substation located far from the existing load centre. Moreover, substation equipment within the same area is also typically in poor condition. If the switchgear at the adjacent substation also fails, it can create a cascading effect that can lead to more customer outages. In many cases, load transfer is also not possible due to geographical constraints.

In the case of TSs, transferring load to adjacent sub-stations would require the receiving TS to have spare capacity, sufficient feeder positions, and physical space for additional infrastructure. The location of the receiving station would also need to be sufficiently close to the load centre to avoid a voltage drop. These conditions cannot be met for any of the TSs addressed by this program.

(iii) Convert the existing 4.16 kV load to 27.6 kV and decommission Switchgear

This option only applies to MS Switchgear. Toronto Hydro's program to convert the 4.16 kV stations to 27.6 kV infrastructure would be expected to result in improvements to safety, reliability, system efficiency and operational flexibility. However, this conversion requires large amounts of capital investment and is only feasible if the substation is located on the boundary of the 27.6 kV distribution system. Also, it is only economically reasonable to convert the load if the associated distribution assets are also in poor condition. All the stations selected for MS Switchgear replacement do not meet the criteria for load conversion and are planned to be kept in-service.

(iv) Switchgear Replacement

This option would involve replacing the existing switchgear with metal clad enclosure, Type C arc-resistant design and vacuum circuit breakers, as proposed by Toronto Hydro. This will help address all safety and operational issues concerning the existing switchgear.

Metal clad switchgear encloses all high voltage live parts in a metal built enclosure to ensure safety to operators during operation and maintenance work. To further improve reliability, interlocks installed in the metal clad switchgear prevent potential operational errors.

The Type C design includes arc resistant construction at the front, back and sides, and between compartments within the same cell or adjacent cells. This design does not allow an arc to propagate inside the enclosure into adjacent cells or other parts of the equipment, and protects personnel from injury and surrounding equipment from potential damage.

Vacuum circuit breakers do not require filling of any gas or oil. Therefore, they do not need any auxiliary air system, oil handing, and are free from periodic maintenance. Since no gas decomposition occurs in a vacuum, the sealed breaker does not have any environmental liability. In addition, vacuum circuit breakers can detect and interrupt an arcing fault more quickly in comparison to air magnetic or oil circuit breaker. All these factors help mitigate the risk associated with arc flash and remove hazards concerning non-friable asbestos and flammable oil.

Toronto Hydro's 4.16 kV MSs operate under a first contingency plan. In the event of a switchgear failure, the load from the affected bus can be transferred to an adjacent station. Under this configuration, a single-bus single-breaker configuration is the most cost effective bus configuration for 4.16 kV MS. Also, single bus single breaker scheme is very simple in design and very convenient to operate. Therefore, all new MS Switchgear are expected to be designed as a single-bus single-breaker arrangement.

Downtown Toronto distribution system relies heavily on the stability of the incoming high voltage supply and redundant station equipments. This design provides quick restoration for common failure modes, but does not provide back-up for low-probability, high impact events such as a switchgear failure. TS buses carry high load with no spare capacity to take on additional load. Therefore, downtown Toronto substations do not have load transferring capabilities in the event of a switchgear failure. In the absence of a contingency plan, a breaker-and-a-half bus arrangement is the most reliable and operationally flexible option. Maintenance of a breaker on this scheme can be performed without an outage to any circuit. Furthermore, either main bus can be taken out of service with no interruption to the service.

Recommendation

Of the alternatives, switchgear replacement is the preferred prudent option. It addresses all identified safety and operational issues and helps improve system reliability and efficiency at optimal cost.

The replacement of the Switchgear assets in the first year of the program will result in an avoided estimated risk cost (ARC) of $28.5M, as detailed in Table 11. This value represents the avoided

cost of executing the first year of activities as scheduled as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the assets' probability of failure, and multiplying this by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. For further details on the ARC approach is provided in Section D3.3.

TABLE 11: AVOIDED RISK COST BUSINESS CASE EVALUATION

Business Case Element	**Cost (in Millions)**
Asset Renewal	
Present Value of Net Cost in 2020 **[PV(NET_COST(2020)]**	$43.3
Net Cost for the First Year of Activity **[NET_COST(First Year of Activity)]**	$14.7
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$28.5

E6.13.8 2015 Projects

Table 12 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved Municipal Stations Switchgear and Transformer Stations Switchgear segments as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 12: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	**CIR Projects**
10.1	**1.8**

Table 13 lists all projects that are planned for partial or complete execution as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 13: 2015 PROJECTS

E6.13.8.1 S12416 Scope Description

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Porterfield MS Replace 4kV SWGR Planned Capital

Scope Number: S12416

Scope Year: 2015

Estimated Cost: $437,866.98

(i) Objective

The objective of this project is to design, purchase and install modern single-bus single-breaker arc-resistance switchgear of Type C along with modern RTUs and communication media to replace the existing 4.16 kV aging and obsolete switchgear connected to T1-T2 transformer at Porterfield MS.

(ii) Scope of Work

TABLE 14: S12416 SCOPE OF WORK DETAILS

District Neighborhood	WEST
Station(s)	PORTERFIELD MS
Bus	T1rT2SG

TABLE 15: S12416 ASSETS REPLACED

Assets (Units)	2015
MS Switchgear	1

(iii) Justification & Benefits

The existing non-arc resistant switchgear at Porterfield MS, as shown in Figure 15, will be 59 years old in 2015 and is past its useful life of 50 years. This switchgear houses oil circuit breakers that are 59 years old, past their useful lives of 40 years. These circuit breakers are obsolete and require a high ongoing maintenance cost. The manufacturer no longer produces these devices and spare parts are difficult to acquire. Presence of flammable oil in oil breakers poses safety risks to Toronto Hydro personnel.

Replacing the existing switchgear with an arc resistant design and vacuum circuit breakers will protect the equipment from arc faults and address all reliability and safety issues concerning oil circuit breakers. Installation of a SCADA communication system will allow Toronto Hydro control operators to monitor the equipment conditions, correct faults remotely, provide automated switching and feeder re-routing in both planned outages and unplanned emergency work. This will improve system reliability and efficiency.

FIGURE 15: NON-ARC RESISTANT METAL-CLAD SWITCHGEAR AT PORTERFIELD MS

E6.13.8.2 S13126 Scope Description

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Neilson Dr MS Replace Switchgear

Scope Number: S13126

Scope Year: 2015

Estimated Cost: $547,333.73

(i) Objective

The objective of this project is to design, purchase and install modern single-bus single-breaker arc-resistance switchgear of Type C along with modern RTUs and communication media to replace the existing 4.16 kV aging and obsolete switchgear connected to T1-T2 transformer at Neilson Drive MS.

(ii) Scope of Work

Station(s)	NEILSON DRIVE MS
Bus	T1rT2SG

TABLE 17: S13126 ASSETS REPLACED

Assets (Units)	2015
MS Switchgear	1

(iii) Justification & Benefits

The existing non-arc resistant switchgear at Neilson Drive MS, as shown in Figure 16, will be 61 years old in 2015 and is past its useful life of 50 years. This switchgear houses oil circuit breakers that are 61 years old, past their useful lives of 40 years. These circuit breakers are obsolete and require a high ongoing maintenance cost. The manufacturer no longer produces these devices and spare parts are difficult to acquire. Presence of flammable oil in oil breakers poses safety risks to Toronto Hydro personnel.

Replacing the existing switchgear with an arc resistant design and vacuum circuit breakers is expected to protect the equipment from arc faults and address all reliability and safety issues concerning oil circuit breakers. Installation of a SCADA communication system will allow Toronto

Hydro control operators to monitor the equipment conditions, correct faults remotely, provide automated switching and feeder re-routing in both planned outages and unplanned emergency work. This is expected to improve system reliability and efficiency.

MS Switchgear	1

(iii) Justification & Benefits

This is a supporting project for Neilson Drive T1-T2 Switchgear replacement. It is done in co-ordination with the switchgear replacement project for resource utilization. See section E6.13.8.1 S13126 Scope Description for more details.

E6.13.8.4 S14070 Scope Description

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Thornton MS Replace Switchgear

Scope Number: S14070

Scope Year: 2015

Estimated Cost: $547,333.73

(i) Objective

The objective of this project is to design, purchase and install modern single-bus single-breaker arc-resistance switchgear of Type C along with modern RTUs and communication media to replace the existing 4.16 kV aging and obsolete switchgear connected to T1-T2 transformer at Thornton MS.

(ii) Scope of Work

TABLE 20: S14070 SCOPE OF WORK DETAILS

District Neighborhood	WEST
Station(s)	THORNTON MS
Bus	T1rT2SG

TABLE 21: S14070 ASSETS REPLACED

Assets (Units)	2015
MS Switchgear	1

(iii) Justification & Benefits

The existing non-arc resistant switchgear at Porterfield MS, as shown in Figure 17, will be 60 years old in 2015 and is past its useful life of 50 years. This switchgear houses oil circuit breakers that are 60 years old, past their useful lives of 40 years. These circuit breakers are obsolete and require a high ongoing maintenance cost. The manufacturer no longer produces these devices and spare parts are difficult to acquire. Presence of flammable oil in oil breakers poses safety risks to Toronto Hydro personnel.

Toronto Hydro expects that replacing the existing switchgear with an arc resistant design and vacuum circuit breakers will protect the equipment from arc faults and address all reliability and safety issues concerning oil circuit breakers. Installation of a SCADA communication system will allow Toronto Hydro control operators to monitor the equipment conditions, correct faults remotely, provide automated switching and feeder re-routing in both planned outages and unplanned emergency work. This is expected to improve system reliability and efficiency.

FIGURE 17: NON-ARC RESISTANT METAL-CLAD SWITCHGEAR AT THORNTON MS

E6.13.8.5 S12045 Scope Description

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Wiltshire TS Replace A3-4W Switchgear

Scope Number: S12045

Scope Year: 2015

Estimated Cost: $109,466.75

(i) Objective

The objective of this project is to purchase, install and commission new double-bus double-breaker arc-resistant Type C, 4-wire, 3000A metal-clad switchgear along with modern RTUs and communication systems to replace the existing 13.8KV A3-4W Switchgear at Wiltshire TS.

(ii) Scope of Work

TABLE 22: S12045 SCOPE OF WORK DETAILS

District Neighborhood	DOWNTOWN TORONTO
Station(s)	WILTSHIRE TS
Bus	A3r4W

TABLE 23: S12045 ASSETS REPLACED

Assets (Units)	2015
TS Switchgear	1

(iii) Justification & Benefits

This is a supporting project for Wiltshire TS A3-4W Switchgear replacement.

The existing non-arc resistant A3-4W Switchgear at Wiltshire TS will be 61 years old in 2015 which is past its useful life of 50 years. This switchgear houses air-blast type circuit breakers which are 60 years old, past their useful lives of 42 years. The original manufacturer no longer produces this device, and spare parts are difficult to obtain and in many cases need to be custom manufactured. This makes the maintenance cost high and unsustainable over the long term.

Since the switchgear is of non-arc resistant design it is vulnerable to internal arc faults. This increases the risk of collateral damage and personnel injury during a catastrophic failure.

Replacement of the existing A3-4W Switchgear with an arc-resistant Type C Switchgear with vacuum circuit breakers is expected to improve the system reliability and address all safety risks associated with the old switchgear.

Note: This is an ICM-approved partial carry-over job from 2014. Most of the work has been completed in 2014.

E6.13.8.6 S13412 Scope Description

Station(s)	CARLAW TS
Bus	A6r7E

TABLE 27: S12557 ASSETS REPLACED

Assets (Units)	2015
TS Switchgear	1

(iii) Justification & Benefits

This is a supporting project for Wiltshire TS A6-7E Switchgear replacement.

The existing non-arc resistant A6-7E Switchgear at Carlaw TS will be 51 years old in 2015 which is past its useful life of 50 years. This switchgear houses air-blast type circuit breakers which are 46 years old, past their useful lives of 42 years. The original manufacturer no longer produces this device, and spare parts are difficult to obtain and in many cases need to be custom manufactured. This makes the maintenance cost high and unsustainable over the long term.

Since the switchgear is of non-arc resistant design, it is vulnerable to internal arc faults. This increases the risk of collateral damage and personnel injury during a catastrophic failure.

Replacement of the existing A6-7E Switchgear with an arc-resistant Type C Switchgear with vacuum circuit breakers is expected to improve the system reliability and address all safety risks associated with the old switchgear.

Note: This is an ICM approved partial carry-over job from 2014. Most of the work has been completed in 2014.

E6.13.8.7 S13433 Scope Description

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Strachan TS Replace A7-8T Switchgear

Scope Number: S13433

Scope Year: 2015

Estimated Cost: $328,400.24

(i) Objective

The objective of this project is to purchase, install and commission new double-bus double-breaker arc-resistant Type C, 4-wire, 3000A metal-clad switchgear along with modern RTUs and communication systems to replace the existing 13.8KV A7-8T Switchgear at Strachan TS.

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Duplex TS A5-6: Capital Contribution Duplex (13.8 kV)

Scope Number: S13415

Scope Year: 2015

Estimated Cost: $2,731,920.65

(i) Objective

The objective of this project is for HONI to replace the incoming circuit breakers connected to Duplex TS A5-6DX switchgear. Toronto Hydro will pay for this HONI work through a Capital Contribution.

(ii) Scope of Work

TABLE 32: S13415 SCOPE OF WORK DETAILS

District Neighborhood	DOWNTOWN TORONTO
Station(s)	DUPLEX TS
Bus	A5r6DX

TABLE 33: S13415 ASSETS REPLACED

Assets (Units)	2015
TS Switchgear	1

(iii) Justification & Benefits

This is a supporting project for Duplex TS A5-6DX Switchgear replacement.

The existing non-arc resistant A5-6DX Switchgear at Duplex TS will be 40 years old in 2015. This switchgear houses air-magnetic type circuit breakers which are 40 years old. There are two other switchgears at this station which are much older than A5-6DX. However, in order to replace those switchgears, A5-6DX needs to be replaced first based on the position of the switchgears. There is also the risk of the basement being flooded with water from the HONI deluge system which is located on the main floor above the switchgear. To mitigate this risk, and to address the aging issue of the switchgears, Toronto Hydro plans to replace in stages all the switchgear at Duplex TS which are located in the basement with waterææsistant switchgear. The A5æ6DX switchgear is the first to be replaced. This switchgear is in a fair condition. However, it must be replaced first in

order to be able to replace the A1a2DX switchgear which is in a very poor condition but could not be replaced first due to space constraint.

Note: This is a partial carry-over job from 2014. Most of the work has been completed in 2014.

E6.13.8.9 S14005 Scope Description

Portfolio: Stations

Program: Switchgear Renewal

Scope Title: Windsor TS A5-6WR Switchgear Replacement

Scope Number: S14005

Scope Year: 2015

Estimated Cost: $1,094,547.11

(i) Objective

The objective of this project is to purchase, install and commission new double-bus double-breaker arc-resistant Type C, 4-wire, 3000A GIS (SF6) switchgear along with modern RTUs and communication systems to replace the existing 13.8KV A5-6-9-10WR Switchgear at Windsor TS.

(ii) Scope of Work

Station(s)	WINDSOR TS
Bus	A5r6WR

TABLE 35: S14005 ASSETS REPLACED

Assets (Units)	2015
TS Switchgear	1

(iii) Justification & Benefits

The existing non-arc resistant A5-6WR Switchgear at Windsor TS, as shown in Figure 18, will be 60 years old in 2016, past its useful life of 50 years. This switchgear houses air-blast type circuit breakers that are 57 years old, past their useful lives of 42 years. The original manufacturer no longer produces this device, and spare parts are difficult to obtain and in many cases need to be custom manufactured. This makes the maintenance cost high and unsustainable over the long term.

Since the switchgear is of non-arc resistant design, it is vulnerable to internal arc faults. This increases the risk of collateral damage and personnel injury during a catastrophic failure.

Replacement of the existing A5-6WR Switchgear with an arc-resistant Type C Switchgear with vacuum circuit breakers is expected to improve the system reliability and address all safety risks associated with the old switchgear.

This project is planned for completion over a three-year period starting 2014 and ending in 2016.

E6.14 Power Transformer Renewal

NEW TRANSFORMER INSTALLATION AT CHAPMAN MS

E6.14.1 Summary

Program Description

The Power Transformer Renewal program is a continuation of the activities previously presented in the OEB-approved Station Power Transformer segment that formed part of Toronto Hydro's 2012-2014 rates application[1]. Toronto Hydro plans to replace 24 power transformers located at 22 municipal stations (MS) across the city over the 2015-2019 planning horizon. Figure 1 depicts the locations of projects comprising the 2015-2019 Station Transformer Renewal program.

Of the 24 transformers identified for replacement, 22 have been in service for longer than 45 years (the useful life of a transformer) as of 2015. The two remaining transformers, Flemingdon MS TR1 and Redcliff MS TR2, require replacement due to specific technical considerations. For each of the 24 transformers, Toronto Hydro considered the need to modify each transformer's capacity based on the load in each of their respective service areas. In all cases, Toronto Hydro determined that a like-for-like replacement of station transformers is optimal. The transformers range in capacity from 4 MVA to 12 MVA.

[1] EB-2012-0064, Application and Evidence (May 10, 2012), Tab 4, Schedule B12.

The anticipated benefits of this program are summarized in Table A below.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	A total of 19,109 customers are expected to experience: ƒ a reduced risk of long-duration outages caused by individual transformer failure (see Section E6.14.3.2(ii)), and ƒ improved system reliability
Reliability	By replacing Toronto Hydro's highest risk transformers and decreasing the proportion of transformers past their end-of-life, Toronto Hydro intends to: ƒ reduce the probability of the distribution system operating under contingency (See Section E6.14.3.1), ƒ reduce the frequency of outages due to transformer failure
Safety	Expected reduction in the risk of fires due to transformer failure, thereby improving the safety of working personnel and the residents or businesses adjacent to the transformer.
Efficiency	As part of the Power Transformer Renewal program, Toronto Hydro will remove overhead bus structures at stations where present. This work is expected to: ƒ Remove the potential for animal contact, ƒ Increase the work efficiency of station crews, and ƒ Increase the reliability of stations (by design) where more than one transformer is present
Environmental Benefit	ƒ Along with the new power transformers, Toronto Hydro will install concrete pad oil containment systems that reduce the risk of environmental soil contamination from potential oil leaks.

Program Drivers

This program is required to mitigate the possibility of widespread and prolonged outages due to the failure of a power transformer. The trigger driver for this program is summarized below.

TABLE B: STATION POWER TRANSFORMERS RENEWAL PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ By 2015, an estimated 51.6% of in-service station power transformers will be beyond their expected useful lives of 45 years, with an additional 10% reaching end-of-life by 2020. ƒ Risk of prolonged outages to customers connected to aged and poorly performing transformers. ƒ Increased strain on the system during contingencies compromises the security of power supply to customers beyond the area of immediate impact of a failed transformer.

A power transformer failure will result in an outage to all connected customers lasting between one and six hours. In addition, when a failure occurs, Toronto Hydro reconfigures the system to re-supply the affected customer, which places the system in a state of contingency that can strain the system. In addition, since the majority of these transformers are past their useful lives of 45 years, Toronto Hydro may have to renew these transformers reactively rather than proactively in the event of a power outage.

Preferred Alternative

Toronto Hydro considered the following alternatives for mitigating the safety and reliability risks associated with these assets:

(1) Do Nothing. Accept the risk of a potential transformer failure and address it on a reactive basis

(2) Voltage Conversion of the MS that the transformer serves, thereby eliminating the need for the step down transformer

(3) Replace the aged transformers with new ones, thereby maintaining the existence of the MS

Option 2 depends on the timing of distribution feeder projects to convert load from 4 kV to higher standard voltages. If a voltage conversion project is planned for the service area of an MS whose transformer has reached end-of-life, then Toronto Hydro chooses to address the transformer's need for replacement by decommissioning after the voltage conversion project has been completed. All of the transformers addressed in this program will be required for 4 kV service during the 2015-2019 period and beyond. Therefore, Option 3 is the preferred alternative for these assets because it allows Toronto Hydro to proactively mitigate the failure risk posed by end-of-life and poor condition power transformers within its system and thereby reduce the risk of outages to customers.

The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $2.66 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.14.7).

Timing and Pacing

Toronto Hydro plans to continue to address its aging station power transformer population through proactive replacement of units identified as being at the highest risk and consequence cost of failure. To stabilize annual costs and labour requirements, the program is paced as uniformly as possible. The proposed annual investment for the program along with the historical costs is provided in Table C below. Toronto Hydro plans to address approximately five of the highest risk power transformers per year over this period. Toronto Hydro also expects to decommission approximately three transformers per year.

TABLE C: PROPOSED ANNUAL PACING AND INVESTMENT

	Historical Costs					Future Investment					
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
CAPEX ($M)	1.83	4.04	2.66	1.68	1.30	1.68	2.61	2.58	2.72	2.72	12.30

E6.14.2 Program Description

The Power Transformer Renewal program is a continuation of the activities previously presented in the OEB approved Station Power Transformer segment that formed part of Toronto Hydro's 2012-2014 rates application.[2] Toronto Hydro plans to replace 24 power transformers located at 22 municipal stations (MS) across the city over the 2015-2019 planning horizon. Figure 1 depicts the locations of projects comprising the 2015-2019 Station Transformer Renewal program.

FIGURE 1: STATIONS COMPRISING THE 2015-2019 STATION TRANSFORMER RENEWAL PROGRAM BY YEAR

Toronto Hydro identified this group of assets for replacement using a combination of the following criteria:

[2] EB-2012-0064, Application and Evidence (May 10, 2012), at Schedule B-12.

- Asset condition and Health Index (HI) Score (refer to Asset Condition Assessment - Section D3.1.2.1 (ii));
- Asset age (relative to a 45-year useful life);
- Probability of failure (refer to Hazard Rate Distribution of Assets – Section D3.1.1.2); and
- Cost of failure (refer to Impact Cost of Failure - Section D3.1.2.1 (i))

Prior to identifying transformers for replacement, Toronto Hydro considers converting the area that a transformer serves to a higher voltage and decommissioning the transformer, thereby eliminating the need for replacement. None of the transformers comprising this program are located in areas which are planned for voltage conversion.

Of the 24 transformers identified for replacement, 22 have been in service for longer than 45 years (the useful life of a transformer) as of 2015. The two remaining transformers, Flemingdon MS TR1 and Redcliff MS TR2, require replacement due to specific technical considerations. Flemingdon MS TR1 was chosen for replacement because of poor oil tests results as discussed in Section E6.14.4.1; Redcliff MS TR2 was chosen for replacement because of the presence of an overhead bus structure as discussed in the paragraph below. For each of the 24 transformers, Toronto Hydro considered the need to modify each transformer's capacity based on the load in each of their respective service areas. In all cases, Toronto Hydro determined that a like-for-like replacement of station transformers is optimal. The transformers range in capacity from 4 MVA to 12 MVA.

The transformers scheduled for replacement at Norseman MS, Redcliff MS, and York MS use an obsolete overhead bus structure, shown in Figures 2 and 3 below. The purpose of the overhead bus structure is to connect the power transformers to their 27.6 kV supply lines, but the bus structure obstructs access to the power transformers from above, which is required for replacement. The bus structure also requires that the entire MS be taken out of service when one transformer is taken out of service, which impacts the reliability of the MS. Additionally, the bus structure introduces a risk associated with animal contact. Animals occasionally climb on top of the bus structure and then attempt to climb down the bushings of the transformer. When this occurs, the animal serves as a short circuit which results in an outage. Accordingly, as part of the Transformer Renewal program, Toronto Hydro proposes to remove the overhead bus structures at Norseman MS, Redcliff MS, and York MS, and replace them with a more modern padmount design.

FIGURE 2: CLOSE-UP OF OVERHEAD BUS STRUCTURE AND TRANSFORMERS AT REDCLIFF MS

The alternative padmount design uses a padmount switch to connect transformers to their supply lines, and permits one transformer to be taken out of service at a time. The padmount switch also allows the transformer to be safely isolated by station crews. Otherwise, with overhead bus structures, station crews may require assistance from overhead crews to complete this isolation safely. Consequently, replacement of the overhead bus structure with the padmount design is expected to save time and expenses for future maintenance, repairs, and replacements. Centre Dr. MS was converted from the obsolete overhead bus structure setup to the modern padmount setup in 2008, and is shown in Figure 3.

FIGURE 3: CENTRE DRIVE MS AFTER CONVERSION TO PADMOUNT SETUP (NOTE THE PADMOUNT SWITCH IN THE BOTTOM RIGHT, AND THE UNOBSTRUCTED OVERHEAD ACCESS TO THE TRANSFORMER)

At Redcliff MS, there is an overhead bus structure with two transformers (See Figure 4); one transformer has passed end-of-life, and the second transformer is near end-of-life. In this case, it is more cost effective to replace both transformers at the same time. Since both transformers are connected to the bus structure, Toronto Hydro needs to remove the entire bus structure in order to replace a single transformer. If Toronto Hydro does not eliminate the bus structure by replacing it with a padmount switch (which requires the replacement of both transformers), then the bus structure would have to be reinstalled after the first transformer replacement. When the second transformer is replaced in the future, the bus structure would have to be removed and put back a second time. For this reason, it is economically preferable to replace both transformers at the same time, in order to remove the bus structure once and permanently replace it with a padmount switch.

FIGURE 4: TRANSFORMERS AND OBSOLETE OVE RHEAD BUS STRUCTURE SETUP AT REDCLIFF MS

Since most of the transformers identified for replacement came into service in the 1950s and 1960s, a number of them do not have an oil containment system to prevent the environmental impact of oil spills that may cause soil contamination. When replacing old transformers, Toronto Hydro plans to correct this legacy deficiency by installing concrete oil containment systems for transformers that currently lack them. This oil containment system is composed of a concrete pad on which the transformer is placed, a concrete dyke which surrounds the pad and base of the transformer (and switchgear if applicable), a drain from the concrete pad, and an underground tank. Should oil leak from the transformer, it will be captured in the dyke and drained into the underground tank until it can be properly collected and disposed. Figure 5 shows the concrete dyke which surrounds the transformer and switchgear at Chapman MS. The underground tank is accessed through manholes near the transformers, which are shown in Figure 6.

Toronto Hydro plans to include a project to install oil containment at Jane MS in this program. The two power transformers at Jane MS have been replaced recently. During activities at Jane MS to replace the switchgear and rebuild civil structures to support the switchgear replacement, the oil containment project was delayed to avoid conflict of work schedules. Large underground pipelines installed by other gas and oil industries are located in close proximity to Jane MS. As a

proactive and preventative measure, Toronto Hydro plans to install an oil containment system to prevent any potential environmental damage to the surrounding soil, and to mitigate the risk of damage to any of the large industry pipelines.

FIGURE 5: OIL CONTAINMENT CONCRETE DYKE

FIGURE 6: OIL CONTAINMENT UNDERGROUND TANK MANHOLES

The following table summarizes the anticipated benefits of the Power Transformer Renewal program.

TABLE 1: SUMMARY OF PROGRAM BENEFITS

Customer Value	A total of 19,109 customers are expected to experience: x a reduced risk of long-duration outages caused by individual transformer failure (see Section E6.14.3.2(ii)), and x improved system reliability (see below). The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $2.66 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.14.7).
Reliability	By replacing Toronto Hydro's highest risk transformers and decreasing the proportion of transformers past their end-of-life, Toronto Hydro intends to:

	x reduce the probability of the distribution system operating under contingency (See Section E6.14.3.1), x reduce the frequency of outages due to transformer failure, and x prevent further transformer wear.
Safety	Expected reduction in the risk of fires due to transformer failure, thereby improving the safety of working personnel and the residents or businesses adjacent to the transformer.
Efficiency	As part of the Power Transformer Renewal program, Toronto Hydro plans to remove overhead bus structures at stations where present. This work is expected to: x Reduce the potential for animal contact, x Increase the work efficiency of station crews, and x Increase the reliability of stations (by design) where more than one transformer is present
Environmental Benefit	x Along with the new power transformers, Toronto Hydro plans to install concrete pad oil containment systems that reduce the risk of environmental soil contamination from potential oil leaks. x When transformers fail, they may leak oil to their surroundings. By replacing transformers without oil containment systems and that are identified to have a material risk of failure, Toronto Hydro will prevent potential oil contamination to the surrounding environment

E6.14.3 Why the Program is Needed

The replacement of station transformers is required to mitigate the risk of prolonged outages to customers served by these at-risk assets. When a power transformer fails, along with the potential safety risk to personnel and the public, all customers connected to the failed transformer will experience an outage lasting between one to six hours. Even when Toronto Hydro transfers the affected customers to an alternate supply source, system reliability remains at risk until the failed transformer is replaced, as other parts of the system are put under increased strain. Given their age and condition, Toronto Hydro proposes to replace 24 transformers over 2015-2019 period to improve the security of supply to the customers they serve, and maintain system reliability as a whole.

E6.14.3.1 Program Drivers

The purpose of the Power Transformer Renewal program is to optimally manage Toronto Hydro's portfolio of station power transformers for the long term, with the objective of minimizing the risk of customer outages, maximizing system reliability and stabilizing future annual transformer replacement costs. The trigger driver of the Power Transformer Renewal program is failure risk.

Accordingly, the Power Transformer Renewal program falls under the System Renewal investment category for distribution system assets.

TABLE 2: STATION POWER TRANSFORMERS RENEWAL PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ By 2015, an estimated 51.6% of in-service station power transformers will be beyond their expected useful lives of 45 years, with an additional 10% reaching end-of-life by 2020. ƒ Risk of prolonged outages to customers connected to aged and poorly performing transformers. ƒ Increased strain on the system during contingencies compromises the security of power supply to customers beyond the area of immediate impact of a failed transformer.

The immediate and direct impact of station transformer failure is the interruption of supply to the customers connected to the failed transformer. Should a failure occur, Toronto Hydro must restore power to customers by reconfiguring the system into a contingency state, i.e. a backup configuration designed to isolate the failed equipment and restore supply to as many affected customers as possible. While these measures provide short-term relief, leaving Toronto Hydro's system in a contingency state places the system at an elevated level of risk due to the following issues:

- Increased Vulnerability to Further Outages: When a transformer fails, Toronto Hydro transfers its customers' load, by opening and closing tie switches between adjacent feeders in the distribution system, to a supporting transformer located either at the same station or at a nearby station. Should the supporting transformer also fail, the affected customers will experience an outage until at least one of the two transformers is replaced. Additionally if other equipment in the distribution system should fail, such as the tie switches or adjacent feeders needed to support the load, then customers will experience an outage even if the supporting transformer is available to receive load. For these reasons, Toronto Hydro's system experiences an increased vulnerability to further outages during a contingency state.

- Longer and Larger Outages: Should a supporting transformer fail following the initial failure, affected customers would experience an outage of about 72 hours until at least one transformer is replaced. This outage would also affect even more customers than those initially interrupted. (See Section E6.14.3.2ii).

- Increased Risk of Failure on Supporting Transformers: When a transformer fails, the supporting transformers receive additional load such that their loading level could go up to 100% of their capacity, which is much higher than the normal load level of 50% or lower. Operating at loading levels well above the norm tends to increase the risk of failure of the supporting transfers, even after the system is restored to its normal state out from the contingency state.

- Increased Replacement Costs: Replacing a transformer on an emergency basis is approximately twice as expensive as a planned replacement under the proposed program. This is due to additional costs such as unplanned work from control center for interruption schedule, inefficiency due to diversion of work from other planned capital work, and increased labour cost for overtime work.

By 2015, over half of Toronto Hydro's station power transformers will be beyond their 45-year useful lives. Allowing these transformers to remain in operation increases their probability and frequency of failure. Given the severity of potential consequences of transformer failure, it is necessary to replace these high-risk station transformers proactively, in the manner proposed in this program.

E6.14.3.2 Asset Details

(i) Asset Lifecycle

Power transformers typically fail when their internal windings experience an electrical fault as a result of deteriorated insulating materials. The major insulating materials of a power transformer are the mineral oil surrounding the windings, and the cellulose paper wrapped around the wire of the windings. Figure 7 displays the internal core and windings of a typical station transformer.

FIGURE 7: INTERNAL CORE AND WINDINGS OF A POWER TRANSFORMER

Degradation of insulation materials occurs naturally and inevitably. However, the rate of degradation is strongly influenced by exposure to three factors: oxygen, moisture, and high temperature.

When a power transformer is new, the oxygen and moisture content of its insulating oil are at their minimum. Over time, oxygen and moisture seep into the transformer from the atmosphere through seasonal heating and cooling cycles. Oxygen reacts with the mineral oil to form alcohols and acids, which reduce the insulating properties of the oil. Along with the acids produced in the oil, oxygen also reacts with the paper insulation, which causes decomposition of the paper. Moisture has the same effect on the oil and paper insulation under the influence of high temperature or the strong electric field present near the transformer windings.

Under normal operating conditions, a power transformer will generate heat due to the small but unavoidable transformer winding losses. This heat gradually causes the mineral oil to degrade into simple gases (such as methane and ethane). These gases are poor insulators compared to the mineral oil and, as a result, reduce the insulating ability of the mineral oil. When a fault

occurs, a transformer produces more heat than normal, causing its insulating materials to reach high temperatures. High heat causes the rates of all above-noted degradation processes to increase drastically. In addition, the occurrence of faults themselves causes significant degradation of insulating materials in the manner described below.

There are typically two main types of faults which power transformers may experience: electrical and thermal. An electrical fault happens when unintentional current flow occurs, usually due to a breakdown of the transformer's insulating materials. This type of fault tends to char the paper insulation, and cause rapid degradation of the oil insulation into simple gases due to the electrical phenomena of the fault. A thermal fault occurs when a transformer overheats, usually due to overloading. The intense heat also causes charring of the paper insulation; once charred, the paper loses its insulating ability and becomes prone to flaking. Thermal faults have a tendency to decrease the insulating properties of the paper and ultimately deteriorate the paper insulation on the transformer windings.

While it is possible to restore the condition of the oil through the process of oil reclamation, which filters out the moisture and contaminants, it is not possible to restore the condition of the paper insulation once it has deteriorated. Toronto Hydro regularly undertakes oil reclamation for power transformers showing poor oil condition. However, when the condition of the power transformer has deteriorated and/or when the transformer has exceeded its useful life, oil reclamation is typically not an economic solution. For power transformers beyond their useful lives and/or those whose condition has deteriorated, the risk of failure increases significantly. Toronto Hydro takes action to proactively replace these transformers before they fail.

Toronto Hydro's power transformer population currently consists of 248 units, excluding 20 transformers that serve only the Toronto Transit Commission. In 2015 over half the transformer population (51.6% or 128 transformers) will have been in operation past their useful lives (see Figure 8). If no transformer interventions occur by 2020, the proportion of transformers past their end-of-life will increase to approximately 60% (149 units).

FIGURE 8: HISTOGRAM OF YEARS IN-SERVICE FOR TORONTO HYDRO'S TRANSFORMER POPULATION AS OF 2015

As more transformers continue aging past their end of useful life, the probability and frequency of failure increases. As the above figure indicates, in addition to a significant proportion of transformers at or near the end of their expected useful lives, a large subset of Toronto Hydro's transformers are far beyond their useful lives, further amplifying the failure risk. If Toronto Hydro does not renew its aging fleet of transformers, then at some point in the near future the power transformers would fail faster than the proactive replacement program. Given the severity of potential consequences of transformer failure (discussed in the following Section E6.14.3.2(ii)), Toronto Hydro prefers proactive transformer replacement, compared to the run-to-fail approach. The Power Transformer Renewal program is planned with a focus on long term benefits, to help ensure that in the future, Toronto Hydro will be able to implement similar proactive transformer replacement programs at reasonable paces, in order to avoid the run-to-fail approach (and thereby mitigate outage and reliability risks to customers).

(ii) Asset Failure Impacts

When a power transformer fails, numerous customers experience an outage ranging from one to six hours until the load of the failed transformer is transferred to the adjacent station transformers. When this occurs, the distribution system in the affected area is operating under contingency. Each of the transformers scheduled for replacement over the 2015-2019 period currently serves an average of 796 customers, with an average peak load of 3,333 kVA (see Table 4). As noted in

section E6.14.3.1, even though power can be restored after a single transformer failure, Toronto Hydro's distribution system operations are constrained and under contingency after a power transformer failure. Until Toronto Hydro replaces the failed transformer, customers in the general area remain at an elevated level of outage risk compared to normal operating conditions. For instance, should a supporting transformer fail following the failure of the original transformer, than the customers served by these units will experience an outage until at least one transformer is replaced. It typically takes Toronto Hydro 72 hours to replace at least one failed transformer, causing a prolonged outage to the customers served by the originally failed unit, and those served by the supporting unit.

Under normal circumstances, procurement of a station transformer unit typically takes 12 months once an order has been placed. For this reason, Toronto Hydro carries spare transformers to manage the duration of outages caused by transformer failures. With a spare transformer available, a failed transformer can be replaced in 3 to 5 days, while the affected customers continue receiving supply from the adjacent supporting transformers. Table 4 provides the number of customer served by each power transformer proposed for replacement.

TABLE 3: NUMBER OF CUSTOMERS SERVED BY EACH POWER TRANSFORMER

Power Transformer	Peak Load (kVA)	Customers Served
BELLAMY-LAWRENCE-TMSTR1	3,930	1,756

Average:	3,333	796

In extreme case, a transformer failure may involve a rupture of the oil tank, and subsequent fire upon ignition of the exposed oil. In addition to lengthy outages, transformer failure events accompanied by a fire can cause significant damage to the surrounding properties, and pose a significant potential safety risk to working personnel and the residents adjacent to the MS.

Toronto Hydro experienced a transformer failure accompanied by fire in June 2003, when a 49-year old power transformer TR2 at Dupont MS failed and caught fire, and set two other power transformers at the station on fire. The two adjacent transformers experienced minor damage by the fire, but not to the point of failure. The failure of the TR2 transformer and the associated restoration efforts resulted in interruptions to a total of 5,675 customers, with a total of 23,341 customer hours interrupted. The outage lasted 6.6 hours from when the first transformer failed to when all customers were restored to service. Figures 9 to 11 depict the aftermath of the Dupont MS fire, and illustrate the possible impact of a transformer failure accompanied by fire.

FIGURE 9: FAILED POWER TRANSFORMER AT DUPONT MS (NOTE THE CHARRING OF THE TRANSFORMER)

FIGURE 10: FAILED POWER TRANSFORMER AT DUPONT MS (NOTE THE DAMAGE TO THE MS WALL TO THE LEFT, AND THE NUMEROUS BRICK FRAGMENTS ALONG THE GROUND)

FIGURE 11: FAILED POWER TRANSFORMER AT DUPONT MS (NOTE THE VARIOUS FLUIDS EXPOSED ON THE GROUND)

E6.14.4 Timing & Pacing of the Program

Toronto Hydro plans to continue to address its aging station power transformer population through proactive replacement of units identified as being at the highest risk and consequence cost of failure. To stabilize annual costs and labour requirements, the program is paced as uniformly as possible. The proposed annual investment for the program along with the historical costs is provided in Table 5 below.

TABLE 4: PROPOSED ANNUAL PACING AND INVESTMENT

	Historical Costs					Future Investment					
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
CAPEX ($M)	1.83	4.04	2.66	1.68	1.30	1.68	2.61	2.58	2.72	2.72	12.30

The transformers selected for this program are all past their expected useful lives with the exception of Flemingdon MS TR1 and the Redcliff MS TR2. The Flemingdon MS TR1 was selected because its oil tests show evidence of a high thermal fault (>700 °C). A high thermal fault such as this indicates significant damage to the paper insulation of the transformer, whose condition cannot be improved using oil reclamation. The Redcliff MS TR2 is proposed for replacement because of work efficiencies associated with the removal of the overhead bus structure, required for the replacement of Redcliff MS TR1, as explained in Section E6.14.2.

Table 6 provides more details regarding the transformers that are included in this program. Based on transformer age and condition, the insulating materials of these units are expected to have deteriorated, or are expected to soon deteriorate, to the point that the associated risk of failure is such that the transformers must be replaced (see Section E6.14.3.1i). Toronto Hydro anticipates that deferring these transformer replacements beyond the 2015-2019 period will raise the risk of severe reliability impacts due to failure, and increase the proportion of transformers past end-of-life from 51.6% to 60.1% by 2020.

TABLE 5: SUMMARY OF AGE AND HEALTH OF TRANSFORMERS PLANNED FOR REPLACEMENT

Transformer	Age at Time of Proposed Replacement	Health Index Score	Remark
BELLAMY LAWRENCE MS TR1	55	48	
BLAKETON MS TR1	45	67	Evidence of medium-range thermal fault (see Section E6.14.9.1)

YORK MS TR1	65	63	Overhead bus structure present (See Section E6.14.2)
YORK MS TR2	61	63	Overhead bus structure present (See Section E6.14.2)

The units that Toronto Hydro proposes to replace over the 2015-2019 timeframe are part of a long-term plan to prudently manage the backlog of in-service, end-of-life power transformers. Replacing eight of the highest risk transformers per year will help mitigate the risk to system

reliability of the aging transformer population, at a pace that is achievable given the resources available for this type of work.

During the 2015-2019 period, voltage conversion work is planned at rate that should allow for the decommissioning of three transformers per year on average. On top of that, approximately five replacements are planned annually so that eight transformers in total will be removed from service each year. This pace for transformer replacement will also match Toronto Hydro's average historical investment over the 2010-2014 period.

E6.14.4.1 Ranking & Prioritization

To determine the sequencing for replacement of its fleet of 248 station power transformers, Toronto Hydro considers a combination of the following criteria:

- Asset condition and Health Index (HI) score [refer to Asset Condition Assessment - Section D3.1.2 (ii)];
- Asset age;
- Probability of failure [refer to Hazard Rate Distribution of Assets – Section D3.1.1]; and
- Cost of failure [refer to Impact Cost of Failure - Section D3.1.2 (i)]

Having removed the units eligible for area voltage conversion and those whose condition and vintage do not warrant replacement, Toronto Hydro produces a prioritized transformer replacement schedule. This way, transformers in greatest need of replacement are replaced first.

For stations with both an overhead bus structure (which must be removed in order to remove the old transformer) and two transformers, if at least one transformer is justified for replacement, then it can be more economical to replace both transformers at the same time, rather than replacing the two transformers at different times. Such transformers are added back into the program; as is the case with Redcliff TR2 described in Section E6.14.2.

Finally, Toronto Hydro derives significant benefits from coordinating all planned station work, thereby avoiding taking a station out of service multiple times. When a station is taken out of service, part of Toronto Hydro's system must be put into a contingency state, with associated risks that are described in section E6.14.3.1; therefore, minimizing station outage times minimizes outage risks to customers. Additionally when station work is coordinated, Toronto Hydro can use its labour resources more efficiently. For these reasons, the priority for certain transformers

selected for replacement in the 2015 – 2019 period was adjusted in order to coordinate the Power Transformer Renewal program with the Switchgear Renewal program (see Section E6.16).

E6.14.5 Program Execution

The Power Transformer Renewal program planning process considers any proposed voltage conversion to confirm that transformer replacement does not occur at municipal stations where transformers will soon be decommissioned. The Power Transformer Renewal program is also aligned with the MS Switchgear Renewal program (see Section E6.16) to ensure transformer and switchgear replacement occur at the same time, in order to reduce planned station outages and maximize labour efficiencies. The following steps comprise the task of transformer replacement:

(1) Design and Procurement : once station designers complete a detailed design of the new transformer's configuration, Toronto Hydro issues a Request for Proposal (RFP) to its suppliers. It normally takes one year for a winning supplier to build the transformer and deliver it to Toronto Hydro. If a replacement transformer is targeted for a station with an overhead bus structure design, Toronto Hydro also procures a padmount switch at the same time.

(2) Decommissioning : in coordination with the control centre, Toronto Hydro switching crews seamlessly switch all customers supplied by the MS receiving the new transformer to an adjacent MS, and take the targeted MS out of service. Station crews remove all connections to the transformer; and where present, construction crews dismantle the overhead bus structure. After this, an overhead crane removes the transformer and places it onto a flatbed truck to be taken away.

(3) Installation : prior to installing the new transformer, construction crews install the oil containment tank and the associated concrete pad and dykes. Once this work is complete, a crane places the replacement transformer into its position as shown taking place at Chapman MS in Figure 12.

FIGURE 12: NEW TRANSFORMER INSTALLATION AT CHAPMAN MS. NOTICE THAT IF AN OVERHEAD BUS STRUCTURE WERE PRESENT, IT WOULD BE AN OBSTRUCTION TO THE CRANE AND REPLACEMENT WORK WOULD BE MUCH MORE COMPLICATED.

(4) Connection: Once the new transformer is in position, workers remove the old segment of the direct-buried primary Paper Insulated Lead Covered (PILC) cable that connected the transformer to its primary supply feeder. In the place of the old PILC cable, workers install a concrete-encased Cross-Linked Polyethylene (XPLE) cable. For MSs where an overhead bus structure has been removed, workers also install a pad-mounted switch on the ground, which allows crews to disconnect the supply feeder from the transformer. The workers then connect all the primary and secondary cables to the new transformer. Once the control room energizes the new transformer, workers transfer customers to their new transformer.

E6.14.5.1 Program Risks

As evidenced by the description in the section E6.14.6, the transformer replacement process requires a significant amount of coordination between the design technicians, supply chain specialists, construction and switching crews, and control room operators. Moreover, given the need to take an entire MS out of service and transfer its customers to an alternate source of supply, this work can only occur during limited times of the year when station loading levels permit the necessary switching. Misalignment of any of these procedural steps constitutes a considerable risk to timely program execution. Toronto Hydro mitigates these risks through careful advanced planning and coordination of the responsible parties.

E6.14.6 Evaluation of Alternatives

E6.14.6.1 Quantification/Evaluation of Options

When a power transformer is in need of intervention based on its condition or age and oil reclamation is no longer a reasonable alternative (see Section E6.3.2i), Toronto Hydro considers three options as listed below:

(1) No Transformer Intervention : With this option, no intervention is performed on the power transformer. This option may be chosen if the MS that the power transformer serves has already been planned for voltage conversion (see option 2 below). This strategy carries the risk and associated costs of a potential power transformer failure occurring prior to completion of the voltage conversion.

Applying this option to the transformers planned for renewal in this program (which are not subject to decommissioning due to voltage conversion) would have the following implications:

Outage Risk: All power transformers but Redcliff MS TR2 were selected for replacement because they have passed their useful life and/or are in poor condition (see Section E6.14.4). Each of these transformers has a material potential for failure that may cause long outages to an average of 796 customers; replacement costs are expected to double if failed transformers are replaced reactively.

Reliability impacts: Should a power transformer's health decrease significantly, it may need to be off-loaded to reduce further stress while in-service. This in turn would increase the stress placed on other units. Additionally, the available capacity to deal with a system contingency is expected to decrease along with overall system reliability.

Safety: Transformer failure can be accompanied by fire or an explosion, which may result in collateral damage to other transformers, other station equipment, and, if staff are present, potential injury to personnel.

Applying this option to the general transformer population would lead to an anticipated increase in the frequency of transformer failures due to an increase in the number of transformers operating beyond end-of-life over the 2015 to 2019 period and beyond. Consequently, customers throughout Toronto Hydro's service territory will likely experience more transformer failures.

(2) Voltage Conversion of an MS : With this option, the transformer's need for replacement is addressed through a voltage conversion project, i.e. a project where all 4 kV distribution assets within the service area of an MS are replaced with assets that operate at 13.8 or 27.6 kV. Once the voltage conversion project is completed, the area's MS and power transformer are no longer needed, and are therefore decommissioned.

A voltage conversion project is inherently a distribution feeder project, and is therefore planned independently of transformer age or condition. However, if a voltage conversion project is planned for the service area of an MS whose transformer has reached end-of-life, then Toronto Hydro chooses to address the transformer's need for replacement by decommissioning after the voltage conversion project has been completed.

All of the transformers included in the Power Transformer Replacement program are located in areas which have not been planned for voltage conversion. Therefore, this option was not chosen as the preferred alternative for addressing the transformers of this program.

(3) Power Transformer Replacement: This option involves replacement of aging and/or poor condition transformers. This option is preferred if voltage conversion of an MS is not planned.

Power Transformer Replacement is more economical than the "No Transformer Intervention" option (Option 1). This option also reduces the risk to other MSs whose customers are served by these transformers under contingency. This option was chosen as Toronto Hydro's preferred alternative to address the transformers of this program.

The replacement of the power transformer assets in the first year of the program will result in an avoided estimated risk cost (ARC) of $2.66 million, as detailed in Table 7 This value represents the avoided cost of executing the first year of activities as scheduled as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the probability of failure of the assets, and multiplying this by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. For further details on the ARC approach is provided in Section D3.3.

TABLE 6: BUSINESS CASE EVALUATION FOR THE TRANSFORMER REPLACEMENT PROGRAM

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$2.94
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$0.28
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - NET_COST(First Year of Activity))]	$2.66

E6.14.7 2015 Projects

Table 8 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

(a) previously filed projects that appeared as jobs in the OEB approved Stations Power Transformers segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and

(b) projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 7: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Jobs	CIR Projects
0.55	1.13

Table 9 lists all projects that will be partially or completely executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015. For reference, projects that originally appeared as ICM segment jobs have been flagged as "ICM".

TABLE 8: 2015 PROJECTS

Project Number	Project Name	Total Project Cost (K)	Start Date	Project Type (ICM or CIR)
S13168	Blaketon MS Replace TR1 Transformer	$165	2015	ICM
S13155	High Level MS Replace TR2 Transformer	$219	2015	ICM
S13463	Jane MS Install Oil Containment	$161	2015	ICM
S15096	Coronation Bennett MS: Replace Station Transformer TR1	$516	2015	CIR
S15186	Norseman MS Replace Transformer TR1	$616	2015	CIR

E6.14.7.1 S13168 Blaketon MS – Replace TR1 Transformer

Investment Category: System Renewal

Program: Stations Power Transformer Renewal

Project Title: Blaketon MS Replace TR1 Transformer

Project Number: S13168 (ICM)

Project Year: 2015

Estimated Cost: $164,570

(i) Objective

To replace the existing 7.5/10 MVA, 27.6/13.8 kV station transformer, TR1, with a new 7.5/10 MVA, 27.6/ 13.8 kV station transformer at Blaketon MS.

(ii) Scope of Work

TABLE 9: S13168 SCOPE OF WORK DETAILS

District Neighborhood	ETOBICOKE
Station(s)	BLAKETON MS
Transformer	TR1

The project is located at Blaketon MS. The scope of work for the replacement is described in Section E6.14.6. There is no overhead bus structure present.

(iii) Justification & Benefits

The transformer TR1 at Blaketon MS was manufactured in 1970 and will have reached the end of its useful life by 2015. Dissolved gas analysis (DGA) performed by Weidmann Diagnostic Solutions indicates that a medium-range thermal fault (between 300-700°C) and thermal decomposition of the cellulose paper insulation has occurred. The results of these tests are shown in Table 11.

TABLE 10: WEIDMANN DIAGNOSTIC SOLUTION'S SUMMARY OF DGA FOR BLAKETON MS TR1

Together with transformer TR2, TR1 at Blaketon MS supplies approximately 275 customers. If TR2 fails, it is possible TR1 will overload. Additionally, if TR2 were to fail and start a fire, there is a strong possibility that TR1 will be damaged and result in an outage to the 275 customers. Therefore, to improve the reliability of Blaketon MS and to avoid a significant customer outage, TR2 needs to be replaced.

E6.14.7.2 S13155 High Level MS Replace TR2 Transformer

Investment Category: System Renewal

Program: Power Transformer Renewal Program

Project Title: High Level MS Replace TR2 Transformer

Project Number: S13155 (ICM)

Project Year: 2015

Estimated Cost: $219,427

(i) Objective

To replace the existing 12/15 MVA, 13.8/4.16 kV station transformer, TR2, with a new 12/15 MVA, 13.8/4.16 kV station transformer at High Level MS.

(ii) Scope of Work

TABLE 11: S13155 SCOPE OF WORK DETAILS

District Neighborhood	TORONTO
Station(s)	HIGH LEVEL MS
Transformer	TR2

The project is located at High Level MS. The scope of work for the replacement is described in Section E6.14.6. There is no overhead bus structure present.

(iii) Justification & Benefits

The transformer TR2 at High Level MS was manufactured in 1947 (68 years old in 2015) and has reached the end of its useful life.

In addition, the transformer HI score, which is formulated based on a combination of oil leakage, corrosion, bushing, oil quality tests, age, and dissolved gas analysis is 48 out of 100. This score indicates that the transformer is in poor condition.

Together with transformers TR1 and TR3, TR2 at High Level MS supplies approximately 4,117 customers. If TR2 fails, it is possible TR1 and TR3 will overload. Additionally, if TR2 were to fail and start a fire, there is a strong possibility that TR1 and TR3 will be damaged and result in an

outage to the 4,117 customers. Therefore, to improve the reliability of High Level MS and to avoid a large-scale customer outage, TR2 needs to be replaced.

E6.14.7.3 S13463 Jane MS Install Oil Containment

Investment Category: System Renewal

Program: Power Transformer Renewal Program

Project Title: Jane MS Install Oil Containment

Project Number: S13463 (ICM)

Project Year: 2015

Estimated Cost: $160,758

(i) Objective

To install an oil containment system for the two power transformers at Jane MS.

(ii) Scope of Work

TABLE 12: SCOPE OF WORK DETAILS

District Neighborhood	NORTH YORK
Station(s)	JANE MS

The project is bound by Jane MS. The scope of work for the oil containment installation is described in Section E6.14.6, Step 3.

(iii) Justification & Benefits

Jane MS is in close proximity to large pipelines owned by other gas and petroleum utilities. If an oil leak should occur from either of the two transformers at Jane MS, it is possible that these pipelines may be damaged, as well as potential harm to the local environment. Therefore, to mitigate the risk of pipeline damage, an oil containment system needs to be installed at Jane MS.

E6.14.7.4 S15096 Coronation Bennett MS: Replace Station Transformer TR1

Investment Category: System Renewal

Program: Power Transformer Renewal Program

Project Title: Coronation Bennett MS : Replace Station Transformer TR1

Project Number: S15096

Project Year: 2015

Estimated Cost: $515,582

(i) Objective

To replace the existing 5 MVA, 27.6/4.16 kV station transformer, TR1, with new 5 MVA, 27.6 kV/4.16 kV, station power transformer at Coronation Bennett MS.

(ii) Scope of Work

TABLE 13: S15096 SCOPE OF WORK DETAILS

District Neighborhood	SCARBOROUGH
Station(s)	CORONATION-BENNETT MS
Transformer	TR1

The project is located at Coronation Bennett MS. The scope of work for the replacement is described in Section E6.14.6. There is no overhead bus structure present.

(iii) Justification & Benefits

The transformer TR1 at Coronation Bennett MS was manufactured in 1958 (57 years old in 2015) and has reached the end of its useful life.

In addition, the transformer HI score, which is based on a combination of oil leakage, corrosion, bushing, oil quality tests, age, and dissolved gas analysis is 36 out of 100. This indicates that the transformer is in poor condition.

If the transformer fails, it will result in a power outage to over 800 customers. Therefore, to improve the reliability of Coronation Bennett MS and to avoid a large-scale customer outage, TR1 needs to be replaced.

E6.14.7.5 S15186 Norseman MS Replace Transformer TR1

Investment Category: System Renewal

Program: Power Transformer Renewal Program

Project Title: Norseman MS Replace Transformer TR1

Project Number: S15186

Project Year: 2015

Estimated Cost: $615,921

(i) Objective

To replace the existing 5/6.7 MVA, 27.6/4.16 kV station transformer, TR1, with a new 5/6.7 MVA, 27.6 kV/4.16 kV, station power transformer at Norseman MS.

(ii) Scope of Work

TABLE 14: S15186 SCOPE OF WORK DETAILS

District Neighborhood	ETOBICOKE
Station(s)	NORSEMAN MS
Transformer	TR1

The project is located at Norseman MS. The scope of work for the replacement is described in Section E6.14.6. There is an overhead bus structure present.

(iii) Justification & Benefits

The transformer TR1 at Norseman MS was manufactured in 1958 (57 years old in 2015), and has reached the end of its useful life of 45 years. It will be in service 12 years beyond it useful life in 2015.

If the transformer fails, it will result in a power outage to over 500 customers. Therefore to improve the reliability of Norseman MS and to avoid a large-scale customer outage, TR1 needs to be replaced

E6.15 Circuit Breaker Renewal

TYPICAL EXISTING CIRCUIT BREAKERS

E6.15.1 Summary

Program Description

The Circuit Breaker Renewal program is a continuation of the activities previously presented in the OEB approved Stations Circuit Breakers segment of Toronto Hydro's 2012-2014 ICM application. The ongoing proactive replacement of circuit breakers through this program is required to mitigate the acute failure risks associated with functionally obsolete oil circuit breakers.

Toronto Hydro prioritizes its oil circuit breaker renewal plan based on asset condition and/or asset age. Those selected based on age and condition are further prioritized by the amount of load or the number of customers that would be impacted if the circuit breaker fails. Based on the above prioritization method, Toronto Hydro plans to replace 35 stand-alone outdoor oil circuit breakers with vacuum circuit breakers over the 2015-2019 period.

The following table summarizes the anticipated benefits of this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigation of significant reliability and system performance risks associated with circuit breaker failure and catastrophic failure.
Reliability	ƒ Mitigation of the reliability risk associated with oil circuit breakers, improving the reliability of power supply to the connected customers. ƒ Improved overall reliability of the terminal station by reducing the risk of catastrophic failure of the oil circuit breakers. ƒ Replacement of the associated feeder protection relay enables future feeder automation and other smart grid functionality, which is expected to further increase the reliability of power supply to customers.
Safety	ƒ Mitigation of safety risks associated with catastrophic failure of an oil circuit breaker.
Efficiency	ƒ The vacuum circuit breakers that Toronto Hydro plans to install have 50% less maintenance cost compared to the oil circuit breakers because the oil handling expenses associated with oil circuit breakers are eliminated, and vacuum circuit breakers have less moving parts to maintain.
Environmental Benefit	ƒ Replacement of the oil circuit breaker reduces the likelihood of oil with PCBs being spilled, which could contaminate the soil and groundwater and could entail high clean-up costs for the utility.

Program Drivers

The stand-alone oil circuit breakers currently in service are obsolete. Spare parts for these types of circuit breakers are no longer available and the technology is no longer supported by manufacturers. The combination of functional obsolescence, environmental risk (from leaking oil), reliability, and safety issues all indicate the need for these assets to be removed from Toronto Hydro's electrical distribution system as soon as possible. The trigger and secondary drivers for this program are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Procurement of replacement parts for legacy, stand-alone oil circuit breakers is becoming increasingly problematic, making it difficult to extend the life of these assets through maintenance ƒ A large number of these assets are at or beyond their useful lives and/or are in poor condition ƒ Catastrophic failure of end-of-life oil circuit breakers could release oil containing PCBs greater than 50 ppm into the environment.

Secondary Drivers	Reasoning
Failure Risk	ƒ Oil circuit breakers can fail catastrophically when they approach or exceed end-of–life. ƒ Catastrophic failure of oil circuit breakers can cause collateral damage that can result in expensive replacement costs and long outages to customers.
Safety	ƒ Catastrophic failure can result in flying debris and subsequent fire, creating a safety hazard to nearby personnel.

Preferred Alternative

Toronto Hydro considered the following alternatives for addressing the assets in this progam.

(1) Continue to maintain and repair oil circuit breakers currently in service.

(2) Increase maintenance to reduce failure risk of circuit breakers currently in service.

(3) Proactively replace these oil circuit breakers with vacuum circuit breakers.

Option III is the preferred alternative as it offer the best mitigation of the risks of unwanted outages, safety, and environmental concerns that can occur when an oil circuit breaker fails. Toronto Hydro also projects that under this option, maintenance costs would be lower than under the status quo scenario, as maintenance time of an oil circuit breaker is double than that of a vacuum circuit breaker.

The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $16.8 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.15.7 for details).

Timing and Pacing

The condition of the oil circuit breakers that are currently in service is deteriorating, as demonstrated by an increasing frequency of reactive circuit breaker repairs. Due to the potential reliability and safety risks posed by the failure of a circuit breaker, Toronto Hydro must continue its proactive replacement program during the 2015-2019 planning horizon. Toronto Hydro intends to replace 35 outdoor stand-alone oil circuit breakers over this period. This includes all outdoor

stand-alone oil circuit breakers that are in poor condition and/or that will have reached the end of their useful lives within the planning period.

Table C shows the historical and forecasted spending for the continuing activities in the Circuit Breaker Renewal program.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.00	0.91	0.22	1.02	2.09	1.66	1.80	1.79	2.11	1.78

E6.15.2 Program Description

The Circuit Breaker Renewal program is a continuation of the activities previously presented in the OEB approved Stations Circuit Breakers segment of Toronto Hydro's 2012-2014 ICM application. The ongoing proactive replacement of circuit breakers through this program is required to mitigate the acute failure risks associated with functionally obsolete oil circuit breakers.

Toronto Hydro prioritizes its oil circuit breaker renewal plan based on asset condition and/or asset age. Those selected based on age and condition are further prioritized by the amount of load or the number of customers that will be impacted if the circuit breaker fails. Based on the above prioritization method, Toronto Hydro is planning to replace 35 stand-alone outdoor oil circuit breakers with vacuum circuit breakers over the 2015-2019 period as summarized in Table 1. A typical existing stand alone KSO oil circuit breaker is shown in Figure 1.

TABLE 1: NUMBER OF CIRCUIT BREAKERS TO BE REPLACED

Assets (Units)	2015	2016	2017	2018	2019	Total
KSO Oil Circuit Breaker	10	6	6	7	6	35

FIGURE 1: TYPICAL EXISTING KSO OIL CIRCUIT BREAKER

These circuit breakers are distributed across the following group of stations, the geographical locations of which are shown in Figure 2:

- Bathurst TS: 7 circuit breakers
- Bermondsey TS: 3 circuit breakers
- Fairchild TS: 4 circuit breaker
- Finch TS: 9 circuit breakers
- Leslie TS: 11 circuit breakers
- Rosscowan Pharmacy MS: 1 circuit breaker

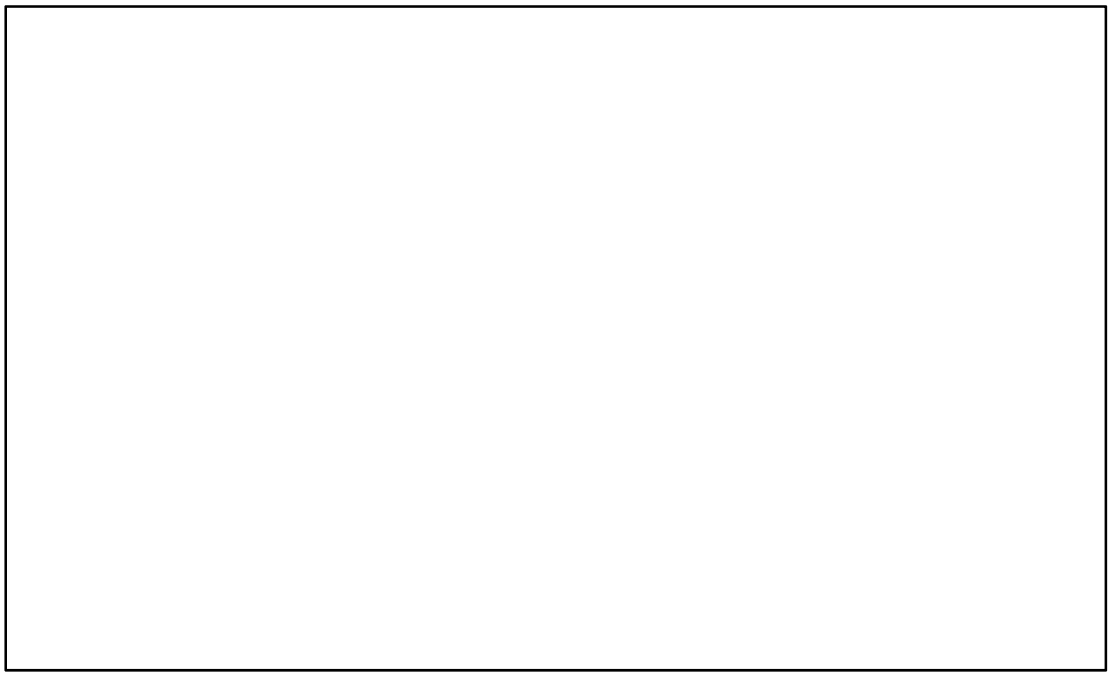

FIGURE 2: LOCATION OF CIRCUIT BREAKERS TO BE REPLACED (2015 – 2019)

Circuit breakers are switches designed to protect electrical circuits from damage caused by overloads, short circuits, or other contingency events. Their basic function is to interrupt current flow when a protective station feeder relay detects fault current or overload current in the circuit. The station feeder relay sends a signal to the circuit breaker to interrupt the current flowing through it in order to ensure the safety of upstream or downstream equipment. Unlike fuses, which must be replaced upon operation, circuit breakers can be reset to resume normal functioning once the fault is cleared.

Toronto Hydro currently utilizes three types of stand-alone outdoor circuit breakers in its distribution system:

(1) Oil circuit breakers

(2) SF_6-gas circuit breakers

(3) Vacuum circuit breakers

Circuit breaker technology has been continually evolving. Oil circuit breakers are the oldest technology of the three circuit breaker types listed above. Toronto Hydro no longer installs oil

circuit breakers in its distribution system due to the risks associated with their potential catastrophic failure (e.g., station fires), oil leaks, and the availability of better technology in terms of reliability, cost of ownership, and environmental stewardship. Toronto Hydro expects to have 46 outdoor stand-alone oil circuit breakers in service in 2015, 42 of which are 27.6 kV Kinetic Solenoid Operating (KSO) oil circuit breakers manufactured by General Electric and four of which are 13.8 kV oil circuit breakers manufactured by Montel.

Toronto Hydro has primarily used the KSO oil circuit breakers on the 27.6 kV outdoor open air transformer stations (TS) in the North York area, where it owns the feeder breaker and downstream assets. The other four outdoor stand-alone oil circuit breakers manufactured by Montel are found in Toronto Hydro-owned 13.8 kV municipal substations in the Scarborough area. All of the stand-alone oil circuit breakers, regardless of manufacturer, have the same obsolescence and end-of-life issues. Toronto Hydro also plans to replace the associated obsolete electromechanical feeder protection relays, which are more or less in the same vintage as the oil circuit breakers, with modern microprocessor relays.

Toronto Hydro plans to replace the existing stand-alone oil circuit breakers with modern stand-alone vacuum circuit breakers. A vacuum circuit breaker, illustrated in Figure 3, insulates its contacts by surrounding them in a vacuum as opposed to a medium such as oil. A vacuum exhibits strong insulating qualities as there is no possibility for the arc current to continue to flow through the open contacts of the vacuum circuit breaker, ensuring that the fault or overload current is completely interrupted. Fault current and overload current must be interrupted as fast as possible to prevent equipment damage.

FIGURE 3: STAND-ALONE OUTDOOR VACUUM CIRCUIT BREAKER

Toronto Hydro expects vacuum insulated circuit breakers to provide a number of additional benefits compared to the oil circuit breakers that are being replaced:

- Vacuum circuit breakers are environment friendly, since interruption takes place in a vacuum medium and does not require gas or liquid addition. This eliminates the possibility of leakage of gas (or any material) that can be harmful to the environment. The oil inside some of the existing stand-alone circuit breakers contains PCBs greater than 50 ppm, which Toronto Hydro has an obligation to remove from its distribution system in order to comply with Environment Canada regulations.
- Mitigation of the fire risk and risk of collateral damage associated with the existing oil circuit breakers.
- The ongoing maintenance cost of a vacuum circuit breaker is half of that of an oil circuit breaker.

- There are no gas decomposition products in the vacuum and hence the sealed vacuum interrupter mitigates environmental effects on the circuit breaker, which increases the asset life.

- There are fewer moving parts in vacuum circuit breakers compared to other types of circuit breakers, further increasing asset life.

Toronto Hydro's total estimated cost for this program is $9.13 million over the 2015-2019 period, which allows for the replacement of an estimated 35 circuit breakers and the associated mechanical feeder relays with modern vacuum circuit breakers and microprocessor feeder relays respectively. The following table summarizes the anticipated benefits of this program.

TABLE 2: PROGRAM BENEFITS

Customer Value	• Mitigation of significant reliability and system performance risks associated with circuit breaker failure and catastrophic failure. • The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $16.8 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.15.7 for details).
Reliability	• Mitigation of the reliability risk associated with oil circuit breakers, improving the reliability of power supply to the connected customers. • Improved overall reliability of the terminal station by reducing the risk of catastrophic failure of the oil circuit breakers. • Replacement of the associated feeder protection relay enables future feeder automation and other smart grid functionality, which is expected to further increase the reliability of power supply to customers.
Safety	• Mitigation of potential safety risks associated with catastrophic failure of an oil circuit breaker, which has the potential to send flying debris from the ruptured tank into the air, and can cause injury.
Efficiency	• The vacuum circuit breakers that Toronto Hydro plans to install have 50% less maintenance cost compared to the oil circuit breakers because the oil handling expenses associated with oil circuit breakers are eliminated, and vacuum circuit breakers have less moving parts to maintain.
Environmental Benefit	• Replacement of the oil circuit breaker eliminates the likelihood of oil with PCBs being spilled, which could contaminate the soil and groundwater and could entail high clean-up costs for the utility.

E6.15.3 Why the Program is Needed

The stand-alone oil circuit breakers currently in service are obsolete. Spare parts for these types of circuit breakers are no longer available and the technology is no longer supported by manufacturers. The catastrophic failure of a stand-alone oil circuit breaker can cause an explosion resulting in flying debris, which could injure workers on-site, and inflict collateral damage to adjacent equipment resulting in increased outage time for customers and environmental damage that necessitates costly cleanup. These circuit breakers are also connected to the 27.6 kV and 13.8 kV distribution feeders and therefore serve many customers over a large area. The combination of functional obsolescence, environmental risk (from leaking oil), reliability, and safety issues all indicate the need for these assets to be removed from Toronto Hydro's electrical distribution system as soon as possible.

E6.15.3.1 Program Drivers

Table 3 summarizes the trigger and secondary drivers for replacing outdoor stand-alone oil circuit breakers. This is a System Renewal initiative with a trigger driver of functional obsolescence.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Procurement of replacement parts for legacy, stand-alone oil circuit breakers is becoming increasingly problematic, making it difficult to extend the life of these assets through maintenance ƒ A large number of these assets are at or beyond their useful lives and/or are in poor condition ƒ Catastrophic failure of end-of-life oil circuit breakers could release oil containing PCBs greater than 50 ppm into the environment
Secondary Drivers	**Reasoning**
Failure Risk	ƒ Oil circuit breakers can fail catastrophically when they approach or exceed end-of–life ƒ Catastrophic failure of oil circuit breakers can cause collateral damage that can result in expensive replacement costs and long outages to customers
Safety	ƒ Catastrophic failure can result in flying debris and subsequent fire, creating a safety hazard to nearby personnel.

The critical function of circuit breakers is to interrupt the flow of current under normal and fault conditions. Under fault conditions, a fast response and complete interruption are essential to protect the rest of the power system from the faulted component in order to maintain grid

reliability. A failure of an oil circuit breaker is a very significant event in terms of customer impact, system performance, and personnel safety.

The trigger driver of this program is the functional obsolescence of the stand-alone outdoor oil circuit breakers. Toronto Hydro has had difficulty obtaining spare parts from the original manufacturers of these assets in order to properly maintain them. In some cases, these breakers are kept in service using salvaged second-hand parts from retired equipment, and at other times by purchasing custom made parts. As the in-service population of oil circuit breakers continues to age and deteriorate, this method of getting spare parts becomes less sustainable.

The secondary driver of this program is failure risk. As shown in Figure 6 in section E6.15.3.2, out of the total in-service stand-alone oil circuit breaker population, 61% are expected to be past the end of their useful lives of 45 years by 2015. If these oil circuit breakers are not replaced proactively, the likelihood that they may fail while in service is expected to increase. Toronto Hydro has recently started experiencing circuit breaker failures on units that are approaching, but have not reached, the end of their projected useful lives; for example, circuit breaker 80M3 at Fairchild TS and circuit breaker 51M6 at Leslie MS (both replaced in 2013) started failing when they were 39 and 44 years old, respectively. Similarly, the Hydro One owned circuit breaker that failed catastrophically at Manby TS in 2010 was only 32 years old.

There are also safety and environmental concerns associated with the stand-alone oil circuit breakers that have aged beyond their useful lives. A key safety risk associated with the failure of an oil circuit breaker, particularly under short circuit conditions, is a catastrophic failure and subsequent oil fire. Such an event can damage or destroy other electrical equipment in the vicinity to the extent that an entire station could be forced out of service. This, in turn, could cause a prolonged outage for all customers supplied by that station. A catastrophic failure of a circuit breaker is also a potential safety risk to any personnel on site.

A recent example of a catastrophic failure of a single circuit breaker was the July 2010 fire at the Manby Transformer Station (TS) owned by Hydro One Networks Inc. (HONI). As a result of this event, thousands of customers in the downtown and west-end of Toronto suffered long outages, while the area surrounding the station sustained extensive fire damage as shown in Figure 4.

FIGURE 4: CATASTROPHIC FAILURE OF AN OUTDOOR OIL CIRCUIT BREAKER AT MANBY STATION

The condition of stand-alone outdoor circuit breakers in Toronto Hydro's system continues to decline. This is demonstrated by the increasing trend in the number of stand-alone oil circuit breakers with major component malfunctions due to asset degradation (e.g., worn-out circuit breaker contacts, failure to close, flash over, and burnt potheads) all of which required immediate reactive repair in 2006 to 2013 as illustrated in Figure 5. As noted earlier, Toronto Hydro is facing increasing difficulty in obtaining spare parts for these circuit breakers to allow for continued operation. This overall increasing trend in repairs is consistent with the increasing proportion of oil circuit breakers approaching or exceeding end-of-life conditions.

FIGURE 5: QUANTITY OF STAND-ALONE OIL CIRCUIT BREAKERS REPAIRED PER YEAR (2006 TO 2013)

To mitigate the risks associated with catastrophic failure of the stand-alone oil circuit breakers, Toronto Hydro plans to proactively replace all stand-alone oil circuit breakers that have reached end-of-life and/or are in poor condition using a planned approach.

The oil circuit breakers are designed to normally carry 1200 A at 27.6 kV. However, fault current could go up to 9,000 A or more depending on the location of the fault. This substantial amount of uncontrolled energy could create a catastrophic failure event if the circuit breaker fails to interrupt the flow of this fault current. A catastrophic failure of oil circuit breakers would result in collateral damage leading to long outages, and potential injuries to personnel on site and environmental risks. To mitigate these risks, Toronto Hydro plans to continue the proactive replacement of its aging stand-alone oil circuit breakers.

As it replaces the existing stand alone oil circuit breakers, Toronto Hydro also plans to replace the associated obsolete electromechanical feeder protection relays which are more or less in the same vintage as the oil circuit breakers with modern microprocessor relays. Toronto Hydro is experiencing failure of the existing electromechanical feeder protection relays that were not replaced during the previous oil circuit breaker replacements. For example, on November 20th, 2012, the 53M25 SF_6 circuit breaker at Bermondsey TS was required to clear high fault current (9 kA). The circuit breaker failed to lockout as per its design and the upstream bus differential protection system had to operate to interrupt the fault current resulting in a substantial outage, with power interrupted to 2,390 customers for about 26 minutes. A similar event also occurred on

March 4, 2014 at Bermondsey TS with the SF_6 circuit breaker 53M8. This event interrupted 12,181 customers for 113 minutes. An investigation of the outage revealed that the feeder relay, associated with the SF_6 circuit breaker which is also part of the protection scheme was found to be defective and was at the end of life; the relay was replaced reactively.

Review of these events established that the electromechanical relays are also at the end-of-life. Toronto Hydro has concluded that it is more cost effective and operationally efficient to upgrade the existing feeder protection relays to microprocessor relays along with the associated oil circuit breaker replacement rather than retrofitting them with microprocessor relay at a later date or on a reactive basis to ensure the reliable operation of the protection scheme. The microprocessor relays will also enable future feeder automation and/or smart grid functionality. The cost of upgrading the feeder protection relays is included in the cost of each of the associated circuit breakers proposed to be replaced.

E6.15.3.2 Asset Details

(i) Asset Lifecycle

Figure 6 illustrates the age profile of the stand-alone oil circuit breakers deployed in Toronto Hydro's system. An oil circuit breaker has an expected useful life of 45 years. Toronto Hydro expects that 61% of its outdoor stand-alone oil circuit breakers will exceed their useful lives by 2015.

FIGURE 6: STAND-ALONE OUTDOOR OIL CIRCUIT BREAKER AGE PROFILE

(ii) Asset Failure Impacts

Table 4 tabulates the number of customers and the amount of load connected to each of the circuit breakers that Toronto Hydro proposes to replace over the 2015-2019 period. In the event of a circuit breaker failure, those customers would be without power for approximately two hours while power is re-routed from elsewhere on the network. For example, oil circuit breaker 51M6 at Leslie MS failed on May 17, 2006 and power supply to 1,735 customers was interrupted. It took an hour and 47 minutes to switch these customers to another source and restore their power. Another example is oil circuit breaker (80M4) at Fairchild TS, which failed on July 3, 2010. Power supply was interrupted for 9,901 customers for about 40 minutes until they were switched over to an alternate power source

TABLE 4: ASSET FAILURE IMPACT

Proposed Year	Station Name	Circuit Breaker name	Connected Load (MVA)	No of Connected Customers
2015	Bermondsey TS	53M1	5.3	69

	Bathurst TS	85M5	19	4,878

E6.15.4 Timing & Pacing of the Program

The condition of the oil circuit breakers that are currently in service is deteriorating, as previously demonstrated by the increasing frequency of reactive circuit breaker repairs in Figure 5. Due to the potential reliability and safety risks posed by the failure of a circuit breaker and the

obsolescence issues discussed earlier, Toronto Hydro must continue its proactive replacement program during the 2015-2019 planning horizon. Toronto Hydro intends to replace 35 outdoor stand-alone oil circuit breakers over this period. This includes all outdoor stand-alone oil circuit breakers that are in poor condition and/or that will have reached the end of their useful lives within the planning period.

Table 5 shows the historical and forecasted spending for the continuing activities in the Circuit Breaker Renewal program.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending ($Million)					Future Spending($Million)				
YEAR	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.00	0.91	0.22	1.02	2.09	1.66	1.80	1.79	2.11	1.78

The age profile of the eleven stand-alone oil circuit breakers that will remain in service in 2020 is illustrated in Figure 7. Four of these breakers will be past their useful life in 2020 and will require replacement in 2020, with additional replacements to be evaluated at the time.

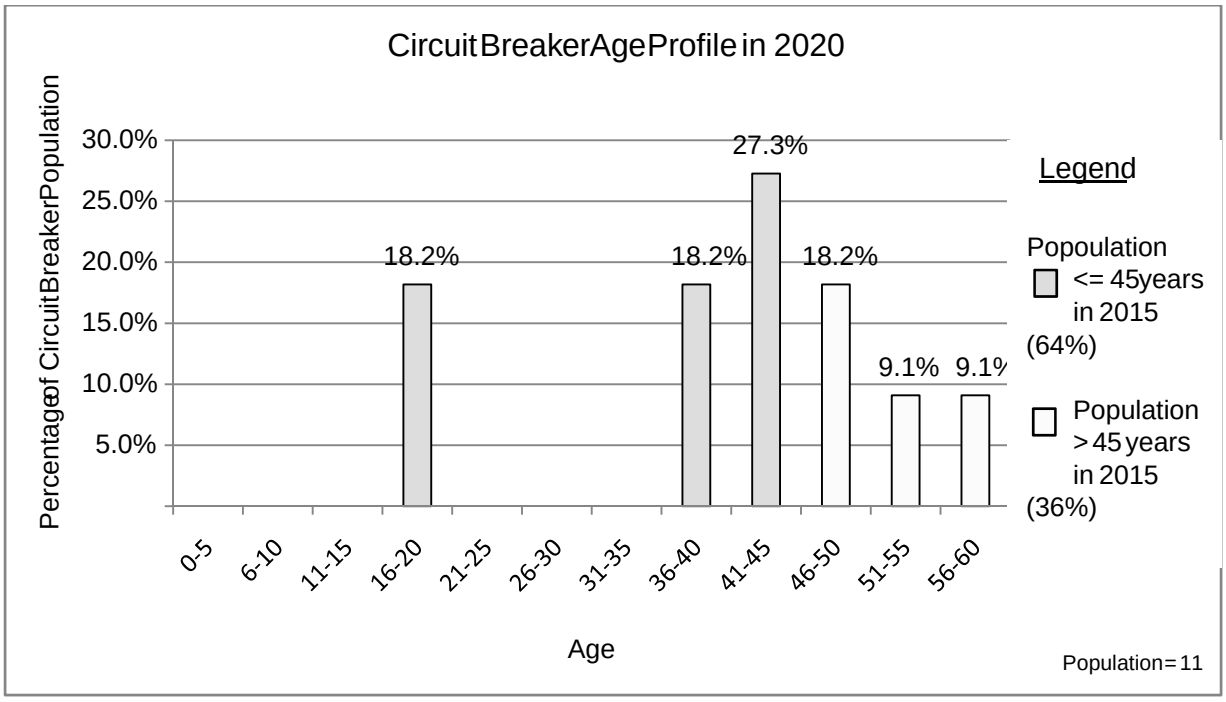

FIGURE 7: AGE PROFILE OF STAND ALONE OIL CIRCUIT BREAKERS IN 2020

E6.19.4.1 Ranking & Prioritization

The list of outdoor stand-alone oil circuit breakers proposed for replacement in 2015-2019 has been prioritized based on asset condition and asset age. Poor condition circuit breakers are of the highest priority for replacement, followed by circuit breakers prioritized according to age. Where more than one circuit breaker has the same health index score and age, Toronto Hydro further prioritizes the assets by the number of customers and the amount of load served by each. Circuit breakers with relatively higher loads or numbers of customers served will generally have a greater impact on customers if they fail.

E6.15.5 Program Execution

Toronto Hydro's proposed circuit breaker renewal program consists of a series of discrete projects. Field personnel coordinate a scheduled outage with Toronto Hydro's power system controllers before executing each project. Customers normally served by the circuit breaker being replaced would be temporarily served by another part of the network and would typically experience no interruption.

Individual projects must be coordinated with HONI, as circuit breakers need to be disconnected from the HONI-owned bus and new circuit breakers require testing once installed. Once the scheduled outage is agreed upon, Toronto Hydro installs the circuit breaker and test its functionality jointly with HONI. Once confirmed to be working according to specification, the circuit breaker is energized and customers are transferred back to the newly installed circuit breaker, completing the project.

E6.15.5.1 Proposed Work Plan

Table 6 summarizes the replacement plan for 2015 to 2019.

TABLE 6: 2017-2019 LONG TERM PLAN

Year	Feeder	Station

2019	80M4	Fairchild TS

E6.15.5.2 Program Risks

The following are some of the risks/constraints that can impact the completion of this program:

System conditions may not allow the planned outages necessary to replace oil circuit breakers, especially during high season (summer or winter). At these times, most of the feeders are highly loaded and unable to accept additional load from the feeder on which the oil circuit breaker is to be replaced which could impact the replacement schedule. This risk can be mitigated through effective advance communication with system controllers to develop a workable and coordinated outage plan.

Potential work coordination issues with Hydro One could delay program completion. Hydro One is required to review the protection system of the new vacuum circuit breakers and associated feeder protection relays. Hydro One must also test the protection system for the circuit breakers together with Toronto Hydro to ensure that it is coordinated with the Hydro One protection system, since these circuit breakers will be connected to the Hydro One bus. Any delay in Hydro One's work could impact the timely completion of this program. This risk can be mitigated by

effective communication with Hydro One to ensure that the work requirements are known to Hydro One ahead of time so that the requirements can be included in their work plans.

E6.15.6 Evaluation of Alternatives

E6.15.6.1 Quantification/ Evaluation of Options

(i) Status Quo

Under the status quo scenario, Toronto Hydro would continue to maintain and repair oil circuit breakers currently in service. There would be no proactive replacement of these assets. This option is not preferred because it would not address the functional obsolescence, reliability, and safety risks noted earlier.

(ii) Increase Maintenance Activities

This option requires more frequent maintenance to be performed on the oil circuit breakers to reduce failure risk. While in theory this would be a viable alternative, the availability of spare parts is critical to this option. As previously explained, spare parts for the oil circuit breakers are increasingly difficult to procure, limiting the feasibility of this option.

(iii) Planned Replacement

This option involves the proactive replacement of 35 oil circuit breakers with vacuum circuit breakers over five years. This option mitigates the risks of unwanted outages, safety, and environmental concerns that can occur when an oil circuit breaker fails. Toronto Hydro also projects that maintenance costs would be lower than under the status quo scenario as maintenance time of oil circuit breaker is double that of a vacuum circuit breaker. The vacuum circuit breaker has less moving parts and therefore less components to maintain. The additional maintenance cost required to drain/maintain the oil in the oil circuit breakers is also eliminated.

The replacement of the circuit breakers in the first year of the program is expected to result in an avoided estimated risk cost (ARC) of $16.8 million, as detailed in Table 7. This value represents the costs avoided by executing the first year of activities as scheduled as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the probability of failure of the assets, and multiplying this value by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions,

emergency repairs, and replacement. For further details on the ARC approach is provided in Section D3.3.

TABLE 7: BCE RESULTS

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$19.68
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$2.88
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$16.80

E6.15.7 2015 Projects

Table 8 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

- previously filed projects that appeared as jobs in the OEB approved Stations Circuit Breakers segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and
- projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

E6.15.7.1 S13146 Project Description

Investment Category: System Renewal
Program: Circuit Breaker Renewal
Project Title: Bermondsey TS Replace KSO Oil Circuit Breaker (53M1, 53M9 & 53M11)
Project Number: S13146
Project Year: 2015
Estimated Cost: $0.18

(i) Objective

The objective of this project is to replace the KSO oil circuit breakers 53M1, 53M9 and 53M11 at Bermondsey TS.

(ii) Scope of Work

TABLE 10: S13146 SCOPE OF WORK DETAILS

District Neighborhood	NORTH YORK
Station(s)	BERMONDSEY TS
Feeder(s)	53M1, 53M9 & 53M11

TABLE 11: S13146 ASSET REPLACED

Assets (Units)	2015
KSO Oil Circuit Breaker	3

(iii) Justification & Benefits

The 53M1, 53M9 and 53M11 KSO oil circuit breakers are in poor condition and are obsolete. Spare parts for this type of circuit breaker are no longer supported by manufacturers and, as a result, it is becoming difficult to keep the circuit breakers in good working condition. Replacement of the circuit breakers with a modern vacuum circuit breaker is necessary to mitigate reliability, environmental and safety risks, and possible collateral damage that could result from a potential catastrophic failure.

E6.16 Stations Control & Monitoring

TYPICAL RTUS AT ETOBICOKE STATIONS AND AT DOWNTOWN TORONTO SUBSTATIONS, RESPECTIVELY

E6.16.1 Summary

Program Description

The objective of the Stations Control and Monitoring program is to replace aging and obsolete remote terminal units (RTUs), install supervisory control and data acquisition (SCADA) systems at substations that currently do not possess SCADA capabilities, and upgrade obsolete pilot-wire relays and communication channels that supply large users.

RTUs, SCADA systems and pilot-wire configurations are tools that Toronto Hydro uses to clear and manage faults. Faults are hazardous if not cleared, as they can damage distribution equipment (prolonging and complicating repairs), customer equipment (possibly resulting in an outage to the customer), and Toronto Hydro's station equipment (which can result in long duration outages to large numbers of customers). Faults can also potentially set fire to the affected equipment. To prevent these serious risks, Toronto Hydro's distribution system must be capable of clearing all potential faults as designed.

This program addresses the following issues with the aforementioned assets.

- Existing RTUs and their associated communication systems are past their useful lives of 22.5 years and are now functionally obsolete. Spare parts for the existing RTUs are no

longer available in the market. With increasing RTU failures every year, the maintenance of these devices is becoming more difficult and expensive.

- The electromechanical relays and copper communication channels used for highly loaded customers with pilot-wire configurations are not technologically obsolete, lacking the capability to monitor the integrity of supply to pilot-wire customers outside of Toronto Hydro's equipment – a deficiency that can result in unnecessary outages or damage to customer equipment. The existing relays are also functionally obsolete, as the original suppliers no longer manufactures spare parts and/or new replacement parts for electromechanical relays. Another major disadvantage of electromechanical relays is the lack of accuracy of current and voltage measurements, which makes it difficult to recognize fault conditions within tight boundaries.

- Many of Toronto Hydro's municipal substations in Scarborough area are not connected to the SCADA system. These substations are technologically obsolete without the presence of SCADA connection. This prevents control room operators from having access to the real-time information and operation of the substation, such as breaker control, remote switching capabilities, alarm status and other distribution system parameters which can be analyzed and optimized to improve system efficiency.

Table A summarizes the anticipated benefits associated with the Stations Control and Monitoring program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	- Reduce the duration of station-related outages and the risk of extended outages - Allow customers to connect a Human Machine Interface (HMI) to the relays for data acquisition and load monitoring features
Reliability	- Reduce the risk of RTU failure and avoid potential prolonged station related outages - Enable Toronto Hydro to monitor and control feeder loading - Provide the ability to monitor the status of customer breakers, enabling Toronto Hydro to take immediate actions against pilot-wire faults
Efficiency	- Enable remote troubleshooting and switching capabilities that can result in labour cost savings by eliminating the need for station crews to go on-site to identify problems and perform manual switching - Automatic switching capability can help achieve maintenance efficiency by reducing the number of maintenance crew hours needed to complete the same work through a more effective

	streamlining of functions ƒ Can reduce costs associated with repairing obsolete RTUs and their supporting communication channels ƒ Allows control room operators to optimize power distribution system and improve data analysis through data obtained from SCADA system
Safety	ƒ Enhance safety by reducing the crews' exposure to safety hazards when they perform manual switching to restore power to customers
Cyber-security	ƒ New SCADA devices are built with stronger cyber security features than those currently deployed

Program Drivers

The trigger and secondary drivers for this program are summarized in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Large number of RTU assets are past their useful lives ƒ Replacement parts for RTUs and electromechanical relays are no longer available from the original manufacturer ƒ SCADA installations are required at Scarborough substations in order to bring these stations into alignment with modern control and monitoring standards
Secondary Drivers	**Reasoning**
Reliability	ƒ RTU failures have increased substantially over the past decade. ƒ SCADA technology is currently lacking at Scarborough substations. CHI would be reduced significantly if SCADA technology was introduced. ƒ Electromechanical relays used in current pilot-wire configuration do not have customer circuit breaker monitoring abilities, which may result in unnecessary customer outages.
Cyber Security	ƒ Cyber threats increasingly become more sophisticated for the existing SCADA system. ƒ Potential risk of compromising the RTU or communication channel device which can allow: shutting down entire or portion of a substation, stealing or altering metering data.

Preferred Alternative

Toronto Hydro considered the following options for addressing the end-of-life and obsolete assets in this program:

(1) Continue a "run to failure" approach where existing MOSCAD RTUs and associated DARCOM radio systems at Etobicoke substations and DACSCAN MDO-11 type RTUs in downtown Toronto are replaced only when the system completely fails.

(2) Replace or Install RTU and Communication System/Upgrade Pilot-Wire Relays

While the continuation of the status quo would allow Toronto Hydro to defer asset replacement temporarily, Toronto Hydro would incur additional costs to maintain these legacy units in the interim. Option II is the preferred option, as it cost-effectively addresses the failure risks associated with these obsolete communication and control assets while maximizing the value and performance of existing stations assets in Scarborough.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $0.1 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.16.7). Accounting for capital program costs, the first year's activities (approximately $80,000 in expenditures in first year) deliver a positive NPV of $0.02 million, confirming the economic prudence of the investments (see Section E6.16.7).

Timing and Pacing

Investment needs in this program did not arise before 2012 and thus, no projects were implemented in 2010 and 2011. Capital spending from 2012 to 2014 was fairly low because only five substations were targeted for RTU replacement. Since this program was a new initiative, the first of the five projects were used to adequately train Toronto Hydro personnel to quickly and efficiently complete the remaining RTU replacement projects. For this reason, the first project was designed to take longer to complete than the others. As a result, the first project was completed in 2013, and the remaining four are in-progress to be completed by the end of 2014.

Table C summarizes the historical and forecasted spending for this program.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0.12	0.46	0.24	0.08	0.94	1.11	1.49	1.44

For a detailed discussion of the pacing of investments in this program over the 2015-2019 period, please refer to Section E6.16.4

E6.16.2 Program Description

Toronto Hydro's substations feature control and monitoring assets that are essential to the efficient and reliable delivery of electricity. In particular, Toronto Hydro uses the supervisory control and data acquisition (SCADA) system to support the reliable functioning of substations and pilot-wire protection schemes (explained in detail in section E6.16.2.2 below) to provide a continuous supply of electricity to very large individual customers.

SCADA equipment automates the monitoring, command and control functions of critical substation equipment, enabling Toronto Hydro to remotely troubleshoot problems and respond to outages at substations. This is achieved by connecting station power equipment to remote terminal units (RTUs) via communication channels.

The pilot-wire feeder configuration automates feeder monitoring and troubleshooting to protect distribution equipment and to provide continuous load supply to large customers in the event of feeder faults. This configuration requires a pair of relays on each feeder to operate. Similar to RTUs, the relays are connected via communication channels. The relays and communication channels are the components responsible for the "intelligence" of the protection used in pilot-wire configuration. Without the proper functioning of the relays and communication channels on pilot-wire feeders, faults will not clear as intended.

The objective of the Stations Control & Monitoring program is to replace aging and obsolete remote terminal units (RTUs), install supervisory control and data acquisition (SCADA) systems at substations that currently do not possess SCADA capabilities, and upgrade obsolete pilot-wire relays and communication channels that supply large users.

Toronto Hydro plans to invest an estimated $5.05 million over the 2015 to 2019 period in this program. Table 1 summarizes the number of assets that are forecasted for replacement or installation over the 2015 to 2019 period.

TABLE 1: ASSETS TO BE REPLACED/INSTALLED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Etobicoke RTU Replacement	2	5	5	5	5	22
Scarborough SCADA Installation	0	2	2	2	1	7
Downtown RTU Replacement	0	1	1	2	2	6
Pilot-wire Relay Upgrade	0	6	10	12	12	40

Figure 1 shows a map of all the stations which are targeted by the Station Control & Monitoring program during the 2015-2019 period.

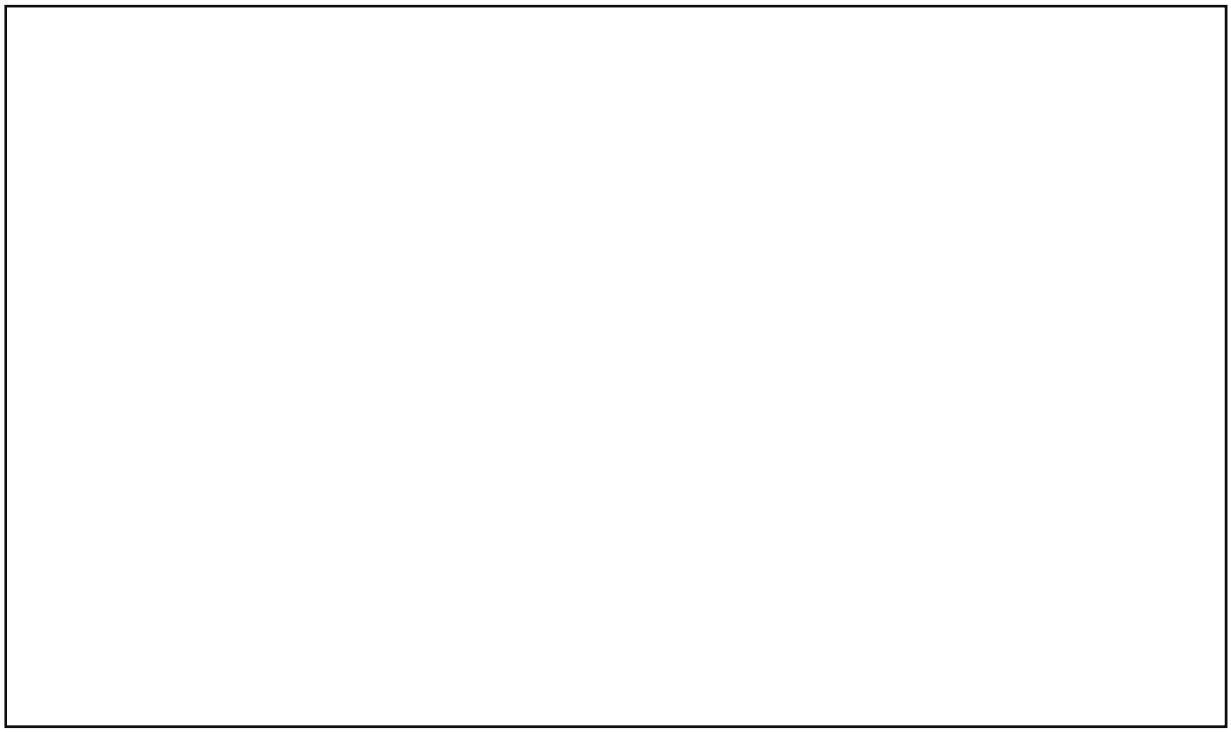

FIGURE 1: MAP OF STATION LOCATIONS SELECTED FOR THE 2015-2019 STATION CONTROL & MONITORING PROGRAM

The following sections describe the above mentioned activities in detail.

E6.16.2.1 SCADA RTU System

RTUs, SCADA systems and pilot-wire configurations are tools that Toronto Hydro uses to clear and manage faults. Faults are hazardous if not cleared, as they can damage distribution equipment (prolonging and complicating repairs), customer equipment (possibly resulting in an outage to the customer), and Toronto Hydro's station equipment (which can result in long duration outages to large numbers of customers). Faults can also potentially set fire to the affected equipment. To prevent these serious risks, Toronto Hydro's distribution system must be capable of clearing all potential faults as designed.

The Role of RTUs in the SCADA system

RTUs are installed at each monitored substation location. These units use a data concentrating device that connects to device sensors and relays to monitor and gather data on various types of substation equipment, including switchgear, circuit breakers and transformers. To be useful, this data must be communicated to the central SCADA console in Toronto Hydro's control room for real-time analysis. An RTU enables the communication channels to read the data that is then transmitted to the SCADA console. It also allows the central SCADA console to remotely control substation equipment by activating commands issued by the SCADA console to the station equipment. In the event of an outage, the SCADA system's data collection capabilities can help control room operators quickly identify the exact location of the outage without waiting for customer calls. The SCADA system then sends commands to SCADA-enabled switches to help operators isolate the outage and open adjacent automatic switches to reroute power quickly to unaffected sections. Absent a SCADA system, isolating the outage and rerouting power involves a time-consuming visual inspection by a line worker in the field to identify the exact nature and location of the problem.

Upgrading Obsolete RTUs

Toronto Hydro's existing station SCADA infrastructure includes two types of RTUs: Motorola SCADA (MOSCAD) RTUs at Etobicoke municipal substations and Motorola DACSCAN MDO-11 RTUs at downtown Toronto transformer substations, as illustrated in Figures 2 and 3, respectively. The different types of assets are a residual result of the amalgamation of Toronto Hydro and neighbouring utilities.

FIGURE 2 AND FIGURE 3: TYPICAL RTUS AT ETOBICOKE STATIONS AND AT DOWNTOWN TORONTO SUBSTATIONS, RESPECTIVELY

These two types of RTUs and their associated communication systems are past their useful lives of 22.5 years and are now functionally obsolete. Spare parts for the existing RTUs are no longer available in the market. With increasing RTU failures every year, the maintenance of these devices is becoming more difficult and expensive.

Aside from the current implementation becoming functionally obsolete, there are number of reliability and security issues associated with the RTU, including cyber security risks. As technology throughout the world continues to advance, and the level of technology in obsolete RTUs remains constant, it is becoming easier for cyber criminals to undermine the security of Toronto Hydro's existing obsolete RTUs. A successful cyber attack can cause significant damage to the utility's grid.

Toronto Hydro proposes to address these problems through a proactive RTU replacement program. Toronto Hydro's proposed solution is to replace the existing RTUs and supporting radio

communication channels at Etobicoke municipal substations and replace the obsolete RTUs at downtown Toronto transformer substations.

Expanding the SCADA System to Scarborough Municipal Stations

Many of Toronto Hydro's municipal substations in Scarborough area are not connected to the SCADA system. These substations are technologically obsolete without the presence of SCADA connection. This obsolescence prevents control room operators to have any access to the real-time information and operation of the substation such as breaker control, remote switching capabilities, alarm status and other distribution system parameters which can be analyzed and optimized to improve system efficiency. Currently, SCADA operators rely on customer calls to be made aware of any customer outages as a result of a failure at a non-SCADA substation. Toronto Hydro dispatches field crews to go on-site to perform extensive troubleshooting to resolve the problem. As a result, Toronto Hydro is unable to provide acceptable service to customers.

In addition to technological obsolescence, there are number of safety and efficiency issues associated with the non-SCADA substations. Station crews perform manual switching to isolate the problem during a customer outage. Manual switching is performed on live equipments and thus poses unforeseen safety hazards to station crews. Moreover, electrical distribution tasks such as manual switching or station maintenance takes longer and costs more without SCADA connection since remote operation is not available.

Toronto Hydro plans to mitigate these problems by expanding the existing SCADA system to non-SCADA Scarborough municipal substations.

E6.16.2.2 Pilot-Wire System

Pilot-wire configuration is a special power supply and protection scheme for individual customers whose load demand is 10 MVA or higher. Customers served by the pilot-wire configuration are generally those that cannot afford power outages for any period of time, like hospitals or large financial institutions. If the pilot-wire relay and communications equipment fails, a customer may experience an unnecessary outage and/or equipment damage.

Unlike the RTU system, the pilot-wire configuration is composed of several discrete components. As a result, understanding the pilot-wire system requires some background information. This section describes the composition of the pilot-wire system and its operation.

Pilot-wire Background

Pilot-wire configuration is made up of six basic components:

(1) feeders,

(2) current transformers (CTs),

(3) potential transformers (PTs),

(4) relays,

(5) communication channels, and

(6) circuit breakers (CBs).

A schematic diagram of the configuration is shown in Figures 4 and 5. Every pilot-wire configuration has at least two or more feeders for each customer, where one feeder continuously supplies electricity while the remaining feeder(s) act as backup(s). With this design, if one feeder experiences a fault, the customer will not experience a power interruption since there is at least one other feeder to continue supplying the customer. The feeders are the only components of pilot-wire configuration responsible for supplying customers with electricity; all other components are part of the protection scheme.

FIGURE 4: SIMPLIFIED OVERVIEW OF THE ARRANGEMENTS OF ELEMENTS IN PILOT-WIRE PROTECTION

FIGURE 5: TWO PILOT-WIRE LINES PER FEEDER BETWEEN THE SUPPLYING STATION AND CUSTOMER

Each feeder has two CTs and two PTs. A set, made up of one CT and one PT, is placed at the start of the feeder in one of Toronto Hydro's substations and the other set is placed at the end of the feeder in the customer's electrical room. The CTs and PTs are the measuring tools of the

protection system; the CTs measure the current on each feeder and the PTs measure the voltage on each feeder. The CTs and PTs then pass on their current and voltage measurements to the relays.

There are two relays for each feeder; and like the CTs and PTs, one relay is placed at the start of the feeder in one of Toronto Hydro's substations and the other relay is placed at the end of the feeder in the customer's electrical room. The relays are the "intelligence" of the protection system, because they are the components that recognize a fault in the feeder by analyzing the current and voltage measurements within a protection zone. This protection zone is the feeder region between Toronto Hydro's circuit breaker and customer circuit breaker. A pair of relays recognizes fault conditions by communicating with one another using the communication channel.

Each feeder is given a pair of communication channels that connect the pair of relays (see E6.16-2). The communication channel allows the pair of relays to communicate with one another. One communication channel is called a "main" and the other is called an "alternate".

The relays recognize a fault condition by the differential principle: if the pair of relays does not see the same measurements, then there is a fault. Each relay is connected to its own CT and PT, and using the communication channel, the relays compare their current and voltage measurements with one another. If there is a difference in the measurement seen by the relays (hence the "differential" principle), then there is a fault somewhere in the protection zone. If the relays recognize a fault condition in the feeder they are monitoring, then they will signal the feeder's circuit breakers to open (or "trip").

There are two circuit breakers in line with each feeder: one at the start of the feeder and one at the end of the feeder. The purpose of the circuit breakers is to stop electrical power flow through the feeder. When the relays detect a fault, they will signal the circuit breakers to open, which will completely isolate the feeder electrically and stop the fault. It is necessary that both circuit breakers open and not just the circuit breaker located at Toronto Hydro's substation; because otherwise, electricity will backflow from the customer into the faulting feeder, and the fault will continue.

Pilot-wire Upgrades

Toronto Hydro historically used now-obsolete GE Westinghouse CPD, Alston MBCI and ABB HCB or HCB-1 type electromechanical relays and copper communication channels for highly loaded customers with pilot-wire configurations. These technologically obsolete assets lack the

capability to monitor the integrity of supply to pilot-wire customers outside of Toronto Hydro's equipment – a deficiency that can result in unnecessary outages or damage to customer equipment. The existing relays are also functionally obsolete, as the original suppliers no longer manufactures spare parts and/or new replacement parts for electromechanical relays. Another major disadvantage of electromechanical relays is the lack of accuracy of current and voltage measurements, which makes it difficult to recognize fault conditions within tight boundaries.

Toronto Hydro proposes to address these problems through a proactive pilot-wire relay upgrade program. Toronto Hydro's proposed solution is to replace the existing electromechanical relays and the associated copper communication lines with microprocessor relays and fiber optic communication lines, respectively.

E6.16.2.3 Program Benefits

This program provides value to customers by reducing the duration of station-related outages and the risk of extended outages. These extended outages may occur as a result of SCADA system inoperability at stations or due to technical obsolescence of electromechanical relays as part of pilot-wire configuration. From 2008 to 2012, SCADA-enabled substations were, on average, responsible for far fewer customer hours interrupted (CHI) than stations without SCADA capabilities. Figure 6 and Figure 7 show a yearly comparison of CHI of stations with and without SCADA technology in the Etobicoke and downtown Toronto area, respectively. A significant contributor to this is the remote monitoring and control functions that SCADA devices provide to system controllers. SCADA system controllers can identify when an outage occurs and take immediate steps to address the problem, avoiding the need to wait for notification from an affected customer, as well as the need to send a crew to the substation to take remedial action. This typically reduces the amount of time that customers are without power during a station-related outage from three hours to thirty minutes.

Feeders with pilot-wire configurations supply individual customers whose load demands are much higher than average (10 MVA or more). Typically, the continued functioning of these customers is vital for keeping the City of Toronto running smoothly. For example, some pilot-wire customers include: hospitals, sewage treatment plants, public transit, large office towers, and stadiums. Generally, a power outage experienced by any of these customers has a significant and noticeable impact on the City of Toronto. This program is expected to enable faster relay operation and allow data acquisition. Customers may also be able to connect a HMI to the relays and use data acquisition and monitoring features for energy management purposes.

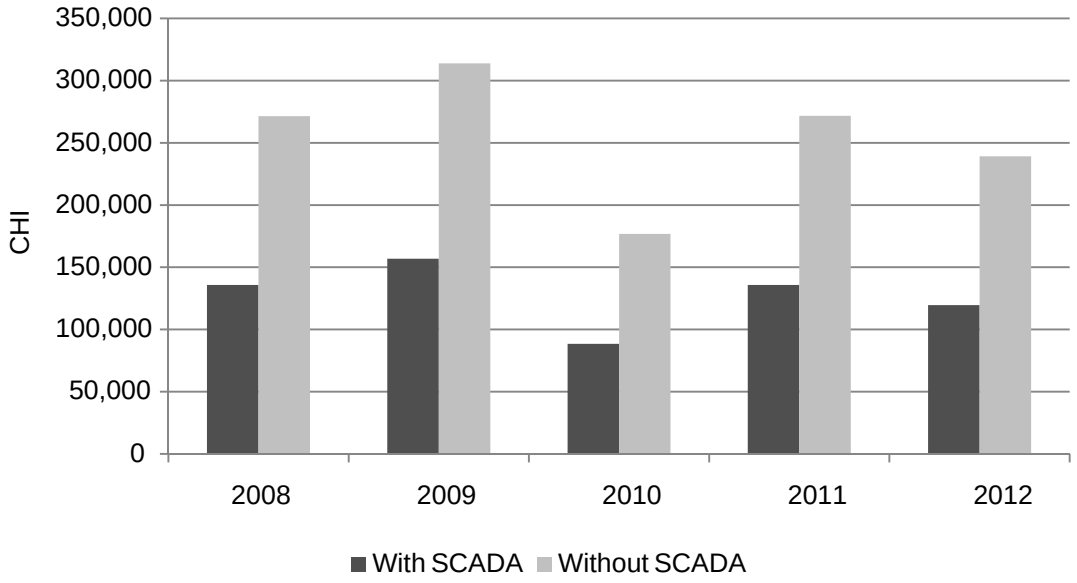

FIGURE 6: CHI WITH AND WITHOUT SCADA TECHNOLOGY IN ETOBICOKE SUBSTATIONS FROM 2008 TO 2012

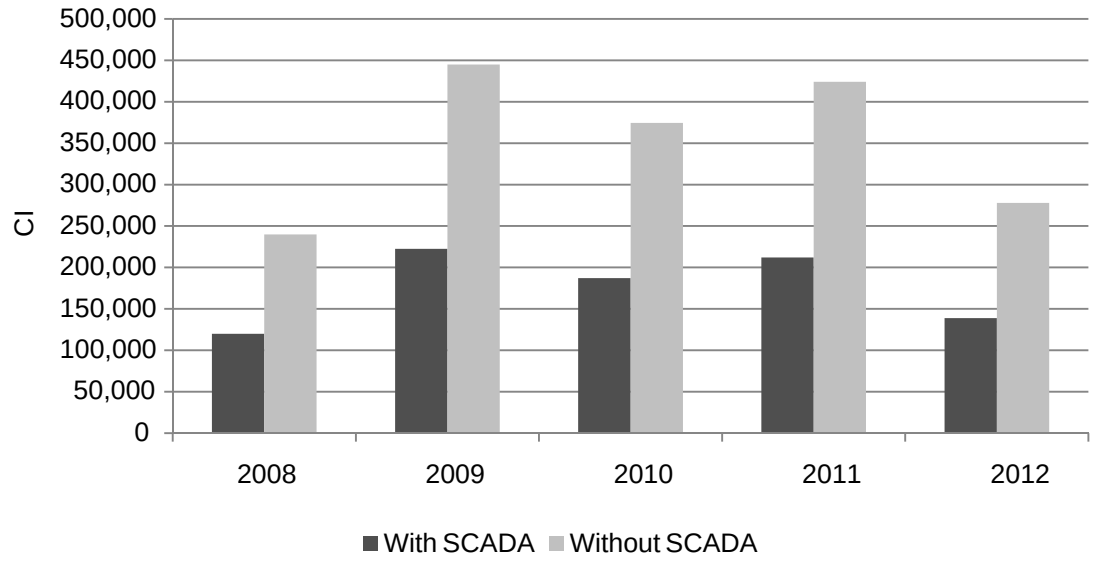

FIGURE 7: CHI WITH AND WITHOUT SCADA TECHNOLOGY IN DOWNTOWN TORONTO SUBSTATIONS FROM 2008 TO 2012

Investments made in this program are expected to improve reliability by reducing the risk of the RTU failure, which renders the SCADA system inoperative, and prolongs the duration of station-related outages.

By the end of 2015, all the RTU devices deployed at Toronto Hydro substations will have reached the end of their useful lives. Not coincidently, these assets have become more prone to failure in recent years. Figure 8 shows the number of RTU failures at Toronto Hydro as they age from 11 years to 19 years.

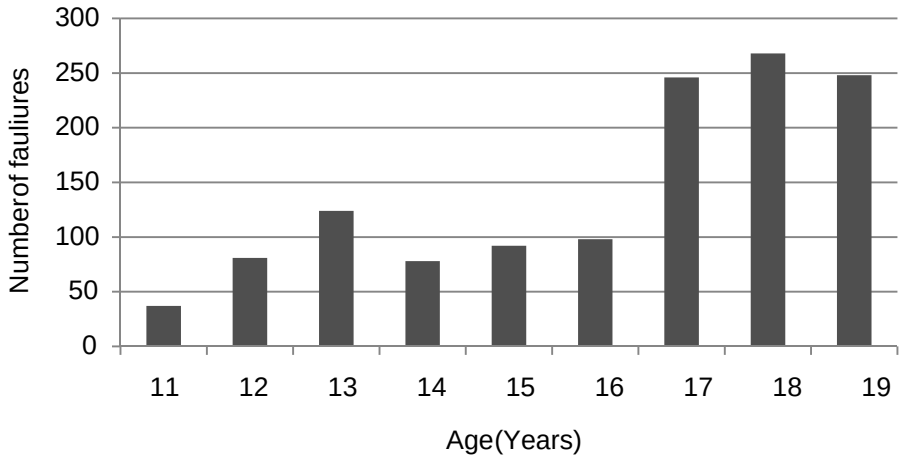

FIGURE 8: NUMBER OF RTU FAILURES WITH INCREASING AGE FROM 11 YEARS TO 19 YEARS

The failure rate will continue to increase in the absence of a replacement plan, which will result in a greater need for spare parts. But since the original manufacturer of the existing RTU devices no longer provides support and spare parts are no longer available in the market, maintaining these assets will become increasingly difficult for Toronto Hydro.

Toronto Hydro expects this program to improve reliability in the Scarborough area by enabling SCADA technology to be installed at a number of stations that currently do not have these capabilities. With this technology, Toronto Hydro will able to monitor and control feeder loading by re-routing electrical supply faster and more efficiently during planned outages and emergency situations

This program also plans to replace current electromechanical relays with digital relays, which will provide Toronto Hydro with the ability to monitor the status of customers' circuit breakers. This new ability allows Toronto Hydro to react to any pilot-wire faults (such as in Section E6.16.3.2ii) before an outage can occur. In this way, customers are likely to experience a greater level of reliability through pilot-wire upgrades.

The Stations Control & Monitoring program is expected to result in efficiencies relating to:

- labour cost,
- maintenance cost,
- optimize power distribution system, and
- maintain system parameters at desired level.

Toronto Hydro relies on manual labour to perform many of the electrical distribution tasks at sub-stations without SCADA capabilities. By replacing the obsolete RTUs and connecting additional substations to the SCADA system, Toronto Hydro expects to be able to automate many of the tasks such as problem troubleshooting and station equipment maintenance.

Remote troubleshooting allows SCADA console operators to identify the exact location of the outage and perform automatic switching to isolate the outage. Task automation is expected to result in labour cost savings by preventing the need for station crews to go to site and perform lengthy inspections and manual switching.

Automatic switching capability achieved through SCADA system installation is expected to help improve maintenance efficiency by reducing maintenance crew hours to complete the same work through harmonization of tasks and elimination of redundancies. As a result, planned maintenance outages and related maintenance cost would decrease. In addition, maintenance cost savings are also derived from SCADA monitoring data such as voltage deviation, hours of operation, number of breaker closures and transformer temperatures to extend useful life of the station assets. The analysis of these data enables Toronto Hydro to make adjustments and corrections, which may prevent an outage from occurring.

Toronto Hydro also expects this program to reduce the costs associated with repairing RTUs and their supporting communication channels. When obsolete RTUs fail, Toronto Hydro has to procure specialized support to repair them because spare parts and manufacturers' support are no longer available. There might be cases where repairing the asset would not work and

replacement is the only option. In this case, a like-for-like replacement would not be possible since the existing assets are obsolete and no longer available in the market. The only remaining option is replacing the existing asset with the new modern RTUs and communication channels. This requires planning and available spare resources. However, carrying out a big replacement job on a reactive basis is not feasible due to limited resource availability, difficulty of new asset procurement on short notice and system upgrade requirements to make the new asset compatible with the existing equipment. This program can help prevent the need for such expensive reactive replacement work.

SCADA system provides powerful analytical tools to operators that give real-time view into operations. This allows operators to optimize power distribution system in order to maximize efficiency. SCADA system also helps with data management to simplify data analysis. These recorded data provide comprehensive load profiles and growth planning to meet future demands. Similarly, microprocessor relays are capable of storing important data related to pilot-wire, which can be communicated to SCADA system for further analysis.

Furthermore, the ability to analyze trends and recorded historical data of substation operation helps maintain desired power factors, voltage levels and other system parameters at desired levels. With the evolution of power distribution system, these parameters are becoming more complex and difficult to maintain. Modern SCADA systems are developed to keep up with the increasing complexity that can be used to improve operational efficiency of substations.

SCADA system enhances safety of employees working in the distribution system, as they do not have to be physically exposed to electrical and operational hazards when they are troubleshooting and performing switching operations to re-route or restore power to a customer. Safety and operational hazards associated with not having a SCADA system are further magnified when crews have to set-up traffic protection in different types of weather just to be able to operate a switch. Switches, at times, are hard to operate causing muscular strain/ stress on workers legs, shoulders, back and hands. The SCADA system mitigates these safety risks by reducing the exposure of personnel to manual switching.

RTUs, communication channels and relays are all connected to a single SCADA console from where they are monitored and operated. Cyber security breaches of a SCADA system could result in wide-ranging adverse impacts. If a SCADA system is hacked, it may result in failure to transmit timely accurate commands to substation power equipment. As a result, the station equipment may fail or completely shut-down and compromise the safety of personnel working in

the station vicinity. Modern technologies in the new RTUs and communication channel are more resilient to cyber security risks. They help mitigate SCADA system vulnerabilities such as RTU spoofing or intruder eavesdropping. RTU spoofing involves intruders sending bogus status before a valid RTU response such as changing threshold of safety parameters. This can result in unpredictable outcomes including loss of confidential information, system disruption, or catastrophic failure. With a more secured system in place, electronic intruders will be less likely to be able to exploit vulnerabilities and gain access to SCADA system where they can gather sensitive and confidential information such as protection settings, circuit breaker position, metering data and more.

Table 2 summarizes the anticipated benefits of this program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduce the duration of station-related outages and the risk of extended outages ƒ Enable faster relay operation to customers ƒ Allow customers to connect a Human Machine Interface (HMI) to the relays for data acquisition and load monitoring features ƒ The difference in the cost of ownership between existing and renewed assets (ΔCOO) for the first year of the program is $0.1 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.16.7). ƒ Accounting for capital program costs, the first year's activities (approximately $80,000 in expenditures in first year) deliver a positive NPV of $0.02 million, confirming the economic prudence of the investments (see Section E6.16.7).
Reliability	ƒ Reduce the risk of RTU failure and avoid potential prolonged station related outages ƒ Enable Toronto Hydro to monitor and control feeder loading ƒ Provide the ability to monitor the status of customer breakers, enabling Toronto Hydro to take immediate actions against pilot-wire faults
Efficiency	ƒ Enable remote troubleshooting and switching capabilities that allow labour cost savings by eliminating the need for station crews to go on-site to identify problems and perform manual switching ƒ Automatic switching capability enables maintenance efficiency by reducing the number of maintenance crew hours needed to complete the same work through a more effective streamlining of functions ƒ Analysis of SCADA monitoring data can help Toronto Hydro make adjustments and corrections, which may result in corrective maintenance cost savings ƒ Reduce costs associated with repairing obsolete RTUs and their

	supporting communication channels ƒ Allow control room operators to optimize power distribution system and improve data analysis through data obtained from SCADA system ƒ Help improve operational efficiency of substations by keeping up with the increasing complexity of maintaining desired substation system parameters such as power factors and voltage levels
Safety	ƒ Enhance safety by reducing the crews' exposure to safety hazards when they perform manual switching functions
Cyber-security	ƒ New SCADA devices are built with stronger cyber security features than those currently deployed

E6.16.3 Why the Program is Needed

This renewal program is needed to address several obsolescence issues affecting the reliability of stations control and communications infrastructure. The RTU equipment replaced in this program is no longer produced by the manufacturer, meaning that spare parts are not available and the supplier no longer provides operational support. Renewal of pilot-wire relay and communications equipment is needed as the equipment has aged and is technically obsolete. In addition, Toronto Hydro has substations in the Scarborough that lack SCADA capabilities. Automating the electrical distribution system at these Scarborough substations by the installing SCADA system is expected to improve system reliability, minimize power disruptions, and reduce outage times for customers.

E6.16.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for replacing and installing RTUs and pilot-wire electromechanical relays.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Large number of RTU assets are past their useful lives ƒ Replacement parts for RTUs and electromechanical relays are no longer available from the original manufacturer ƒ SCADA installations are required at Scarborough substations in order to bring these stations into alignment with modern control and monitoring standards
Secondary Drivers	Reasoning

Reliability	ƒ RTU failures have increased substantially over the past decade. ƒ SCADA technology is currently lacking at Scarborough substations. CHI would be reduced significantly if SCADA technology was introduced. ƒ Electromechanical relays used in current pilot-wire configuration do not have customer circuit breaker monitoring abilities, which may result in unnecessary customer outages.
Cyber Security	ƒ Cyber threats increasingly become more sophisticated for the existing SCADA system. ƒ Potential risk of compromising the RTU or communication channel device which can allow: shutting down entire or portion of a substation, stealing or altering metering data.

E6.16.3.1.1 SCADA RTU System

The trigger driver for this program is functional obsolescence. MOSCAD RTUs – along with the supporting communication channel – DACSCAN MDO-11 type RTUs are legacy equipment. The manufacturer of these units has discontinued production and no longer supply spare parts, which will soon be needed given that all RTUs will have passed their end of life by the end of 2014. Additionally, these manufacturers no longer supply the associated software, firmware, vulnerability patches or technical support for installed units. It is very expensive to custom make or track down rare parts for Toronto Hydro's equipment compared to purchasing mass-produced parts provided by manufacturers.

Toronto Hydro has moved towards integration of SCADA into substations to automate electrical distribution system. Scarborough substations without SCADA capabilities are now technologically obsolete and unable to provide acceptable service to customers. Power equipment and alarms at these stations cannot be remotely monitored, which would otherwise allow SCADA operators to quickly spot and address operational problems. Currently, Toronto Hydro relies on customer calls to be made aware of any customer outages as a result of a failure at these substations. Toronto Hydro also has monthly inspections and station crews ready to be dispatched to mitigate the risks associate with having no real-time monitoring capabilities. Moreover, in order to balance and co-ordinate Toronto Hydro's system, the control room must be aware of the load demand at each station. Without access to real-time load data at substations, controllers must send station personnel to determine the load on site at a specific time.

Intelligent Electronic Devices (IEDs) are critical SCADA components within Toronto Hydro's distribution system. An IED is a SCADA system component that collects information from sensors

and power equipment within SCADA operations. When an IED senses a fluctuation of these values from the desired range, it activates control function to correct the problem and bring the value to normal range. RTUs are interfaced with IEDs to collect the data and pass it to the master SCADA console. Since IEDs serve a number of important roles in the SCADA system, it is important to ensure that they are operating properly. Hence, RTUs monitor these IEDs and report alarm information to the master SCADA console to notify operators of any problem.

A physical cable connection is necessary to connect the existing RTUs to multiple newer IEDs at a station. Terminating multiple cables at a single RTU is labour intensive, costly and difficult to troubleshoot. The RTU models currently in use lack the ability to feasibly interface with newer IEDs.

Current RTUs cannot support modern communication channels and protocols. Legacy protocols used by the older RTUs have limitations that do not allow them to take advantage of the quantity, resolution and accuracy of modern data acquisition. This limits the existing SCADA system to improve its data security and data integrity in the future.

RTU failure rates have increased over the past eight years and are expected to continue to increase as the assets age. When a RTU fails, the communication between the central SCADA console and the substation is broken. In that situation, a substation with or without SCADA capabilities suffer the same consequences. Without SCADA control and monitoring, Toronto Hydro system control personnel cannot access critical information about the station assets, including alarms for circuit breaker trips, loss of transformer voltage, cable overloading, loss of battery power, and transformer pressure, oil level and temperature. This lack of real-time information can prolong the duration of outages associated with station asset failures. For example, at a substation without SCADA capabilities, the typical restoration time for a feeder outage is three hours because station field crews must attend the affected location to identify the problem and perform manual switching to end the outage. As a result, station crews are exposed to safety hazards associated with manual switching while trying to restore power to customers. With a SCADA system, the restoration time can be reduced to as little as thirty minutes by utilizing the remote diagnostic and switching capabilities of the system. Moreover, a SCADA system also enhances the safety of the station crews by reducing the need to perform manual switching.

Cyber security threats are another risk associated with obsolete RTU and its supporting communication channel design. As technology advances, cyber threats become increasingly

sophisticated, and as a result, obsolete RTUs and its communication system currently used by Toronto Hydro becomes more susceptible to cyber attacks. If an electronic intruder gains access to substation control or protective system they will be able to shut down the substation or any portion of the subsystem controlled by the compromised device and, steal or alter metering data gathered by SCADA system. Modern technologies in the new RTUs and supporting communication channel are equipped with complex encryption and additional safeguards, which makes them more resilient to cyber security risks. Installing the modern RTU devices and supporting communication channels will help Toronto Hydro to mitigate the risk of electronic intrusion and other system vulnerabilities.

E6.16.3.1.2 Pilot-Wire System

The trigger driver for this program is functional obsolescence. CPD, MBCI and HCB or HCB-1 type electromechanical relays are legacy equipment. The manufacturer of these units has discontinued production and no longer supplies spare parts, associated software, firmware, vulnerability patches or technical support for installed units. It is very expensive to custom make or track down rare parts for Toronto Hydro's equipment compared to purchasing mass-produced parts provided by manufacturers.

Electromechanical relays are technologically obsolete, consisting of mechanical parts that require routine calibration to stay within intended tolerances. They are not capable of providing many important features such as storage of fault current data and integration with other Intelligent Electronic Devices (IEDs).

Forty two percent (42%) of the pilot-wire distribution feeders in service are equipped with the GE Westinghouse CPD relays and one percent (1%) with Alston MBCI relay, while fifty one percent (51%) have the ABB HCB or HCB-1 relay. None of these relay models are equipped with real-time pilot-wire supervision. This lack of supervision can increase the risk of a customer outage (See Section E6.16.3.2ii). When modern pilot-wire equipment is installed, Toronto Hydro will be able to monitor the load of highly loaded customers, and make necessary provisions to minimize outage risks should part of the protection system fail. Accordingly, renewal of pilot-wire relay and communications channel will increase Toronto Hydro's reliability to its customers.

E6.16.3.2 Asset Details

(i) Asset Lifecycle

RTUs have a useful life of 22.5 years. The DACSCAN MDO-11 RTUs were installed in 1987. The MOSCAD RTUs and DARCOM radio communication system were installed in 1993. By the end of 2015, all of the RTUs will have reached the end of their useful lives.

The life expectancy of electromechanical relays is assumed to be approximately 30 years based on industry averages. The selected GE Westinghouse CPD, Alston MBCI and ABB HCB or HCB-1 type electromechanical relays and copper communication channel on pilot-wire feeders will be 30 years old by the end of 2015. The original manufacturer of these devices no longer produces them and thus, spare parts are not available in the market. While the HCB-1 relay model can still be custom made through ABB, the cost is substantially higher in comparison to a digital relay. The existing electromechanical relays are both functionally and technologically obsolete and prone to age related wear and tear.

The Stations Control & Monitoring program proposes to proactively replace these devices, as opposed to running them to failure, to mitigate the risk of equipment failure, prolonged outage duration and increased maintenance cost.

(ii) Asset Failure Impacts

The RTU is an integral part of the SCADA system. When an RTU fails, the communication link between the central SCADA console and Toronto Hydro substation assets is disrupted, causing power system controllers at the control centre to lose monitoring and controlling capabilities over Toronto Hydro's substation assets. Without the SCADA system in place, Toronto Hydro relies on customer calls to address feeder outages. Since Toronto Hydro personnel need to perform manual switching instead of remote switching to troubleshoot the problem, restoration time during a feeder outage increases from an average of thirty minutes to three hours. Since automatic switching eliminates the need for station crews to travel, SCADA installation will reduce CO_2 emission from trucks, ease traffic congestion as a result of vehicles being taken off the road and avoid many roadways blocking that is required to allow safe access to switching locations.

The pilot-wire relays and communication cables are vital components used for the protection of customer feeders, as described at the start of Section E6.16.3.2. When relays fail, circuit breakers aren't opened during a fault, which can potentially result in damage to feeders supplying customers and even customer equipment. If the communication channel between the relays fails,

then the relays are unable to communicate with each other, and this can also result in improper functioning of the circuit breakers. In worst-case scenario, the feeder fault can circle back to the station bus and take it offline. The consequences of such a scenario could be significant, resulting in a loss of load of up to 72MVA and thousands of customers.

In October 2013, electromechanical relays on a pilot-wire circuit failed to operate, which resulted in a four hour outage at one of the TD buildings located in the financial district of Toronto. The outage was the result of an accidental cut of the pilot-wire cable during a construction job in the City of Toronto. This customer was supplied by two feeders from Windsor Transformer Station (TS). When the relays lost communication with one another, the circuit breaker of one feeder opened on the customer side, but not at the supplying station. This left the customer to be supplied by only one feeder. Since the circuit breaker at the station did not open and Toronto Hydro does not have monitoring capabilities over customer breakers, Toronto Hydro's Control Room was unaware that the customer was being fed by one feeder instead of the usual two. Eventually, the second feeder supplying the customer failed while troubleshooting the communication channel, initiating the power outage. This outage could likely have been prevented if Toronto Hydro had monitoring capabilities of the customer's circuit breaker through the relays.

In the example above, the affected customer was a critical institution which is fed about 5 MVA of load. Multiple major businesses reside and operate from this building and cannot afford to experience an outage for any period of time.

E6.16.4 Timing & Pacing of the Program

Toronto Hydro plans to replace obsolete RTUs at substations that have SCADA technology and to install SCADA systems at substations that do not have this technology. Additionally, Toronto Hydro proposes to replace obsolete pilot-wire relays and communication cables. During the 2015-2019 period, Toronto Hydro plans to:

- replace the existing MOSCAD RTUs and supporting communication infrastructure at 22 Etobicoke substations,
- replace existing DACSCAN MDO-11 type RTU at six downtown Toronto stations,
- install SCADA system, which includes RTUs and communication channels, at seven Scarborough municipal stations; and

- replace the pilot-wire relays and communication channels for 22 feeders, which includes 44 relays and communication channel.

The total cost of the Stations Control & Monitoring program over the five year period from 2015-2019 is an estimated $5.05 million, as shown in Table 4 below.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending ($M)					Future Spending ($M)				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0.12	0.46	0.24	0.08	0.94	1.11	1.49	1.44

Table 4 also shows the historical spending associated with the Station Control & Monitoring program. The need for this program was recognized in 2012 and thus no projects were implemented in 2010 and 2011. Capital spending from 2012 to 2014 was fairly low because only five substations were targeted for RTU replacement. These five substations were selected based on several factors as mentioned in section E6.16.4.1 Ranking & Prioritization. Since this program was a new initiative, the first of the five projects was used to adequately train Toronto Hydro personnel to quickly and efficiently complete the remaining RTU replacement projects. For this reason, the first project was designed to take longer to complete than the others. As a result, this project was completed in 2013, and the remaining four are in-progress and scheduled to be completed by the end of 2014. Toronto Hydro owns 70 substations in Etobicoke; out of these 70 substations, 46 are either included in the 2015 to 2019 Switchgear Replacement Program (See E6.13) or in system renewal programs that include load conversion plans such as Box Construction Conversion (E6.7), Overhead Circuit Renewal (E6.4), Underground Legacy Infrastructure (E6.3) and Load Demand (E5.4). A typical Switchgear replacement includes the replacement of an RTU and its supporting communication channel. In the case of load conversion, all the station assets are decommissioned. In both cases, RTU issues are addressed. Therefore, Toronto Hydro has excluded those stations from the Station Control & Monitoring program. Toronto Hydro proposes to replace the RTUs at the remaining 24 substations through this program.

Toronto Hydro has 66 substations located in the Scarborough, 44 of which are SCADA-enabled. Similar to RTU replacement in Etobicoke substations, SCADA installation in the Scarborough area is planned under the Station Switchgear Renewal program (E6.13) and other renewal

programs that include load conversion plans. The remaining substations without SCADA capabilities are planned to be fitted with RTUs and communication channel.

The work involved in Station Control & Monitoring program uses labour resources such as Station engineer, Station designer, certified substation electrician and Information Technology (IT) personnel. The same resources are required for Toronto Hydro's other station renewal programs such as Switchgear Renewal program (See E6.13), Power Transformer Renewal program (See E6.14) and Circuit Breaker Renewal program (E6.15). Based on limited availability of resources, Toronto Hydro can target only a certain number of substations every year for each program. To account for these constraints, Toronto Hydro plans to replace RTUs at five Etobicoke stations and to install SCADA systems at two Scarborough stations every year from 2016 to 2019. Given the available resources, Toronto Hydro plans to replace RTUs at only two Etobicoke stations in 2015.

The Stations Control & Monitoring program also targets Transformer Stations (TS) located in downtown Toronto. Because of the resource constraints mentioned above, Toronto Hydro plans to begin replacing RTUs at TS from 2016. Toronto Hydro plans to replace RTUs at one TS every year in 2016 and 2017 and then continue to replace RTUs at a rate of two TS every year in 2018 and 2019. Due to presence of higher volume of power equipments at TS, replacing SCADA RTUs and its supporting communication channel at TS is more difficult than doing it at MS. Moreover, the new RTUs use modern technology that requires training Toronto Hydro's station crews to install, operate and maintain these new devices. Therefore, the first two RTU replacement projects in 2016 and 2017 are planned to have resources allocated for training programs. Toronto Hydro plans to replace RTUs at two downtown Toronto stations every year from 2017 to 2019.

Toronto Hydro has approximately 67 distribution feeders equipped with pilot-wire protection in the downtown Toronto distribution system. These feeders serve 27 customers distributed across eight TS. Currently, three new customers have been installed with digital fibre optic line differential relays, while 64 feeders are equipped with the traditional electromechanical pilot-wire relays. Toronto Hydro plans to upgrade the electromechanical relays and its supporting copper communication channel on 22 highly loaded pilot-wire configured feeders from 2015 to 2019.

Additionally, the electromechanical relays and copper communication channels are critical to the protection of highly loaded pilot-wire feeders. These highly loaded feeders supply load to large buildings mostly located in the financial district of downtown Toronto. Many businesses operate from these buildings and rely on uninterrupted power supply. Any power disruption for even a small period of time may result in large loss of revenue for a customer. The existing relays and

communication channels on these feeders are obsolete. These relays are about 30 years old and have extensive wear and tear through chemical reactions as a result of aging. In addition, they do not possess the ability to monitor pilot-wire circuit or electronically store event information and transmit the data to remote location for analysis. Due to the risk of large impact, it is important for Toronto Hydro to implement this program starting 2015 in order to upgrade Toronto Hydro's protection equipment to modern standards, improve reliability and provide better analysis capabilities.

Similar to replacing RTUs at downtown Toronto TS, the pilot-wire relay and communication channel upgrade aspect of the program is a new project for Toronto Hydro. This project includes replacement of existing electromechanical relays and copper communication channels with modern digital relays and fibre optic communication, respectively. Toronto Hydro plans to replace these existing relays and communication channel at three pilot-wire feeders in 2016. Additional resources are planned to be allocated in 2016 for training station crews to perform the replacement work. Starting 2017, Toronto Hydro proposes to increase the pace of the program to target five feeders in 2017 and six in 2018 and 2019 (See Figure 1).

E6.16.4.1 Ranking & Prioritization

Identifying substations for RTU replacement and SCADA system installation are based on several factors. These include:

- Mitigate sub-station risks: Toronto Hydro's sub-stations for RTU replacement and SCADA installation were selected on the basis of on the immediate threat they inflict on customer value and the potential safety and operational risks they impose on the system. In order to mitigate these risks, stations that supply power to large number of customers and are highly loaded were selected to improve reliability and system efficiency at high impact stations.

- Coordination with Switchgear Replacement: The Switchgear Renewal program includes RTU replacement and SCADA system installation. The two programs are planned to be coordinated in order to avoid wasted resources and redundant work.

- Co-ordination with Maintenance Program: SCADA RTU replacement or installation work involves taking the bus offline on which the new RTU will be replaced or installed. Toronto Hydro plans to co-ordinate this work with the Maintenance program (Exhibit 4A, Tab 2, Schedule 1), so that RTUs can be replaced when stations are de-energized for regular maintenance tasks. Toronto Hydro expects that this will facilitate a more efficient

execution of the work program and reduce the effects on customers by minimizing the frequency of planned station outages.

- Avoiding replacing legacy 4.16kV station assets: 4.16kV Stations targeted for load conversion within the Box Construction Conversion (E6.7), OH Circuit Renewal (E6.4), UG Legacy Infrastructure (E6.3) and Load Demand (E5.4) programs are not included in this program. During load conversion, all station equipment is removed. Hence it is redundant to replace or install a RTU at 4.16kV station.

Toronto Hydro currently serves 26 pilot-wire customers using technically obsolete pilot-wire relay and communications technology. Toronto Hydro uses the following prioritization criteria to select customers for pilot-wire relay and communications upgrade (criteria weight in a descending order):

(1) Lack of an existing alternate pilot-wire circuit: The current Toronto Hydro standard is to have two pilot-wire lines per feeder. But, in a few cases, Toronto Hydro has customers with one pilot-wire line per feeder. These customers experience elevated outage risk. Therefore, they are targeted for upgrade before other customers. Toronto Hydro plans to take this opportunity to install two pilot-wire lines per feeder: both "main" and "alternate", while installing new digital relays.

(2) Customer criticality (nature of load): Toronto Hydro's customers include a variety of institutions which must receive uninterrupted power supply such as hospitals, sewage treatment plants and banks. Proper functioning of these institutions is critical to the operation of the City of Toronto. Any failure at these locations would have a high impact. Therefore, Toronto Hydro plans to mitigate high impact risks by targeting these critical customers.

(3) Customer peak load: Load characterizes the size of the customer. A customer with higher load tends to experience a greater impact in the event of an outage. Similar to customer criticality, Toronto Hydro plans to mitigate high impact risks by targeting these high load customers.

(4) Locations currently utilizing a leased communication circuit: Toronto Hydro has some customers whose pilot-wire communication lines are owned by an external source, rather than Toronto Hydro itself. Toronto Hydro plans to move away from this practice by replacing all these externally owned communication lines with lines

owned by Toronto Hydro. This allows Toronto Hydro to more efficiently monitor the status of these lines.

This prioritization method helps Toronto Hydro plan work in a manner that first addresses customers with the greatest reliability risk and greatest need for uninterrupted supply.

E6.16.5 Program Execution

The Stations Control & Monitoring program consists of multiple discrete replacement and installation projects over the 2015 to 2019 period. Sections E6.16.8 and E6.16.9 contain the full list of projects that make up this program. Toronto Hydro has identified a number of risks and constraints involved with the Stations Control & Monitoring program that need to be taken into consideration prior to executing this work. The work involved in replacing RTUs and their supporting communication infrastructure, installing SCADA systems and replacing existing pilot-wire relays is described below:

(i) Replacement of RTUs and Supporting Communication System

The replacement projects at both Etobicoke MS and Downtown Toronto TS consist of removing the existing MOSCAD RTU and DACSCAN MDO-11 RTU, respectively, and installing the new RTU along with the supporting communication channel. In addition, the following RTU supporting components will also be replaced with newer devices:

- Power supply
- CPU
- I/O Modules
- Housing and Chassis
- Software

(ii) SCADA System Installation

The work involved in SCADA system installation is similar to the replacement work discussed above, in the sense that both involve the same skill set for installing a new RTU, communication channel and other supporting components as mentioned in section E6.16.6(i). However, there will be additional work to prepare the substation for SCADA devices for the first time, namely the

installation of new cable connections. The cost of this additional work is incorporated into the estimates for this program.

(iii) Pilot-Wire Relay & Communication Line Replacement

The pilot-wire relay upgrade of Toronto Hydro's high load customers involve removing the existing electromechanical relays which include GE Westinghouse CPD, Alston MBCI and ABB HCB or HCB-1 type relays and their respective copper communication channel. Once removed, SEL411 microprocessor relays are installed along with fiber optic communication cables.

E6.16.5.1 Proposed Work Plan

TABLE 5: 2015-2019 LONG TERM PLAN

Year	Project Type	Station
2015	Etobicoke RTU Replacement	Blaketon MS
2015	Etobicoke RTU Replacement	Walney MS
2016	Etobicoke RTU Replacement	Albion MS
2016	Etobicoke RTU Replacement	Centre Drive MS
2016	Etobicoke RTU Replacement	Palmwood MS
2016	Etobicoke RTU Replacement	Annabelle MS
2016	Etobicoke RTU Replacement	Royalcrest MS

2019	Downtown RTU Replacement	Charles TS
2019	Downtown RTU Replacement	George & Duke TS
2019	Pilot-wire Relay Upgrade	Windsor TS

E6.16.5.2 Program Risks

There are multiple risks associated with the execution of Stations Control & Monitoring program.

RTU replacement or SCADA installation requires planned station outages where the entire municipal station is taken offline since live cables are connected to the RTUs. In the case of replacing RTUs at transformer stations, transferring load to adjacent sub-stations would require the receiving TS to have spare capacity and sufficient feeder positions. The location of the receiving TS would also need to be sufficiently close to the load centre to avoid voltage drop. Since these conditions cannot be met for any of the TS addressed by this program, feeder outages would be performed instead of station outages in order to execute RTU replacement jobs. Similarly, relay and communication channel replacement on a pilot-wire feeder requires the feeder to be taken out of service. This leaves the customer to be fed by one less feeder. Even though they are being supplied by the remaining feeder(s), the customer could experience an outage in the event of an equipment failure or presence of fault current.

Both planned station and feeder outages are done through switching. Switching is expensive and requires significant Toronto Hydro resources. The switching process by its very nature is performed on live equipment, and despite best planning efforts, there is always a risk of unforeseeable safety issues or switching errors.

Toronto Hydro plans to mitigate these risks through careful advanced planning and coordination of the responsible parties. Toronto Hydro also expects to takes other precautions to mitigate the risks on customers being fed by highly loaded pilot-wire feeders. These measures include keeping dispatch crews on standby during the entire duration of the work or coordinating with customer equipment maintenance work. Moreover, stations maintenance programs also require planned station or feeder outages to perform maintenance work on station assets. To address the risks associated with planned outages, RTU replacement or installation projects will be scheduled in co-ordination with the maintenance plan, whenever possible.

E6.16.6 Evaluation of Alternatives

E6.16.6.1 Quantification/ Evaluation of Options

The value of proceeding with the Stations Control & Monitoring program proposed here can be quantified by comparing it to a "status quo" scenario on the basis of cost of ownership.

(i) Status Quo

The status quo scenario consists of maintaining a "run to failure" approach. In this case, the existing MOSCAD RTUs and its associated DARCOM radio system at Etobicoke substations and DACSCAN MDO-11 type RTU at downtown Toronto would be replaced only when the system completely fails. Similarly, the electromechanical relays and communication channels on pilot-wire feeders would be replaced only when they fail, meaning that Toronto Hydro would take on the large failure risks associated with these failures as described in section E6.16.3.2ii. In general, these obsolete devices would be regularly maintained or repaired, which includes testing the functionality of RTU communication system, relay settings, operation of communication channels and checking the wiring and connections for faults. Maintenance work also includes performing open/close operation on SCADA connected switches to ensure they are functioning up to standard. Any warning signal or malfunction of RTU, electromechanical relays, communication channels or any of their supporting components will be reported for follow-up repair. While the continuation of the status quo would allow Toronto Hydro to defer asset replacement temporarily, Toronto Hydro would incur additional maintenance costs to maintain these legacy units in the interim. The realization of the added benefits relating to reliability, efficiency and the mitigation of cyber security risks would also be delayed. Under the status quo scenario, substations in Scarborough would continue to operate without SCADA system

capabilities. As noted in earlier section of the evidence, this typically leads to longer outage times and additional expenditures due to the need for on-site troubleshooting and maintenance.

(ii) Replace or Install RTU and Communication System/Upgrade Pilot-Wire Relays

This option involves the proactive replacement of existing MOSCAD RTUs and DARCOM radio system with modern RTUs and communication channel at Etobicoke and downtown Toronto substations, as discussed above, and the installation of modern RTUs and communication channel system at Scarborough substations. It also includes the replacement of GE Westinghouse CPD, Alston MBCI and ABB HCB or HCB-1 type relays on pilot-wire feeders with SEL411 microprocessor type relays.

The cost of ownership (COO) and program net present value (NPV) associated with Station Control & Monitoring program is further detailed in Table 6. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned investments in this program. The cost of ownership (COO) of a state reflects the risk of asset failure including both direct and indirect costs. These costs include customer interruptions, emergency repairs, and asset replacements associated with that design. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Station Control & Monitoring program produces a NPV value of $0.02 million, as shown in Table 6 and Table 7.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$0.19
Non Asset Risk [NAR_E]	$0
Maintenance Cost [MC_E]	$0
Additional Quantifiable Benefits [AQB_E]	$0
Cost of Ownership of Existing Assets [COO_E]	$0.19

TABLE 7: BOX CONSTRUCTION CONVER SION BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 2: Conversion to Standardized 13.8kV Feeders (N)	
Asset Risk [AR_N]	$0.09
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0
Additional Quantifiable Benefits [AQB_N]	$0
Cost of Ownership of New Assets (Conversion to 13.8kV) [COO_N]	$0.09
Option 2: Project Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	$0.10
Program Cost [PC_1]	$0.08
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	$0.02

E6.16.7 2015 Projects

Table 8 lists the projects scheduled for completion as a part of the 2015 work program. Additional detail on projects for year 2015 is provided in the following sections.

TABLE 8: 2015 PROJECTS

Project Number	Project Name	Area	Cost
29869	S15248 Walney MS MOSCAD RTU Replacement	Etobicoke	$0.04M
29713	S16050 Blaketon MS MOSCAD RTU Replacement	Etobicoke	$0.04M

E6.16.7.1 S15248 Project Description

Investment Category: System Renewal

Program: Stations Control & Monitoring

Project Title: Walney MS MOSCAD RTU Replacement

Project Number: S15248

Project Year: 2015

Estimated Cost: $0.04M

(i) Objective

The objective of this project is to replace the obsolete MOSCAD RTU and DARCOM radio communication channel at Walney MS with SEL AXION RTU and MDS SD9 radio system to improve system reliability.

(ii) Scope of Work

TABLE 9: S15248 SCOPE OF WORK DETAILS

District Neighbourhood	ETOBICOKE
Station(s)	WALNEY MS

TABLE 10: S15248 ASSETS REPLACED

Assets (Units)	2015
RTU & Communication Channel	1

(iii) Justification & Benefits

The Motorola MOSCAD RTUs and supporting communication system used at Walney MS are past their useful life of 22.5 years. These legacy units are obsolete and spare parts are not available from the manufacturer. When these aging RTUs fail, control for switching restoration is unavailable, which can result in significantly longer customer outages. This program is expected to improve reliability by replacing these legacy units with newer and modern RTUs and communication channel. Replacing RTUs is expected to improve system reliability and reduce operational and maintenance cost as detailed in this exhibit.

E6.16.7.1 S16050 Project Description

Investment Category: System Renewal

Program: Stations Control & Monitoring

Project Title: Blaketon MS MOSCAD RTU Replacement

Project Number: S16050

Project Year: 2015

Estimated Cost: $0.04M

(i) Objective

The objective of this program project is to replace the obsolete MOSCAD RTU and DARCOM radio communication channel at Blaketon MS with SEL AXION RTU and MDS SD9 radio system to improve system reliability.

(ii) Scope of Work

TABLE 11: S16050 SCOPE OF WORK DETAILS

District Neighbourhood	ETOBICOKE
Station(s)	BLAKETON MS

TABLE 12: S16050 ASSETS REPLACED

Assets (Units)	2015
RTU & Communication Channel	1

(iii) Justification & Benefits

The Motorola MOSCAD RTUs and supporting communication system used at Blaketon MS are past their useful life of 22.5 years. These legacy units are obsolete and spare parts are not available from the manufacturer. When these aging RTUs fail, control for switching restoration is unavailable, which can result in significantly longer customer outages. This program is expected to improve reliability by replacing these legacy units with newer and modern RTUs and communication channel. Replacing RTUs is expected to improve system reliability and reduce operational and maintenance cost as detailed in this exhibit.

E6.17 Stations Ancillary Systems

ANCILLARY POWER SUPPLY LOCATED IN A STATION BASEMENT

E6.17.1 Summary

Program Description

Through the Station Ancillary Systems Program, Toronto Hydro plans to replace ancillary systems that are at risk of failure and functionally obsolete with more reliable, modern technologies. Examples include air compressor systems, station service power supply systems, fire alarm systems, and fire suppression systems. This program predominately targets stations that do not possess load transfer capabilities in order to mitigate the risk of prolonged outages for customers. The program is also intended to improve crew safety.

Table A summarizes the anticipated benefits associated with the Stations Ancillary Systems program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ The ancillary systems program mitigates risks to the reliability of power supply to 108,248 customers ƒ Proposed installation of the fire barrier system at Strachan B MS expected to mitigate fire hazards to customer property stemming from catastrophic failures of transformers ƒ A reliable fire alarm system notifies system controllers of a station fire so

	that preventive actions can be taken to control the issue before it migrates
Reliability	ƒ New air compressors planned mitigate risks to the reliable operation of the associated air blast circuit breakers, which isolate fault current and prevent damage to upstream or downstream equipment ƒ Reliable fire alarm systems report the presence of station fires to system controllers so that preventive action can be taken before a catastrophic event occurs ƒ Installation of fire barrier system helps to prevent catastrophic transformer failure from causing station outages ƒ Reliable station power supply helps to ensure the reliable operation of the station
Efficiency	ƒ Toronto Hydro expects the Stations Ancillary Systems program to minimize the time taken to acquire spare parts for deteriorating ancillary systems, freeing up maintenance time for other areas of need
Safety	ƒ A reliable fire alarm system notifies personnel on site of the presence of a station fire ƒ A reliable fire alarm system helps to prevent the spread of station fires reducing risks to customers and their property ƒ Proposed fire barriers at Strachan B MS expected to mitigate the fire hazard to customer property and customers' fire safety risk

Program Drivers

Toronto Hydro's proposed Station Ancillary Systems program plans to address ancillary systems that face a risk of failure and that are functionally obsolete. If left in service, a failure of these systems could have a negative impact on the safe and reliable operation of Toronto Hydro's transformer stations. The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Inspection data shows that the ancillary systems targeted in this program are at end-of-life and require frequent repairs ƒ Acquiring spare parts to maintain outdated station ancillary systems is becoming increasingly difficult ƒ Failure of ancillary systems has a potential to cause a failure of the associated station assets
Secondary Driver	**Reasoning**
Functional Obsolescence	ƒ Ancillary systems targeted to be replaced in this program are obsolete ƒ Spare parts are no longer supported by their

	manufacturers • Keeping these ancillary systems in service is increasingly difficult due to a lack of spare parts.
Safety	• Unreliable fire alarm system could impact the safety of personnel in the event of a station fire as they may not be notified early enough to leave the indoor stations • Public safety close to the stations could be at risk in the event of station fire as it is possible that a fire can migrate out of the station to nearby areas.

Preferred Alternative

Toronto Hydro evaluated the following options for addressing the ancillary systems in this program.

(1) Continue to utilize obsolete ancillary systems until they fail; or

(2) Replace existing ancillary systems with new equipment that will contribute to the safe and reliable operation of Toronto Hydro stations.

Option II is the preferred alternative because it mitigates risks to safe and reliable operation of Toronto Hydro stations in a cost-effective manner.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $2.22 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.17.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $1.53 million, confirming the economic prudence of the investments (see Section E6.17.7).

Timing and Pacing

The following table summarizes the historical and forecasted spending for this program.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.15	0.12	0.24	0.63	0.22	0.69	0.59	0.37	0.26	0.38

The air compressors planned for replacement in 2015 serve large customers in the downtown financial district. Fire suppression systems are planned for installation at Cavanagh TS in 2015 and Strachan B MS and Glengrove TS in 2016.

Relocation of a below grade station service power supply at George and Duke MS is planned for 2015 to mitigate the risk of failure that could be caused by flooding. Toronto plans to replace fire alarm systems in 2017-2019, beginning with those that are the oldest and most deteriorated.

E6.17.2 Program Description

In order to function effectively, Toronto Hydro's stations require a number of ancillary systems, including air compressor systems, fire alarm systems, heating and lighting systems, battery and charger systems, station service power supply systems, sump pump systems, and fire barrier or fire suppression systems. The ancillary systems that are addressed in this program are:

- air compressor systems,
- station service power supply systems,
- fire alarm systems, and
- fire suppression systems

These systems are vital to the safe and reliable operation of stations equipment. Toronto Hydro plans to invest $2.29 million over the 2015 to 2019 period to maintain the integrity of these systems at a number of distribution stations throughout the city, as illustrated in Figure 1.

FIGURE 1: LOCATIONS OF STATION ANCILLARY SYSTEMS TO BE REPLACED/INSTALLED

The following sections provide a detailed description of each of the ancillary systems addressed in this program.

E6.17.2.1 Air Compressor System

Toronto Hydro plans to replace functionally obsolete air compressors. A typical air compressor currently in use is shown in Figure 2.

FIGURE 2: TYPICAL EXISTING AIR COMPRESSOR SYSTEM

Reliable air compressors help to ensure that circuit breakers function as designed to clear faults when needed. If a circuit breaker fails to operate and interrupt a fault current due to a failure of the air compressors, the circuit breaker can be significantly damaged and power supply to customers associated with it will be disrupted. For example, a circuit breaker which failed to interrupt a fault current at George and Duke MS on July 5, 2012 was significantly damaged and as a result power was interrupted to 6,500 customers in the central Toronto area for 8 hours.

Toronto Hydro currently has twenty air compressors in service in some of its 4.16 kV and 13.8 kV stations where there are switchgears fitted with air blast circuit breakers which require air compressors to operate. Twelve out of the total are at the end of their lives and require frequent repairs and six out of these twelve air compressors are planned to be removed from service as a result of the Switchgear Renewal Program (see Section E6.13), and do not require replacement because the new switchgears use vacuum circuit breakers that do not require air compressors to operate. However, the remaining six air compressors must be replaced as they continue to operate the associated air blast circuit breakers. The locations of the stations that house these air compressors are shown in Figure 3.

TABLE 1: AGE OF AIR COMPRESSOR SYSTEM IN PROGRAM

Station Name	Air Compressor System Age in 2015 (years)
High Level MS	16
Windsor MS	17
Runnymede MS	18

FIGURE 3: LOCATIONS OF AIR COMPRESSORS TO BE REPLACED (2015 – 2019)

E6.17.2.2 Relocation of Below-Grade Service Equipment

The Station Ancillary Systems program includes investments to relocate below grade station service power supply, specifically the service transformer and associated secondary distribution panel and the battery and charger system of George and Duke Municipal Station (MS). The station service transformer and the associated secondary distribution panel (shown in Figure 4 and Figure 5, respectively) supply power to the lighting, heating and ventilation systems, fire alarm systems, battery charger systems and sump pump systems of George and Duke MS, which all provide essential services required for the station to operate safely and reliably.

The battery and charger system, shown in Figure 6 in turn supplies DC power to all protective relays of the station and their control circuits, alarms and the actuating of equipment such as circuit breakers, SCADA control system, and emergency lighting fire protection.

At George and Duke MS, the station service transformer and the associated secondary distribution panel and the battery and charger system are located in the basement of the station as shown in Figures 4 to 6.

FIGURE 4: STATION SERVICE TRANSFORMER LOCATED IN BASEMENT OF GEORGE & DUKE MS

FIGURE 5: STATION SERVICE SECONDARY DISTRIBUTION PANEL LOCATED IN BASEMENT OF GEORGE & DUKE MS

FIGURE 6: STATION BATTERY SYSTEM LOCATED IN THE BASEMENT OF GEORGE & DUKE MS

If the station basement is flooded due to heavy rain or a broken water main, and if the rate of water entering the basement exceeds the capability of its sump pump to drain the water, then the power supply to the station assets which provide essential services mentioned previously can be

severely impacted, which in turn would impact the ability of George and Duke MS to safely and reliably supply power to over 6,500 customers in the downtown area. Toronto Hydro has taken some measures such as plugging cable ducts, installing bigger size sump pump to reduce the risk of flooding; however, it is still possible that the basement can be flooded due to heavy storm rain or a broken water main. To mitigate this risk, Toronto Hydro plans to install a new station service transformer and associated secondary distribution panel and new battery and charger systems above ground to replace those which are currently located in basement. The location of the station where this power supply system is in service is shown in Figure 7.

FIGURE 7: LOCATIONS OF STATION POWER SUPPLY TO BE RELOCATED

E6.17.2.3 Fire Alarm System

Toronto Hydro plans to replace functionally obsolete, end-of-life fire alarm systems currently in service at a number of stations. Early detection of fire is critical to the safety of personnel on site and for the safety the general public in the surrounding area. It is also essential that fire events in station facilities be detected as early as possible to minimize operational disruptions and asset damage.

Toronto Hydro has fire alarm systems inside 32 stations whose load cannot be transferred to any other stations if the power supply to the initial station is disrupted. Consequently, a fire at any one of these stations could potentially be highly disruptive for customers. Of these 32 fire alarm systems, Toronto Hydro plans to replace five which have reached the end of their useful lives and are obsolete. Spare parts for this type of fire alarm system are no longer available from the manufacturers and it is becoming increasingly difficult to maintain the systems in service. A typical existing fire alarm control panel is shown in Figure 8.

The replacement of the fire alarm systems that are at end-of-life and obsolete will help ensure that fires initiated inside stations are reported to the control room so that fire authorities can be dispatched in a timely manner.

FIGURE 8: TYPICAL EXISTING FIRE ALARM CONTROL PANEL

FIGURE 9: NEW FIRE ALARM CONTROL PANEL

The new fire alarm system shown in Figure 9 contains improved detection technology: it has aspirating smoke detectors that quickly and reliably differentiate between smoke and other causes that previously may have led to false alarms. The new control panels and fire terminals are also easier to operate because they display important, customized intervention text right on

the control panel to facilitate appropriate action in the event of an alarm. In addition to smoke and heat, the new fire alarm systems are also able to detect carbon monoxide (CO).

TABLE 2: AGE OF FIRE ALARM SYSTEM IN PROGRAM

Station Name	Fire Alarm System Age in 2015 (years)
George & Duke MS	17
Dufferin TS	18
Charles TS	21
Glengrove TS	17
Terauly TS	17

The locations of the fire alarm systems requiring replacement in 2015-2019 are shown in Figure 10.

FIGURE 10: LOCATION OF FIRE ALARM SYSTEM TO BE REPLACED (2015 – 2019)

E6.17.2.4 Fire Suppression Systems

Toronto Hydro plans to install fire barrier systems in stations where there are multiple transformers that face the risk of collateral damage if any single transformer fails catastrophically. A catastrophic transformer failure occurs when an internal short-circuit arc takes place inside a

transformer resulting in a significant release of energy into the insulating oil and builds internal pressure which raptures the tank and burns the transformer oil. The fire caused by a catastrophic failure of a transformer can migrate to the adjacent transformers and can damage other equipment in the station.

Fire barriers can be passive or active. A fire barrier system is passive if it contains the fire within the boundary of a transformer so that a potential fire does not migrate and damage any other transformer(s) in the vicinity. Another method of preventing fire from damaging additional transformers is the installation of a fire suppression system. A fire suppression system is called an active fire barrier because it puts out fire actively. Fire suppression systems use a combination of dry chemicals and/or wet agents to suppress equipment fire. These systems are typically water sprinklers or foam spraying systems that can extinguish a fire before it spreads and potentially damages other transformers.

Toronto Hydro also plans to install a fire barrier wall between the station service transformers of Glengrove terminal station (TS) which are very close to each other as shown in Figure 11. A catastrophic failure of any one of them will impact the second one. In the even to catastrophic failure, the station essential services will interrupt and this could negatively impact the reliability of power supply to all the customers connected to Glengrove TS. Therefore, to mitigate the reliability risk, one of the station service transformers is to be relocated far enough so that space will be the fire barrier between the two transformers.

FIGURE 11: STATION SERVICE TRANSFORMERS AT GLENGROVE TS

The locations of these stations are shown in Figure 12.

TABLE 3: NUMBER OF CONNECTED CUSTOMERS

Station Name	Number of Customers Connected
Cavanagh TS	16,363
Strachan B MS	1,191
Glengrove TS	12,647

FIGURE 12: LOCATION OF FIRE BARRIER/SUPPRESSION SYSTEM INSTALLATION (2015-2019)

The assets that Toronto Hydro plans to replace/install under the ancillary system program are summarized by asset class in Table 4.

TABLE 4: ASSETS TO BE REPLACED/INSTALLED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Air Compressors	4			2		6
Station Service Power Supply		1				1
Fire Alarm System			2	1	2	5
Fire Barrier/Suppression System	1	2				3

In addition to addressing obsolete and aging assets, Toronto Hydro anticipates that the Stations Ancillary Systems program will offers a number of benefits as shown in Table 5.

TABLE 5: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigates risks to the reliability of power supply to 108,248 customers ƒ Proposed installation of the fire barrier system at Strachan B MS mitigates fire hazards to customer property stemming from catastrophic failures of transformers ƒ A reliable fire alarm system notifies system controllers of a station fire so that appropriate steps can be taken to control the issue before it migrates ƒ The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $2.22 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.17.7). ƒ Accounting for capital program costs, the first year's activities are expected to deliver a positive NPV of $1.53 million, confirming the economic prudence of the investments (see Section E6.17.7).
Reliability	ƒ New air compressors mitigate risks to the reliable operation of the associated air blast circuit breakers, which isolate fault current and prevent damage to upstream or downstream equipment ƒ Reliable fire alarm systems report the presence of station fires to system controllers so that appropriate steps can be taken before a catastrophic event occurs ƒ Installation of fire barrier systems help to prevent catastrophic transformer failure from causing station outages ƒ Reliable station power supply helps to ensure the reliable operation of the station
Efficiency	ƒ Toronto Hydro expects the Stations Ancillary Systems program to minimize the time taken to acquire spare parts for deteriorating ancillary systems, freeing up maintenance time for other areas of need
Safety	ƒ A reliable fire alarm system notifies personnel on site of the presence of a station fire

	ƒ A reliable fire alarm system will help prevent the spread of station fires reducing risks to customers and their property ƒ Fire barriers at Strachan B MS mitigate the fire hazard to customer property and public safety risks

E6.17.3 Why the Program is Needed

Toronto Hydro's proposed Station Ancillary Systems program plans to address ancillary systems that face a risk of failure and that are functionally obsolete. A failure of these systems could have a negative impact on the safe and reliable operation of Toronto Hydro's transformer stations. This program also addresses the need for fire barriers and fire suppression systems in certain stations.

E6.17.3.1 Program Drivers

Table 6 specifies the trigger and secondary drivers for the Station Ancillary Systems program.

TABLE 6: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Inspection data shows that the ancillary systems targeted in this program are at end-of-life and require frequent repairs ƒ Acquiring spare parts to maintain outdated station ancillary systems is becoming increasingly difficult ƒ Failure of ancillary systems has a potential to cause a failure of the associated station assets
Secondary Drivers	**Reasoning**
Functional Obsolescence	ƒ Ancillary systems targeted to be replaced in this program are obsolete ƒ Spare parts are no longer supported by their manufacturers ƒ Keeping these ancillary systems in service is increasingly difficult due to a lack of spare parts.
Safety	ƒ Unreliable fire alarm systems could impact the safety of personnel in the event of a station fire since personnel may not be notified early enough to leave the stations ƒ The safety of customers close to the stations could be at risk in the event of station fire since it is possible that fire can migrate out of the station to nearby areas.

(i) Failure Risk of Air Compressor Systems

In Toronto Hydro's distribution system, air compressor systems supply compressed air for air blast circuit breakers. The air compressor system of a station consists of two air compressors, two air receivers, a moisture separator, a drain system and an arrangement of pipes and valves, which together are designed to deliver compressed air to operate circuit breakers.

When the air blast circuit breaker is activated to clear a fault current, it uses the compressed air for both the opening of the arcing contacts and the quenching of the arc during interruption. The contacts close as soon as the air flow stops and are held closed by a spring. If the air compressor system fails, the breaker is unable to clear the fault and the fault current cascades upstream to the next protective device resulting in a sustained outage to the entire switchgear and all connected customers. Should the switchgear not be arc-resistant, adjacent cells and other nearby station equipment can face collateral damage risk, creating safety concerns for personnel on site.

Toronto Hydro has 20 air compressors currently in service in a number of its 4.16 kV and 13.8 kV stations. Inspection data shows that twelve of these air compressors are at the end of life. The number of major repairs performed on the air compressor population is shown in Figure 13. Toronto Hydro has kept these air compressors in service using spare parts from retired air compressors. However, these spare parts are finite and once Toronto Hydro runs out of them, it will be difficult to keep the air compressors in service to ensure a reliable operation of the existing air blast circuit breakers.

The air compressors are no longer being manufactured and spare parts are also no longer available. To address the risk of failure and functional obsolescence issues facing these air compressors, Toronto Hydro plans to proactively replace the obsolete air compressors with modern air compressors in order to mitigate the risk of a major failure which can cascade to a circuit breaker failure, which in turn can impact the switchgear it connected to it.

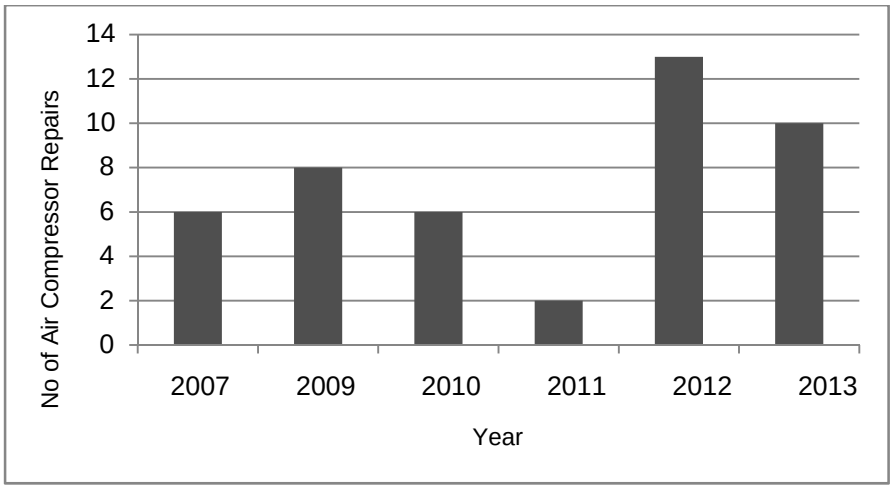

FIGURE 13: AIR COMPRESSORS REPAIR RATE

(ii) Flooding Risk to Below-Grade Service Equipment

Within the Toronto downtown core, station essential services (lighting system, heating and ventilation systems, fire alarm systems, battery charger systems and sump pump systems) are usually powered by two sources for contingency purposes. These sources could be two station service transformers connected to two different buses within the substation, or by one Toronto Hydro-owned station service transformer backed-up by either a Hydro One owned supply source or by Toronto Hydro's secondary network service connected to a different bus. In this arrangement, if one power source fails, the second source can still carry the load.

However, there are situations where the station service transformer and the associated secondary distribution panel, which supplies power to the station ancillary systems, are located in the basement, as is the case of George & Duke MS (see Figures 4 to 6), where the power supply to the station ancillary systems can be interrupted due to heavy rain that can flood the basement. If flooding occurs, the station service power supply system would fail. The failure of the station power supply would interrupt the functions of the ancillary systems of the station, impacting its safe and reliable operation. Failure of the essential station services can lead to long outages to 7,924 customers of George and Duke MS since the load cannot be transferred to adjacent station(s) because the station has no load transfer capability. This issue arose on July 8, 2013 when the City of Toronto received heavy rain that caused flooding, which impacted stations owned by Hydro One (HONI), resulting in long outages for up to 500,000 customers in the Etobicoke and downtown Toronto area. To avoid the risks associated with flooding, the station

service transformer and the associated secondary distribution panel and battery and charger system must be moved above grade. These assets were originally installed in the basement due to space constraints that existed in the station; however, as a result of load conversion and removal of station equipment, space is now available above ground level.

(iii) Fire-Related Risks

While Toronto Hydro takes precautions to prevent faults that can lead to a fire, the risk of station fires remains. Station fires can be initiated as a result of catastrophic failure of station equipment such as circuit breakers, oil insulated current transformers, and oil insulated pothead termination. To mitigate the risks of fire-related damage to station equipment and long outages for customers, Toronto Hydro has fire alarm systems installed in 32 stations. These stations have no load transfer capability, so that if a fire occurs in any one of these station and the power supply is disrupted as a result of the fire, the load cannot be transferred to adjacent station(s) as would be the case with other stations. As a result, fire alarm systems are installed to prevent or minimize the impact of fires initiated inside the station.

The fire alarm system detects fire at a very early stage, even before the presence of smoke, and notifies Toronto Hydro's power system controllers of the danger. System controllers can then take preventive actions such as sending personnel to the station to assess the situation and/or notifying the fire department. A functioning fire alarm system is therefore critical to preventing damage to station assets that could lead to catastrophic station failure, employee safety risks, and long outages for customers.

The affected stations are located in the congested downtown area of Toronto. Fire alarm systems were installed in these stations to not only protect Toronto Hydro's station assets and personnel on site, but to also enhance the safety of the general public in the area since it is possible for a fire to migrate off-site and impact the neighbourhood.

Out of the 32 fire alarm systems, Toronto Hydro plans to replace five which are functionally obsolete and at their end-of-life. Spare parts are no longer available from manufacturers, making it increasingly difficult to keep these alarm systems in service. The number of major repairs done on the fire alarm system population is shown in Figure 14, which supports the need for their replacement.

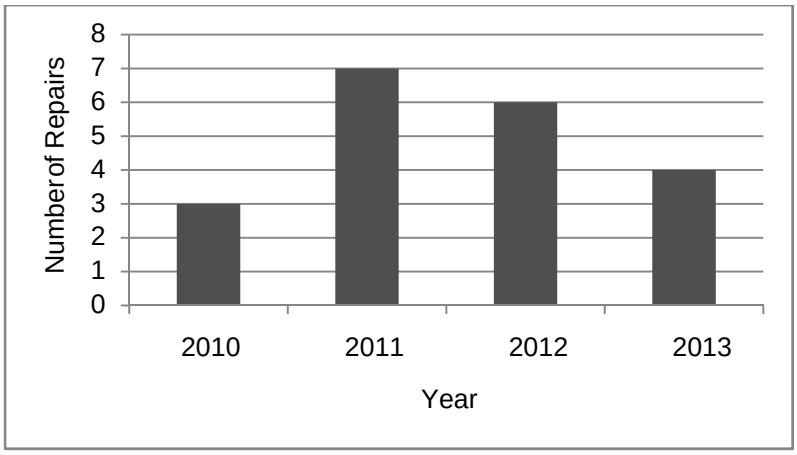

FIGURE 14: FIRE ALARM SYSTEM REPAIRS

TABLE 7: AGE OF FIRE ALARM SYSTEM IN PROGRAM

Station Name	Fire Alarm System Age in 2015 (years)
George & Duke MS	17
Dufferin TS	18
Charles TS	21
Glengrove TS	17
Terauley TS	17

Toronto Hydro also plans to install fire barrier system in stations with two or more transformers that do not have a fire barrier system to mitigate the risk of transformers being affected by a catastrophic failure of any neighbouring transformers.

Some of Toronto Hydro's municipal stations (MS) have no load transfer capability, and each is comprised of two or more transformer banks, which contain large volumes of flammable mineral oil. During a catastrophic transformer failure event, the transformer oil can be ignited by any number of sources including solid particles of insulation, internal component failure, or short circuit electrical arcing inside the tank. The energy released from the short circuit builds pressure inside the insulating oil and the tank raptures as a result of pressure build up. Once a rupture occurs, air rushes into the tank and the tank explodes, resulting in a blast scattering debris onto the surrounding area. This type of catastrophic failure can ignite neighbouring transformers. For example, in 2003, one of the transformers at Dupont MS failed catastrophically, causing a fire. The fire damaged the two adjacent transformers, as shown in Figure 15.

FIGURE 15: FIRE ALARM SYSTEM AGE PROFILE

Uncontained fires caused by catastrophic transformer failure can quickly result in the partial or total loss of the entire station, leading to lengthy outages to potentially thousands of customers. In addition, the cost of replacing damaged or burned station transformers ranges from $1.2 million to $3 million, depending on the size and voltage of the transformer.

Catastrophic transformer failures can be difficult to anticipate and prevent. Despite regular maintenance, transformers can fail catastrophically before warning signs are detected since the conditions that can create a catastrophic failure can develop in the transformer in between the maintenance cycles. However, collateral damage is preventable with the proper fire containment plan in place. Sound precautions include the installation of fire barrier systems or fire suppression systems.

Toronto Hydro plans to install fire suppression system at Cavanagh TS and a fire barrier wall at Strachan B municipal station to mitigate risk of collateral damage and long outages to the large number of affected customers as shown in Table 11.

The transformers at Cavanagh TS are two 125 MVA, transmission type transformers which step down voltage from 230 kV to 27.6 kV. A fire barrier wall was installed between the two transformers but a fire barrier wall could not be installed between the transformers and the

building where the switchgear is housed because of space limitations. However, according to the IEEE standard 979-1994, if large oil filled transformers are located between 20 and 50 ft of a building, the exposed walls of the building should constitute, or be protected by at least a 2 hour-rated fire wall. Even though the catastrophic failure of one of the transformers will not impact the second one due to the fire wall in place, it can impact the building where the switchgear of Cavanagh terminal station is located which can cause outages to all customers supplied by Cavanagh terminal station. Although the load of Cavanagh terminal station can be transferred to adjacent stations for a limited period of time, the transferred load will create an overload situation that can cause outage on the receiving stations during summer and winter peak time; this compounds the power outage issue. Toronto Hydro has no spare transformer to replace any of these transformers during emergency. The replacement cost of the affected switchgear will be at least $3M and it takes at least two years to replace them on a planned basis. Therefore, to avoid the risk associated with catastrophic failure of a transformer, it is necessary to install a fire suppression system that extinguishes any potential fire before it damages a transformer and spreads to the neighbouring switchgear building.

The City of Toronto formally asked Toronto Hydro to install fire barrier system between the Toronto Hydro owned transformers of Strachan B MS and the city owned Canadian National Exhibition (CNE) building which is very close to the transformers. The distance criteria between the transformers and the CNE building falls under the requirement of the IEEE standard 979-1994 mentioned earlier (see Figure 12) so fire barrier is necessary to protect the building from fire hazard caused by catastrophic failure of a transformer. Catastrophic failure of any of the transformers will impact the other two transformers and the CNE general building. Therefore, installation of fire barrier system in between the transformers and between transformers and the CNE general building is necessary to mitigate the reliability risk of Strachan B MS and the fire hazard to the CNE building.

Similarly the station service transformers of Glengrove terminal station are located very close to each other as shown in Figure 13 and if any one of them fails catastrophically, the second one will also be impacted hence, the power supply to all ancillary systems of Glengrove terminal station will be interrupted and this in turn will impact the safe and reliable operation of Glengrove terminal station. Therefore, to mitigate the risk, one of the transformers will be relocated to create space between each other so that if one of them fails catastrophically, the second one will not be impacted and will continue to supply power to the ancillary systems of the station.

E6.17.3.2 Asset Details

(i) Asset Lifecycle

The age profile for the in service air compressor population is shown in Figure 16.

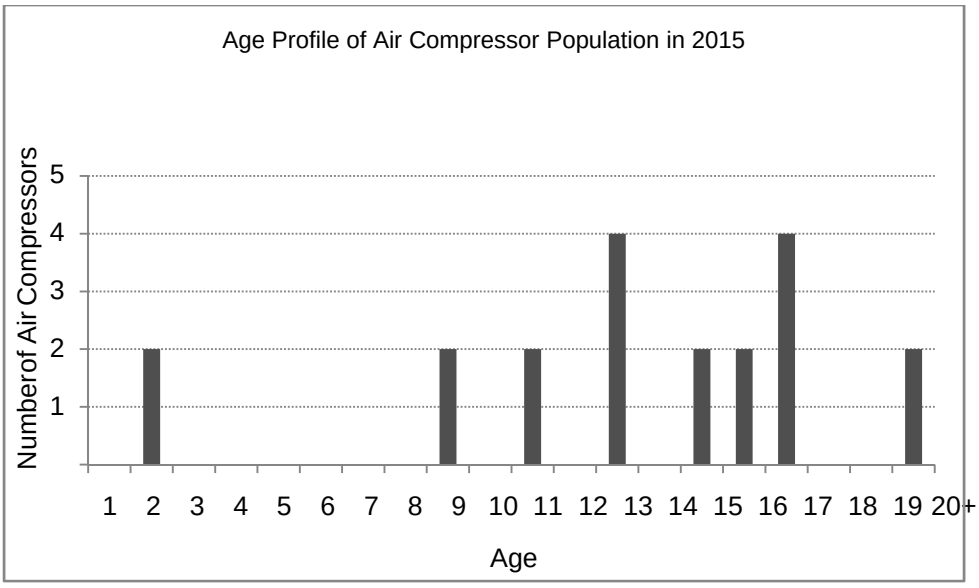

FIGURE 16: AGE PROFILE OF AIR COMPRESSOR POPULATION IN 2015

The age profile for the in-service fire alarm systems is shown in Table 8.

FIGURE 17: FIRE ALARM SYSTEM AGE PROFILE

(ii) Asset Failure Impacts

As discussed in Section E6.17.3.1, an air compressor system failure will result in a circuit breaker not being able to interrupt fault current, and therefore resulting in the fault cascading upstream and creating an outage to all customers connected to the switchgear. This type of outage can last for several hours. For example, in July 2012, an outage caused by the failure of a circuit breaker to clear a fault at George and Duke MS impacted over 6,000 customers connected to the switchgear for nearly eight hours.

TABLE 8: STATIONS REQUIRING AIR COMPRESSOR SYSTEM REPLACEMENTS

Station Name	Number of Customers Connected
High level MS	11,368
Windsor TS	5,536
Runnymede MS	4,025

If a station's fire alarm system fails, Toronto Hydro will not be notified of an actual fire unless (a) a member of the public reports the incident to emergency authorities or (b) damage to stations equipment caused by the fire triggers an alarm at the distribution control centre. In either case, there is substantial risk that fire damage to equipment will cause a significant power outage for customers since the load of any of these stations cannot be transferred to other adjacent station(s) like in the horseshoe areas.

In 2009 a fire occurred at Station J MS which had no load transfer capability. Since Station J MS had no fire alarm system and early intervention was not possible the fire consumed the station switchgear and the entire load was disrupted. (Fortunately in this case, most of the original Station J MS load had already been previously converted to a higher voltage supplied from another station, and the remaining load was converted and transferred to a higher voltage after the fire.) Reliable fire alarm systems are important for early intervention to minimize the impact of fire on the station equipment and on power supply to customers.

TABLE 9: STATIONS REQUIRING FIRE ALARM SYSTEM REPLACEMENTS

Station Name	No. of Connected Customers
George & Duke MS	7,924
Dufferin TS	20,013
Charles TS	7,851
Glengrove TS	11,298

Station Name	No. of Connected Customers
Terauley TS	1,151

The stations that require fire suppression systems to be installed either do not have load transfer capability or the transfer capability is limited. Typically, a station is supplied by two or three transformers such that if one fails, the remaining transformers carry the load. However, if one of the transformers fails catastrophically, impacting the remaining transformer(s), the station's entire load can be impacted and customers can experience long outages. For example, in 2003 one of the transformers at Dupont MS failed catastrophically causing a fire. The fire damaged the two adjacent transformers, as shown in Figure 15, and the entire station was lost due to collateral damage. Over 5,000 customers were without power for several hours because Dupont MS did not have load transfer capability. To prevent similar events from occurring, fire barrier or fire suppression systems are needed at Cavanagh terminal station.

TABLE 10: STATION REQUIRING FIRE BARRIER/SUPPRESSION SYSTEM INSTALLATION

Station Name	No. of Customers connected
Cavanagh TS	16,393
Strachan B MS	2,118
Glengrove TS	12,647

A failure of the power supply to ancillary systems will render those systems incapable of supporting the reliable operation of the distribution station. A failure of the power supply to the ancillary systems will cause the battery and charger system and the air compressor system, which are critical to the reliable operation of the station, to stop giving the operational support required by the station to provide a reliable power supply to customers.

TABLE 11: STATION REQUIRING STATION POWER SUPPLY IMPROVEMENT

Station Name	No. of Customers Connected
George & Duke MS	7,924

E6.17.4 Timing & Pacing of the Program

The ancillary systems that are targeted to be replaced and the new ancillary systems proposed to be installed over the next five years are shown in Table 4 and the associated estimated cost is shown in Table 12.

TABLE 12: HISTORICAL AND FUTURE SPENDING OF STATION ANCILLARY SYSTEMS

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.15	0.12	0.24	0.63	0.22	0.69	0.59	0.37	0.26	0.38

The air compressors planned for replacement in 2015 serve large customers in the downtown financial district. Inspection data shows that these air compressors are deteriorating and to secure their reliable operations, these air compressors must be given higher priority. The air compressors planned for replacement in 2018 are associated with lower risk, since the load of the station is expected to be reduced as a result of 4.16 kV to 13.8 kV load conversion, meaning that these air compressors will not operate as often as the air compressors planned for replacement in 2015.

The installation of the fire barriers is prioritized based on the magnitude of impact in terms of asset replacement cost and number of customers that will be impacted in the event of catastrophic failure of transformers. Fire suppression systems are planned for installation at Cavanagh TS in 2015 and Strachan B MS and Glengrove TS to in 2016.

Relocation of the below grade station service power supply at George and Duke MS is planned for 2015. These assets are currently vulnerable to flooding. Toronto plans to replace fire alarm systems from 2017 – 2019, beginning with those that are the oldest and most deteriorated.

E6.17.4.1 Ranking & Prioritization

Ancillary assets to be replaced were prioritized based on:

- asset failure risk – assets that are in poor condition and requiring frequent repair
- asset obsolescence – assets that are no longer manufactured and for which spare parts are no longer available
- number of customers that could be impacted due to asset failure
- level of flooding and fire risks

Ancillary systems in the stations where the load will be converted from 4 kV to 13.8 kV or that have scheduled switchgear replacement (in the case of air compressor replacement, the air blast

circuit breakers could be replaced with vacuum circuit breakers when switchgear is replaced) in the foreseeable future are not included as part of the program. Replacement of ancillary systems was prioritized based on the asset condition and magnitude of impact in the event of failure. Installation of new ancillary systems was prioritized based on the magnitude of impact if assets fail catastrophically.

E6.17.5 Program Execution

The projects planned under this program will be designed by Toronto Hydro station designers. After all necessary design drawings and documents are prepared, work will be issued for construction. Some of the jobs, such as fire alarm systems and fire barrier/suppression systems would typically be executed by external contractors, while the remainder (air compressor systems, power supply systems) would typically be completed by Toronto Hydro crews.

The replacement of the air compressors and fire alarm systems will require no station equipment outages, but the suppression system to be installed at Cavanagh TS will require temporary station outages, in which case the associated load will need to be transferred to adjacent stations. This load transfer will require coordination with HONI and will be completed during low load season to safeguard the reliability of the power supply under contingency. The relocation of station power supply at George & Duke MS requires that new station service power supply and distribution panel to be installed first, then the load will be transferred to the new power supply system followed by the decommissioning of the existing power supply system.

E6.17.5.1 2015-2019 Long Term Plan

The long term ancillary system replacement/installation program is shown in Table 13.

TABLE 13: 2015-2019 LONG TERM PLAN

Year	Station	Project Type
2015	High Level MS	Replacement of 2 Air compressors
2015	Windsor TS	Replacement of 2 Air compressors
2015	Cavanagh TS	Installation of Fire suppression system
2016	Strachan B MS	Installation of Fire barrier system
2016	Glengrove TS	Installation of Fire barrier system
2016	George & Duke MS	Relocation of below-grade ancillary system
2017	Dufferin TS	Replacement of Fire alarm system

Year	Station	Project Type
2017	George & Duke MS	Replacement of Fire alarm system
2018	Charles TS	Replacement of Fire alarm system
2018	Runnymede MS	Replacement of 2 Air compressors
2019	Glengrove TS	Replacement of Fire alarm system
2019	Terauley TS	Replacement of Fire alarm system

E6.17.5.2 Program Risks

The implementation of the Station Ancillary Systems Program, especially the installation of fire suppression system at Cavanagh TS, requires HONI's involvement. The load of Cavanagh TS which is owned by Toronto Hydro will need to be transferred to HONI owned station(s) so HONI needs to be closely involved during the load transfer. However, if HONI's work plan does not align with Toronto Hydro's, the execution of the program will be delayed. This issue can be mitigated by Toronto Hydro by discussing the project with HONI in advance and establishing a mutually agreed upon implementation plan at the early stages of the program.

E6.17.6 Evaluation of Alternatives

E6.17.6.1 Quantification/ Evaluation of Options

(i) Option 1: Status Quo

Maintaining the status quo involves utilizing existing obsolete ancillary systems until they fail. Since the condition of the ancillary systems are deteriorating, keeping them in service, especially as the availability of spare parts diminishes, presents a number of risks, including failure. Failure of the ancillary systems to provide support to the stations can lead to unreliable stations and increased safety risks. In turn, this could impact the reliability of the power supply to customers connected to those stations. Due to the potential high cost of equipment replacement and long outages to customers as a result of catastrophic transformer failure associated, this option is not recommended.

(ii) Option 2: Replace/Install Ancillary Systems

Replacing deteriorating ancillary systems and installing new ones where needed facilitates the safe and reliable operation of Toronto Hydro stations. It is prudent to take this course of action because it allows Toronto Hydro to be able deliver a consistent power supply to customers in an efficient and cost-effective manner, while also protecting the safety of its staff and the general public.

The cost of ownership (COO) and program net benefit (NPV) associated with ancillary systems program is further detailed in Table 14. The cost of ownership is established for both the existing state (COO_E), and the proposed new state (COO_N) based on the first year of planned activities in this program. The COO of a state reflects the risk of asset failure, including both direct and indirect costs. These costs include the customer interruptions, emergency repairs, and asset replacements associated with a given design. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3.

TABLE 14: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$3.98
Non Asset Risk [NAR_E]	$0
Maintenance Cost [MC_E]	$0
Additional Quantifiable Benefits [AQB_E]	$0
Cost of Ownership of Existing Assets [COO_E]	$3.98

When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the ancillary systems program produces a net benefit (NPV) value of $1.53 million, as shown in Tables 14 and 15.

TABLE 15: NEW CASE BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 2:	
Asset Risk [AR_N]	$1.76
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0
Additional Quantifiable Benefits [AQB_N]	$0
Cost of Ownership of New Assets [COO_N]	$1.76
Option 2: Project Net Benefit (NPV $_2$)	
Difference in Cost of Ownership [$\hat{u}COO_2 = (COO_E - COO_N)$]	$2.22
Program Cost [PC_1]	$0.69
Program Net Benefit [NPV $_1 = (\hat{u}COO_1 - PC_1)$]	$1.53

E6.17.7 2015 Projects

Table 16 lists the 2015 projects for the Stations Ancillary Systems program.

TABLE 16: 2015 PROJECTS

Project Number	Project Name	Cost	Start Date	Project Type (2014 Carry-over or 2015 New)
29860	High Level MS: Replace 2 Air Compressors	$0.11 M	2015	CIR
29857	Windsor TS: Replace 2 Air Compressors	$0.11 M	2015	CIR
30519	Cavanagh TS: Install Fire Suppression System	$0.31 M	2015	CIR
11491	Jane MS: Install Firewall barrier	$0.15 M	2015	CIR

E6.17.7.1 S15340 Project Description

Investment Category: System Renewal

Program: Stations Ancillary Systems

Project Title: High Level MS: Replace 2 Air Compressors

Project Number: S15240

Project Year: 2015

Estimated Cost: $0.11 million

(i) Objective

The objective of this project is to replace the two air compressors at High Level TS.

(ii) Scope of Work

TABLE 17: S15240 SCOPE OF WORK DETAILS

District Neighborhood	TORONTO
Station(s)	HIGH LEVEL MS
Feeder(s)	NA

TABLE 18: S15340 ASSETS REPLACED

Assets (Units)	2015
Air Compressor	2

(iii) Justification & Benefits

The existing air compressors at High Level MS are 15 years old and inspection and maintenance data shows that they are deteriorating and are obsolete. Spare parts for these air compressors are no longer available from the manufacturer and it is becoming increasingly difficult to maintain these units in good working condition. Therefore, the air compressors must be replaced in order to secure the reliable operation of the air blast circuit breakers.

E6.17.7.2 S15345 Project Description

Investment Category: System Renewal

Program: Stations Ancillary Systems

Project Title: Windsor TS: Replace 2 Air Compressors

Project Number: S15245

Project Year: 2015

Estimated Cost: $0.11 million

(i) Objective

The objective of this project is to replace the two air compressors at Windsor TS.

(ii) Scope of Work

TABLE 19: S15245 SCOPE OF WORK DETAILS

District Neighborhood	TORONTO
Station(s)	WINDSOR TS
Feeder(s)	NA

TABLE 20: S15245 ASSETS REPLACED

Assets (Units)	2015
Air Compressor	2

(iii) Justification & Benefits

The existing air compressors at Windsor TS are 16 years old and inspection data shows that they are at the end of their lives and are obsolete. Spare parts for these air compressors are no longer available from the manufacturer and it is becoming increasingly difficult to maintain these units in good working condition. Therefore, the air compressors need to be replaced in order to secure the reliable operation of the air blast circuit breakers.

E6.17.7.3 S15564 Project Description

Investment Category: System Renewal

Program: Stations Ancillary Systems

Project Title: Cavanagh TS; Install Fire Suppression System

Project Number: S15564

Project Year: 2015

Estimated Cost: $0.31 million

(i) Objective

The objective of this project is to install a fire suppression system at Cavanagh TS.

(ii) Scope of Work

TABLE 21: S15564 SCOPE OF WORK DETAILS

District Neighborhood	SCARBOROUGH
Station(s)	CAVANAGH TS
Feeder(s)	NA

TABLE 22: S15564 ASSETS REPLACED

Assets (Units)	2015
Fire Suppression System	1

(iii) Justification & Benefits

The power transformers at Cavanagh TS are unique to Toronto Hydro. Toronto Hydro does not have spare transformers to replace these transformers if they fail. As well, there is currently no fire suppression system in place to prevent fire from spreading and damaging the switchgear building and the switchgear inside it if any of the transformers fail catastrophically. To prevent a loss of service due to fire, it is necessary to install a fire suppression system.

E6.17.7.4 S11491 Project Description

Investment Category: System Renewal

Program: Stations Ancillary Systems

Project Title: Jane MS: Install Firewall barrier

Project Number: S11491

Project Year: 2015

Estimated Cost: $0.15M

(i) Objective

The objective of this project is to install firewall barrier at Jane MS.

(ii) Scope of Work

TABLE 23: S11491 SCOPE OF WORK DETAILS

District Neighborhood	TORONTO
Station(s)	JANE MS
Feeder(s)	NA

TABLE 24: S11491 ASSETS INSTALLED

Assets (Units)	2015
Fire suppression system	1

(iii) Justification & Benefits

Jane MS is located in the residential area and the transformers of Jane MS are very close to residential homes. In the event of a catastrophic transformer failure, fire could migrate to these residential houses. There is currently no firewall to protect the neighboring residents and their homes, so a fire wall must be installed between the transformers and these houses.

E6.18 Station Building Infrastructure

DETERIORATED STATION BUILDING

E6.18.1 Summary

Program Description

This program addresses 11 stations in the downtown Toronto area that are showing multiple signs of structural deterioration. Recent civil assessments revealed evidence of deteriorated foundations, cable pit areas and roof structures that require immediate intervention. Multiple examples of cracks in the brick masonry walls were also noted. These deficiencies present an increased risk of water infiltration, moisture ingress, compromised structural integrity, rodent infestation, building security deficiencies and other potential safety hazards. Toronto Hydro plans to repair and/or replace the identified critical structural and foundation issues in the stations to minimize the risks associated with water infiltration and to improve structural integrity.

Table A summarizes the benefits associated with this capital investment program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigation of security, safety and reliability risks with respect to the valuable assets housed inside these buildings.
Reliability	ƒ Mitigation or elimination of substructure damage, cracked walls and ceilings, leaking roofs and other identified issues in the selected stations will improve the station buildings' ability to protect assets and the crew housed within.
Safety	ƒ Water infiltration can cause flooding in buildings and damage to electrical equipment, resulting in electrical short-circuit/arching, or equipment failure. ƒ Weak foundations, and/or cracked walls can cause buildings to collapse, resulting in equipment damage and risking both worker and public safety. ƒ Broken or damaged doors and windows expose the building to external elements, which can cause serious damage to the equipment housed within. ƒ Compromised doors and windows can also lead to increased incidents of unauthorized entry to premises, a definite security concern.
Efficiency	ƒ Cost containment - repair and resource costs can be proactively managed. ƒ Superior equipment efficiency and a reduction in equipment failure via improved HVAC systems that will allow equipment to operate as intended ƒ Improved building life expectancy via the integration of new and improved building materials and construction practices.
Other Benefits	ƒ The majority of the identified buildings are designated as historic structures by the City of Toronto. Accordingly, investment is designed to maintain the historic value of the designated building.

Program Drivers

The trigger driver of the Station Building Infrastructure program is the risk associated with the building's ability to protect and safeguard the equipment and crew housed within.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Water infiltration into the station building, compromising the equipment housed within. ƒ Compromised building structural integrity. ƒ Building security deficiencies due to broken doors and windows.
Secondary Driver	**Reasoning**
Safety	ƒ Water infiltration can result in short circuit, arcing and/or catastrophic failure of electrical equipment, including electrical fires, which are hazardous to Toronto Hydro crews and the community/general

	public surrounding the building. ƒ Aged and deteriorating foundational/structural elements of the building may result in station building collapse, causing harm to the equipment, crew, and the public. ƒ Damaged/deteriorated building access stairs may cause a worker to trip and fall.

Preferred Alternative

Toronto Hydro considered two options in developing its plan: 1) maintain the status quo or 2) correct deficiencies. Maintaining the status quo with minimal maintenance and making reactive repairs was determined to be unsatisfactory. By pursuing this alternative, Toronto Hydro would see its facilities continue to age and deteriorate over time, ultimately leading to substantial issues requiring expensive solutions. The integrity of these stations cannot be adequately maintained without capital investment during the 2015-2019 period. Taking a proactive approach to improve existing station buildings is expected to extend their serviceable life and to cost less than other solutions considered.

The completion of the first year of activities in this program will result in an avoided estimated risk cost (ARC) of $0.65 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.18.7).

Timing and Pacing

Toronto Hydro has been able to prudently manage deterioration and/or damaged station building components on a reactive manner in the past. However, the average age and condition of the utility's station buildings has reached the point where a more robust renewal program is required. A steady investment program is required, beginning in 2015, so that the utility can pace the capital investments over a number of years and avoid the accumulation of a more difficult to manage backlog of renewal needs toward the end of the forecast period. Toronto Hydro proposes to repair and/or replace the identified structural deficiencies over the 2015 to 2019 period at a total cost of $11.1 million, as shown in Table C.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	$0	$0	$0.53	$0.003	$0.16	$0.5	$2.5	$2.3	$2.6	$3.3

E6.18.2 Program Description

The Station Building Infrastructure program proposed for 2015 to 2019 consists of work to correct noted deficiencies as identified in a civil assessment, which entails the required restoration of failing building components that are showing signs of deterioration. Since their construction in the early 20th century, the industry has seen improvements in building standards and materials used for construction. With the completion of the proposed work, Toronto Hydro expects to see an increase in overall building life expectancy by incorporating current standards and modern materials in their construction. As well, the proposed program is expected minimize, and in some cases eliminate, risks associated with the dilapidated condition of the stations.

This program focuses primarily on the structural integrity of station buildings, which, when deteriorated, can have a negative impact on the performance and safe operation of electrical equipment. Of particular concern are issues related to water infiltration, moisture ingress, structural integrity, rodent infestation, building security deficiencies and other potential safety hazards. Occurrence of any of these events has the potential to cause damage to impacted electrical equipment and can increase repair costs needed with respect to reactive work and loss of power to customers.

Pictures taken at Carlaw and High Level stations during a civil assessment (November and December 2013), illustrate some of the identified issues and concerns that Toronto Hydro plans to rectify:

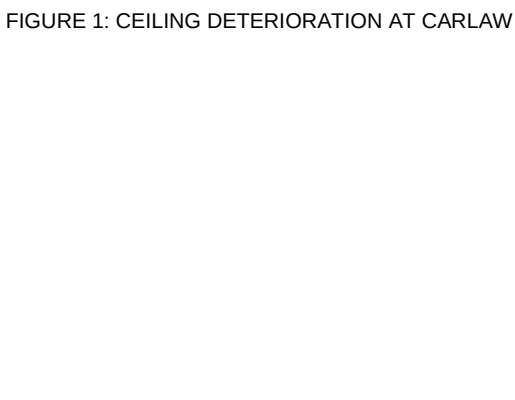

FIGURE 1: CEILING DETERIORATION AT CARLAW

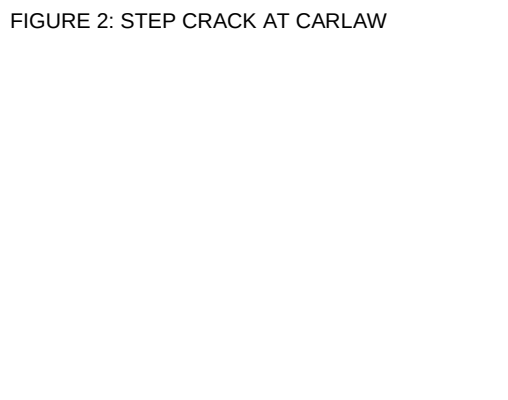

FIGURE 2: STEP CRACK AT CARLAW

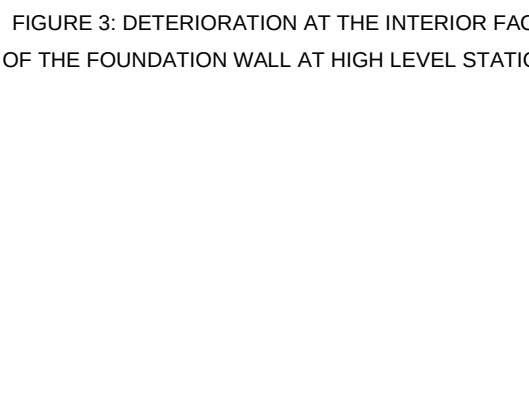

FIGURE 3: DETERIORATION AT THE INTERIOR FACE OF THE FOUNDATION WALL AT HIGH LEVEL STATION

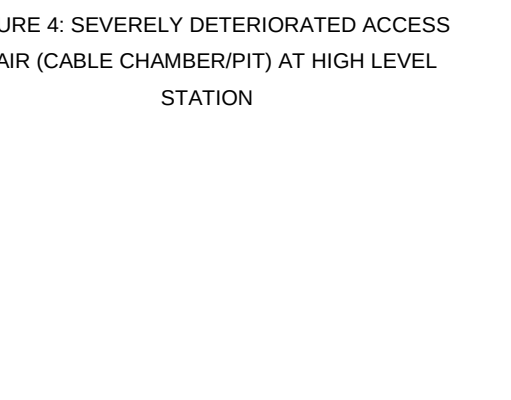

FIGURE 4: SEVERELY DETERIORATED ACCESS STAIR (CABLE CHAMBER/PIT) AT HIGH LEVEL STATION

FIGURE 5: DAMPNESS, PAINT PEELING, DELAMINATION AND SPALLING AT HIGH LEVEL STATION

FIGURE 6: GUTTER SECTIONS DAMAGED DUE TO SNOW AND ICE

Toronto Hydro's Station Building Infrastructure program targets eleven stations with critical deficiencies that require immediate attention. As buildings age, it is impractical and financially infeasible to replace them with new structures. Instead, maintenance and upkeep is needed to preserve structural integrity. By investing in and maintaining building infrastructure, critical electrical equipment is better protected against water ingress, rodent infestation and security breaches, which all can cause harm to electrical equipment. If the electrical equipment in stations is damaged, customers are likely to be directly impacted by prolonged outages across multiple feeders.

Well maintained building infrastructure and well-protected equipment keeps customers and the general community safe from various hazards that can arise if building infrastructure and/or equipment is compromised. Given that the identified station buildings are located in the former City of Toronto, a densely populated area, they are in close proximity to densely populated communities. Water and/or moisture ingress due to failed building infrastructure could easily cause a short circuit, resulting in a fire and/or a catastrophic equipment failure, posing a serious safety risk to workers, the public and nearby structures.

Through the Station Building Infrastructure program, Toronto Hydro plans to make investments to mitigate the risk of a potentially catastrophic failure and avoid costly reactive repair and restoration work. The following table summarizes the expected benefits of this program.

TABLE 1: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigation of security, safety and reliability risks with respect to the valuable assets housed inside these buildings. ƒ The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $0.65 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.18.7).
Reliability	Mitigation or elimination of substructure damage, cracked walls and ceilings, leaking roofs, inefficient heating, ventilation and air-conditioning systems, damaged windows, and other identified issues improves the ability of stations buildings to protect assets and the crew housed within. Otherwise, the aforementioned issues can: ƒ lead to water ingress, resulting is damage to equipment, compromised crew safety, and corroding building structural elements such as support beams; ƒ invite rodent infestation due to broken and/or damaged doors and windows; ƒ impact crew safety due to uneven and/or deteriorating pavement and stairs; and ƒ create neighboring public safety concerns due to station building fires that might be caused by a short-circuit.
Safety	The following concerns will be addressed by the program, which will improve overall safety: ƒ Water infiltration can cause flooding in buildings and damage to electrical equipment, resulting in electrical short-circuit/arching, or equipment failure. These events risk worker safety and can potentially harm people and structures nearby. ƒ Weak foundations, and/or cracked walls can cause buildings to collapse, resulting in equipment damage and risking both worker and public safety. ƒ Holes and cracks in foundations and walls can allow rodent infestation to occur. Rodents create unsanitary conditions for workers and can damage cables/equipment. ƒ Broken or damaged doors and windows expose the building to external elements, which can cause serious damage to the equipment housed within. Compromised doors and windows can also lead to increased incidents of unauthorized entry to premises, a definite security concern. ƒ Settled and failed interlock paving and asphalt can cause water accumulation, increasing the risk of slip, trips, and falls.
Efficiency	The following efficiency benefits are generated by the program: ƒ Cost containment - repair and resource costs can be proactively managed. ƒ Superior equipment efficiency and a reduction in equipment failure via improved HVAC systems that allow equipment to operate as intended ƒ Improved building life expectancy via the integration of new and improved building materials and construction practices.

Other Benefits	ƒ The majority of the identified buildings are designated as historic structures by the City of Toronto. Accordingly, investment is designed to maintain the historic value of the designated building.

Figure 7 is a map showing the location of the identified stations that are addressed in the Station Building Infrastructure program.

FIGURE 7: STATION LOCATIONS

E6.18.3 Why the Program is Needed

Transformer stations (TS) and municipal stations (MS) serve a critical purpose in Toronto's distribution system; these stations contain power transformers, switchgear, station controls, fire protection and security systems, cable pits, racks and associated cable ingress/egress structures

– items that are essential to the safe and reliable delivery of electricity to customers throughout the system.

Electricity demand continues to increase along with the growing population of the City of Toronto. To meet the increasing demand efficiently and reliably, Toronto Hydro is relying largely on a diminishing amount of spare stations capacity, complimented by expansion of stations capacity where economical and the renewal of existing stations assets that are at or nearing end-of-life. In order to protect the value of these investments and to continue addressing the energy needs of a growing customer base, station buildings must be maintained in good working order throughout the useful life of the equipment contained within.

The goal of the Station Building Infrastructure program is to bring the identified stations – those with the most severely deteriorated infrastructure – to an acceptable industry standard by addressing the deficiencies noted as part of a civil assessment. The severity of deterioration as identified in the assessment can be seen in the Figures 8 to 19 below.

FIGURE 17: CONCRETE SOFFIT SPALLING AT CARLAW SUBSTATION

FIGURE 18: EXTENSIVE WALL DETERIORATION AT CARLAW SUBSTATION

FIGURE 19: CABLE CHAMBERS/PITS SHOWING SIGN OF WATER INFILTRATION AT CARLAW

By taking a proactive approach to addressing station building infrastructure deficiencies, Toronto Hydro can better plan and manage its workload and costs, and can reduce unexpected disruptions and issues relating to these assets. If steps are not taken to address the noted deficiencies, Toronto Hydro is likely incur higher costs associated with managing building or equipment failure and customers are likely to face an elevated risk of power disruptions due to failures. There are also potential worker and public safety risks. Toronto Hydro expects that this program faciliate improved safety, system reliability and efficiency. As can be seen in Figures 8 to 19 above, the identified work is complex and requires a proactive approach and planning.

E6.18.3.1 Program Drivers

The primary function of a station building is to provide protection from the elements, wildlife and intruders for station crews at work and the critical stations assets housed within. Components of the 11 station buildings targeted in this program are approaching a level of deterioration that could compromise the integrity of these essential building functions. The goal of the Station Building Infrastructure program is to proactively address the building infrastructure elements that are at risk of failure, thereby mitigating the associated risks to safety and reliability. The table below explains the trigger and secondary drivers of the program.

TABLE 2: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	x Many of Toronto Hydro's stations buildings we constructed in the early to mid-1900s, with some buildings currently over 100 years old. x An assessment of these buildings indicates the need to proactively address deficiencies in order avoid the risk of failure. x Deteriorated building infrastructure can result in: o water infiltration into the station building, compromising the equipment housed within, o electrical outages, o compromised building structural integrity, o rodent Infestation, and o building security deficiencies due to broken doors and windows.
Secondary Driver	**Reasoning**
Safety	The identified stations pose a heightened safety risk to workers, the community because: x water infiltration can result in short circuit, arcing and/or catastrophic failure of electrical equipment, including electrical fires, presenting a safety risk/hazard to Toronto Hydro crews and the general public surrounding the building, x aged and deteriorating foundational/structural elements could station buildings to collapse, and x damaged/deteriorated building access stairs increase the risks of trips and falls

The trigger driver of the Station Building Infrastructure program is the risk associated with the building's ability to protect and safeguard the equipment and crew housed within. The 11 stations covered by this program represent the highest risk stations in the fleet because of their respective conditions, age, loading, and impact to customers. The civil assessment provides evidence of deteriorated foundations, cable pit areas and roof structures. These deficiencies present an increased possibility of water infiltration, moisture ingress, compromised structural integrity, rodent infestation, building security deficiencies and other potential safety hazards. Water sources include seasonal snowmelt, heavy rains, high ground water levels and failure of adjacent municipal water pipes and storm sewers. The water related issues raise the risk of flooding and/or moisture in stations, which can cause the failure of station electrical equipment due to short-circuit events and ground faults. In short, water ingress, as seen in the pictures below, into the energized substation equipment could cripple the functioning of a station.

The civil assessment also provided Toronto Hydro with examples of severe structural deficiencies (for example Figure 18 shows damage to the windowsill at Carlaw station, which could cause severe damage, up to and including the wall collapsing, if not addressed). Foundation cracks noted in the civil assessment also point to the possibility of rodent infestation within station building, as they allow a pathway into the station building, and access to electrical equipment and cables housed within. Multiple signs of water ingress were also identified, e.g., Figures 20 and 21.

FIGURE 20: WATER PENETRATION THROUGH CABLE DUCK BANK AT HIGH LEVEL STATION

FIGURE 21: WATER PONDING, STAINING AND SEDIMENTATION AT HIGH LEVEL STATION

Toronto Hydro strives to maintain its existing station buildings and its components on an ongoing basis, but many of the station building components are approaching, and in some cases exceeding, their useful lives, thus increasing the burden and frequency of ongoing maintenance. These buildings require investments in the near-term so that Toronto Hydro can maintain system reliability, minimize unplanned outages and mitigate potential safety risks. The level of investment is intended to return the stations to a stable state where standard maintenance would keep them in good working order.

E6.18.3.2 Asset Details

Toronto Hydro assessed the current condition and expected service life of station buildings. Based on these inspections, the Station Building Infrastructure program was developed to target station buildings that are in the worst and/or most critical condition and those that pose substantial risk to Toronto Hydro's operations during the 2015-2019 period.

(i) Asset Lifecycle

The identified stations were constructed in the early and mid 1900s. Table 3 shows the year of construction and the age of the building as of 2014.

TABLE 3: YEAR OF CONSTRUCTION AND AGE OF STATION BUILDINGS

Station Name	Construction Year	Age in Years (as of 2014)
High Level MS	1910	104
Carlaw TS	1916	98
Terauley TS	1929	88
George & Duke MS	1929	85
Windsor TS	1950	64
Glengrove TS	1930	84
Junction MS	1910	104
Danforth MS	1967	47
Duplex TS	1967	47
Dufferin TS	1957	57
Wiltshire TS	1923	91

Each building is unique and has been assessed on an individual basis. The station buildings listed above have been selected for detailed assessment based on a number of factors, including: facility age, severe foundation deterioration, significant flooding risk and a potential for highest risk impact to customers. Even though ongoing maintenance has been performed, the station buildings each exhibit heightened degree of deterioration to their various components. These buildings retain certain components that date back to their original construction (e.g., foundation, walls, doors/windows, site work), and are showing signs of age and deterioration. The pictures below taken at Terauley and High Level stations, for example, show extensive signs of corrosion and damage at the foundation walls.

FIGURE 22: EFFLORESCENCE AND CORROSION AT THE FOUNDATION WALLS OF TERAULEY STATION

FIGURE 23: EFFLORESCENCE AND CORROSION AT THE FOUNDATION WALLS OF TERAULEY STATION

FIGURE 24: CORRODED SUPPORT STEEL POST AT HIGH LEVEL, SOUTH CHAMBER.

FIGURE 25: DAMAGED AND DETERIORATED TERRAZZO IN THE BASEMENT AT HIGH LEVEL STATION

(ii) Asset Failure Impacts

As identified in Table 3 above, the majority of the stations identified were constructed in the early 1900s and retain some of their original elements – elements that are showing signs of

deterioration, and that are in need of repair and/or restoration above and beyond ongoing reactive maintenance work. Water infiltration, flooding, and roof leaks have been identified at some of the stations, problems which are generally caused by failing building infrastructure components. These events increase the risk of station electrical equipment failure due to short-circuit events and ground faults, and pose a safety risk to employees and the public.

Water ingress occurred at Terauley Station in January 2005 and at Dufferin Station in January 2009, causing system outages, as further detailed below. These two recent examples demonstrate the damage that water ingress/flooding can cause to the equipment housed within the station building, the outages that can occur and the reactive work that needs to be performed, i.e., potential damage that flooding/water ingress can cause.

- Terauley Station Outage: On January 23, 2005 Terauley Station experienced water ingress that contributed to a station outage. Over 3,500 customers were affected for over a ten-hour period while the repairs were made, and the power restored. Further analysis into the cause pointed to a nearby ruptured water main, resulting in water ingress through the cable ducts. Terauley Station had to be removed from service for approximately 10 hours to pump the excess water out of the station, causing extensive and extended customer inconvenience, including the time and cost associated with reactive repair work incurred by Toronto Hydro.

- Dufferin Station Outage : In January 2009, Dufferin Station experienced a ruptured deluge system on the main level, causing damage to multiple switchgears in the basement of the station building. These events led to a substantial outage that affected 34,000 customers. Water was extracted from the basement in a timely manner, repairs made, and the power was restored, but this incident gave Toronto Hydro a good insight into the damage that can be caused by any form of water ingress into the station building.

Water infiltration into a station building occurs due to damaged or deteriorated building components, such as deteriorating roof and eaves trough conditions, broken or damaged doors and windows, cracked or damaged building and foundation walls, and may also be caused by uneven area paving and drainage system that fails to remove the water away from the building. This program plans to restore these station building components, as identified in the recently performed civil assessment.

FIGURE 26: WATER INFILTRATION AS NOTED AT HIGH LEVEL STATION

FIGURE 27: WALL AND ROOF SLAB SOFFIT DETERIORATION DUE TO WATER INFILTRATION AT HIGH LEVEL STATION

FIGURE 28: OVERVIEW OF THE COMPLETED REPAIR WHERE A ROOF LEAK HAS BEEN REPORTED. TERAULEY STATION ROOF.

FIGURE 29: TARGET MEMBRANE FLASHING FOR A DRAIN SEPARATING FROM THE FIELD. POTENTIAL FOR WATER INFILTRATION (HIGH LEVEL ROOF)

Substructure integrity, which includes building foundations and basement condition are vital to the overall strength of the building structure. Any signs of deterioration to this element of the station building needs immediate attention, as the safety and integrity of the entire building and its

contents are at risk. These are complex jobs, and require a proactive, planned approach to rectify the identified issues.

FIGURE 30: CABLE CHAMBER WALL AND ROOF FRAMING DETERIORATION AT HIGH LEVEL STATION

FIGURE 31: SETTLED SIDEWALK AND FAILED MORTAR JOINTS IN THE WALL/SIDEWALK JUNCTION AT HIGH LEVEL STATION

FIGURE 32: PAINT PEELING AT HIGH LEVEL STATION

FIGURE 33: DAMAGE TO THE CONCRETE STAIRS IN THE SOUTH CABLE CHAMBERS AT HIGH LEVEL STATION

Access to the building was studied to gain a better understanding of the safety issues facing the general public and workers. One specific point of emphasis was recessed and uneven ground that holds water; this condition can lead to improper drainage that can damage the building.

FIGURE 34: EXAMPLE OF FAILED MORTAR JOINTS AT THE EXTERIOR STEPS TO THE MAIN ENTRANCE AT HIGH LEVEL STATION.

FIGURE 35: FAILING MORTAR JOINTS, LEADING TO WATER INFILTRATION

The identified station buildings are located in the densely populated areas and serve a large number of customers. Any building component failure that has a potential of causing damage to equipment, such as water infiltration causing short circuits or collapsed support beams due to corrosion, can result in customer outages with long durations. Table 4 below shows the number of customers that could be affected by station building related outages. The costs associated with repair, both to the equipment and building can be substantial.

TABLE 4: NUMBER OF CUSTOMERS AND LOAD

Station Name	Station Address	Number of Customers	Peak Load (MVA)
High Level	292 MacPherson	7,010	144
Carlaw	369 Carlaw Avenue	10,600	75
Terauley	532 Bay Street	1,148	190
George & Duke	233 Adelaide St. East	6,330	311
Windsor	253 Wellington Street West	3,749	311
Glengrove	2829 Yonge Street	9,830	66
Junction	20 Ruskin Avenue	4,976	18.6
Danforth	2357 Danforth Ave	3,254	17
Duplex	390/400 Duplex Ave	9,286	109
Dufferin	1047 Dufferin St	29,038	141
Wiltshire	39 Wiltshire Ave	541	51

Collectively, these stations serve 85,762 customers and 1433.6 MVA of peak load.

Generally, any repair work due to water ingress in a station building requires the entire station to be deactivated due to safety concerns. While Toronto Hydro plans to attempt to restore power to all affected customers by transferring load during repair work, it is important to note that load transfer may not always be possible.

E6.18.4 Timing & Pacing of the Program

Toronto Hydro has been able to prudently manage deterioration and/or damaged station building components on a reactive manner in the past. However, the average age and conditions of the utility's station buildings have now reached a point where a more robust renewal program is required. As noted above, the recently conducted civil assessment gave Toronto Hydro a more comprehensive look at station building conditions, and has highlighted elements that need to be addressed in a planned fashion (e.g., foundational and/or structural repair work) so as to minimize the impact to customers. A steady investment program is required, beginning in 2015, so that the utility can pace the capital investments over a number of years and avoid the accumulation of a more difficult to manage backlog of renewal needs toward the end of the forecast period.

Toronto Hydro plans to address the identified deficiencies associated with each of the eleven targeted stations over the 2015-2019 planning horizon. Station building repair work entails

extensive planning, including contractor and city permit coordination prior to implementation, and load transfers (where feasible) to ensure minimal customer service disruptions during execution.

Station work has been prioritized based on the degree of deterioration and the severity of the possible impact to customers, the crew and the assets housed within each station. Table 5 below shows Toronto Hydro's historical and forecasted future spending.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending ($M)					Future Spending ($M)				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	$0	$0	$0.53	$0.003	$0.16	$0.5	$2.5	$2.3	$2.6	$3.3

E6.18.4.1 Ranking & Prioritization

In a recent review, Toronto Hydro identified the station buildings that need immediate attention based on age, failure risk (i.e., potential impact of failure), and field observations. The eleven stations identified in this program (see Table 3) were selected because they ranked poorly in these three areas.

Following the initial selection, a detailed civil assessment of the station buildings was performed. The objective of the assessment was to document the condition of the station buildings and to identify specific tasks necessary to ensure that the facilities are in compliance with all applicable industry standards, and to minimize risks to equipment reliability and worker safety. Of particular concern were any issues related to moisture/water ingress, structural integrity, rodent infestations, building security deficiencies and any potential safety hazards.

The civil assessment allowed Toronto Hydro to review the station buildings' infrastructure condition (pictures and engineering notes), which included cost estimates to perform the repair work. The magnitude and risk of deterioration in addition to the complexity of work (to ensure pacing of work) was used to further prioritize the sequence of work to be performed in 2015 and beyond.

E6.18.5 Program Execution

Toronto Hydro plans to address each of the identified station buildings as separate projects because the degree and severity of deterioration varies from one station building to another. As well, the identified station building components that need attention also vary from one station to

another. Where possible, Toronto Hydro plans to advantage of efficiencies that may be available by retaining contractors or procuring materials for multiple projects.

Toronto Hydro plans to manage and coordinate the required work and approvals amongst all parties involved, including external contractors, City authorities, and Hydro One Networks Inc. (HONI). During construction, extensive coordination may be required to isolate equipment in order to properly de-energize electric equipment as required and transfer load to adjacent station buildings, if necessary. In addition, if the construction work impacts HONI systems and/or equipment, coordination with HONI is required.

In terms of involvement with the City of Toronto, Toronto Hydro and its assigned contractors are responsible for initiating and completing any coordination work with city authorities.

E6.18.5.1 Program Risks

- External Contractor: Building infrastructure repair and maintenance work is generally sub-contracted to external vendors rather than being performed by Toronto Hydro employees. Usually, multiple vendors need to be engaged over the duration of the project including roofers, painters, foundation repairers, brick layers, etc. Accordingly, external contractor availability, timelines and expertise will impact the scope and timeline of the project. Proactive planning, including scheduling based on contractor selection and availability should minimize the risk associated with prolonged and/or slipped timelines. Upfront identification of contractor dependencies will be scheduled accordingly.

- Load Transfer: During construction, it may be necessary to transfer load between busses in order to manage load and electricity requirements. In some cases this load transfer might not be possible, resulting in temporary outages. In all cases, Toronto Hydro would know beforehand if load transfers are required, and appropriate actions would be taken off prior to any work being performed in the station building. In instances where load transfer is not possible, scheduled outages must be planned and communicated to all impacted customers and/or mitigated accordingly.

- City of Toronto: Prior to undertaking any major construction repair/maintenance project Toronto Hydro is required to obtain building permits from the City of Toronto. Delays to receiving permits are common and at times, alterations to original plans are required in order to obtain approval. The assigned project manager is typically aware of the timelines

as outlined by City, and tries to reflect them as accurately as possible in the project schedule.

- Community: Construction may cause inconveniences to the general community. In order to minimize impact, Toronto Hydro would typically undertake community engagement activities to inform the general public of its work and to seek valuable feedback.

E6.18.5.2 External Constraints

Formal agreement with HONI is required for certain building infrastructure repair work since it might affect their equipment. It is also important to take into account scheduling conflicts, since HONI's schedule may not align with Toronto Hydro's. Additionally, HONI may own a portion of the property/station building, thus requiring coordination between Toronto Hydro and HONI.

E6.18.6 Evaluation of Alternatives

E6.18.6.1 Quantification/ Evaluation of Options

Toronto Hydro considered two options to mitigate the reliability and safety risks associated with the deteriorated state of the eleven priority stations that are addresses by this program:

- Option 1: Maintain status quo
- Option 2: Correct Deficiencies

(i) Maintain Status Quo

Toronto Hydro considered maintaining the status quo and taking action only when the stations building components fail, i.e., a "run-to-fail" approach. Generally, station building components have specific useful lives that can be extended with ongoing maintenance work and improvements up to a point. If Toronto Hydro were to choose this alternative for the duration of the forecast period, some station building components would inevitably fail or reach a point beyond repair, and the cost associated with failure and repair could far outweigh the costs of maintaining the stations on an ongoing basis, due to the potential impact that a failed station building component could have on the equipment housed within or the crew working in the station. Also, a station outage would negatively affect customer service and the associated crumbling infrastructure would represent a potential risk to worker and public safety.

Past facility improvement and maintenance work on these stations has been minimal, as outlined in the historical spend table, Table 5. Less than $0.7 million a year has been invested in facility repair and improvement across Toronto Hydro's major downtown stations between 2010 and 2014. This past work has been directed to emergency and/or minimal repair work only. The status quo approach of minimal and reactive repairs it is now insufficient given the degree of deterioration.

(ii) Correct Deficiencies

The alternative choice involves addressing the identified deteriorating components of the station buildings proactively, by replacing and repairing older worn out components with newer, improved components. While this approach involves up-front costs, over the long term, it is the most cost-effective approach. For example, repairing the deteriorating roof of a station building proactively is cheaper than the cost associated with repairing a roof once it is completely damaged. In addition, a leaked/failed roof at a station building can cause water damage to other components, such as walls and ceilings, which would also require costly repairs. Additionally water infiltration due to a failed roof can cause flooding, damage and/or the destruction of equipment and poses safety risks for workers and the public in the surrounding area. Also, potential outages during repair work can be substantial.

As demonstrated, the chain reaction of a failed building infrastructure can be costly and can pose serious safety risk. By employing a proactive approach, existing electrical equipment and feeder arrangements can be maintained with minimal disruption achieved if the work is carefully planned out. Work can be compartmentalized and individual bus/feeders can be transferred while the balance of the station remains operational.

The proposed work is to be completed over a period of five years, from 2015 to 2019, at an average cost of $2.2 million per year, for a total of $11.1 million over the five years.

The first year of Stations Building Infrastructure investments is expected to results in avoided estimated risk cost (ARC) of $0.65 million, as detailed in Table 6. This value represents the avoided cost of executing the first year of activities as scheduled as opposed to deferring these activities until 2020. These avoided costs include quantified risks, taking into account the probability of failure of the assets, and multiplying this by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. Further details on the ARC approach is provided in Section D3.3.

TABLE 6: AVOIDED RISK COST BUSINESS CASE EVALUATION

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$0.65
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$0
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$0.65

E6.18.7 2015 Projects

Table 7 list the project that Toronto Hydro has planned for completion in 2015. Detail on this project ar provided in the following subsection.

TABLE 7: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Start Date
S15371	High Level TS Shell and Roofing Improvements	$549,751	2015

E6.18.7.1 High Level TS She ll and Roofing Improvements

Investment Category: System Renewal

Program: Stations Building Infrastructure

Project Title: High Level TS Shell and Roofing Improvements

Project Number: S15371

Project Year: 2015

Estimated Cost: $ 549,751

(i) Objective

The objective of the High Level TS shell and roofing improvement project is to correct deficiencies in the roofing and outer shell at High Level TS to mitigate the risk of damage to critical station electrical equipment. This project is expected to bring the shell and roof of this facility up to an acceptable condition. Deficiencies include a degraded sacrificial layer on the roof, split stones on the surface of the station, degraded windows and a rear loading door in poor condition.

(ii) Scope of Work

TABLE 8: HIGH LEVEL TS CIVIL INFRAS TRUCTURE SCOPE OF WORK DETAILS

Station(s)	HIGH LEVEL TS
Feeder(s)	N/A

The scope of this project involves completion of the following tasks:

- Repaint roofing with a new aluminum reflective coating to seal the open laps in the sacrificial layer. It will be necessary to eliminate debris and vegetation from the roof drains before painting. Installation of a new membrane and flashings is necessary to complete the work.
- Repaint all stonework or faux-stone concrete masonry units. Prior to painting, it is necessary to wash the surfaces of the building to clean them of stains and dirt. Split stones and gaps in mortar joints, feature bandings, and sills are to be repaired with mortar.
- Replace the windows on two sides of the skylights. While replacing the windows, clear the corrosion of the steel window well grilles and repaint.

(iii) Justification & Benefits

The above deficiencies were identified through a condition assessment of the building. Completion of the identified improvements is necessary to prevent damage to critical station infrastructure housed within the station. In particular, water ingress is a significant concern since it can damage to electrical equipment.

Failure to complete this work as planned could result in a continued and increasing risk to system reliability, and eventually necessitate more extensive and costly improvements. Addressing these issues is expected to extend the life of the station building and to mitigate significant safety and reliability risks. The proposed repairs are expected to increase the safety of individuals in or around the station by removing potential slip or trip hazards and by minimizing the amount of water around electrical equipment.

E6.19 Stations DC Battery System Renewal

LEGACY TYPE BATTERY BANK

E6.19.1 Summary

Program Description

The Stations DC Battery System Renewal Program plans to replace aging direct-current (DC) batteries and chargers at various Municipal Stations (MS) and Transformer Stations (TS) to maintain operational effectiveness, minimize potential outages to customers, and comply with provisions within the Transmission System Code. Toronto Hydro currently has 194 battery and charger sets at various MS and TS locations. The DC battery system becomes a critical component when main power to the station itself is lost, as it continues to provide the necessary power supply to control and operate the associated circuit breaker assets.

Sixty-five of the 67 battery systems proposed for replacement during 2015-2019 are at least ten years old. Two of the battery systems are less than ten years old, but are planned for replacement in order to take advantage of work efficiencies by coordinating with transformer replacements planned at the same stations (Flemingdon MS and Oberon MS – refer to section E6.14 for details on planned power transformer replacements).

Table A summarizes the anticipated benefits associated with this capital investment program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Mitigation of the risk of long duration outages for approximately 137,000 customers supplied from the stations addressed in this program.
Reliability	ƒ Improved system reliability by mitigating the risk that SCADA and protection systems will be inoperable. Inoperable protection and control systems can result in lengthier and more widespread outages than would otherwise be necessary. ƒ Prevention of the propagation of feeder faults to a larger supply grid, and mitigation of the reliability risk introduced to the larger supply system by battery failures. ƒ Mitigation of the risk that the collection of system data (e.g. current, voltage and kVA readings on transformers, busses and feeders) by associated SCADA systems will be interrupted. These data points are important to Toronto Hydro planners for analysis of historical events and for future planning considerations.
Safety	ƒ Reduced likelihood that manual switching activities will be required as a result of battery system failure. Manual switching is one of the most electrically hazardous activities performed by field crews. ƒ Reduction in the potential risk of exposure to acid and fumes that may cause harm by eliminating the need to refill VLA batteries with distilled water.
Efficiency	ƒ Potential cost savings can be realized by planning replacements proactively as opposed to making reactive replacements following battery failure.

Program Drivers

The trigger and secondary drivers are summarized in the following table.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ 65 of the 67 batteries identified for renewal have exceeded their ten-year useful lives and require replacements to ensure proper operation of circuit breakers during contingencies. ƒ When a battery fails, the SCADA system cannot isolate feeder faults, which can cause prolonged outages and propagation of faults to the upstream supply grid. Replacement of end-of-life batteries is expected to mitigate the battery failure risk. ƒ Battery replacements are required to maintain alignment with the Transmission System Code Section 10.7.1, which specifies that customers (e.g., local distributors) must maintain battery systems capable of operating for at least eight hours per single battery bank.
Secondary Drivers	**Reasoning**
Safety	ƒ When the DC battery system fails to provide sufficient energy to

	operate breakers to isolate feeder faults through SCADA remotely, manual switching is required to isolate feeder faults to restore power to customers. Manual switching work is one of the most hazardous electrical activities performed by field crews because of the potential for electrical arc flash.

Preferred Alternative

Toronto Hydro considered two options in developing its plan: 1) maintain the status quo (run-to-fail) or 2) planned replacements. A run-to-failure approach would involve replacing these assets reactively when they fail.

Maintaining the status quo is likely to result in higher replacement costs, an increased risk of significant station-level outages to customers, and potential diversion of resources from planned capital work to replace the failed battery reactively. With the increasing percentage of batteries exceeding their expected useful lives, there is a heightened risk that battery failures could occur at any time in an unpredictable manner. Taking a proactive approach to replace the targeted battery systems that are beyond end-of-life is expected facilitate optimal planning of resources and materials allowing for replacements to be carried out in an effective and efficient manner at the lowest possible cost.

The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $5.10 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program.

Timing and Pacing

As shown in Table C, Toronto Hydro proposes to spend $3.14 million over the 2015 to 2019 period for this program.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.19	0.17	0.39	0.31	0.58	0.27	0.67	0.71	0.74	0.73

Based on the age of the battery population and the selection criteria described in Section E6.19.4.1, Toronto Hydro plans to replace DC battery systems at a pace that will maximize the

use of the remaining life of existing battery assets while mitigating the risk of untimely and potentially high-impact failures. The program also allows flexibility for selective replacements to coordinate with other asset replacements, such as stations power transformers or switchgear, to minimize the number of outages required for planned work at a station.

With approximately 14 battery replacements per year, Toronto Hydro's proposed program is intended to substantially reduce the growing backlog of batteries operating beyond end-of-life by 2019. The utility estimates that a slower rate of battery replacements would result in increased risk of additional outages associated with failed batteries and higher life-cycle costs due to replacements of the failed batteries on a reactive basis.

E6.19.2 Program Description

Direct current (DC) battery systems are installed in distribution stations to provide the DC power supply required to operate and control stations circuit breakers. The circuit breakers are used to isolate feeder faults and to restore service to customers during outages. Toronto Hydro's Stations DC Battery System Renewal program will replace battery systems (i.e., batteries and chargers) that have reached or exceeded their expected useful lives of ten years, at which point the potential risk of failure increases. Toronto Hydro also plans to replace two non end-of-life systems in coordination with planned station power transformer replacements.

Toronto Hydro anticipates that adopting a proactive replacement approach will minimize the likelihood of battery system failure, mitigating the risk that DC power supply from the battery system will be unavailable when needed. A reliable battery system allows isolation of feeder faults in an effective manner, whereas an unreliable battery system raises the potential risk of lengthy outages. Proactive replacement is also expected to lower replacement costs by enabling the relatively efficient organization of replacement activities compared to replacement during emergency situations.

The proposed battery replacement work involves removal of the old battery system and installation of a new battery system on a 'like-for-like' basis. Figure 1 illustrates the locations of the 67 battery systems that Toronto Hydro proposes to replace during the 2015-2019 period.

FIGURE 1: MAP OF 67 BATTERY SYSTEM REPLACEMENTS

Toronto Hydro plans to install modern valve-regulated lead-acid (VRLA) batteries when replacing the existing vented lead-acid (VLA) battery systems. The advantages of the VRLA battery are as follows:

- maintenance free (i.e. unlike VLA batteries, VRLA batteries do not require refilling with distilled water);
- less stringent ventilation requirements compared to VLA batteries as the VRLA battery does not release chemical fumes under normal operating conditions;
- lower potential safety risks from exposure to chemicals – specifically the risk of potential eye injuries during maintenance of the flooded acid type batteries. (Exposure to chemical fumes is also reduced.)

Figure 2 illustrates a typical set up of the new battery system for a 300 Amp-hour (Ah) VRLA battery and charger.

FIGURE 2: TYPICAL SET UP OF 300AH VRLA BATTERY SYSTEM (BATTERY BANK ON LEFT AND CHARGER ON RIGHT)

Figure 3 illustrates the older, flooded type 330 Ah battery bank.

FIGURE 3: 330AH FLOODED TYPE BATTERY BANK (THE OLDER TYPE)

The battery system size used at various Toronto Hydro stations varies depending on station requirements such as the load requirements of the different alarm systems, emergency lights, SCADA protection system and RTUs, the number of circuit breakers, etc. Table 1 below shows the number of battery systems proposed for replacement broken down by size and proposed replacement year.

TABLE 1: PROPOSED DC BATTERY SYSTEM REPLACEMENTS

Assets (Units)	2015	2016	2017	2018	2019	Total
Battery System 50 Ah	2	8	5	6	5	26
Battery System 80 Ah					1	1
Battery System 100 Ah	3	8	7	5	7	30
Battery System 200 Ah			1			1
Battery System 300 Ah		1	2	2		5
Battery System 400 Ah	1	1			2	4

Table 2 below summarizes the anticipated benefits of the Stations DC Battery System Renewal program.

TABLE 2: STATION DC BATTERY SYSTEM RENEWAL PROGRAM BENEFITS

Customer Value	ƒ Mitigation of the risk of long duration outages for approximately 137,000 customers supplied from the stations addressed in this program. ƒ The completion of the first year of activities in this program is expected to result in an avoided estimated risk cost (ARC) of $5.10 million. A positive ARC value is indicative of a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) through the renewal of the assets within this program (see Section E6.19.7).
Reliability	ƒ Improved system reliability by mitigating the risk that SCADA and protection systems will be inoperable. Inoperable protection and control systems can result in lengthier and more widespread outages than would otherwise be necessary. ƒ Prevention of the propagation of feeder faults to a larger supply grid, and mitigation of the reliability risk introduced to the larger supply system by battery failures. ƒ Mitigation of the risk of interruption to the collection of system data (e.g. current, voltage and kVA readings on transformers, busses and feeders) by associated SCADA systems. These data points are important to Toronto Hydro planners for analysis of historical events and for future planning considerations.
Safety	ƒ Reduced likelihood that manual switching activities will be required as a result of battery system failure. Manual switching is one of the most electrically hazardous activities performed by field crews. ƒ Reduction in the potential risk of exposure to acid and fumes that may cause harm by eliminating the need to refill VLA batteries with distilled water.
Efficiency	ƒ Potential cost savings can be realized by planning replacements proactively as opposed to making reactive replacements following battery failure.

E6.19.3 Why the Program is Needed

Of Toronto Hydro's 194 battery systems currently in service, 27% are expected to be past their useful lives of ten years in 2015 (as shown in Figure 6 in Section E6.19.3.2(i)), with an additional 33% of the current population expected to reach end-of-life by 2020. The Stations DC Battery System Renewal program is required to mitigate the potential failure and safety risks associated with this growing backlog of end-of-life battery systems. A functional DC power supply is vital to the reliable operation of critical station level protection and control systems.

E6.19.3.1 Program Drivers

Table 3 below provides a summary of the trigger and secondary drivers for the Stations DC Battery System Renewal program. This program is System Renewal initiative with a trigger driver of failure risk.

TABLE 3: STATIONS DC BATTERY SYSTEM RENEWAL PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ 65 of the 67 batteries identified for renewal have exceeded their ten-year useful lives and require replacements to ensure proper operation of circuit breakers during contingencies. ƒ When a battery fails, the SCADA system cannot isolate feeder faults, which can cause prolonged outages and propagation of faults to the upstream supply grid. Replacement of end-of-life batteries is expected to mitigate the battery failure risk. ƒ Battery replacements are required to maintain alignment with the Transmission System Code Section 10.7.1, which specifies that customers (e.g., local distributors) must maintain battery systems capable of operating for at least eight hours per single battery bank.
Secondary Drivers	**Reasoning**
Safety	ƒ When the DC battery system fails to provide sufficient energy to operate breakers to isolate feeder faults through SCADA remotely, manual switching is required to isolate feeder faults to restore power to customers. Manual switching work is one of the most hazardous electrical activities performed by field crews because of the potential for electrical arc flash.

The risks described in the table above are further detailed below.

(i) End-of-Life Failure Risk

Based on historical data on battery failures, the average useful lifespan of existing DC batteries is approximately ten years, as represented in Figure 4 in section E6.19.3.2 (i). As the batteries age

beyond their useful lives, the risk of battery failure increases and the battery systems can eventually fail in the field if not replaced. Toronto Hydro plans to replace the batteries that are at or beyond their useful lives because of the increased risk of battery failure. The reliability impacts associated with failed batteries are discussed in section E6.19.3.2 (ii).

(ii) Alignment with the Transmission System Code

The Transmission System Code (TSC) sets out the obligations between a transmitter and its customers, including distributors.. With respect to battery banks and DC supply, section 10.7.1 of the TSC specifies that customer batteries must have enough capacity to operate for at least eight hours for a single battery system (or at least six hours for each of the batteries in a two battery system). For batteries that are operating beyond end-of-life, there is a higher potential risk that these units will not be able to supply necessary power for the minimum amount of time specified in the TSC. As previously mentioned, failure of the battery system can render the protection and control systems inoperable, which, during a Loss of Supply event, can have reliability impacts on the larger supply grid.

(iii) Safety Risk

If a battery system fails to provide sufficient energy to operate the circuit breaker to isolate the feeder fault, the Control Center has dispatch a field crew to perform manual switching by opening (tripping) the circuit breaker to isolate the fault. Manual switching work is one of the most hazardous electrical activities performed by field personnel due to the potential for electrical arc flashes.

E6.19.3.2 Asset Details

(i) Asset Lifecycle

Battery failure data from 2011 through to 2013 (Figure 4) demonstrates that the average age of battery failure has historically been approximately ten years. On this basis, Toronto Hydro considers its existing stations DC battery systems to have reached end-of-life at ten years of age.

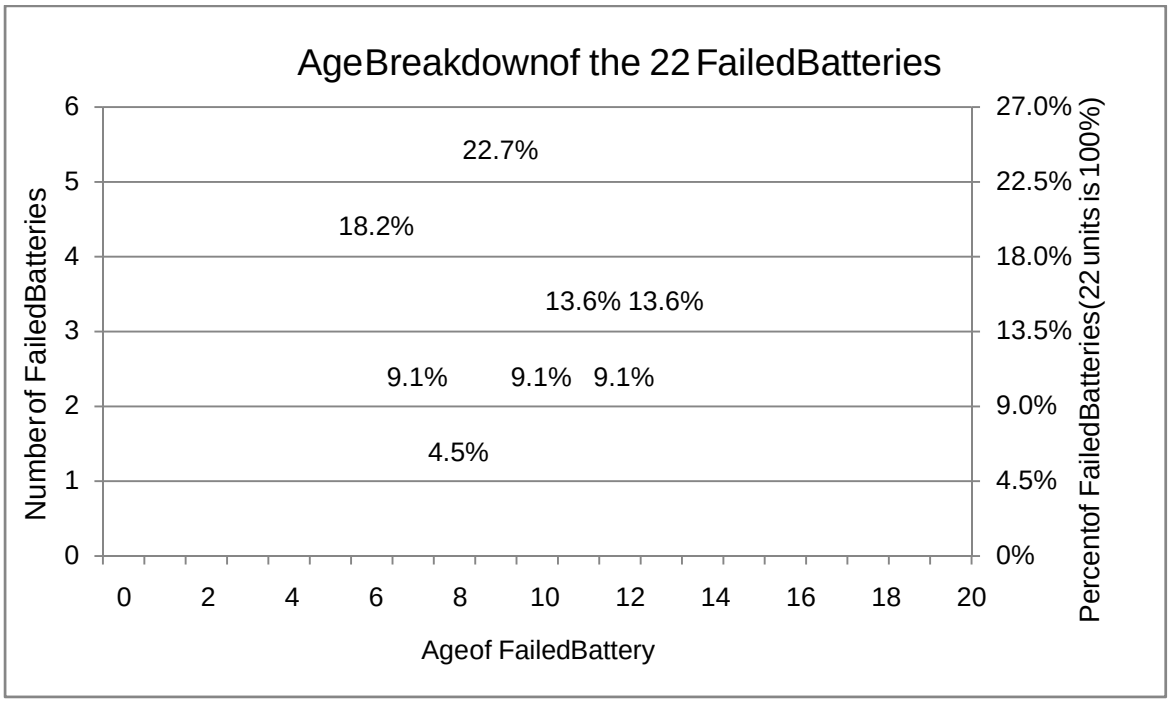

FIGURE 4: AGE OF BATTERIES THAT FAILED FROM 2011 TO 2013

A number of factors can lead to the failure of station batteries. A battery is essentially failed when the total capacity of the battery is significantly reduced, or when abrupt losses of power frequently occur. Typical factors contributing to the failure of VRLA and VLA batteries include: elevated operating temperature, excessive discharge-recharge cycling, improper floating voltage, and improper installation.

VRLA and VLA batteries operate at optimal temperatures of 25ºC, and operation above this temperature can cause the float charge current at float charge voltage to increase. This contributes to an increased rate of grid corrosion and is a frequent source of battery failure. At higher operating temperatures than 25ºC, the acceptable float charge voltage needs to be decreased, and operation at the manufacturer specified voltage can cause damage to the battery grid structure. Lastly, excessive discharge-recharge cycling of the battery causes repeated expansion and contraction of $PbSO_4$, which can accelerate grid corrosion in the cell.

Low capacity failures normally develop slowly over time due to a combination of the factors described above. Therefore, they do not generally cause sudden or expensive outages. In

contrast, abrupt "power cuts", caused, for example, by severely corroded grids, require immediate attention and replacement of the battery.

Figure 5 below illustrates the percentage of the total DC battery population that is currently more than ten years old as of 2015 and also provides a projection to 2020 that shows how the number of batteries beyond ten years old is projected to grow. If Toronto Hydro doesn't replace any battery systems between now and 2019, a high percentage (59.8%) of the battery population is expected to be more than ten years old by 2020.

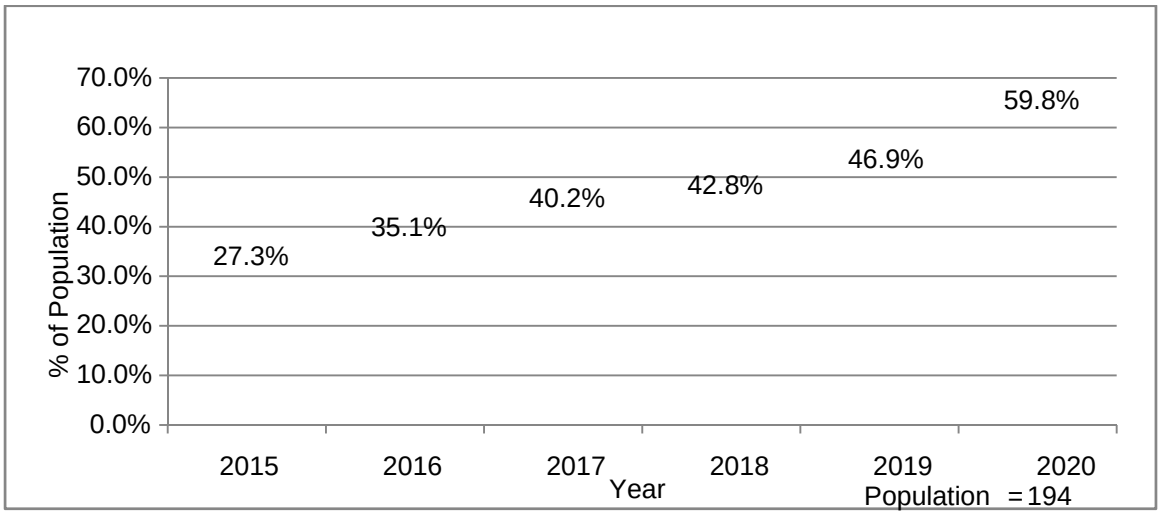

FIGURE 4: PERCENTAGE OF BATTERY POPULATION AT OR BEYOND 10 YEARS OF AGE FROM 2015 TO 2020 (IN ABSENCE OF A RENEWAL PROGRAM)

Figure 6 below shows the age profile of the 194 in-service battery systems as of 2015, where 27.3% (53 battery systems) are at or beyond the ten-year age threshold.

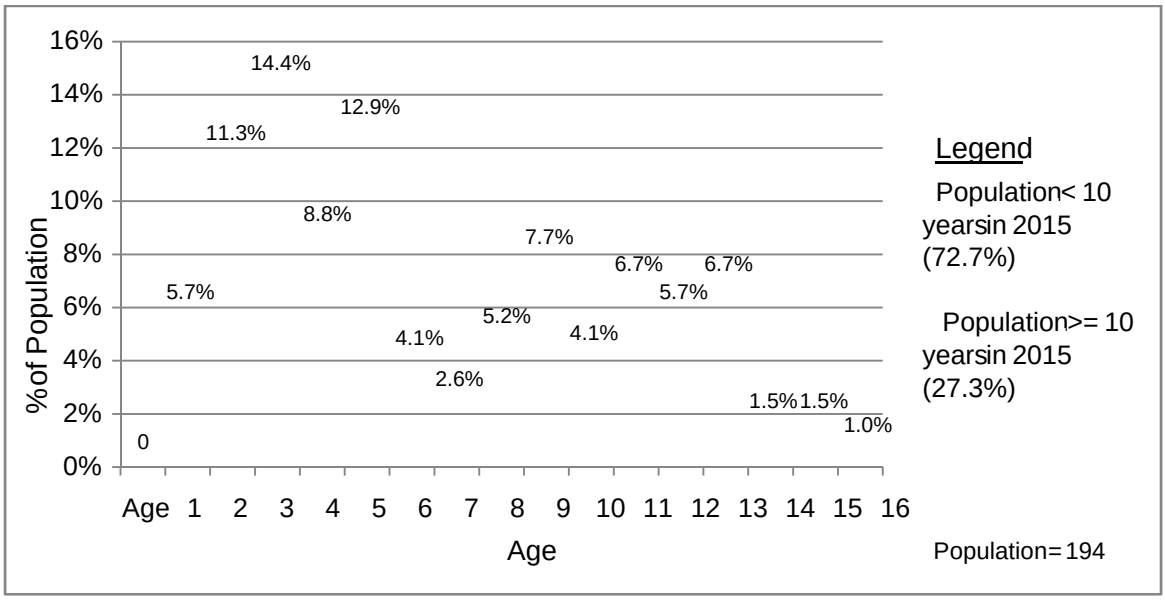

FIGURE 5: AGE PROFILE OF BATTERY POPULATION IN 2015

To help ensure that the battery system population remains in working order, Toronto Hydro proposes to replace a total of 67 battery systems, or about 14 battery systems per year from 2015 to 2019 inclusively. Figure 7 below shows the age profile of the 67 battery systems (with their sizes in Amp-hours (Ah)) identified for replacement during the 2015-2019 period.

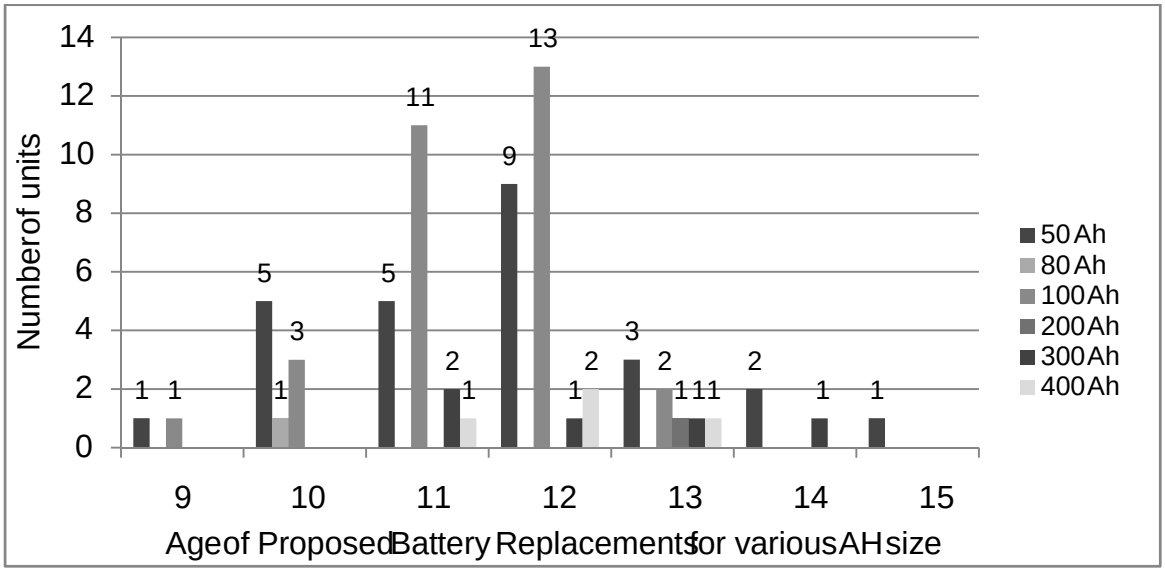

FIGURE 6: AGE OF THE PROPOSED 67 BATTERY SYSTEM REPLACEMENTS

As shown above, 65 of the 67 battery systems proposed for replacements are at least ten years old. Two of the battery systems are less than ten years old, but are planned for replacement in order to take advantage of work efficiencies by coordinating with transformer replacements planned at the same stations (Flemingdon MS and Oberon MS – refer to section E6.14 for details on planned power transformer replacements).

(ii) Asset Failure Impacts

The impact of a failed DC battery system depends on operating conditions of the grid at the time of the failure. For example, if a tree branch made contact with a feeder emanating from a station with a deteriorating DC battery system, the battery may still possess sufficient voltage to permit the breaker to open and isolate the fault. If the battery functions as required, the breaker would then be closed remotely by the power system controller at the control centre, and therefore only a momentary outage would occur. However, if the DC battery supply does not have sufficient voltage to close the circuit once the tree branch is no longer in contact with the feeder, customers would experience a substantially longer outage, as Toronto Hydro would be required to dispatch field crews to perform manual switching in order to restore power to the affected customers. This manual switching process could take anywhere from one to three hours.

In a more severe case, where the DC battery system has insufficient voltage to open the circuit breaker to isolate the initial fault, the fault could cascade to the upstream supply system, resulting in a wider outage, affecting customers beyond those on the immediately affected feeder and station. At that point, significantly more time would be required to restore service to a much larger number of customers.

The worst case outage scenario with the greatest impact to customers would occur if the upstream power supply to the station was completely lost (i.e. a Loss of Supply outage event), and the battery system failed to function properly, which would disable the protection system. This combination of events could cause a wide-spread outage impacting a very large number of customers.

One of the most severe impacts due to failure of a protection system occurred on July 8, 2013 at Manby TS, resulting in a widespread outage to the Greater Toronto Area (GTA). A storm caused severe flooding at Manby TS and Richview TS, rendering the protection system and SCADA inoperable. To minimize upstream damages, a total of 3,770 MW load was interrupted, causing a wide spread outage to the GTA area that affected up to 500,000 customers for at least eight hours, with some customers experiencing outages of more than 48 hours. While the outage in

this instance was not caused by a failed battery system, it is nonetheless indicative of the magnitude of the potential impact (i.e., the number of customers interrupted) that could result from a battery failure during a Loss of Supply event, which would similarly render the protection system and SCADA inoperable for a period of time until the battery could be replaced.

E6.19.4 Timing & Pacing of the Program

Table 4 below shows the historical spending and the proposed annual investment for the Stations DC Battery System Renewal program.

TABLE 4: STATION DC BATTERY SYSTEMS RENEWAL PROGRAM HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending ($M)				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0.19	0.17	0.39	0.31	0.58	0.27	0.67	0.71	0.74	0.73

Based on the age of the battery population and the selection criteria described in section E6.19.4.1, Toronto Hydro plans to replace DC battery systems at a pace that maximizes the use of the remaining life of existing battery assets while mitigating the risk of untimely and potentially high-impact failures. The program also allows flexibility for selective replacements to coordinate with other asset replacements, such as stations power transformers or switchgear, to minimize the number of outages required for planned work at a station.

With approximately 14 battery replacements per year, Toronto Hydro's proposed program is intended to substantially reduce the growing backlog of batteries operating beyond end-of-life by 2019. The utility estimates that a slower rate of battery replacements would result in increased risk of outages associated with failed batteries and higher life-cycle costs due to replacements of the failed batteries on a reactive basis.

Table 5 shows relatively lower spending in 2010 and 2011. This is due to the fact that failed batteries were previously replaced under the Reactive Capital program (refer to section E6.20 for details on this program).

E6.19.4.1 Ranking & Prioritization

Projects within this program are prioritized according to the following criteria:

- Age: the batteries addressed are ten years or older, with the oldest batteries being the most urgent.

- Coordination (i.e., opportunistic replacement): a battery is replaced when other activities are also occurring at the same station. For example, there are two stations where the batteries are less than ten years old, but replacement is warranted to coordinate with transformer renewal at the same station.

- Prudence: Toronto Hydro avoids proactive replacement of battery systems at stations that are scheduled for decommissioning due to conversion of station load to a higher voltage.

The ranking and prioritization process consists of sorting the battery population in an ascending order based on age and then checking the list against the list of scheduled voltage conversion projects to ensure battery replacements only take place at stations that will remain in service in the long-term. Once this is done, Toronto Hydro cross-references the resulting list with the switchgear replacement list and the power transformer replacement list to coordinate work execution efficiency and avoid multiple outages, as discussed in Section E6.19.5.

E6.19.5 Program Execution

Execution of Stations DC Battery System Renewal projects involves design and planning, procurement of materials, request for station outages, work to remove the old battery and charger systems, and the installation of new battery and charger systems with appropriate capacity. The work may involve the installation of additional switches, where necessary, to bring the installation up to the current standard of battery system design for easy isolation and replacements in future. Once the design is up to standard, future replacements of battery systems are less likely to require an outage at the station.

If a station has multiple assets requiring replacement (e.g. switchgear, transformers, battery systems, etc.) within the same timeframe, Toronto Hydro plans to schedule a single station outage to efficiently replace all the targeted assets simultaneously. Taking a station offline is a major undertaking and can only be carried out within certain windows of time during low load seasons (i.e. spring and fall).

E6.19.5.1 Program Risks

A significant complexity associated with the Stations DC Battery System Renewal program is the requirement that all associated station assets be de-energized to allow the battery system to be replaced safely. Before the station can be taken offline, the control center must determine that the adjacent stations have sufficient capacity and the distribution system has adequate availability to

transfer the loads from the interrupted station to adjacent stations. Toronto Hydro is unable to de-energize stations during high load seasons (i.e. summer and winter). Toronto Hydro mitigates this program risk by scheduling projects during the low load seasons.

E6.19.6 Evaluation of Alternatives

E6.19.6.1 Quantification/ Evaluation of Options

Toronto Hydro considered two alternatives for battery system replacement as described below.

(i) Run-to-Fail

Under this option, Toronto Hydro would replace battery systems reactively when they fail. This alternative is likely to result in higher replacement costs, an increased risk of significant station-level outages to customers, and potential diversion of resources from planned capital work to replace the failed battery reactively. With the increasing percentage of batteries exceeding their expected useful lives, there is a heightened risk that battery failures could occur at any time in an unpredictable manner.

(ii) Planned Replacement

The preferred option is to proactively replace the targeted battery systems that are beyond end-of-life. This alternative facilitates more efficient planning and use of resources and materials and allows for replacements to be carried out in an effective manner at the lowest possible cost. This alternative also minimizes the potential for lengthy customer outages, reduces the safety risks to personnel who may otherwise be required to perform manual switching, and ensures alignment with distributor-specific requirements in the Transmission System Code.

The replacement of the station DC battery systems planned for the first year of the program is expected to result in an avoided estimated risk cost (ARC) of $5.10 million, as detailed in Table 5. This value represents the cost avoided by executing the first year of activities as scheduled, rather than deferring these activities until 2020. These avoided costs include quantified risks, taking into account the probability of failure of the assets, and multiplying this by the various direct and indirect costs associated with in-service asset failures, including the costs of customer interruptions, emergency repairs, and replacement. Further details on the ARC approach are provided in Section D3.3.

TABLE 5: AVOIDED RISK COST OF DC BATTERY SYSTEM RENEWAL PROGRAM FOR 2015 PROJECTS

Business Case Element	Cost (in Millions)
Asset Renewal	
Present Value of Net Cost in 2020 [PV(NET_COST(2020)]	$5.83
Net Cost for the First Year of Activity [NET_COST(First Year of Activity)]	$0.74
Avoided Risk Cost of Executing Work for the First Year of Activities [ARC = (PV(NET_COST(2020)) - (NET_COST(First Year of Activity))]	$5.10

E6.19.7 2015 Projects

Table 6 lists the Stations DC Battery System Renewal projects that Toronto Hydro plans to execute in 2015.

TABLE 6: 2015 PROJECTS

Project Number	Project Name	Battery System Age (years)	Total Project Cost	Project Start Date
28185	S14578 Porterfield MS replace battery system	13	$33,142	2015
29823	S15171 Brimley Shaddock MS replace battery system	13	$31,455	2015
30386	S15524 Cavanagh TS replace UPS battery system	11	$24,538	2015
29815	S15172 Coronation Bennett MS replace battery	12	$17,511	2015
29861	S15243 Dufferin B MS replace battery system	13	$31,006	2015
29877	S15258 Dufferin TS replace battery system	12	$136,305	2015

E6.20 Reactive Capital

TORONTO HYDRO CREW MEMBERS MAINTAINING POLES

E6.20.1 Summary

Program Description

The Reactive Capital program accounts for unplanned, non-discretionary capital expenditures required to repair or replace assets. Reactive expenditures are comprised of replacing failed or failing overhead, underground, stations, and metering assets. With proper budgeting and resource allocation, timely reactive work improves safety, lowers the backlog of assets waiting to be maintained, avoids depriving other planned capital programs of resources and reduces strain on the distribution system from failed assets.

A summary of the anticipated benefits for this investment program are provided in Table A.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduced customer interruptions and durations by replacing all failed assets immediately
Reliability	ƒ Maintaining and indirectly improving system performance and reliability through enhancements that occur when assets that have failed are replaced
Safety	ƒ Mitigation of the risk of catastrophic asset failure events from the replacement of high-risk assets approaching imminent failure

Efficiency	ƒ Projected 2015-2019 expenditures are in line with historical levels, despite the projection of higher asset failures, thanks to increased emphasis on assets being addressed proactively opposed to reactively across Toronto Hydro's planned capital and maintenance programs. The overall cost-efficiency of greater amounts of proactive renewal is expected to be higher than a more reactive approach.
Other	ƒ Reducing the possibility of greenhouse gases, harmful chemicals, waste, or debris being released in the environment as a result of a catastrophic asset failure ƒ Economic benefits derived from the mitigation of outages to businesses through the replacement and enhancement of assets in a timely manner

Program Drivers

The Reactive Capital program is primarily driven by Failure, and as such, is categorized as a System Renewal investment. The program's purpose is to fund capital expenditures that are non-discretionary and need to happen in a moment's notice mainly due to asset failures. By having the capital funds available, Toronto Hydro is better able to maintain system performance and reliability and can manage or eliminate certain potential safety risks to the public and Toronto Hydro employees. The secondary drivers of this program are safety and reliability. Both the trigger and secondary drivers for the Reactive Capital program are outlined in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure	ƒ High population of assets in poor condition and beyond their useful lives, requiring replacements as they fail ƒ Timely replacements are required to avoid running the system on contingency (i.e. with any number of feeders or assets interrupted and unable to provide backup supply in the event of an outage) ƒ Asset failure presents environmental risk; common environmental risks include the release of greenhouse gases into the atmosphere, and oil spilling into ground water
Secondary Drivers	**Reasoning**
Safety	ƒ Electrical and civil asset failures can create injury and health risks to the public and Toronto Hydro employees ƒ Common safety risks associated with the risk of faulted/failed equipment include electrical contacts, arc flashes, and fires that could have serious consequences
Reliability	ƒ Asset failures generally have a direct impact on system reliability performance and customer service. To mitigate reliability impacts, resulting in reduced customer service and system performance

	reliability.

Preferred Alternative

Toronto Hydro considered the following options for addressing failed and about to fail assets:

(1) Performing reduced reactive capital work

(2) Performing no reactive capital work

(3) Performing the Reactive Capital program as set out in this narrative

Option III is the preferred alternative as it accounts for sufficient capital funding to effectively replace and repair failed assets over the 2015-2019 planning horizon. Accounting for the amount of aging distribution infrastructure in Toronto, anticipated reactive capital expenditures are expected to maintain system performance, improve reliability, increase customer satisfaction and eliminate safety risks.

Timing and Pacing

The total forecasted spending for the Reactive Capital program from 2015 to 2019 is $165.5 million. As seen in Table C, the future spending from 2015 to 2019 is relatively constant and aligned with projected corrective work requests as further discussed in Section E6.20.3.2 (iii).

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	25.1	28.6	29.2	37.4	32.1	31.9	32.7	33.1	33.6	34.2

E6.20.2 Program Description

The Reactive Capital program is comprised of expenditures made to overhead, underground, secondary network, stations and metering assets. The purpose of reactive work is to restore service to customers and maintain system reliability by addressing failed assets. Reactive work is unplanned, and either occurs in response to an asset failure or to the detection of a severe asset deficiency (e.g., a severely cracked pole) that cannot be addressed by planned capital replacement procedures and timelines and must be reactively replaced to ensure the safety of the public and Toronto Hydro employees. Reactive work is usually executed on the same day, following the detection of an asset requiring replacement. The scope of all reactive work covers Toronto Hydro's entire distribution system and affects all asset classes.

Within Toronto Hydro's predictive and preventive maintenance programs[3], crews designate a rating of one to five on their inspection forms to indicate the state of an asset. An asset identified as having a Level 4 deficiency exhibits major deterioration, operates at a lower efficiency and requires replacement soon. An asset is given Level 5 deficiency if it requires replacement in response to both a failure or if the asset is causing a significant safety, environmental or reliability risks. Based on the severity of the situation, Level 4/5 deficiencies are issued corrective work requests to be performed immediately, which are funded from the reactive capital budget.

Overhead reactive work includes the replacement of poles, primary and secondary conductors, transformers, switches and overhead line hardware equipment. Underground reactive work includes the replacement of cables, installation of splices for direct buried cables, joints, transformers, switches and civil infrastructure. In addition, grounding compliance issues related to both non-conforming submersible transformer vaults and pole-top transformers are covered. Secondary network assets, including automatic transfer switches, reverse power breakers, network protectors and network transformers are combined with underground reactive work. Stations reactive work includes all system components between the demarcation point at the Hydro One Networks Inc. (HONI) supply point and the line disconnect device on the distribution feeder circuit. Reactive metering work includes meter asset replacements, including smart meters.

[3] Exhibit 4A, Tab 2, Schedule 1

Although Toronto Hydro has performed trending analysis based on past unplanned reactive capital work, by its very nature, this type of work is inherently difficult to anticipate. As well, reactive capital work cannot be deferred and addressed by other programs at a later date because of the immediate safety, environmental and reliability risks associated with this work as described above.

Table 2 summarizes the expected benefits of the Reactive Capital program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduced customer interruptions and durations by replacing all failed assets immediately
Reliability	ƒ Maintaining and indirectly improving system performance and reliability through enhancements that occur when assets that have failed are replaced
Safety	ƒ Mitigation of the risk of catastrophic asset failure events from the replacement of high-risk assets approaching imminent failure
Efficiency	ƒ Projected 2015-2019 expenditures are in line with historical levels, despite the projection of higher asset failures, thanks to increased emphasis on assets being addressed proactively opposed to reactively across Toronto Hydro's planned capital and maintenance programs. The overall cost-efficiency of greater amounts of proactive renewal is expected to be higher than a more reactive approach.
Other	ƒ Reducing the possibility of greenhouse gases, harmful chemicals, waste, or debris being released in the environment as a result of a catastrophic asset failure ƒ Economic benefits derived from the mitigation of outages to businesses through the replacement and enhancement of assets in a timely manner

E6.20.3 Why the Program is Needed

An increasing percentage of Toronto Hydro's asset population is either approaching or is already beyond its useful life. As shown in Table 3, the total number of corrective work requests within Toronto Hydro's asset population is projected to steadily increase every year through 2015 to 2019, primarily due to the growing trend of assets beyond their useful lives as explained in Section E6.20.3.2 (i).

TABLE 3: HISTORICAL AND PROJECTED NUMBER OF CORRECTIVE WORK REQUESTS TO ADDRESS OVERHEAD, UNDERGROUND, SECONDARY NETWORK & STATIONS DEFICIENCIES

	Historical				Forecast					
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Number of Corrective Work Requests (in thousands)	10.1	10	6.5	8.3	9.2	9.4	9.6	9.9	10.1	10.3

The number of asset failures requiring reactive intervention varies from year to year. For example, Toronto Hydro experienced fewer asset failures and instances of defective equipment in 2012, signified by the lower number of corrective work requests as compared to 2011. Due to the unpredictable nature of asset failures, there may be volatile swings in the number of corrective work requests from year to year, as further discussed in Section E6.20.4. Catastrophic failures[4] of assets can require very large investments by Toronto Hydro – investments that, in the absence of a dedicated reactive capital budget, would deprive other capital and operational programs of resources and hinder the planned modernization and growth of the utility as a whole. As such, Toronto Hydro requires the Reactive Capital program to manage unavoidable asset failures and address high-risk assets approaching imminent failure, in order to continue to provide reliable, safe, and environmentally sound service to customers from 2015 to 2019 and beyond.

E6.20.3.1 Program Drivers

The purpose of the Reactive Capital program is to fund capital expenditures that are non-discretionary and that may need to be made at a moment's notice in order to maintain system performance and reliability, maintain customer satisfaction, eliminate safety risks to the public and Toronto Hydro employees, mitigate environmental risks and maintain accurate billing through the replacement of failed assets. The trigger and secondary drivers for this program are shown in Table 4 below.

[4] Defined in Section E6.20.3.2 (ii).

TABLE 4: PROGRAM DRIVERS

	Program Drivers	Reasoning
Trigger Driver	Failure	ƒ High population of assets in poor condition and beyond their useful lives, requiring replacements as they fail ƒ Timely replacements are required to avoid running the system on contingency (i.e. with any number of feeders or assets interrupted and unable to provide backup supply in the event of an outage) ƒ Asset failure presents environmental risk such as contamination
Secondary Drivers	Safety	ƒ Electrical and civil asset failures can create safety risks to the public and Toronto Hydro employees ƒ Common safety risks associated with the risk of faulted/failed equipment include electrical contacts, arc flashes, and fires that could have serious consequences
	Reliability	ƒ Asset failures generally have a direct impact on system reliability performance and customer service. Timely replacements mitigate reliability impacts, resulting in increased customer service and system performance reliability.

(i) Failure

The trigger driver of the Reactive Capital program is equipment failure. As a whole, Toronto Hydro's distribution system has experienced improved reliability; however, despite this improvement, a substantial number of assets continue to fail each year. Continued asset failure is mostly attributed to a significant percentage of Toronto Hydro's assets being beyond their useful lives; as they continue to age, their failure probabilities increase.

In addition to the safety and reliability risks of failure discussed below, the failure of assets can also be harmful to the environment. Leaking transformers or cables in underground structures pose a serious environmental risk. Asset failures can also result in the release of harmful contaminants and greenhouse gases into the environment. Timely reactive capital replacements can mitigate the environmental risks associated with asset failure.

(ii) Safety

Another important driver of the program is the safety and health of both the public and Toronto Hydro employees. In order to protect the public and Toronto Hydro employees, the company has systems in place to detect failure incidents, and ensure coordination with all third parties before any replacements occur. Failure modes of equipment, depending on their nature, can have

immediate and serious safety and health consequences. Electrical equipment failures can lead to electrical arcs and arc flashes, which can lead to fires and pose serious risk to workers and the public. Civil failures and the collapse of equipment such as poles and underground vaults can put the public and Toronto Hydro employees at risk.

A reactive capital program can mitigate safety and health risks by replacing assets approaching imminent failure. An example of safety risk mitigation is the replacement of failed network protectors. The failure of a network protector to operate can lead to network vault fires, which poses significant safety risks for firefighters, the public and Toronto Hydro employees. In addition to replacing an asset that has failed, harmful debris and contamination caused by a failed asset, such as asbestos in the case of fibertop network units, are removed and cleaned up. Examples of the effects of an underground network vault fire and asbestos cleanup crews working on removing all asbestos contaminants from a vault are shown in Figures 1 and 2.

FIGURE 1: (LEFT) FAILED PROTECTOR. (RIGHT) BURNT AILC SECONDARY CABLES.

FIGURE 2: ASBESTOS CLEANUP OF VAULT

(iii) Reliability

Finally, reliability is an important driver of the program. Depending on the asset and its location within the distribution system, system reliability will be impacted to varying degrees by an asset failure. Asset failures affect the supply of power to Toronto Hydro's customers and strain the system. See Section E6.20.3.2 (iii) for more information of historical and projected system reliability impacts.

E6.20.3.2 Asset Details

Due to the unplanned nature of reactive work, it is difficult to project the total number of assets that will need to be replaced in a given year through the Reactive Capital program. However, as discussed in Section E6.20.3.2 (iii), assets are continuing to deteriorate as demonstrated by the number of outages caused by failed equipment, and the severe deficiencies and corrective work requests generated by inspectors and work crews. Other factors that are taken into account to help project the number of assets that may fail in a given year include asset age, condition, location, configuration and loading, all of which can affect longevity. Approximately 26% of all assets in the distribution system will be beyond their useful lives by 2015.

(i) Asset Lifecycle

The useful life of an asset is defined as the estimated range in years that it is expected to operate as designed without the need for repair or replacement. Depending on an asset's complexity, operational stress, location and configuration, its useful life will vary. Figure 3 illustrates the assets that will reach end-of-life by 2015, distributed between overhead, underground, network, station and civil categories. Nearly a third of the assets approaching end-of-life in 2015 are stations assets, which pose a significant risk to reliability and customer satisfaction. Due to their location within the distribution system, outages on station assets have the potential to affect a large number of customers.

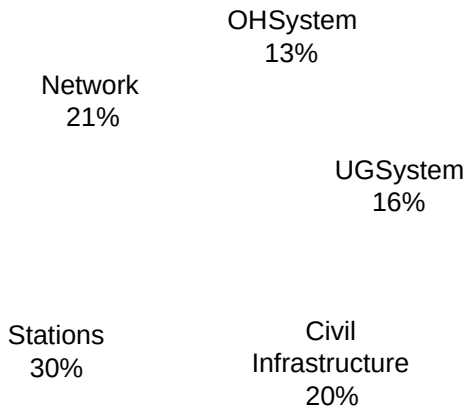

FIGURE 3: DISTRIBUTION OF ASSETS BEYOND THEIR USEFUL LIFE BY 2015

Degradation processes, such as corrosion, water ingress and heavy loading can expedite various failure modes of an asset. Toronto Hydro has maintenance programs in place to address various degradation processes and prevent asset failures; however, all assets, even those that have

been properly maintained, are at risk of failure at any time, whether it is from age related issues or problems beyond the control of maintenance. As such, reactive capital programs play a pivotal role in addressing failed assets.

Figures 4 and 5 illustrate some of the structural deficiencies associated with underground vaults and pole equipment.

FIGURE 4: UNDERGROUND VAULT STRUCTURAL DEFICIENCIES

FIGURE 5: INFRARED (IR) SCAN OF HOT SPOT DEFICIENCY ON POLE EQUIPMENT (INDICATED BY RED ARROW ON RIGHT IMAGE)

(ii) Asset Failure Impacts

Each asset has two or more distinct failure modes that result in a certain consequence cost. Typically, the two modes of failure are a normal failure and a catastrophic failure, as defined below.

Normal Failure

A "normal" failure mode is defined as a typical asset failure, where the outage is only experienced by local, connected customers and where there are usually no further associated events and/or collateral damage that results in "indirect" costs. A typical example of a "normal" failure would be an internal winding fault within a transformer, which would result in an outage to all connected customers and would necessitate replacement of the transformer.

Catastrophic Failure

A "catastrophic" failure mode (Figures 6 and 7) is defined as an extraordinary failure of the asset, where the outage is typically on a larger scale, affecting a greater number of customers up the line fuse or feeder circuit breaker. These failures would typically result in associated events and/or collateral damage, ultimately leading to the incurrence of "indirect" costs. Safety and environmental risks may result from catastrophic failures due to the explosive failure modes of certain asset classes.

FIGURE 6: UNDERGROUND VAULT FIRE ON ST. CLAIR AVE

FIGURE 7: POLE COLLAPSING ONTO A RESIDENCE

The figures above provide examples of two catastrophic asset failures. These asset failures not only reduce system reliability, but may also pose significant safety and environmental risks to the public and Toronto Hydro employees.

(iii) Reliability Impacts

As stated in Section E6.20.3.2 (i), a high number of assets within Toronto Hydro's distribution system are projected to reach end-of-life within the next five years. This will likely result in a greater number of asset failures. Adequate proactive budgeting and resource allocation for reactive work lowers the risk of creating a backlog of failed assets requiring replacement, and depriving other programs of capital resources. Through immediate replacements of failed assets, impact costs to customers (outages and events) and Toronto Hydro (lost revenue) can be reduced, and system reliability can be maintained and improved.

Information presented in the following graphs is derived from historical data of Toronto Hydro's corrective work requests, outages, and defective equipment demographics.

Figure 8 shows that the total number of corrective work requests issued in a given year has been increasing and Toronto Hydro expects this trend to continue in 2015-2019. In 2012, a lower amount of corrective work requests were issued, which resulted in the sharp decline from the previous year, as explained in Section E6.20.3; this reasoning applies to all of the following figures in this section.

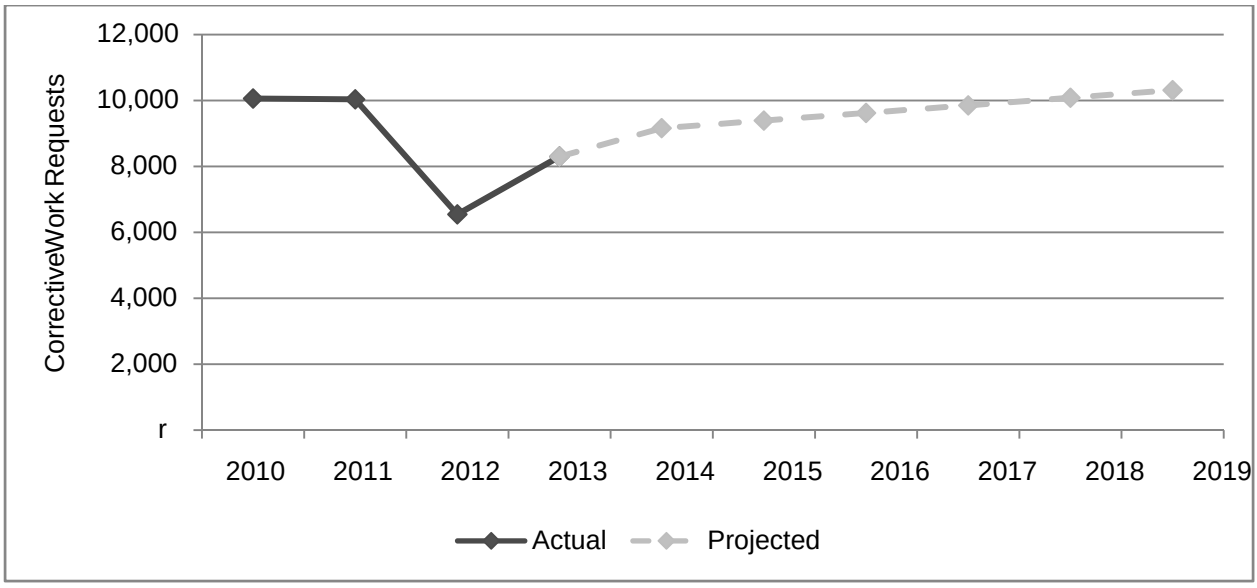

FIGURE 8: TOTAL NUMBER OF CORRECTIVE WORK REQUESTS TO ADDRESS OVERHEAD, UNDERGROUND, SECONDARY NETWORK & STATIONS DEFICIENCIES

Figure 9 shows the total number of asset failures across all systems, recorded by Toronto Hydro's Defective Equipment Tracking System (DETS). Assets tallied here only include those that were found during operational procedures or scheduled maintenance tasks. Over 700 asset failures were detected in 2010 and 2011. While there was a decrease in 2012, the number of failures increased by 12% in 2013.

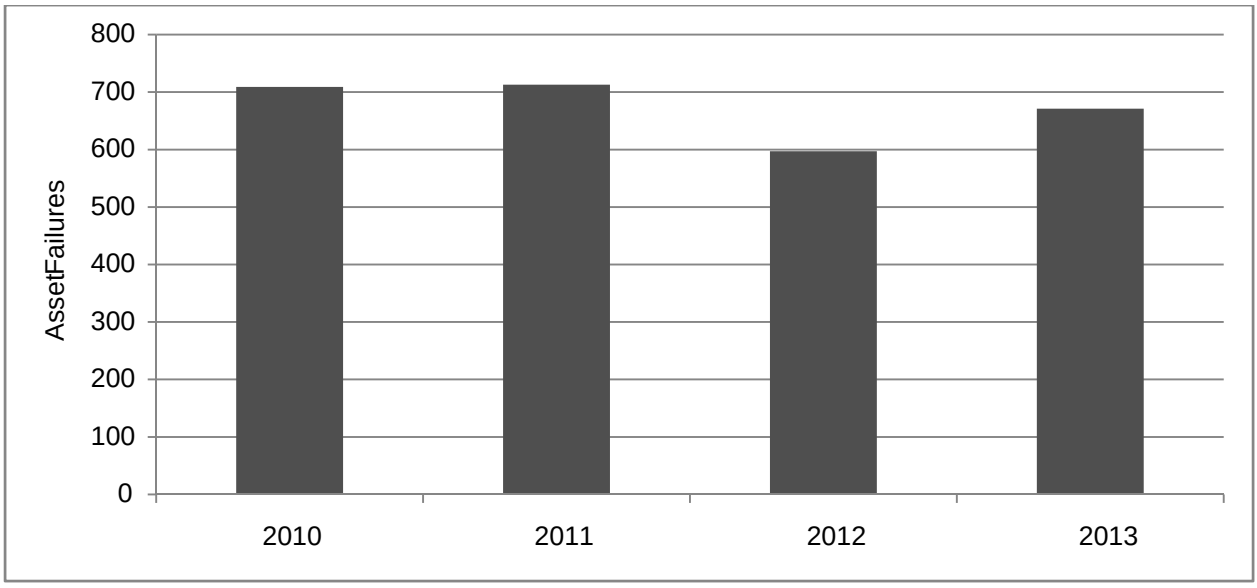

FIGURE 9: TOTAL NUMBER OF ASSET FAILURES ACROSS OVERHEAD, UNDERGROUND, SECONDARY NETWORK & STATION SYSTEMS (DETS)

Figure 10 illustrates the historical trend of the total number of asset failures resulting in outages across all systems; recorded from Toronto Hydro's Interruption Tracking Information System (ITIS). Over 1,000 failures occurred in 2010 and 2011. While there was a decrease in 2012, the number of failures increased by 14% in 2013. Approximately 19% of all failures during the 2010-2013 period in Figure 10 were caused by external factors including adverse weather, tree contacts, animal contacts and foreign interference.

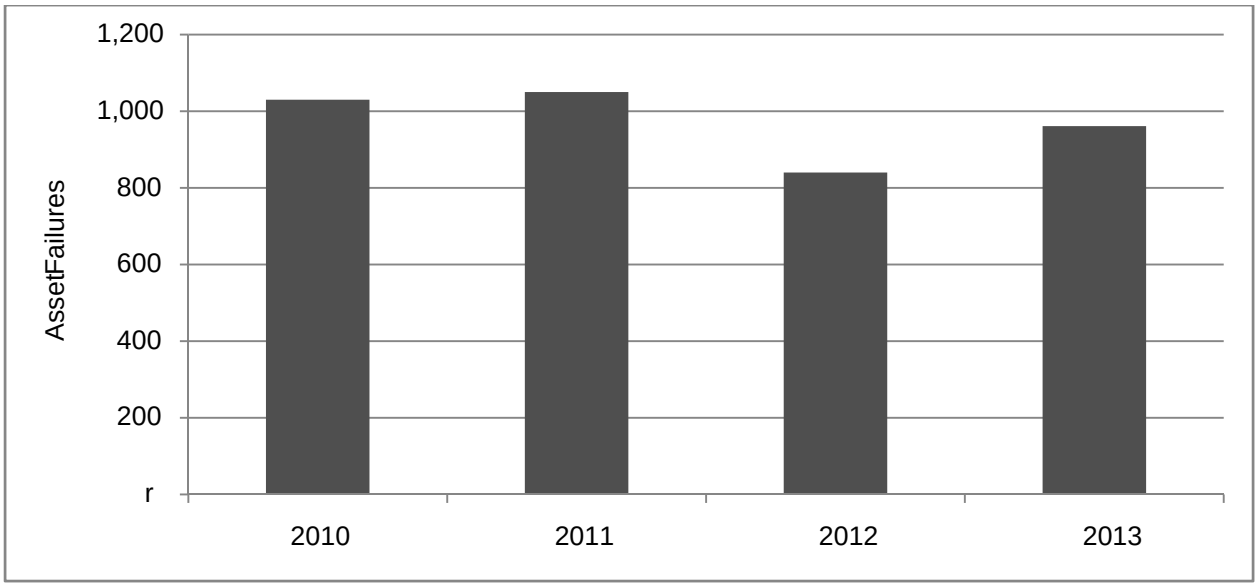

FIGURE 10: TOTAL NUMBER OF ASSET FAILURES RESULTING IN OUTAGES ACROSS OVERHEAD, UNDERGROUND, SECONDARY NETWORK & STATION SYSTEMS (ITIS)

(a) Overhead Assets

The overhead system includes overhead conductor wire, utility poles and their corresponding attached equipment, transformers and switches. Approximately 21% of all overhead assets will reach their end-of-life by 2015, without considering planned capital investments to be completed by then. Overhead assets are much more susceptible to non-asset related deficiencies such as animal/insect/tree contacts, weather and vegetation related incidents. These factors accelerate degradation processes. Figure 11 shows an example of a catastrophic failure of a wood pole collapsing onto neighbouring poles.

FIGURE 11: MULTIPLE POLE COLLAPSE

Figure 12 illustrates the number of overhead asset failures resulting in outages to the system, recorded by ITIS. Toronto Hydro has consistently experienced at least 250 failures annually during the 2010-2013 period. The main overhead assets responsible for the outages illustrated in Figure 12 consist of switches, transformers, lightning arresters, conductor wire, insulators and poles.

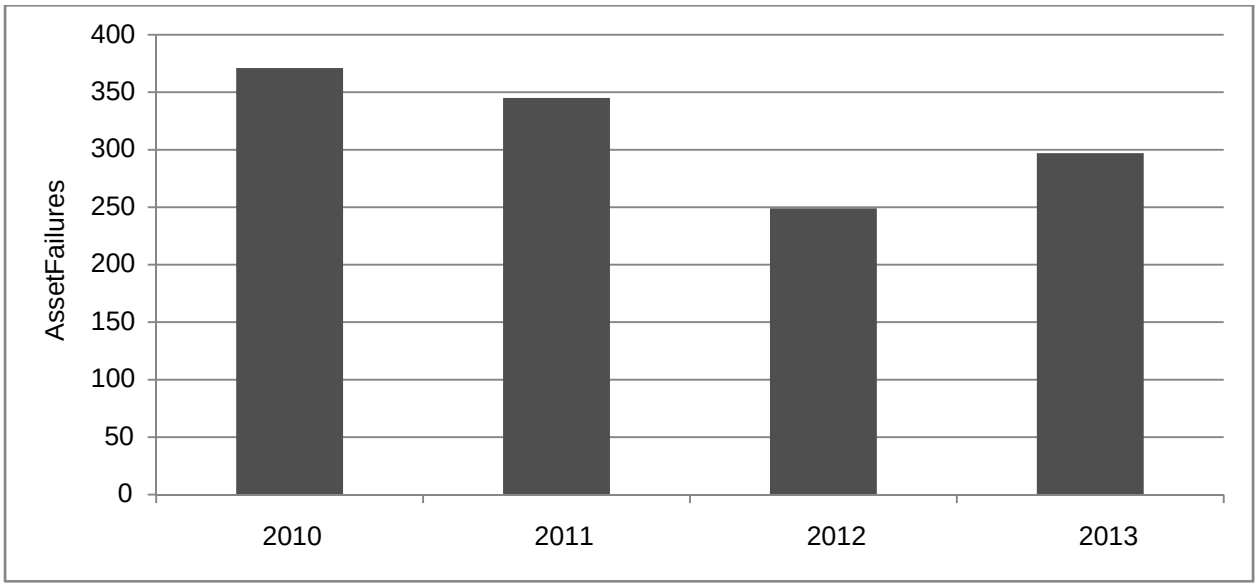

FIGURE 12: NUMBER OF OVERHEAD ASSET FAILURES RESULTING IN OUTAGES (ITIS)

Figure 13 shows a trend of overhead asset failures, recorded by DETS. Assets tallied here only include those that were found during operational procedures or scheduled maintenance tasks. Over 60 asset failures have been found annually during the 2010-2013 period.

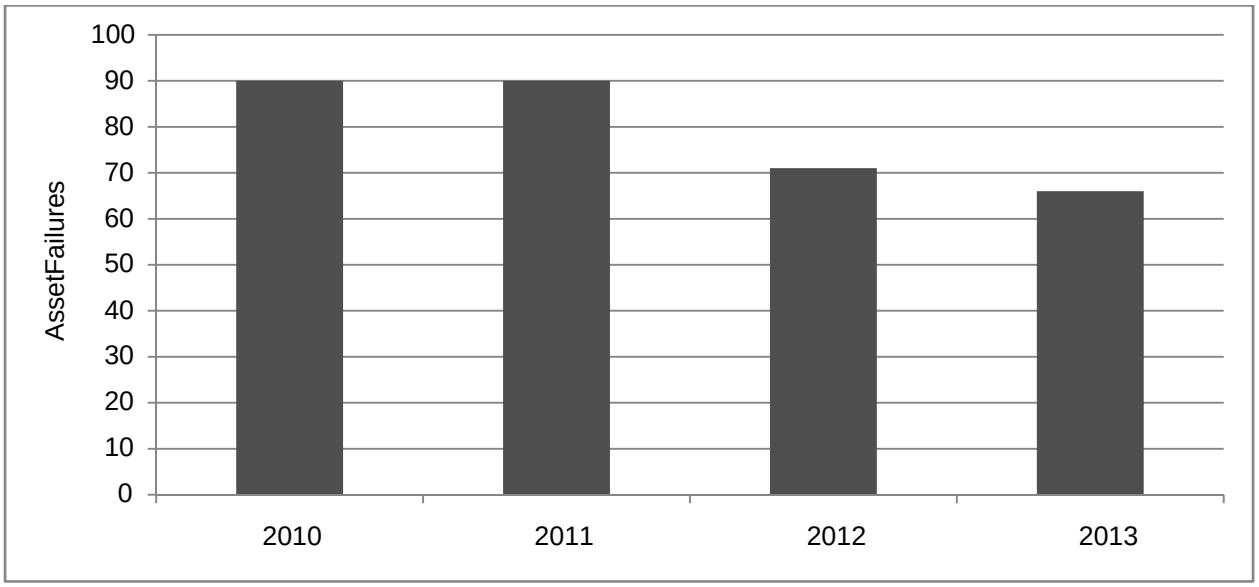

FIGURE 13: NUMBER OF OVERHEAD ASSET FAILURES (DETS)

Figure 14 shows the historical trend for the number of overhead corrective work requests. The number of work requests exceeded 2,500 in 2010 and 2011. Although the number of work requests declined in 2012, there is an increase in 2013. Toronto Hydro projects this increase to continue during the 2015-2019 period as a greater population of overhead assets exceed their useful life.

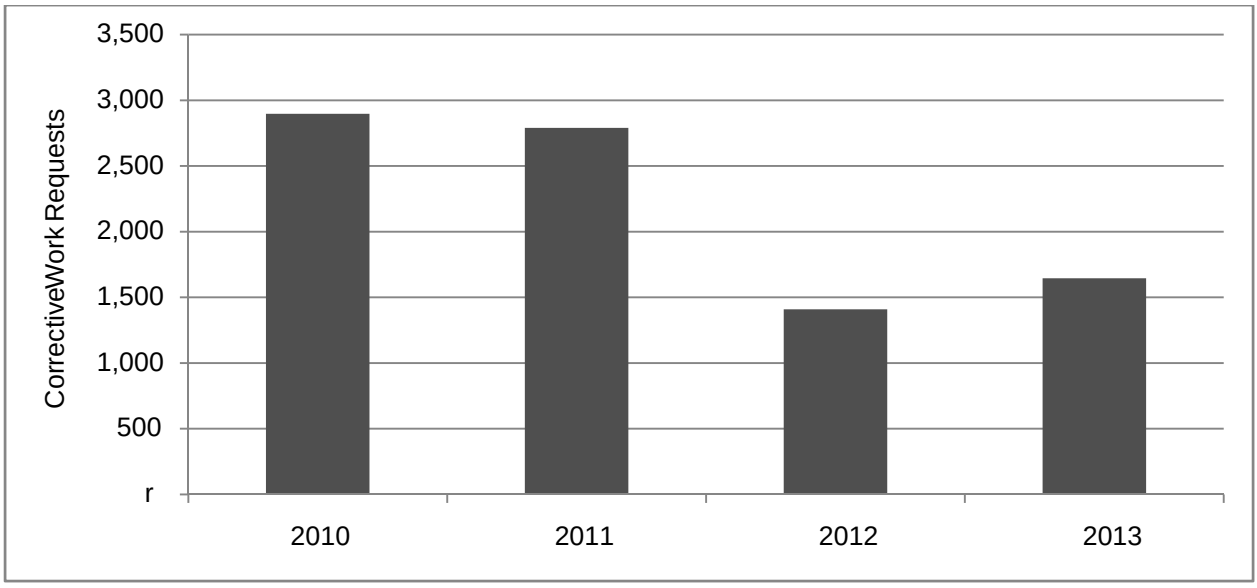

FIGURE 14: NUMBER OF OVERHEAD CORRECTIVE WORK REQUESTS

(b) Underground & Secondary Network Assets

Both the underground distribution system and secondary network system primarily consist of below-grade vaults and cable chambers, and the assets housed within them including cables, splices, joints, transformers and switches. Approximately 26% of underground assets, 35% of secondary network assets and 32% of all civil infrastructure will reach end-of-life by 2015, without considering planned capital investments to be completed by then.

Structural failures of vaults can lead to failures of all the assets inside them. Higher asset failure rates for vaults will reduce system reliability and cause longer outages. The damage to internal electrical equipment as a result of a vault failure (Figure 15) can be significant and replacement costs add to the costs normally required for power restoration. In addition, vault fires can occur when internal protection devices fail to prevent potentially unsafe backfeed conditions (reverse flow of power). These conditions may pose safety and health risks in the case of a network vault fire with fibertop units inside, which are often connected to the secondary grid using asbestos-insulated lead covered (AILC) secondary cables.

Approximately 60% of all network vault enclosures are expected to reach end-of-life within the next 10 years or less, while over 80% of all network vault roofs, which experience greater

exposure to external degradation factors, are already past end-of-life. A single vault can cost $1 million to rebuild.

FIGURE 15: (LEFT) VAULT WITH ROOF SLABS OFF. (RIGHT) TWO FIBERTOP UNITS DAMAGED BY A VAULT FIRE.

Faulted direct-buried cross-linked polyethylene (XLPE) cables are costly to repair due to the high number of labour hours required to locate and repair the fault. Segments of cables with high failure rates may require reactive work to install a standard concrete-encased duct bank to permanently replace the faulted cable segment. This reactive capital work is costly but necessary to remove consistently problematic direct-buried XLPE cable assets from the system, which improves system reliability.

Figure 16 illustrates the number of underground and secondary network asset failures resulting in outages to the system, recorded by ITIS. The number of asset failures has exceeded 400 annually during the 2010-2013 period. The main underground and secondary network assets responsible for the outages in Figure 16 are underground cable, transformers, elbows, switchgears, terminators, joints/splices and potheads.

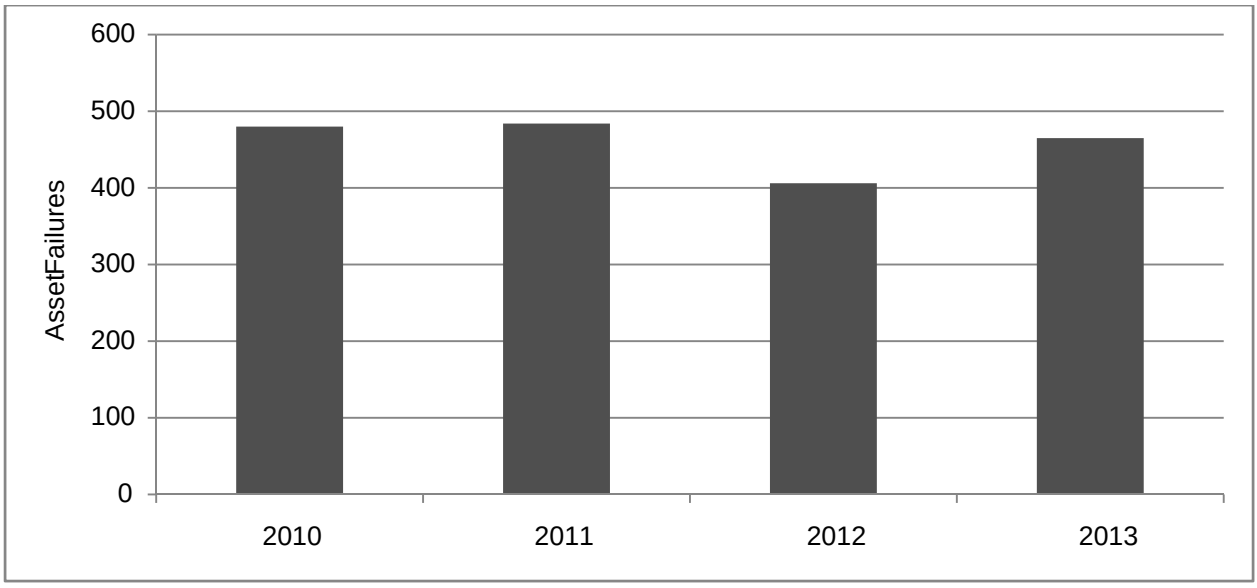

FIGURE 16: NUMBER OF UNDERGROUND & SECONDARY NETWORK ASSET FAILURES RESULTING IN OUTAGES (ITIS)

Figure 17 shows a trend of underground and secondary network asset failures, recorded by DETS. Assets tallied here only include those that were found during operational procedures or scheduled maintenance tasks. Over 200 asset failures have been found annually during the 2010-2013 period. The detection of underground and secondary network asset failures is shown to be on the rise as of 2013.

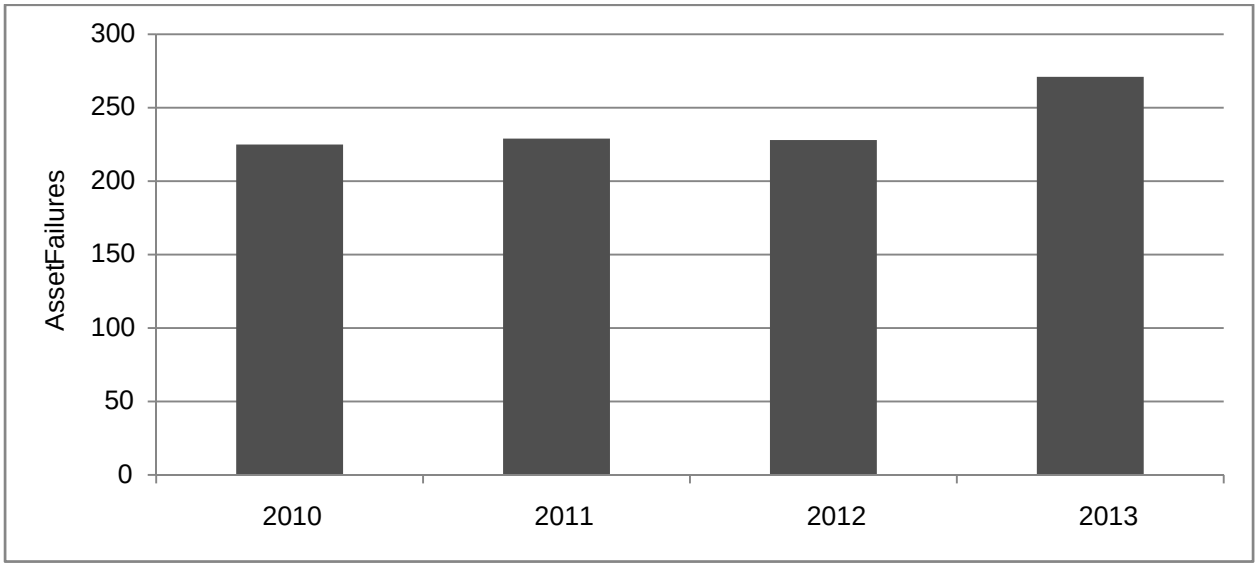

FIGURE 17: NUMBER OF UNDERGROUND & SECONDARY NETWORK ASSET FAILURES (DETS)

Figure 18 shows the historical trend for the number of underground and secondary network corrective work requests. The number of work requests exceeded 5,000 in 2010 and 2011. Although the number of work requests declined in 2012, there was a 53% increase in 2013, bringing the number up to 2010 and 2011 levels. Toronto Hydro projects this increase to continue during the 2015-2019 period, as more underground and secondary network assets exceed their useful life.

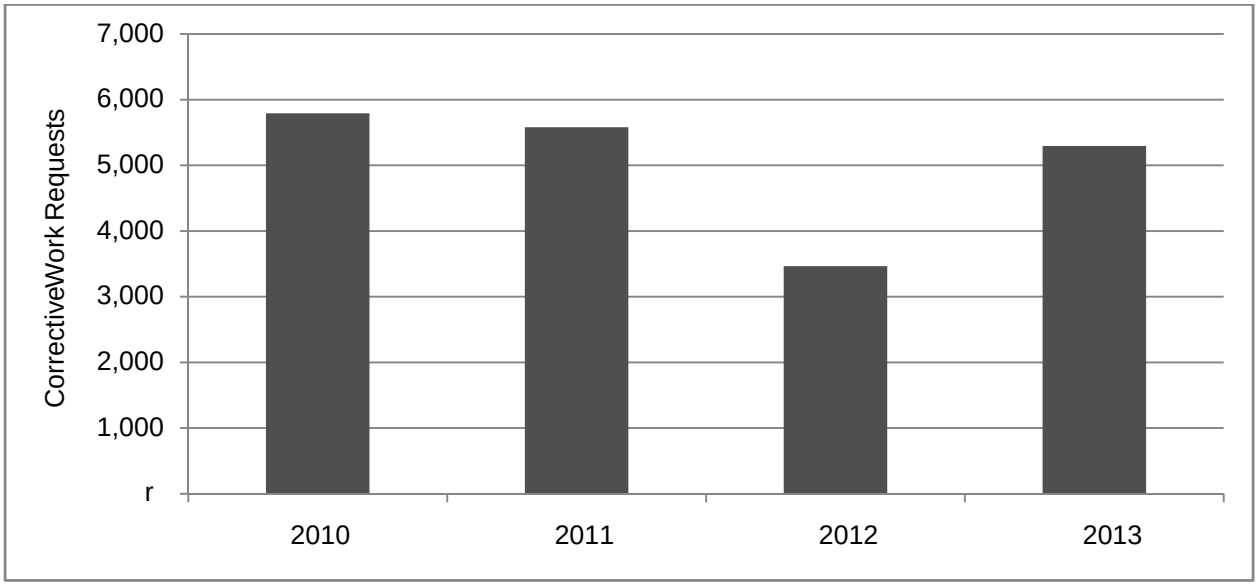

FIGURE 18: NUMBER OF UNDERGROUND & SECONDARY NETWORK CORRECTIVE WORK REQUESTS

(c) Station Assets

Station assets include power transformers, circuit breakers, relays, batteries/chargers, SCADA telemetry and/or control equipment, station alarms, DC panels, station heating, ventilation systems and sump pumps, which are installed across Toronto Hydro's 164 municipal stations and 35 transformer stations. Approximately 50% of all stations assets will reach end-of-life by 2015, without considering planned capital investments to be completed by then.

Figure 19 illustrates the number of station asset failures resulting in outages to the system, recorded by ITIS. The number fluctuates between 10 and 20 assets annually. The number of outages caused by failed station assets is much lower than the number caused by overhead and

underground assets, however station assets have higher failure impact costs to customers (outages and events) and Toronto Hydro (lost revenue). The main station assets responsible for the outages illustrated in Figure 19 are power transformers, cabling/terminations, switchgears, circuit breakers and other protection and control equipment.

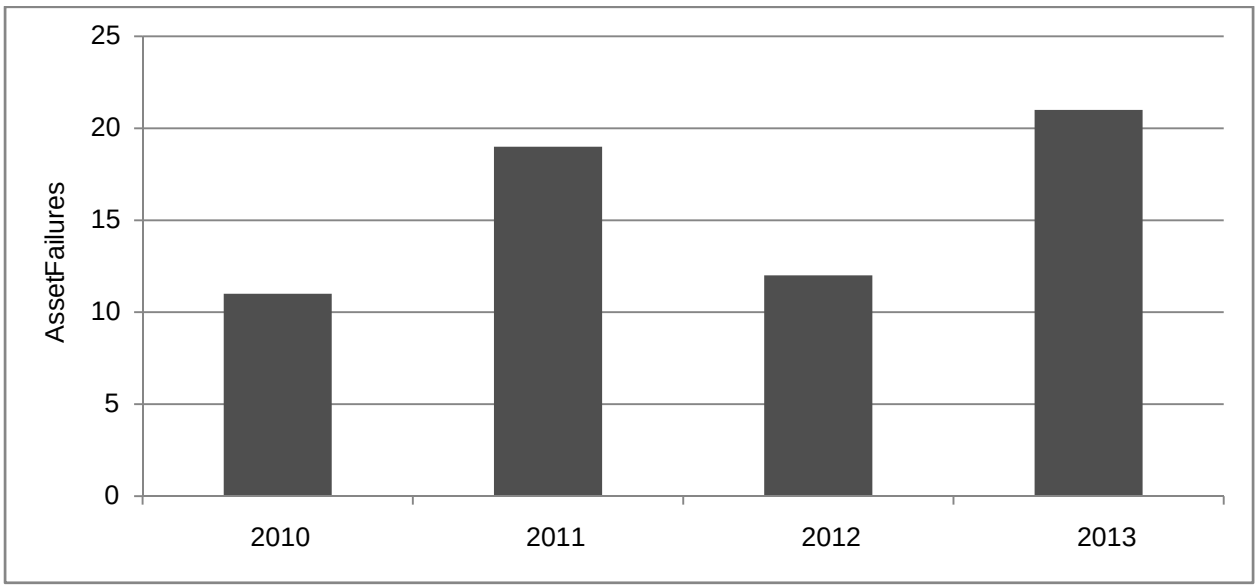

FIGURE 19: NUMBER OF STATION ASSET FAILURES RESULTING IN OUTAGES (ITIS)

Figure 20 shows a trend of station asset failures, recorded by DETS. Assets tallied here only include those that were found during operational procedures or scheduled maintenance tasks. At least 300 failures have been found annually during the 2010-2013 period. The detection of station asset failures are shown to be on the rise as of 2013.

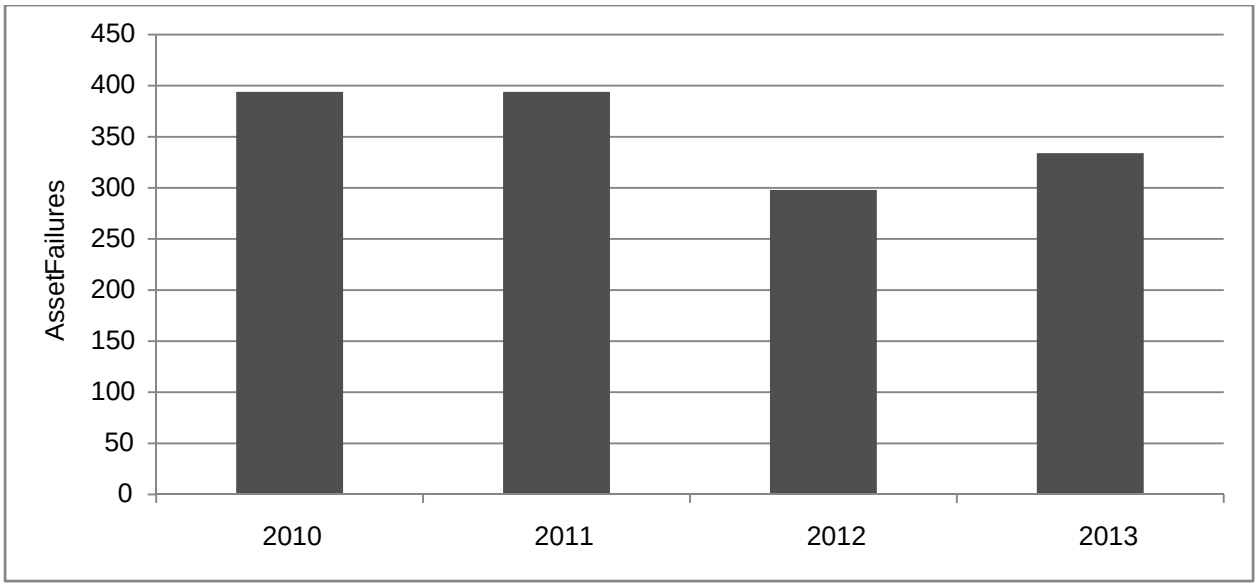

FIGURE 20: NUMBER OF STATION ASSET FAILURES (DETS)

Figure 21 shows a historical trend of the number of stations corrective work requests. The number of corrective work requests averaged over 1,500 in 2011 and 2012. The number of work requests is shown to be on the decline as of 2013, however it is expected the trend will increase again, as a greater population of station assets exceed their useful life.

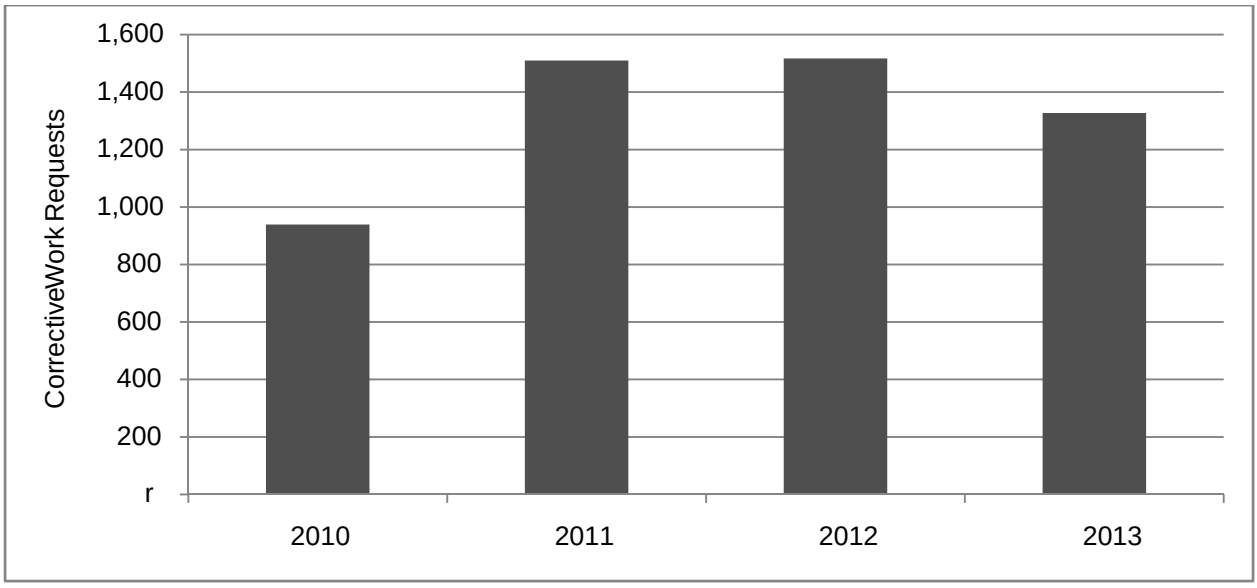

FIGURE 21: NUMBER OF STATIONS CORRECTIVE WORK REQUESTS

(d) Metering Assets

Metering reactive capital work includes replacement jobs for defective Smart Meters, Suite Meters, Interval Meters and Primary Metering units (Current Transformers/Potential Transformers). The failure of the communication module is a primary cause for meter replacements, where data is unable to be received or transmitted. Primary metering unit failures may be due to blown primary current transformer or potential transformer fuses. Meter replacement work is usually performed after hours and requires an outage for the affected customer. Failed smart meters that aren't replaced quickly can result in delayed billing and the need to estimate power consumption.

Table 5 summarizes the total number of meter replacements for each meter type from 2014-2019. The number of Smart Meters, Remotely Interrogated Meters (RIMS) and Quadlogic's requiring replacement is projected to increase significantly in 2015-2019. This is due to the larger population of non-mechanical metering assets now installed. Today's smart meters are configured to perform a self diagnosis every 24 hours and report any potential errors, statuses or warnings. These checks are designed to ensure that the meters are measuring energy accurately. Non-mechanical meters on the other hand provide only one reading every 30 or 60 days for troubleshooting and determining their health. In addition to the smart meters own

diagnostics, Toronto Hydro receives 720 hourly interval and 120 electronic register reads which are validated and checked for anomalies. This level of scrutiny and volume of data has lead to the discovery of meter issues and failures before they impact billing and result in higher meter replacements.

In order to provide this information, smart meters have additional components such as circuit and memory boards, LCD displays, batteries and communication modules, which are susceptible to errors and issues unlike mechanical meters. New meters are required to transmit interval data in five, 15 or 60 minute intervals for time sensitive billing. Billing is based on thousands of reads per month versus conventional meters with demand registers which only use a maximum of three readings. This data is used to bill customers based on time of use rates and provides customers with the ability to have a granular view of their energy use by 8:00 am the following day. Understanding their hourly energy use empowers customers to control their energy costs.

TABLE 5: REACTIVE METER REPLACEMENTS FOR 2014-2019

Meter Type	Projected						
	2014	2015	2016	2017	2018	2019	Total
Smart Meters	1,186	3,930	3,930	3,930	3,930	3,930	23,101
RIMS	10	88	88	88	88	88	470
Quadlogic	287	1,057	1,157	1,257	1,357	1,457	7,022
Total	1,483	5,075	5,175	5,275	5,375	5,475	30,593
Primary Metering Units	8	10	10	10	10	10	50
Total	1,491	5,085	5,185	5,285	5,385	5,485	30,643

TABLE 6: METER ASSET REPLACEMENT COSTS ($ MILLIONS) FOR 2014-2019

Meter Type	Projected						
	2014	2015	2016	2017	2018	2019	Total
Smart Meters	$.45 M	$1.2 M	$1.23 M	$1.25 M	$1.27 M	$1.3 M	$7.14 M
RIMS	$.01 M	$.12 M	$.13 M	$.13 M	$.13 M	$.13 M	$.67 M
Quadlogic	$.09 M	$.26 M	$.29 M	$.31 M	$.34 M	$.36 M	$1.73 M
Total	$.55 M	$1.59 M	$1.64 M	$1.69 M	$1.74 M	$1.8 M	$9.54 M
Primary Metering Units	$.25 M	$.26 M	$.27 M	$.27 M	$.28 M	$.28 M	$1.35 M
Total	$ 0.8 M	$ 1.9 M	$ 1.9 M	$ 2 M	$ 2 M	$ 2.1 M	$ 10.9 M

As explained above, the higher volume of non-mechanical meter failures are expected to result in higher replacement costs in 2015-2019, as shown in Table 6 above. The primary metering category includes one third of 1% of the largest customers who represent approximately 45% of Toronto Hydro's gross revenue. There have been 8-10 failures in this group per year costing up to $35,000 per replacement.

In addition to the increased failure rate of metering assets, Toronto Hydro is regulated by Measurement Canada (sections 9, 11 and 12 of the Electricity and Gas Inspection Act[5]) to ensure that all customers are metered and billed accurately. All meters failing to comply with the act risk being taken out of service, which will result in additional spending and allocation of resources to remove all affected meters.

Replacements of defective primary metering units also ensures Toronto Hydro's customers have accurate data to meet the requirements for Hourly Ontario Energy Price (HOEP) spot market pricing, and OPA programs such as DR3, where accurate internal data is required as part of their contractual obligations.

E6.20.4 Timing & Pacing of the Program

Reactive capital work is generally unplanned and only executed in response to an asset failure or asset approaching imminent failure and requiring immediate replacement. Reactive capital jobs are prioritized for assets that pose the greatest risk to system reliability, customer satisfaction, safety of the public and Toronto Hydro employees, and the environment.

Table 7 below provides historical and forecasted reactive capital spending. The total forecasted spending from 2015 to 2019 is $165.5 million. The projected budgets are relatively constant and aligned with projected corrective work requests as further discussed in Section E6.20.3.2 (iii).

TABLE 7: HISTORICAL AND FUTURE SPENDING (2010-2019)

	Historical Spending					Future Spending				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	25.1	28.6	29.2	37.4	32.1	31.9	32.7	33.1	33.6	34.2

[5] R.S.C., 1985, c. E-4. ["Electricity and Gas Inspection Act"]

Planned capital investments during the 2015-2019 period aimed at eliminating obsolete legacy assets and assets at their end-of-life such as fibertop network units, RPBs, ATSs, and porcelain insulators reduce the risk of these assets resulting in catastrophic failures, requiring replacement. Some of the proposed changes to Toronto Hydro's distribution maintenance programs during the 2015-2019 period focus on improving the detection and correction of deficiencies and move more towards condition based maintenance. These changes include: reduced vegetation management cycles; PCB testing at below-grade structures, pad-mounted equipment locations and customer locations; the use of new technologies, tools and testing methods such as ultrasonic testing to detect partial discharge (corona), infrared scanning to detect faulted components (Figure 8) and oil testing to monitor transformer health; increased proactive maintenance activities at customer locations and substations; the inclusion of street lighting maintenance and cable testing; and increased reactive maintenance activities.

As shown in Table 8 below, the majority of reactive capital expenditures have historically been allocated to overhead and underground distribution system assets. Despite Toronto Hydro having fewer corrective work requests in 2012, reactive expenditures still increased; this is not an inconsistent result, as the expenditures required to address corrective work requests can vary considerably depending on the nature and scope of the work request (e.g., replacement of an overhead switch versus the replacement of a station power transformer); this is also evident for years 2010 and 2011, which differed by 26 work requests and $3.5 million in reactive expenditures. In 2013, $3.6 million was spent on the overhead system to address the December 21st ice storm. Due to the unplanned nature of reactive work, spending varies each year.

TABLE 8: HISTORICAL ALLOCATION OF REACTIVE CAPITAL SPENDING ($ MILLIONS)

Historical Reactive Capital Summary	2010 Actual	2011 Actual	2012 Actual	2013 Actual
Underground Assets	12.9	17.6	17.6	22
Overhead Assets	11.7	10.7	10.2	13.2
Station Assets	0.5	0.3	1.1	1.6
Metering Assets	-	-	0.3	0.7
Total	25.1	28.6	29.2	37.4

E6.20.4.1 Ranking & Prioritization

Reactive capital work takes precedence above all other capital work and may be executed immediately, following the detection of an asset failure or asset approaching imminent failure and posing high safety, environmental and reliability risks. If an asset exhibiting a Level 5 deficiency is

detected within the system, whether it is from planned capital or maintenance work, crews notify Toronto Hydro of the high-risk asset and remain at the site until reactive crews arrive to replace it. In terms of prioritization, Toronto Hydro dispatches crews to address those assets that pose the greatest safety and environmental risks first, followed by assets that have had the greatest impact on system reliability. Toronto Hydro maximizes resources and crew efficiency by strategically dispatching crews to those locations with the highest number of asset failures and customers impacted.

E6.20.5 Program Execution

Work under the Reactive Capital program is not pre-planned or scheduled. All asset replacements are made in response to either an asset failure or corrective work requests indicating high-risk assets that require immediate replacement and cannot be addressed during planned capital replacement.

Based on corrective work requests generated from Toronto Hydro's maintenance programs, assets may be scheduled for immediate replacement if Level 4/5 deficiencies are found, which pose serious potential safety or environmental risks to the public and Toronto Hydro employees. Before reactive capital work can be executed, Toronto Hydro must consider the timing, scheduling and approval of the work, as well as the asset type, its location and the nature of the failure. Once the failed asset is located, and proper coordination with all required third parties is made, crews are dispatched to the site to perform the replacement.

E6.20.5.1 Program Risks

As touched upon in Section E6.20.5, depending on the type of asset and the nature and scope of an asset failure, there are various risks that can delay the completion of reactive work such as resource and logistics constraints, and major storm events. In addition, depending on the location and nature of an asset failure, additional design, planning and approval may be required before the work can be executed.

E6.20.5.2 External Constraints

Depending on the nature, severity and location of an asset that has failed, coordination with third parties may be required to ensure replacement work can be performed in an efficient and safe manner.

E6.20.5.3 Standard & Regulation Adherence

Toronto Hydro must comply with the Minister of Energy's directive on smart meter installation and the metering requirements set out by Measurement Canada and in the Electricity and Gas Inspection Act. Toronto Hydro is responsible for ensuring that all customers are accurately billed and metered. In order to adhere to these requirements, Toronto Hydro must budget reactive capital work for meter replacements. In addition, Toronto Hydro must undertake reactive capital work to address asset failures and maintain compliance with relevant environmental, health and safety legislation.

E6.20.6 Evaluation of Alternatives

Toronto Hydro considered three alternatives for addressing failed assets:

(4) Performing reduced reactive capital work

(5) Performing no reactive capital work, or

(6) Performing the Reactive Capital program as set out in this narrative.

E6.20.6.1 Performing Reduced Reactive Capital Work

This option involves using a lower reactive capital budget to address all reactive capital work in 2015-2019, without taking into consideration Toronto Hydro's aging distribution infrastructure and incremental asset failure rates. Implementing this option would result in inadequate funding to meet the demands of required reactive capital work. A backlog of work would arise and deprive planned capital or maintenance programs of required resources. Inadequate funds would also increase safety risks to the public and Toronto Hydro employees and environmental risks.

Figure 12 shows that the total number of corrective work requests have been increasing, a trend which is projected to continue in 2015 to 2019, while Figures 13 and 14 show the number of asset failures annually across the distribution system have remained relatively constant. These trends are consistent with the fact that the overall asset population is aging, and together, indicate that a reactive capital budget in line with 2014 spending is necessary to address asset failure issues over the 2015 to 2019 period. Thus, the option of allocating a lower budget for reactive capital is not recommended.

E6.20.6.2 Performing No Reactive Capital Work

This option involves no reactive capital budgeting for 2015-2019. The consequences of implementing this option are similar to the previous option above (reduced reactive work), but far more severe. With no reactive capital budget allocated, a significant backlog of work would result in very high capital costs, putting the system in contingency mode, severely limiting system growth and modernization. A consistent reactive capital budget in line with 2014 spending levels is necessary to address emerging problems within the distribution system. Therefore this option is not preferred. .

E6.20.6.3 Proposed 2015-2019 Reactive Capital Work

The proposed Reactive Capital program is necessary to address anticipated reactive capital expenditures. These expenditures are necessary to maintain system performance and reliability, support customer satisfaction, eliminate safety risks to the public and Toronto Hydro employees, mitigate environmental risks and maintain accurate billing. This budget is relatively constant and aligned with corrective work requests as further discussed in Section E6.20.3.2 (iii). This option is recommended.

E6.21 Worst Performing Feeders

TORONTO HYDRO CLEARING EXTREME WEATHER DEBRIS AFFECTING EQUIPMENT FUNCTIONALITY

E6.21.1 Summary

Program Description

The Worst Performing Feeder program is part of Toronto Hydro's effort to improve overall service reliability for customers supplied from poorly performing feeders. The program involves the identification of feeders that have experienced seven or more sustained, unplanned and/or long duration interruptions over a 12-month rolling period. Based on these results, projects are created to determine the root cause of the outages and to resolve the issue in a targeted, timely manner to improve reliability in the short-term.

Table A summarizes the anticipated benefits associated with this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduces the frequency of power interruptions for customers on feeders that are experiencing especially poor reliability performance
Reliability	ƒ Improved reliability on a small number of feeders (less than 50) that nonetheless contribute to approximately one third of annual customer interruptions (CI) and one quarter of annual customer hours interrupted (CHI). Refer to section E6.21.3 for additional details.
Efficiency	ƒ Mitigates the risk of future unplanned reactive work required to restore power to customers on poor performing feeders.
Safety	ƒ Removal of porcelain hardware mitigates the risks of potential catastrophic failure, whereby the hardware could shatter explosively,

	sending debris into the surrounding area.

Program Drivers

The Worst Performing Feeder program's trigger driver is summarized in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Failure of assets and foreign interference can result in power outages for customers connected to the feeder. As demonstrated in Figures 9 and 10, WPF feeders have contributed more than 30% of the annual customer interruptions (CI) and 28% of customer hours interrupted (CHI) over the past five years. ƒ The WPFs on Toronto Hydro's distribution system typically require short-term intervention to mitigate the risk of additional asset failures.

Preferred Alternative

The Worst Performing Feeder program analyzed and evaluated the following options:

(1) Replace all assets proactively as part of a longer term, planned capital rebuild program

(2) Target those feeders experiencing seven or more interruptions for improvement with short term mitigation investments

Option II is the preferred alternative as it provides immediate, targeted reliability improvements to customers experiencing especially poor electrical service.

Timing and Pacing

Table C summarizes the historical and forecasted costs for this program.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	16.7	19.3	6.7	1.2	4.8	1.8	1.8	1.8	1.8	1.8

In 2010 and 2011, Toronto Hydro spent $16.7 million and $19.3 million respectively on its WPF program, which included large rebuild projects designed to renew assets on poorly performing feeders (e.g., direct-buried cable rebuilds). In 2012, Toronto Hydro recalibrated the program to focus on targeted, short-term mitigation work that would yield immediate reliability improvement. Substantial rebuild projects that were previously included in the worst performing program were reallocated to either the planned Overhead or Underground Circuit Renewal programs. This change took effect mid-year, meaning that certain rebuild projects were charged to the WPF program, which resulted in actual spending of $6.7 million in 2012. Using the new, more focused approach in 2013, Toronto Hydro conducted mostly short term, small scale asset installation or replacement work, resulting in total spend of $1.2 million. Spending in 2014 is forecasted to increase to $4.8 million due to a number of projects that were previously delayed but that are still expected to provide considerable reliability improvements in poor performing areas.

As the assets in the field continue to age and deteriorate, Toronto Hydro anticipates ongoing random failures and interruptions. To address these failures, Toronto Hydro has forecasted investments of $1.8 million yearly from 2015 to 2019 for WPF projects.

E6.21.2 Program Description

Toronto Hydro's ongoing Worst Performing Feeder program targets feeders that are at risk of experiencing seven or more sustained power interruptions over a 12-month rolling period (excluding planned outages, major event days and outages caused by loss of supply). This includes feeders that have already experienced seven outages in a previous 12-month period (i.e., FESI-7 feeders[1]) as well as feeders that are trending towards FESI-7 status. This program funds small-scale mitigation measures executed in the short-term to reduce the risk of additional outages on feeders already causing reliability issues. The maps below outline the locations of FESI-7 feeders from 2010 to 2013. Toronto Hydro is plans to allocate a budget of $8.5 million to this program during the 2015 to 2019 forecast period.

FIGURE 1: 2010 FESI FEEDERS

[1] The FESI acronym stands for 'feeders experiencing sustained interruptions'

FIGURE 2: 2011 FESI FEEDERS

FIGURE 3: 2012 FESI FEEDERS

FIGURE 4: 2013 FESI FEEDERS

The WPF program is comprised of relatively quick, targeted actions that yield immediate reliability improvements. Toronto Hydro makes best efforts to constantly monitor the reliability performance of every feeder throughout the distribution system. Feeders that experience a high number of outages or are trending towards increased outages are selected for analysis to determine the cause of outages. As well, possible solutions are examined.

Based on the result of the analysis, field crews perform feeder patrols to assess the condition of equipment in the field. If the crew is examining an overhead feeder, they may carry-out basic mitigation work simultaneously, as required. Mitigation work may include the following (further detailed in this section below):

- animal guard installation,
- bare transformer drop wire replacement,
- metal switch bracket replacement, and
- glass or porcelain insulator replacement.

Animal Guard Installation, Bare Transformer Drop Wire Replacement and Metal Switch Bracket Replacement

Issue

Figure 5 depicts a pole without animal protection that contains a metal bracket, bare transformer drop wire and exposed live connection on the transformer primary bushing termination. In this case, there is a high risk for animal contact at the point between the bare live conductor and the metal bracket or the transformer enclosure that can result in power outages.

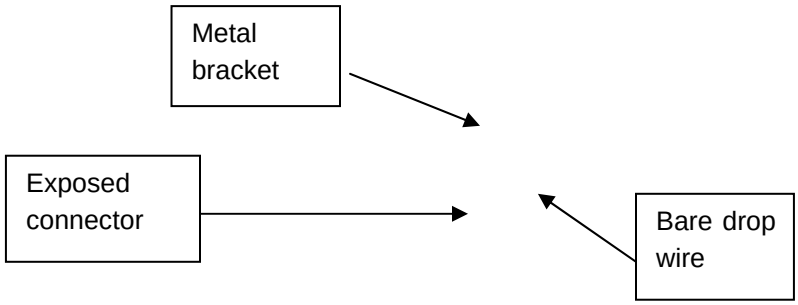

FIGURE 5: POLE WITHOUT ANIMAL PROTECTION

Solution

Figure 6 shows a pole after mitigation work has been completed. It contains a fiber-glass switch bracket, insulated drop wire and animal guard. These remedies insulate live conductors on the pole and prevent contact by animals minimizing the likelihood of power outages.

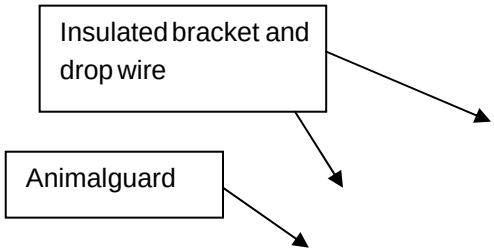

FIGURE 6: POLE WITH PROPER ANIMAL PROTECTION

Insulator Replacement

Issue

Figure 7 shows a pole with porcelain insulator. These assets are susceptible to tracking and flashover that would lead to power outages after sufficient contaminants and moisture accumulate on the insulator surface.

FIGURE 7: POLE WITH PORCELAIN INSULATOR

Solution

Figure 8 shows a pole with polymer insulator after mitigation work has been completed. Polymer insulators have a self-washing feature that minimizes contaminant build up on the insulation surface. In addition, polymer material contains an anti-beading function that naturally prevents water from forming a continuous path over its surface. This prevents the flow of leakage current between live conductor and the grounding point on the pole, which greatly reduces the risk of tracking and flashover over the insulation surface that could lead to power outages.

FIGURE 8: POLE WITH POLYMER INSULATOR

Follow-up Work

Feeder patrol results may also necessitate additional follow-up projects under the Worst Performing Feeder program. This follow-up work can consist of small scale capital replacement work that the crew could not perform during their initial patrol, including "like for like" replacements of select assets in the problem area, such as underground cable, transformers, or overhead conductor and ancillary equipment.

Relationship with Renewal Projects

In some cases, where a majority of assets on a feeder have aged or are in poor condition, a large-scale renewal project may be undertaken to refresh assets on the feeder. In these instances, the small-scale capital replacement performed to mitigate immediate failure risk pursuant to the WPF program would serve as a necessary bridge to provide interim reliability relief before full scale renewal projects are planned and carried out in the field. In addition, the WPF program is complementary to large-scale renewal projects as results from the feeder reliability analysis may be used to re-prioritize existing planned capital rebuild projects to respond to emerging and evolving reliability issues in the field.

Relationship with Maintenance Work

For assets that have not reached the end of their useful service lives or that are in good condition but are installed in areas with exposure to trees and/or excessive environmental contaminants that can cause outages, tree trimming or equipment washing may be required to reduce outage risks. This routine maintenance work is not part of this WPF program but is covered in the operating expenditures part of the WPF budget

The following table is a summary of the anticipated benefits of the WPF program. A detailed discussion of program drivers can be found in the following section.

TABLE 1: PROGRAM BENEFITS

Customer Value	Reduces the frequency of power interruptions for customers on feeders that are experiencing especially poor reliability performance
Reliability	Improved reliability on a small number of feeders (less than 50) that nonetheless contribute to approximately one third of annual customer interruptions (CI) and one quarter of annual customer hours interrupted (CHI). Refer to section E6.21.3 for additional details.
Efficiency	Mitigates the risk of future unplanned reactive work required to restore power to customers on poor performing feeders.
Safety	Removal of porcelain hardware mitigates the risks of potential catastrophic failure, whereby the hardware could shatter explosively, sending debris into the surrounding area.

E6.21.3 Why the Program is Needed

E6.21.3.1 Program Drivers

Toronto Hydro has classified the Worst Performing Feeder (WPF) program as a System Renewal activity because it deals primarily with failure risk on poor performing feeders, as further described in Table 3 below.

TABLE 2: PROGRAM DRIVERS

Trigger Driver	Reasoning
Failure Risk	ƒ Failure of assets and foreign interference can result in power outages for customers connected to the feeder. As demonstrated in Figures 9 and 10, WPF feeders have contributed more than 30% of the annual customer interruptions (CI) and 28% of customer hours interrupted (CHI) over the past five years. ƒ The WPFs on Toronto Hydro's distribution system typically require short-term intervention to mitigate the risk of additional asset failures.

Toronto Hydro's distribution system contains more than 1,600 feeders that supply power to over 700,000 customers in the City of Toronto. While any one of these feeders is subject to random equipment breakdown and foreign interference (e.g., tree and animal contacts) that can cause unplanned outages, certain feeders experience a disproportionate number of problems and cause an unacceptably high number of sustained interruptions. Customers on these feeders experience unreliable service that can lead to frustration and material financial losses. These are the feeders that the WPF program is designed to address.

The WPF program complements Toronto Hydro's general capital program in two ways. Firstly, with respect to feeders that are experiencing poor reliability performance due to contact with foreign objects, but where the majority of assets are not reaching the end of their useful lives and are still in fair working condition, WPF mitigation work is carried out in the form tree trimming and the installation of animal guards to increase service reliability. Secondly, with respect to feeders that contain a large quantity of assets that are operating near or beyond their useful service lives or in poor condition, a large scale planned renewal project may be needed to refresh these assets to reduce reliability risks and provide long-term improvements. Given that these rebuild projects typically take more than one year to complete, the WPF program is designed to provide interim reliability relief until the long-term rebuild program is completed.

Generally, the WPF program deals with probabilistic outcomes that are not entirely mitigated by planned maintenance and capital activities. The bulk of Toronto Hydro's planned activities are carefully designed and paced to address the highest risk assets and the most frequent outage causes in a cost-efficient manner and based on sophisticated risk-based models. Nevertheless, Toronto Hydro anticipates that there will continue to be a relatively small number of feeders that are statistical outliers in terms of the exceptionally poor performance that they exhibit in a 12-month period. These feeders continue to have an outsized impact on system reliability and customer value, and must be managed through the responsive, efficient and targeted interventions described in this program.

Figures 9, 10 and 11 show the historical count of FESI-7 feeders per year and their contribution to overall system reliability in terms of CI and CHI.

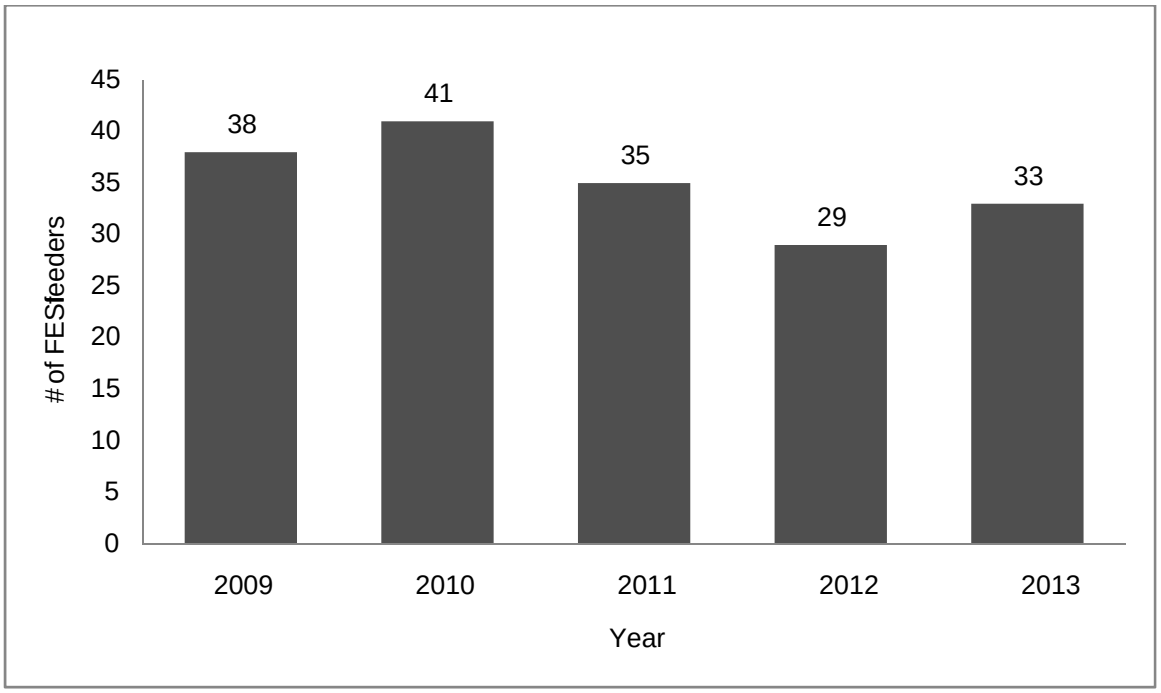

FIGURE 9: HISTORICAL WORST PERFORMING FEEDERS

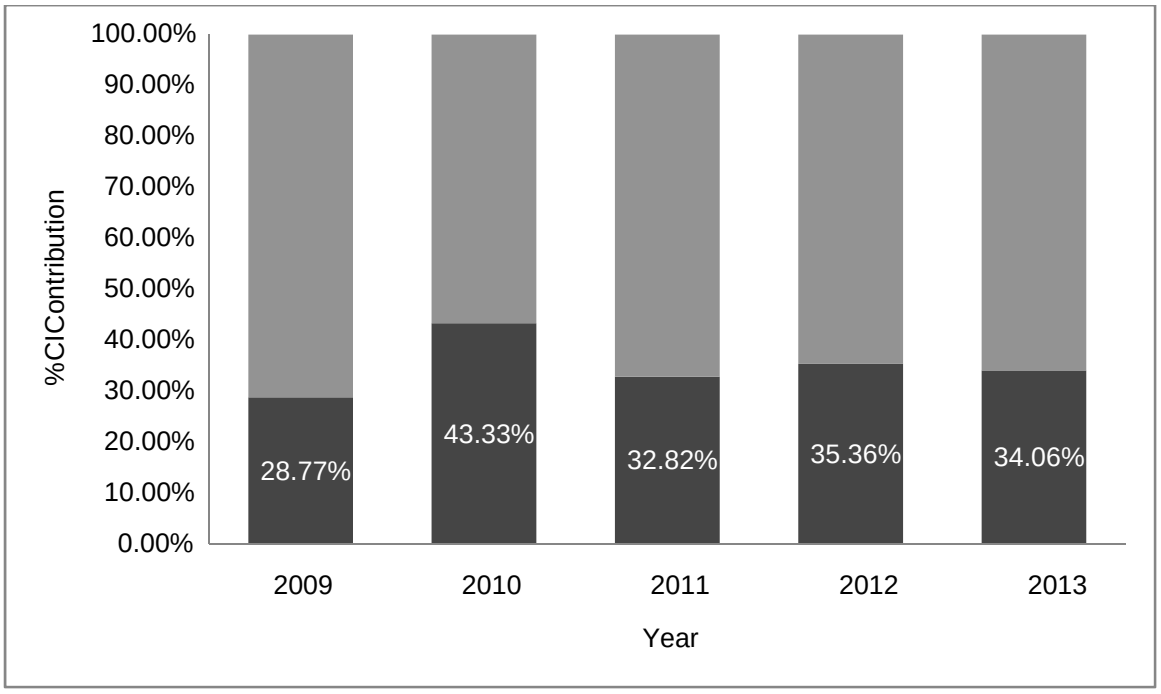

FIGURE 10: CUSTOMERS INTERRUPTED (CI) CONTRIBUTION OF WORST PERFORMING FEEDERS

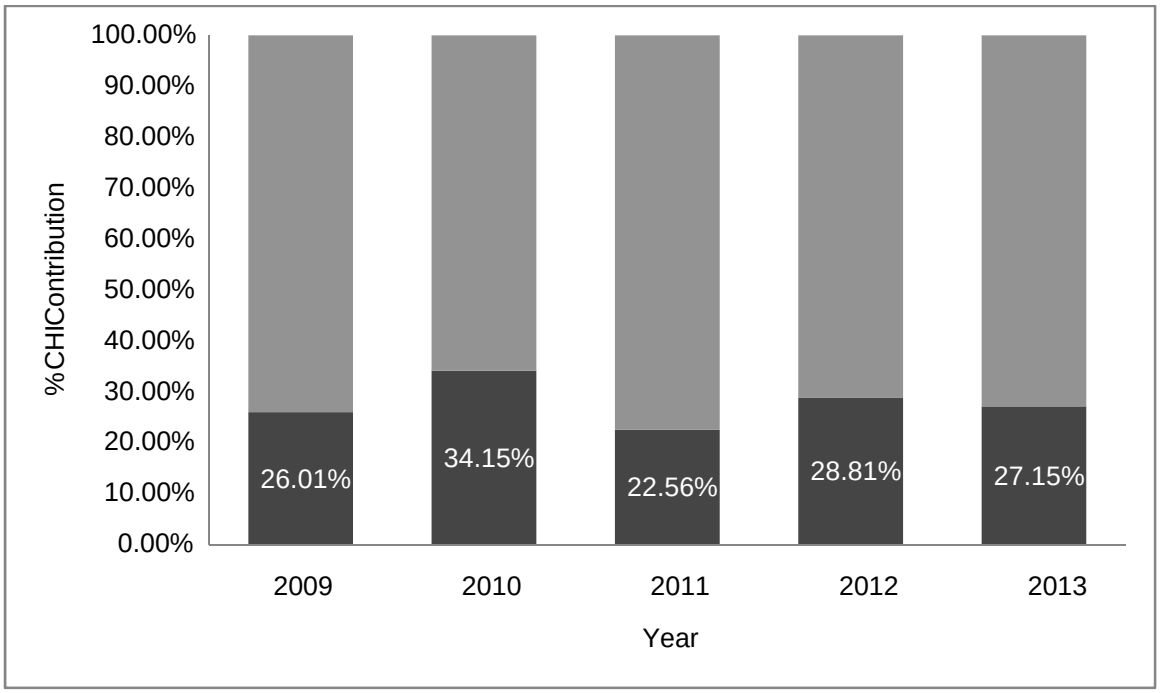

FIGURE 11: CUSTOMER HOURS INTERRUPTED (CHI) CONTRIBUTION OF WORST PERFORMING FEEDERS

The above figures show that while the annual number of WPFs is small (less than 50) relative to over 1,600 feeders that make-up Toronto Hydro's distribution system, they have a disproportionately negative effect on the system's overall reliability performance. As shown previously in Figure 11 and Figure 9, FESI-7 feeders have contributed to more than 34% of the system's annual CI and 27% of CHI in 2013.

Toronto Hydro anticipates that the WPF program will immediately improve system reliability, as demonstrated in Figure 12. The bar on the left shows the cumulative outages on FESI-7 feeders for the 2011 year. The bar on the right shows the cumulative outages on the same set of feeders in 2012. There was an improvement of approximately 50% from 2011 to 2012. Similarly in Figure 13, the bar on the left shows the cumulative outages of FESI-7 feeders in 2012r. The bar on the right shows the cumulative outages on the same set of feeders in 2013. There was an improvement of approximately 37% from 2012 to 2013.

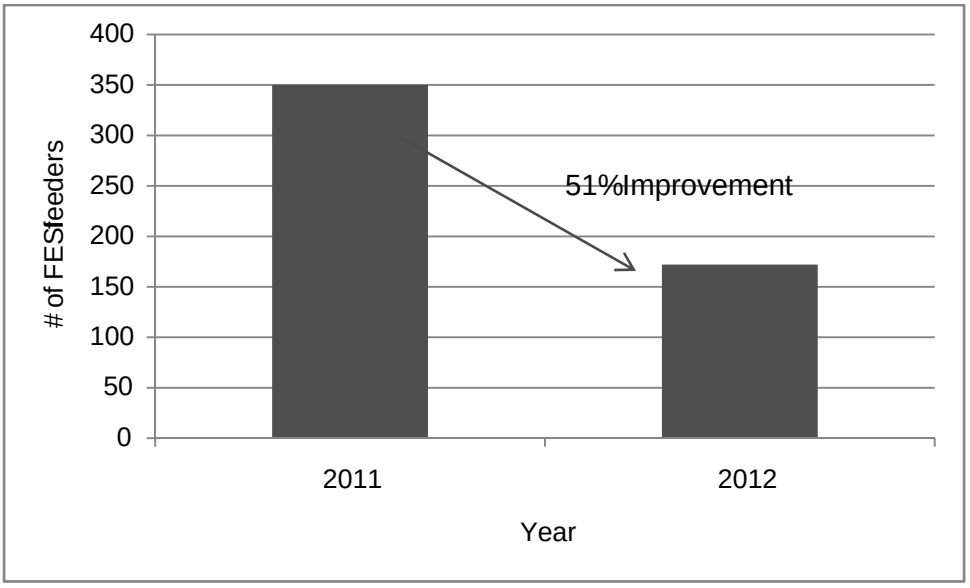

FIGURE 12: 2011 FESI FEEDER CUMULATIVE OUTAGES IN 2012

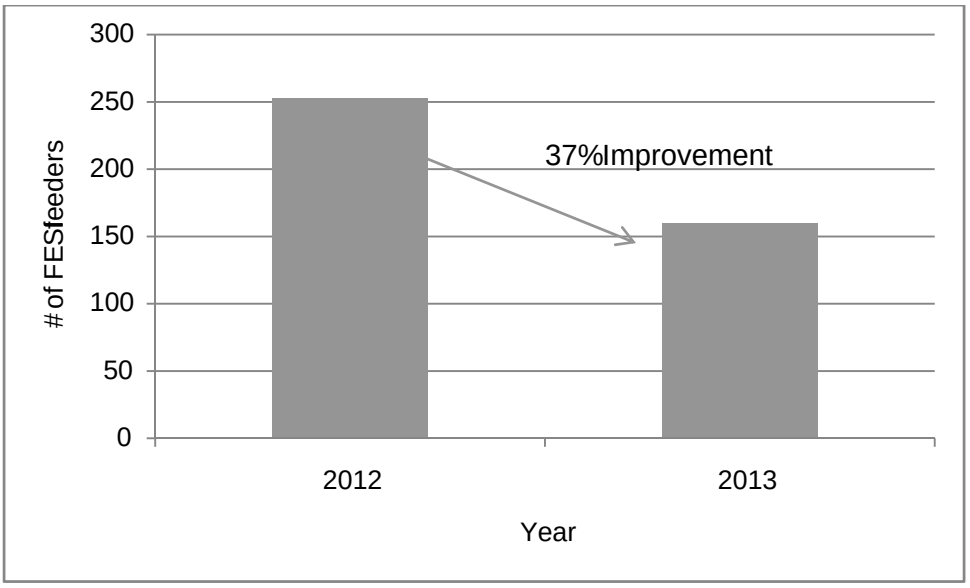

FIGURE 13: 2012 FESI FEEDER CUMULATIVE OUTAGES IN 2013

It is evident that past FESI mitigation work has provided noticeable improvements in the number of interruptions that a group of feeders will experience in a given year. However, as the WPF program is designed be a short term mitigation measure, it is not designed to perform full rebuild of assets on the troubled feeders as the planned asset renewal projects do. As a result, feeders that are addressed by the WPF program still experience random failure and power outages, albeit at a less frequent rate, until permanent, long-term solutions are implemented.

E6.21.3.2 Asset Details

Assets addressed in this program are mostly legacy installations that did not possess some of the features that the current standards require, such as animal protection and insulated overhead accessories. The FESI program studies feeders that are performing poorly to determine necessary mitigation work to strengthen these legacy components in order to prevent future failures. Some of the common components involved in WPF mitigation work are the following:

Transformer drop wire replacement : Transformer drop wire connects the load side of the transformer disconnect switch to the high voltage bushing of the overhead transformer as shown in Figure 5. Traditionally, a bare conductor is used for this connection. However, there is a risk of animal contact between the live conductor on one side of the transformer bushing and the grounded transformer enclosure on the other side, which can result in a short-circuit fault leading to an outage. Replacement of existing bare drop wire with an insulated conductor can prevent animal contact between the energized wire and ground, mitigating the risk of this type of outage.

Toronto Hydro's current standard for transformer drop wire calls for the use of insulated conductor.

Animal guard installation: Animal guards are frequently installed on the top portion of the transformer bushing unit to cover the live conductor connection point. Animal guards can reduce the risk of animal contacts between the live connection points on the bushing and the transformer enclosure. Toronto Hydro's current standard for overhead transformer calls for the use of animal guards.

Metal switch bracket replacement: Metal brackets are used to mount the disconnect switch on the pole as shown in Figure 5. Similar to the area around the transformer bushing, there is a risk of animal contact across the live side of the switch and the grounded metal bracket, which can cause an outage. Proactively replacing these brackets with a non-conductive bracket made of fiber glass material can eliminate the risk of live-to-ground contacts.

Glass or porcelain insulator replacement: Aged glass or porcelain insulators are susceptible to dirt accumulation over the insulator surface. When combined with a sufficient amount of moisture over time, tracking or flashover will occur, which can lead to failure of the insulator and a power outage on the feeder. Replacing these insulators with polymer insulators removes the risk of tracking as the polymer insulator has the anti-beading feature that cuts off the electrical tracking path over the insulator surface.

Underground cable replacement: Aged or poor conditioned underground cables can fail due to deterioration in insulation strength as a result of water ingress or soil contamination, leading to power outages. They can be installed both directly buried or in conduit. Small scale replacement of unreliable segments of cable would eliminate the risk of additional failure from the asset.

Underground transformer replacement: Submersible transformers that are aged or in poor condition can fail, resulting in power outages. Spot replacement of unreliable underground transformer will lower the risk of failure.

(i) Asset Failure Impacts

Assets that are targeted for replacements under the WPF program present various failure impacts. For instance, a lack of animal guards coupled with bare transformer drop wires and metal transformer switch brackets will subject the overhead conductor to the potential risk of animal contact between the live and grounding point connections. On the other hand, dirty

porcelain and glass insulators create the risk of electrical flashover across its surface. One common thread is that asset failures can and will likely lead to customer outages.

E6.21.4 Timing & Pacing of the Program

In 2010 and 2011, Toronto Hydro spent $16.7 million and $19.3 million respectively on its WPF program, which included large rebuild projects designed to renew assets on poorly performing feeders (e.g., direct-buried cable rebuilds). In 2012, Toronto Hydro recalibrated the program to focus on targeted, short-term mitigation work that would yield immediate reliability improvement. Substantial rebuild projects that were previously included in the worst performing program were reallocated to either the planned overhead or underground rebuild programs. This change took effect mid-year, meaning that certain rebuild projects were charged to the WPF program, which resulted in actual spending of $6.7 million in 2012. Using the new, more focused approach in 2013, Toronto Hydro conducted mostly short term, small scale asset installation or replacement work, resulting in total spend of $1.2 million. Spending in 2014 is forecasted to increase to $4.8 million due to a number of projects that were previously delayed but that are still expected to provide considerable reliability improvements in poor performing areas.

As the assets in the field continue to age and deteriorate, Toronto Hydro anticipates ongoing random failures and interruptions. To address these failures, Toronto Hydro has forecasted investments of $1.8 million yearly from 2015 to 2019 for WPF projects.

TABLE 3: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	16.7	19.3	6.7	1.2	4.8	1.8	1.8	1.8	1.8	1.8

E6.21.4.1 Ranking & Prioritization

The WPF program is highly dynamic compared to other, typical planned work programs. Feeder and project prioritization can change quickly and often depending on emerging FESI conditions in the field. As a result, mitigation work is normally placed on high priority and scheduled for field execution based on available resources. Emphasis is placed on feeders that have experienced a high number of outages in a 12-month rolling window. Some feeders may require patrolling to identify components that need to be replaced.

E6.21.5 Program Execution

In order to execute the work under this program, first an initial analysis of locations and root causes of FESI-7 feeder outages must be completed. Depending on the need as revealed by the analysis, field crews may perform field patrols to determine the condition of equipment. In order to be as efficient as possible, field crews may also carry out mitigation work simultaneously with the patrol. Typical mitigation work that would be undertaken during field patrols includes the installation of animal guards, insulator replacement, transformer drop wire replacement and switch bracket replacement. As well, follow up small-scale construction project may be issued by under the WPF program when work is determined to be feasible and required. Small scale construction projects involve the replacement of assets such as underground cable, transformers or overhead conductor to remove immediate failure risks.

E6.21.5.1 Program Risks

The primary program risk is limited resource availability. As the WPF program is a short term measure in nature, delay in timely intervention may result in additional outage. Feeder scheduling/restriction and road work moratoriums may also pose risks to the completion of work in a timely manner.

E6.21.5.2 Standard & Regulation Adherence

All assets installed in this program are approved by Toronto Hydro's Standards Department in compliance with Ontario Regulation 22/04, Electrical Distribution Safety.

E6.21.6 Evaluation of Alternatives

Toronto Hydro considered two alternatives for addressing poor performing feeders.

(i) Option 1: Planned Capital Rebuild

Addressing worst performing feeders through planned capital rebuilds is the optimal long-term solution. However, rebuild projects take time to plan, design, schedule and execute, and are not typically feasible within a period that would allow for the timely mitigation of worsening reliability trends on poor performing feeders. Without targeted, short-term interventions for poor performing feeders, customers would likely continue to experience a high frequency of interruptions, and Toronto Hydro anticipates that the number of worst performing feeders would most likely increase, negatively impacting system SAIFI and SAIDI over time and harming customer

satisfaction. Accordingly, pursuing long-term capital rebuilds without a complementary WPF program is not recommended.

(ii) Option 2: Continue WP F Program (Preferred Option)

The status-quo and preferred option is to perform mitigation work pursuant to the WPF program, as this will help provide immediate reliability improvements to customers served by poor performing feeders at a reasonable cost. This approach acts as a "bridge" solution until planned capital rebuilds can be executed.

E6.22 Distribution System Communication Infrastructure

COMMUNICATION HARDWARE EQUIPMENT

E6.22.1 Summary

Program Description

The objective of the Distribution System Communication Infrastructure (DSCI) program is to install the telecommunication infrastructure that is needed to operate and maintain a safe and reliable distribution system. The execution of the DSCI program allows Toronto Hydro to move away from obsolete legacy technologies and transition to an updated system that enables greater SCADA penetration throughout the system.

The program is divided into three main areas: (1) Distribution System Communication Technology Upgrade; (2) Distribution System Fiber-optic Plant Replacement and Expansion; and (3) Wireless SCADA Infrastructure.

(1) Toronto Hydro currently relies on SONET communication technology at substations on the 13.8 kV system for SCADA communication to operate Remote Terminal Units (RTUs), which provide automated control of station assets such as circuit breakers. There are approximately 200 RTUs at about 45 substations sites in the downtown core that are connected to the SONET ring for RTU communication.

(2) SONET is a legacy communication technology that is no longer supported by the manufacturer and has limited capacity to support increased automation at additional substations. In order to address the limitation of this system, Toronto Hydro plans to install Coarse Wavelength Division Multiplexing (CWDM) technology to decouple SONET technology and Internet Protocol (IP) traffic, preventing the need to upgrade the legacy SONET platform. Toronto Hydro plans to implement CWDM technology at all 45 SONET sites in the system during the 2015-2019 period in order to address the obsolescence of the SONET system.

A fiber-optic cable plant is used to connect the various in-field communication technologies to Toronto Hydro's control room. There is approximately 300 km of fiber-optic cable within Toronto Hydro's communication system. Currently, 225 km, or 75% of all fiber-optic cable, is jointly owned between Toronto Hydro and Cogeco Data Services (CDS). This arrangement limits Toronto Hydro's ability to route diverse fiber-optic cables as required to ensure that there are no overlaps geographically in fiber-optic cable routes which may lead to a single point of failure.

Toronto Hydro plans to replace 117 km of fiber-optic cables, or approximately 50% of the CDS fiber within the existing plant by targeting areas of fiber that are prone to failure. This work will enable Toronto Hydro to reduce dependency on CDS through gradual migration to a Toronto Hydro owned fiber-optic plant.

(3) Toronto Hydro operates five wireless SCADA technologies, including GE TransIt, MOSCAD, DACSCAN, GE SD9, and SpeedNet. Three out of these five technologies – GE TransIt, MOSCAD, and DACSCAN – are legacy systems that are now functionally obsolete. To cost-effectively address these obsolescence issues, Toronto Hydro plans to (1) install four new SCADA SD9 "High-Sites" and (2) migrate GE TransIt SCADA radios, which have reached the end of their useful lives and are functionally obsolete, to GE SD9. [1]

For additional details on these investments, refer to section E6.2.2.2 below.

The anticipated benefits of this program are outlined in Table A.

[1] This program specifically excludes radio replacement for MOSCAD and DACSCAN technology, as they are being handled through radio replacements covered in the Overhead Circuit Renewal program at Exhibit 2B, E6.4.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Upgrade in technology to maintain a reliable and secure communication system to support substation monitoring and control, which results in quicker restoration of power to customers during an outage. ƒ Monitoring and control supported by the proposed upgrade is expected to provide sufficient protection for DG in the event of a power outage, which protects DG customers' assets as well as provides them with undisrupted revenue.
Reliability	ƒ Prevent SCADA communication outages so that Toronto Hydro can remotely operate equipment; this leads quicker restoration times and shorter outages, including during increasingly frequent major storm events. ƒ Allows for increased RTU installations for substations and additional capability to remotely monitor and control circuit breakers.
Safety	ƒ Enables SCADA monitoring at substations and allows power controllers to constantly monitor substation assets, reducing the possibility of equipment failures and related worker and public safety risks. ƒ The updated technology provides increased protection against cyber-security threats and reduces potential safety impacts.
Efficiency	ƒ Efficiency cost saving of approximately $4.5 million that would have been required for the expansion of the existing network system. ƒ Conversion allows for three legacy wireless SCADA infrastructures to be decommissioned, reducing the cost of maintenance.

Program Drivers

The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Obsolete, non-standard, and non-ruggedized LAN equipment is required by the SONET technology. ƒ Continued investment in SONET is costly and strategically limiting due to growing technology, asset obsolescence, and declining availability of qualified support personnel. ƒ Capacity limit with current SONET system has been reached, further expansions (e.g. adding new locations) are very complex and costly. ƒ Obsolete wireless SCADA infrastructure requires upgrades to remain functional, supporting critical portions of the distribution system. ƒ Obsolete MOSCAD and DACSCAN systems have no redundancy while supporting large SCADA presence. ƒ Existing fiber-optic plant exhibits a large number of single points of failure. Joint ownership of Fiber-optic plant with CDS further

	complicates the issue.
Secondary Drivers	Reasoning
System Capital Investment Support	ƒ Upgrading station services by migrating devices from being reliant on legacy SONET to Ethernet/IP networks supports the Stations Monitoring and Control program to upgrade/install RTUs at substations for better monitoring and control of substation assets. ƒ Implementing additional GE SD9 high-sites allows for the migration and consolidation of end-of-life MOSCAD/DACSCAN/GE TransIt wireless SCADA systems to GE SD9. ƒ Increasing the footprint of both fiber-optic plant as well as the coverage of GE SD9 within the system allows for the expansion of the SCADA.
System Maintenance Support	ƒ Communication supports the remote monitoring of stations assets such as circuit breakers and power transformers to alert of issues that may require maintenance or intervention. ƒ Upgrading SONET allows Toronto Hydro to maintain security measures such as access card readers, CCTV cameras and supports in-office work at substations.
Safety	ƒ Communication infrastructure supports monitoring of stations assets to ensure failures do not escalate. ƒ Obsolete communication does not provide the encryption provided by the new Ethernet/IP system to protect against cyber-security threats.

The SONET system was built at a time when monitoring and control functionality were limited. The SONET system can no longer support stations requiring monitoring and control due to its limited capacity. There are approximately 45 SONET sites in the system, which is beyond the number of maximum sites recommended by the manufacturer, and additional sites cannot be added to the SONET backbone. In addition, the legacy SONET multiplexers can cause communication outages that may render SCADA functionality of RTUs in stations inoperable and increase the number of outages that last 30 minutes to three hours. Customers on an entire feeder can be impacted during extended outages. Over the last five years, there were a total of 90 SONET communication outages. In order to rectify these issues associated with the existing SONET infrastructure, the work proposed in this program must be executed as soon as possible.

Preferred Alternative

This program is the preferable to the alternative of maintaining the status quo state of the system. The DSCI program provides the infrastructure required to maintain reliable control and monitoring capability for power controllers such that critical asset performance information will continue to be accessible. Also, without the DSCI program Toronto Hydro may not be able to support other high

value initiatives, such as Generation Protection, Monitoring and Control (Section E5.5), Downtown Contingency (Section E7.7), or Stations Control and Monitoring (Section E6.16).

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $17.01 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.22.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $6.83 million, confirming the economic prudence of the investments (see Section E6.22.7).

Timing and Pacing

As can be seen in Table C below, Toronto Hydro plans to complete the work proposed in this program by the end of 2017 so that the communication system will be available to support advances in monitoring and control within the distribution system.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)		-	-	$1.03	$0.85	$6.06	$6.02	$3.95	-	-

E6.22.2 Program Description

The Distribution System Communication Infrastructure (DSCI) program addresses the foundational technology that underlies and enables distribution operational activities that depend on data and voice communications. This program aims to achieve a balance between functionality, scalability, and operating cost. The DSCI program proposes work that is critical to the business operation of the distribution system at an estimated cost of approximately $16 million during the 2015-2019 period.

There are approximately 1100 SCADA switches within the distribution system, which allow for rapid restoration of customers in un-faulted sections of the feeder during a power outage or provide tie points to transfer load to adjacent feeders. There are approximately 800 distributed generation (DG) connections currently operating on the distribution system and Toronto Hydro estimates that there will be approximately 2,000 new connections over the next five-year period. The increase in connections necessitates additional SCADA capacity and a reliable wireless communication network to enable adequate protection and monitoring as part of the Generation Protection Monitoring and Control initiative (Section E5.5).

The execution of the DSCI program allows Toronto Hydro to move away from obsolete legacy technologies and transitioning to an updated system that enables greater SCADA penetration throughout the system. In addition, performing this work is expected to facilitate operational efficiency, through the decommissioning of obsolete or overlapping communication systems. By enabling SCADA, this program is integral to several of Toronto Hydro's distribution system initiatives, such as:

- Station Control and Monitoring (Section E6.16),
- Stations Switchgear Renewal (Section E6.13),
- Generation Protection Monitoring and Control (Section E5.5),
- Feeder Automation (Section E7.3),
- SCADA-Mate R1 Renewal (Section E6.8),
- Overhead Circuit Renewal (Section E6.4), and
- Downtown Contingency (Section E7.7).

The DSCI program is comprised of three key areas of investment: (1) Distribution System Communication Technology Upgrade; (2) Distribution System Fiber-Optic Plant Replacement and Expansion; and (3) SCADA Wireless Infrastructure.

SCADA technology plays a critical role in reducing restoration times during an outage by allowing power controllers to remotely operate in-field switches to isolate faulted areas and restore customers on unaffected sections of the feeder. In addition, SCADA technology allows for the monitoring of assets, especially at substations, to determine their operating conditions such as transformer oil levels, alarms for pressure and voltage loss, or loss of battery power. Therefore, the lack of SCADA can limit the visibility controllers have on the operating conditions of Toronto Hydro's assets and severely impact their ability to remotely isolate faults during an outage.

E6.22.2.1 Distribution System Communication Technology Upgrade

Toronto Hydro currently relies on SONET technology at substations on the 13.8 kV system for SCADA communication to operate Remote Terminal Units (RTUs), which provide automated control of station assets such as circuit breakers. There are approximately 200 RTUs at about 45 substations sites in the downtown core that are connected to the SONET ring for RTU communication. An example of SONET equipment is shown in Figure 1.

FIGURE 1: SONET TECHNOLOGY – HARDWARE EQUIPMENT

The SONET system connects multiple substations using a ring topology (SONET Ring) as shown in Figure 2 below. This is a legacy communication technology that is no longer supported by the manufacturer and has limited capacity to support increased automation at additional substations.

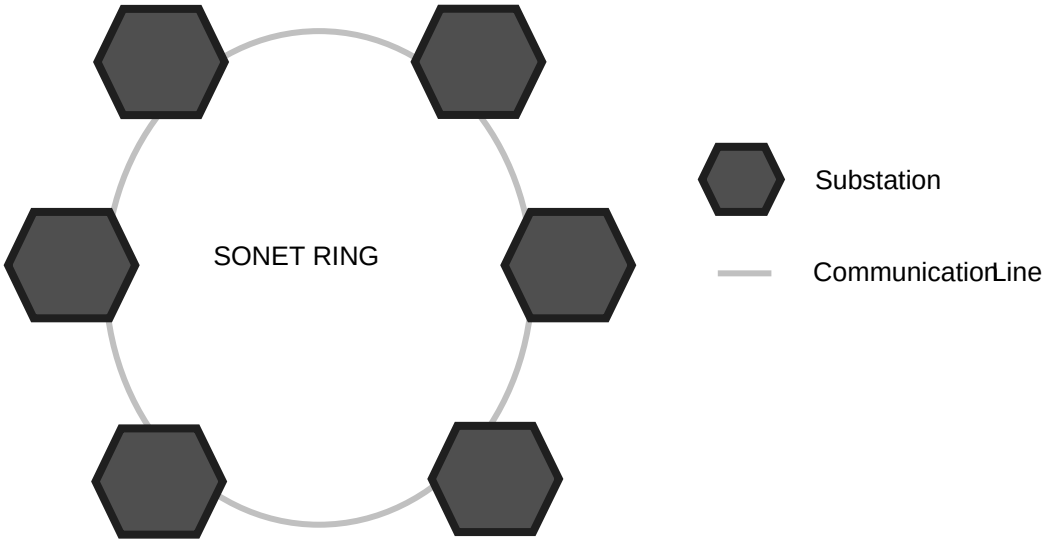

FIGURE 2: SONET RING STRUCTURE WITH SUBSTATIONS

In order to address the limitation of this system, Toronto Hydro plans to install Coarse Wavelength Division Multiplexing (CWDM) technology to decouple SONET technology and Internet Protocol (IP) traffic, preventing the need to upgrade the legacy SONET platform. This involves the installation of CWDM multiplexers as a means of migrating from the legacy SONET system to Ethernet, thereby providing communication through the internet. By taking this action, Toronto Hydro expects to limit the investment required to upgrade the capacity of legacy SONET technology and to allow the utility to eventually decommission the SONET ring, which is functionally obsolete.

Toronto Hydro plans to implement CWDM technology at all 45 SONET sites in the system during the 2015-2019 period in order to address the obsolescence of the SONET system. In addition, this work will enable dedicated 1 Gigabits per second (Gbps) path for Ethernet/IP signal on CWDM multiplexers. Toronto Hydro plans to retain SONET functionality to maintain compatibility

with existing assets; however, the Ethernet/IP based system will be used for all new RTU installations, such that once existing RTUs on the SONET system reach end-of-life, the obsolete SONET technology can be eliminated from the system. Once existing sites with SONET technology are addressed, Toronto Hydro will install Ethernet/IP technology at 34 additional sites to enable greater SCADA presence at substations. Once this work is completed, using IP routers, Toronto Hydro can support high-bandwidth applications at substations, including supporting internet bandwidth for in-office work, closed circuit television, and wireless communication. The routed network allows for maximum performance and to easily expand the capacity of the network as required for additional SCADA connections.

E6.2.2.2.2 Distribution System Fiber-Optic Replacement & Expansion

A fiber-optic cable plant is used to connect the various in-field communication technologies to Toronto Hydro's control room. As such, the fiber-optic cable plays a key role in enabling active communication and control between power controllers and in-field assets. There is approximately 300 km of fiber-optic cable within Toronto Hydro's communication system. Currently, 225 km, or 75% of all fiber-optic cable, is jointly owned between Toronto Hydro and Cogeco Data Services (CDS). This arrangement limits Toronto Hydro's ability to route diverse fiber-optic cables as required to ensure that there are no overlaps geographically in fiber-optic cable routes which may lead to a single point of failure.

Fiber-Optic Plant Replacement and Expansion removes limitations posed by the inadequate availability of fiber-optic connections in the existing fiber-optic network by eliminating fiber-optic cable strands owned by CDS and replacing them with Toronto Hydro owned fiber-optic cables. Taking this action is expected to eliminate single points of failure, which can cause significant SCADA outages.

Toronto Hydro plans to replace 117 km of fiber-optic cables, or approximately 50% of the CDS fiber. within the existing plant by targeting areas of fiber that are prone to failure. This work would enable Toronto Hydro to reduce dependency on CDS through gradual migration to a Toronto Hydro owned fiber-optic plant. In order to achieve this goal, Toronto Hydro plans to selectively replace problematic spans of the existing fiber-optic plant provisioned inside of CDS fiber-optic bundles with fully-diverse configurations where the fiber-optic cable and backup communication

lines do not overlap. This routing ensures the elimination of "flat/folded"[2] sections in the fiber-optic plant that contribute to the potential of concurrent, large-scale SCADA outages.

In addition, Toronto Hydro plans to expand the fiber-optic footprint to provide redundancy to wireless SCADA and substations that require fiber-optic network connectivity for activities such as in-office work or closed circuit television (CCTV). Toronto Hydro proposes to install an additional 238 km of fiber-optic cable. Expanding fiber-optic presence to new locations will enable additional synergies, such as the ability to migrate away from costly third party service providers for communication purposes. This work is expected to reduce Toronto Hydro's dependency on third parties to provide the communication infrastructure by integrating CCTV/Access card and Office LAN functionality with the upgraded Ethernet/IP technology, which in turn is expected to result in future cost avoidance of third party Service Provider fees.

E6.22.2.3 SCADA Wireless Infrastructure

Toronto Hydro operates five wireless SCADA technologies, including GE TransIt, MOSCAD, DACSCAN, GE SD9, and SpeedNet. Three out of these five technologies – GE TransIt, MOSCAD, and DACSCAN – are legacy systems that are now functionally obsolete. Within the distribution system, there are approximately 1,100 in-field overhead or vault RTUs and 800 DG connections that rely on the existing wireless SCADA communication network. By eliminating these legacy technologies, the SCADA wireless infrastructure activities are expected to reduce operational risks such as the reliance on assets with limited support from manufacturers and the lack of redundancy for SCADA systems in western Toronto.

This work includes the addition of four new wireless SCADA SD9 "High-Sites" in addition to the seven existing SCADA High-Sites, as shown in Figure 7 in section E6.22.7 2015 Project Details.

High-sites are installations in the distribution system that communicate with in-field SCADA radios wirelessly and transmit the information back to the control center through fiber-optic cable lines. Figure 3 shows one such site in Toronto's distribution system.

[2] Flat/Folded section - A section of fiber-run is non redundant. An example would be primary and backup fiber-path on a fiber-optic SONET ring that are provisioned inside of the same conduit and failure of the conduit will impact both cables.

FIGURE 3: SCADA WIRELESS HIGH SITES – HARDWARE EQUIPMENT

Toronto Hydro plans to migrate GE TransIt SCADA radios, which have reached the end of their useful lives and are functionally obsolete, to GE SD9. This migration includes the replacement of 483 GE TransIt radios to GE SD9 radios out of the 675 GE TransIt devices still in service. The remaining GE TransIt radios would be replaced as part of other programs targeting SCADA switches such as Overhead Circuit Renewal (Section E6.4) and SCADA-Mate R1 Renewal (Section E6.10). Once migration is complete, the GE TransIt technology will be decommissioned, eliminating any technology overlap. This program specifically excludes radio replacement for MOSCAD and DACSCAN technology, as they are being handled through radio replacements covered in the Overhead Circuit Renewal (Section E6.4) program.

The deployment of four additional GE SD9 high-sites is expected to improve wireless SCADA coverage and enable SCADA capability for in-field assets via greater area coverage. This capacity expansion is necessary for wireless SCADA dependent initiatives such as Generation Protection Monitoring and Control (Section E5.5). The SCADA wireless infrastructure enables SCADA functionality to in-field distribution assets such as small municipal substations and pole-top RTUs that are outside the reach of the current and planned fiber-optic plant. The importance of SCADA are detailed in Section E6.22.2. In addition, this program plans to consolidate wireless SCADA platforms into a single GE SD9 connectivity standard.

The proposed program also allows updated communication networks that have encryption to protect the networks and ensure cyber-security. This is needed in particular for applications such as those proposed under the Station Control and Monitoring (section E6.16) program or

Generation Protection Monitoring and Control (section E5.5) program where protection equipment can be tampered with or breached.

The breakdown of the assets to be addressed from 2015 to 2019 is outlined in Table 2 below.

TABLE 1: ASSETS TO BE RENEWED OR INSTALLED AS PART OF DSCI PROGRAM

Assets (Units)	2015	2016	2017	2018	2019	Total
IP Data Network Retro-fit (SONET Multiplexers to be augmented with CWDM Multiplexers) (Number of Sites)	34	11	-	-	-	45
IP Data Network Installation (Without SONET technology Present) (Number of Sites)	-	34	-	-	-	34
Fiber-Optic Ring Fiber replacement in Toronto (km)	72	-	-	-	-	72
Fiber-Optic Ring Fiber replacement in Scarborough (km)	45	-	-	-	-	45
Fiber-Optic Ring Expansion in Toronto (km)	-	54	48	-	-	102
Fiber-Optic Ring Expansion in Scarborough (km)	-	64	72	-	-	136
New Wireless SCADA SD9 High-Site Deployment (# of Sites)	3	1	-	-	-	4
Wireless SCADA GE TransIt to GE SD9 Endpoint Radio Equipment Migration (# of Radios)	-	194	289	-	-	483

The pacing of the work in this program is based on: (1) the various dependencies of each component as outlined in section E6.22.4.1; and (2) the dependency of other programs and assets on the communication infrastructure. As a result, the pace of replacement is within the first three years due to the urgent nature of this program as discussed in section E6.22.4. Table 3 provides a summary of the benefits that are expected to be attained through the implementation of the DSCI program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Upgrade in technology to maintain a reliable and secure communication system to support substation monitoring and control, which results in quicker restoration of power to customers during an outage. ƒ Monitoring and control supported by the proposed upgrade is expected to provide sufficient protection for DG in the event of a power outage, which protects DG customers' assets as well as provide them with undisrupted revenue. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $17.01 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E6.22.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $6.83 million, confirming the economic prudence of the investments (see Section E6.22.7).
Reliability	ƒ Prevent SCADA communication outages so that Toronto Hydro can remotely operate equipment; this leads quicker restoration times and shorter outages, including during increasingly frequent major storm events. ƒ Allows for increased RTU installations for substations and additional capability to remotely monitor and control circuit breakers.
Safety	ƒ Enables SCADA monitoring at substations allows power controllers to constantly monitor substation assets, reducing the possibility of equipment failures and related worker and public safety risks. ƒ The updated technology provides increased protection against cyber-security threats and reduces potential safety impacts.
Efficiency	ƒ Efficiency cost saving of approximately $4.5 million that would have been required for the expansion of the existing network system. ƒ Conversion allows for three legacy wireless SCADA infrastructures to be decommissioned, reducing the cost of maintenance.

E6.22.3 Why the Program is Needed

As detailed above, the DSCI program is essential to the maintenance of an updated telecommunication system (both physical and wireless) that supports the safe, efficient, and reliable supply of electricity to Toronto Hydro customers. From 2009 to 2013, Toronto Hydro's aging, legacy SONET technology – relied upon by substation RTUs – experienced 90 failures. Any failure of this system will result in the lack of visibility of assets within the distribution system for power controllers and therefore is unacceptable. Furthermore, these types of failures can result in the loss of SCADA functionality, meaning that power controllers cannot remotely operate in-field assets which can extend outages from 30 minutes in length up to three hours. A sound telecommunication system is also a crucial component of cost-effective service delivery for

Toronto Hydro. As well, a large number of capital programs rely on a functional and reliable communication system both at substations and at dispersed locations on the distribution system.

E6.22.3.1 Program Drivers

Table 4 presents the trigger and secondary drivers for the DSCI program. As this program will mitigate critical risks to the continued operations of the electrical distribution system by upgrading the foundational communications infrastructure, it falls within the System Renewal category. The activities within this program are primarily driven by the functional obsolescence of the current communications plant.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Obsolete, non-standard, and non-ruggedized LAN equipment is required by the SONET technology. ƒ Continued investment in SONET is costly and strategically limiting due to growing technology, asset obsolescence, and dwindling qualified support personnel. ƒ Capacity limit with current SONET system has been reached, further expansions (e.g. adding new locations) are very complex and costly. ƒ Obsolete wireless SCADA infrastructure requires upgrades to remain functional, supporting critical portions of the distribution system. ƒ Obsolete MOSCAD and DACSCAN systems have no redundancy while supporting large SCADA presence. ƒ Existing fiber-optic plant exhibits a large number of single points of failure. Joint ownership of fiber-optic plant with CDS further complicates the issue.
Secondary Drivers	**Reasoning**
System Capital Investment Support	ƒ Upgrading station services by migrating devices from being reliant on legacy SONET to Ethernet/IP networks supports the Stations Monitoring and Control program to upgrade/install RTUs at substations for better monitoring and control of substation assets. ƒ Implementing additional GE SD9 high-sites allows for the migration and consolidation of end-of-life MOSCAD/DACSCAN/GE TransIt wireless SCADA systems to GE SD9. ƒ Increasing the footprint of both fiber-optic plant as well as the coverage of GE SD9 within the system allows for the expansion of the SCADA.
System Maintenance Support	ƒ Communication supports the remote monitoring of stations assets such as circuit breakers and power transformers to alert of issues that may require maintenance or intervention. ƒ Upgrading SONET allows Toronto Hydro to maintain security measures such as access card readers, CCTV cameras and supports in-office work at substations.

Safety	ƒ Communication infrastructure supports monitoring of stations assets to ensure failures do not escalate. ƒ Obsolete communication does not provide the encryption provided by the new Ethernet/IP system to protect against cyber-security threats.

This program addresses the Functional Obsolescence of the existing communication infrastructure and provides the required System Capital Investment Support and System Maintenance Support to allow programs aimed at increasing SCADA usage to obtain full benefits by providing a sound communication backbone.

(i) Functional Obsolescence

In recent decades, a number of grid automation technologies have become available to enable remote monitoring and control of distribution system assets. These technologies include electronic sensors and RTUs that require a means of communicating with Toronto Hydro control centers.

Obsolete Fiber-Optic System

Toronto Hydro maintains a substantial SONET technology presence to provide connectivity between substations and control centers. SONET is a technology from the 1980s that is being rapidly phased out in modern communication space in favour of the simpler, cheaper, and more scalable Ethernet and IP networks. Toronto Hydro's current system continues to rely on the original 155 Mbps OC-3 specifications to support legacy grid automation systems that rely on obsolete technologies. Insufficient network bandwidth on the SONET ring has resulted in the deployment of a number of costly and suboptimal stop-gap solutions to overcome network capacity issues and has hindered the proliferation of alternative Ethernet/IP technologies. The SONET system is very limited with support or technical expertise, making all maintenance work with the system more costly (on average $150,000 annually) due to the need for customized solutions from the manufacturer.

In addition, Toronto Hydro has deployed a large fiber-optic presence in the City of Toronto to support the SONET environment. The fiber-optic cabling underlying the SONET network is plagued with folded sections and non-diverse building entrances, where both fiber-optic cable runs to a premise converge to a single path or conduit resulting in multiple potential points of failure across the infrastructure. Depending on the position of the folded section, a single fiber cut may result in a concurrent outage to multiple sites on the same ring, causing unacceptable loss of

SCADA service. The loss of SCADA service can last, on average, three hours as compared to thirty minutes when SCADA services are not lost. Figure 4 illustrates the difference between the logical SONET network topology and the actual physical routing of the underlying fiber cabling.

FIGURE 4: CONCEPTUALIZATION OF IDEAL AND ACTUAL FIBER-OPTIC CONNECTIONS BETWEEN SITES

The existing SONET equipment provides limited 10 Mbps support for Ethernet/IP services. However, with technology evolving and continuous load growth in the system, the device count related scalability limitations prevent further growth for control and monitoring connectivity. The obsolete, non-standard and non-ruggedized LAN equipment required by the SONET technology's limitations and the flat LAN segments that span long-distances are inherently unstable and unreliable, increasing the probability of network outages. The continued investment into a 25-year old legacy technology with aging hardware and rising support costs is disadvantageous to Toronto Hydro's customers from the perspective of delivering value for money over the life of this asset class. Furthermore, bandwidth limitations prevent deployment of 100 Mbps/1Gbps Ethernet/IP services that are needed to support evolving business requirements such as:

- Control Room Network Infrastructure,

- Station Network Infrastructure,
- Station/Field RTU Connectivity, and
- In-field Device Communications.

Further gaps include the fact that there are no gradual migration paths to modern Ethernet/IP technologies; rigid vendor tie-in due to the highly proprietary nature of the solution; and complex, niche technology with a shrinking qualified resource pool in the market.

The installation of Ethernet/IP station LAN will allow for the connectivity to IP enabled distribution grid devices at the substations stations such as Ethernet based RTUs for circuit breakers, switchgears and SCADA switches. Furthermore, it supports IP-based Wireless SCADA communication and support in-office functions at the stations.

Obsolete SCADA Systems

Toronto Hydro currently operates five overlapping wireless SCADA systems, three of which (Motorola DARCOM, Motorola DACSCAN and GE MDS TransIt) are considered legacy systems. The technology within the MOSCAD/DACSCANs platforms is completely unsupported and obsolete with no redundancy supporting the large SCADA presence of Etobicoke. Consolidating these diverse Wireless SCADA technologies on a single, supported platform standard - GE SD9 technology - allows Toronto Hydro to eliminate the need for legacy radio systems, reduces the risk associated with the obsolete and unsupported communication technologies and can prevent large scale SCADA outages.

(ii) System Capital Investment Support

The DSCI program is essential to providing the communication backbone required to monitor and operate major assets such as circuit breakers via the use of RTUs or distribution feeder switches with SCADA functionality.

SCADA Technology at Substations

The use of modern optical technologies, such as Wavelength Division Multiplexing (WDM), enables Toronto Hydro to transition from the legacy SONET multiplexers to a modern, cost-efficient Ethernet/IP based infrastructure. This in-turn allows for the expansion of monitoring and control by allowing for the increased penetration of SCADA technology within the distribution system, including the increased installation of RTUs in substations through initiatives such as

Stations Control and Monitoring (Section E6.16). Under the legacy SONET network, only seven concurrent Ethernet/IP stations can be supported, severely restricting the ability to realize the full benefits of the Stations Control and Monitoring (Section E6.16) program since it must rely on third party communication connections. Furthermore, without the upgrade of the SONET system, RTU technology lock-in with legacy and obsolete serial communications technology (SONET) will occur as RTUs that function on SONET will need to be used even in new installations. The RTU technology lock-in results directly from the obsolescence of the SONET technology. Only a single manufacturer still offers a SONET compatible RTU and as long as Toronto Hydro remains reliant on a SONET system, it remains locked-in to the RTUs provided by that specific manufacturer. This results in vendor dependence which limits Toronto Hydro's ability to use commercially available RTUs from other vendors.

SCADA Technology on Feeders

The installation of remote SCADA switches and RTUs may be limited due to lack of expansion in the fiber-optic plant, thereby limiting the benefits of programs such as Generation Protection Monitoring and Control (Section E5.5) and Stations Control and Monitoring (Section E6.16). The renewal and expansion of the fiber-optic plant is required to ensure a reliable SCADA system for power controllers and to further increase the penetration of SCADA technology into the distribution system.

The functionality of the wireless SCADA systems is to provide monitoring and control to in-field assets outside of the fiber-optic plant perimeter. Furthermore, it enables rapid SCADA connection for in-field assets and ensures security and availability of the data communications network. This program also supports the Overhead Circuit Renewal (Section E6.4) program, which replaces MOSCAD RTUs and DARCOMM radios. These technologies are vintage communication systems and thus need to be migrated to the new standard S&C 6801 RTU and SD9 Radio. Expanded SD9 coverage is required for this to happen. Increased SCADA availability is required for the protection schemes for distributed generation (DG) assets, which are being installed as part of the Generation Protection Monitoring and Control (Section E5.5). A stable and reliable GE SD9 system also allows Toronto Hydro to increase monitoring and implementing advanced initiatives, such as Stations Control and Monitoring (Section E6.16) or Feeder Automation (Section E7.3), to drastically reduce power outage durations.

(iii) System Maintenance Support

The work proposed in this program ensures reliable communication for SCADA functionality. Without SCADA monitoring and control, Toronto Hydro power system controllers do not have access to critical information such as alarms for circuit breaker trip, loss of transformer voltage, loss of battery power, alarms on transformer pressure, oil level, and temperature. This information is critical to ensure that assets are utilized appropriately and to prevent conditions that may rapidly degrade an assets life, thereby allowing Toronto Hydro to maintain its stations assets.

In addition, the program's expansion of the outside fiber-optic plant to select locations expands the communication footprint to better support services such as Voice Radio/Wireless SCADA, Station office facilities, and remote CCTV cameras, allowing for increased security. This infrastructure helps to support security cameras monitoring stations as well as to support access card reader connectivity.

(iv) Safety

Station Asset Monitoring

The lack of reliable communication networks within an area limits the installation of RTUs in substations which provide important information about substation assets. This information is integral in ensuring that a problem on these assets does not escalate into a catastrophic failure that may pose a threat to the station surroundings. By alerting power controllers of key issues with station assets such as circuit breaker trips, low oil levels in power transformers, loss of battery power etc., a flashover or explosion can be avoided.

Failure due to Cyber-security events

For reasons that the utility cannot disclose, the existing systems are more vulnerable to cyber-security threats such RTU spoofing, system disruption, or theft of system data. RTU spoofing occurs and can result in tampering of information such as changes to threshold levels set for safety parameters. Tampered SCADA systems at substations can lead to catastrophic failure of power system assets, and can compromise the safety of Toronto Hydro employees, the public, and station surroundings. This program provides advanced security measures to mitigate these risks.

E6.22.3.2 Asset Details

(i) Asset Lifecycle

The DSCI program contains assets that are functionally obsolete and have passed their useful lives.

- SONET multiplexers have a useful life of 10 years. The assets currently in service range from 10 to 12 years of age.
- Fiber-optic cables have a useful life of approximately 25 years, and given that the existing fiber-optic plant was installed in the 1980s, these cables are well beyond their useful life. Moreover, CDS and Toronto Hydro jointly own major fiber-optic cables, with CDS owning the conduit and many of the strands of fiber-optic cabling within the conduits, and Toronto Hydro owning only the pair of fiber-optic strands that it utilizes within the fiber bundle. The joint ownership limits Toronto Hydro's ability to remediate severe issues with routing, single points of failure, and availability of fiber-optic cabling plant.
- Similarly, the GE TransIt wireless SCADA system is approximately nine years old and has passed its useful life of five years. This system is unable to meet the increasing demands for monitoring and control on the distribution system. GE SD9 is the successor and the natural migration path for the GE TransIt system.

(ii) Asset Failure Impacts

Over the past five years, the existing SONET system experienced a total of 90 communication outages. A communication outage impacting the SCADA system can limit the ability for power controllers to operate substation equipment remotely, and may extend the outage duration from 30 minutes to three hours. The failure of the communication assets within this program, such as the SONET equipment, fiber-optic cables, or obsolete wireless SCADA technology, can impact a multitude of programs as listed in Table 5, preventing the programs from achieving their full benefits.

TABLE 4: THE IMPACTS OF FAILURE ON THE DISTRIBUTION SYSTEM

Areas	Related Programs	Description	Consequences
Distribution System Communication Technology Upgrade	Stations Control & Monitoring (Section E6.16)	ƒ Introduce CWDM technology and decouple SONET multiplexers from IP/Ethernet equipment ƒ Increase the presence and capacity of Ethernet/IP at the stations ƒ Allow for SONET technology to be decommissioned once migration to Ethernet/IP is complete	ƒ Failure of obsolete equipment would result in Toronto Hydro having to rely on customer calls to learn about feeder outages and having to perform manual switching instead of remote switching to troubleshoot problems
	Stations Switchgear Renewal (Section E6.13)		ƒ Visibility and control of installed switchgear would be constrained without this program. Toronto Hydro would be dependent on customer calls to report outages due to operational constraints on the SCADA system
	Generation Protection Monitoring and Control (Section E5.5)		ƒ With current communication equipment, the distribution system is at risk to operate within design and station available short circuit capacity limits ƒ With failure occurring, all inverter-based generators will not be able to cease power production well before the station breaker begins to open, thereby not mitigating the short circuit impact.
Distribution System Fiber-Optic Replacement and Expansion	Stations Control & Monitoring (Section E6.16)	ƒ Will remediate single points of failure, flat/folded sections and suboptimal quality cabling within the existing fiber-optic plant to drastically improve the availability	ƒ Limitation in full monitoring and control of station outages with current system ƒ Concurrent multi-station SCADA outages due to fiber cuts and single points of failure

	Feeder Automation (Section E7.3)	of the core SCADA station network • Will expand the perimeter of the existing fiber-optic plant to provide better coverage • Expand the fiber-optic footprint to provide redundancy to wireless SCADA substations that require fiber-optic network connectivity	• Concurrent outages in the backhaul infrastructure for Feeder Automation due to fiber cuts and single points of failure
	SCADA-Mate R1 Renewal (Section E6.8)		• Interruption of SCADA may render newly installed SCADA-Mate R2 switches useless during power outages, thereby foregoing their benefits
SCADA Wireless Infrastructure	Feeder Automation (section E7.3)	• Will eliminate legacy wireless SCADA technologies that are now obsolete and no longer supported by the manufacturer and thus will reduce the operational risks • Additional GE SD9 high-sites will be installed to improve wireless SCADA coverage and facilitate rapid SCADA provisioning for in-field assets via greater area coverage	• Failure of the infrastructure could affect overhead SCADA and SF_6 URD switches- large customer impact would result since switches are located on the feeder trunk and will limit the ability for restoration • The automation of the system would fail, resulting in FA and URD not operating as intended and failure to deliver the reliability and efficiency benefits it provides • Failure of infrastructure will affect RTUs having the same effect as overhead SCADA - crews would need to be dispatched for manual switching
	SCADA-Mate R1 Renewal (Section E6.8)	• Will allow SCADA functionality to in-field distribution assets such as substations that are outside the fiber-optic backhaul telecom	• If there is no remote connection to SCADA-Mate switches then the function of the SCADA switches is compromised

	Overhead Circuit Renewal (Section E6.4)	perimeter	ƒ A failure of MOSCAD RTUs and DARCOMM radios can lead to the loss of remote functionality of SCADA switches in a large part of Toronto
	Downtown Contingency (Section E7.7)		ƒ Obsolete assets raise the risk of partial or complete station outages, limited visibility and increase of outage duration to three hours on average ƒ Limited operational response capabilities will exist should failure of these assets occur
	Generation Protection Monitoring and Control (Section E5.5)		ƒ Real time monitoring for safety and feeder management for bi-directional distribution grid flows via communications with Toronto Hydro's SCADA system will be strictly limited with the failure of SCADA equipment ƒ Monitoring, control, and generation forecasting of remote distributed generation sites will difficult to do with the failure of SCADA

E6.22.4 Timing & Pacing of the Program

The program's spending forecast for the five year period starting in 2015 is shown below in Table 6, along with the historical spending on communication systems.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)		-	-	$1.03	$0.85	$6.06	$6.02	$3.95	-	-

As can be seen in Table 6, Toronto Hydro plans to complete the work proposed in this program by the end of 2017 so that the communication system will be able to support advances in monitoring and control within the distribution system.

The SONET system was built at a time when monitoring and control functionality were limited. The SONET system can no longer support stations requiring monitoring and control due to its limited capacity. There are approximately 45 SONET sites in the system, which is beyond the number of maximum sites recommended by the manufacturer and therefore, additional sites cannot be added to the SONET backbone. In addition, the legacy SONET multiplexers can cause communication outages that may render SCADA functionality of RTUs in stations inoperable and increase the outage durations from 30 minutes to three hours. Customers on an entire feeder can be impacted for the extended duration. Over the last five years, there were a total of 90 SONET communication outages. In order to rectify these issues associated with the existing SONET infrastructure, the work proposed in this program must be executed as soon as possible.

The work is also urgent because it is needed to improve both the resiliency of the communication network and to allow for increased penetration of SCADA. As detailed in Section E6.5.4.1, Toronto Hydro plans to complete renewal of the existing plant to ensure a resilient communication backbone before expanding the fiber-optic network to allow for increased coverage for SCADA within the distribution system. Deferring this work would limit Toronto Hydro's fiber-optic plant capability and constrain programs such as Station Control and Communication (Section E6.16), Overhead Circuit Renewal (Section E6.4), and Feeder Automation (Section E7.3).

In order to increase the capability of the communication infrastructure to support an increasing trend in control, monitoring, and automation, Toronto Hydro must also create additional SCADA high-sites immediately. SCADA high-sites extend the reach of the communication network and allow for SCADA installation on distribution feeders. As shown in Section E6.5.4.1, once the SCADA high-sites are installed, the obsolete GE TransIt radios must be replaced with GE SD9 radios in order to address the functional obsolescence of the wireless SCADA infrastructure. GE TransIt technology is obsolete and is no longer supported, Toronto Hydro must move to the GE SD9 system to maintain support. Currently, there are five overlapping wireless SCADA technologies in use within the system. This work allows a single technology to be established to support wireless SCADA thereby leading to efficiency savings via the decommissioning of the obsolete systems, as further discussed in Section E6.22.5.3.

E6.22.4.1 Ranking & Prioritization

The program is structured to accommodate the various dependencies outlined in Figure 5.

FIGURE 5: RANKING AND PROCESS OF IMPLEMENTATION OF THE DSCI PROGRAM

Three key aspects of the program must be completed before subsequent work can take place:

- CWDM/IP/Ethernet introduction to the SONET substation network as part of the Distribution System Communication Technology upgrade,
- Fiber-optics plant single point of failure remediation as part of the Distribution System Fiber-Optic Plant Replacement and Expansion, and

- New wireless SCADA high-site deployments must be completed as part of the wireless SCADA infrastructure activities.

Completing the above three activities allows for the strategic expansion of fiber-optic plant to the SCADA high-sites and to substations allowing for increased SCADA presence in the distribution system and IP/Ethernet to be introduced at substations respectively. Once all communications enabled assets have been replaced or upgraded to support Ethernet/IP connectivity, overlapping communication service provider technology will no longer be required and can be eliminated. In parallel with this activity, the migration from the legacy GE TransIt to the GE SD9 technology can be conducted.

E6.22.5 Program Execution

(i) Distribution System Communication Technology Upgrade

Work executed under the Distribution System Communication Technology Upgrade initiative includes the design and implementation of CWDM multiplexers at substations connected to the SONET rings. Concurrently, enablement of support for Ethernet on existing fiber using CWDM will be executed. This will allow for the migration of all IP based station services into the new Ethernet/IP networks, eliminating overlapping service provider solutions. The program will facilitate the migration of stations devices and services from SONET to IP.

The Technology Upgrade project is completed with the following steps:

- Detailed network architecture and design
- Network equipment vendor selection
- Equipment procurement and logistics
- Facilities preparations (space/racks/HVAC/power)
- Equipment installation and testing
- Promotion to production (subject to fiber-optic availability)
- System migration to the new network infrastructure

(ii) Distribution System Fiber-Optic Plant Replacement and Expansion

Work executed within the Fiber-Optic Plant Replacement and Expansion area involves the identification and remediation of single points of failure by designing new fiber-optic plant sections. Furthermore, identification of strategic sites in the distribution system without fiber-optic connectivity would allow these sites to be added to the fiber-optic communication segment through plant expansion. The Fiber-Optic Plant Replacement and Expansion needs to be completed prior to the promotion to production of infield SCADA equipment, since the fiber-optic cables are required to provide the communication network between the equipment and the control room.

The Fiber-Optic Plant Replacement and Expansion project is completed with the following steps:

- Prioritization of key sites and fiber-optic spans
- Fiber contractor selection (competitive bidding)
- Detailed telecom architecture and fiber plant route design
- Fiber route preparation (rodding and roping, “make-ready’s”, etc.)
- Fiber-optic plant installation, splicing and testing
- Demarcation (building entrance and facilities) preparation
- Telecom equipment migration to the new fiber-optic plant

(iii) Wireless SCADA Infrastructure

Work executed within the Wireless SCADA Infrastructure area involves the identification of locations and deployment of four new wireless SCADA high-sites for GE SD9 to improve the coverage radius. Concurrently, all GE TransIt wireless SCADA endpoints are to be upgraded to GE SD9, as well as the decommissioning of legacy wireless SCADA systems (GE TransIt, MOSCAD, and DACSCAN) are executed.

The Wireless SCADA Infrastructure project is completed with the following steps:

- Potential high-site identification and lease negotiation
- Equipment procurement and logistics

- Facilities preparations (space/racks/HVAC/power)
- High-site radio equipment installation and testing
- Promotion to production (subject to fiber-optic availability)
- Planned replacement of RTU TransIt radios with SD9 (no dependencies)

E6.22.5.1 Program Risks

The key risk associated with the DSCI program is that the project schedule may be impacted by the City permit process as well as attaining permission for high-site locations, which may cause delays in program execution. In order to mitigate this risk, the applications for permits and permissions are prepared well in advance such that any issues that arise can be addressed in a timely manner.

E6.22.6 Evaluation of Alternatives

E6.22.6.1 Quantification/ Evaluation of Options

The DSCI program is critical to maintaining the communication backbone of a safe and reliable distribution system. There are two alternatives to this program: (i) maintaining the current practices and legacy infrastructure or (ii) implementing the proposed program.

(i) Status Quo

With the status quo option, Toronto Hydro will simply maintain the platform and bandwidth requirement. This will result in very little new functionality and capability as the emphasis will be on addressing single points of failure and architectural deficiencies.

Maintaining the current state poses a variety of risks including vendor/technology sprawl created by multiple overlapping technologies and vendors, unpredictable availability of capacity on existing communication infrastructure, obsolescence, and lack of technical support. Although the capital investment is low for this particular option, the operational cost has and will continue to rise due to the need to maintain an obsolete system with declining manufacturer support and expertise.

This option would severely limit Toronto Hydro's ability to improve its distribution system through increased monitoring and control. For example, due to capacity issues with the SONET system,

the current state limits Toronto Hydro's ability to connect RTUs at additional substations in the downtown core, thereby limiting the benefits achieved through the execution of programs such as Stations Control and Monitoring (Section E6.16) or Stations Switchgear Renewal (Section E6.13). This limitation affects the amount of control that can be exercised on station assets, which increases the restoration time when a circuit breaker operates, extending the outage to the customer.

Fiber-optic cables now in use are past their useful life and experience outages, impacting the SCADA capability of both substation RTUs as well as distribution feeder SCADA switches, thereby reducing the benefits of increased SCADA penetration introduced by programs such as Overhead Circuit Renewal (Section E6.4), Feeder Automation (Section E7.3), and Generation Protection Monitoring and Control (Section E5.5). Due to interruptions on the fiber-optic network, power controllers lose the ability to see and operate on faults quickly, which can lengthen the time to needed to respond to an outage from 30 minutes to three hours on average. Similarly, on the distribution feeder, SCADA switches are used to restore power to customers quickly when a fault occurs by remotely isolating the fault and restoring power to customers on sections that are not affected by the fault. However, there are many portions of the distribution system where SCADA capabilities are not supported due to the lack of high-sites to communicate with the SCADA switches, impacting Toronto Hydro's ability to delivery this technology to reduce the outage restoration time. This problem is further aggravated by the fact that the GE TransIt system is past its useful life and these radios have become functionally obsolete, thus not providing the intended SCADA capability. A functionally obsolescent communication infrastructure compromises safety by exposing Toronto Hydro to cyber-security threats and limiting the visibility on asset performance and operating condition. Given the impact on the distribution system of an aging communication system, this option is not preferred.

(ii) Implement the Distribution System Communication Infrastructure program

This option involves performing the work outlined in Section E6.22.6 to improve the resiliency and performance of the communication system, while also enabling business initiatives, such as remote control and increased system monitoring. With fiber-connectivity, 1 Gbps Ethernet/IP will be available at all sites. The investment would eliminate single points of failure in the outside fiber-optic plant by running new fiber and will expand outside fiber-optic plant footprint to improve availability and provide high-speed connectivity to strategic sites. The implementation would also standardize and consolidate the wireless SCADA environment to GE SD9 from the obsolete GE

TransIt. In addition, carrying out the proposed program would allow Toronto Hydro to avoid costly investments in obsolete systems (SONET) and to decommission legacy communication technologies and infrastructure, thereby introducing efficiency savings in the communication system. This option is also a foundational enabler technology for various initiatives, including programs like Generation Protection Monitoring and Control (Section E5.5), Overhead Circuit Renewal (Section E6.4), SCADA-Mate R1 Renewal (Section E6.8), and Stations Monitoring and control (Section E6.16), which are essential to increasing the protection, monitoring, and control of the distribution system.

The cost of ownership (COO) and program net benefit (NPV) associated with the Distribution System Communication Infrastructure program is further detailed in Figure E6.22-11. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities within this program. The COO of a state reflects the risk of asset failure including both direct and indirect costs; these costs include customer interruptions, emergency repairs, and asset replacements associated with a given design. For further details on the COO approach, please refer to Section D3.3. The implementation of the DSCI program is critical for enabling the penetration of SCADA technology when SCADA switches are installed on feeders in the affected region. In order to reflect this requirement, the business case takes into account for the installation cost of SCADA switches (SC) to establish the required number of switching regions on feeders in this region in addition to the program cost (PC) of this program. The total cost that is applied is then equal to (SC) and (PC). When the difference in cost of ownership (ûCOO) is compared to the associated total cost, the Distribution System Communication Infrastructure produces a net benefit (NPV) value of $6.83 million, as shown in Tables 7 and 8.

TABLE 6: EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	$ 106.18
Non Asset Risk [NAR_E]	$ 0
Maintenance Cost [MC_E]	$ 0
Additional Quantifiable Benefits [AQB_E]	$ 0
Cost of Ownership of Existing Assets [COO_E]	$ 106.18

TABLE 7: DISTRIBUTION SYSTEM COMMUNICATION IN FRASTRUCTURE BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 2: Implementation of DSCI (N)	
Asset Risk [AR_N]	$ 89.18
Non Asset Risk [NAR_N]	$ 0
Maintenance Cost [MC_N]	$ 0
Additional Quantifiable Benefits [AQB_N]	$ 0
Cost of Ownership of New Assets (Conversion to 13.8kV) [COO_N]	$ 89.18
Option 2: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	$ 17.01
Program Cost [PC_1]	$ 6.06
Switch Replacement Cost [SC_1]	$ 4.12
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	$ 6.83

E6.22.7 2015 Project Details

As part of the 2015 project year, Toronto Hydro plans to remove the limitations posed by the current CDS owned fiber by replacing the cable with Toronto Hydro owned cable. The proposed locations, in downtown Toronto and Scarborough, for replacing existing CDS fiber are listed in Tables 9 and 10, respectively.

Toronto Hydro plans to install 34 Coarse Wavelength Division Multiplexing (CWDM) technology units which will decouple SONET technology and Internet Protocol (IP) traffic, preventing the need to upgrade the legacy SONET platform. Table 11 provides the location for the existing

SONET nodes to be augmented with CWDW deployment. Figure 6 presents a map of these same locations.

Additionally, Toronto Hydro proposes to install three additional SD-9 High-Sites in 2015. High-sites are installations in the distribution system that communicate with in-field SCADA radios

wirelessly and transmit the information back to the control center through fiber-optic cable lines. The proposed SD-9 High-Sites locations for 2015 are shown in Figure 7.

FIGURE 7: MAP OF THE NEW SD-9 HIGH-SITE LOCATIONS FOR 2015

TABLE 1: TRIGGER DRIVERS FOR SYSTEM SERVICE CATEGORY

Driver	Description
Safety	ƒ Assets are exposing known safety-related hazards/risks to crew workers or the general public, or assets are an integral part of maintaining safe work practices, and the failure of those assets would likely result in safety-related hazards or risk exposure
Reliability	ƒ Maintain or improve reliability at a local, feeder-wide or system-wide level
System Efficiency	ƒ The need to improve restoration capability, ultimately resulting in substantial reliability and customer experience improvements ƒ The need to reduce losses in distribution lines
Capacity Constraints	ƒ Expected changes in load that will constrain the ability of the system to provide consistent service delivery ƒ Current or potential incapability of the system to handle demand requirements

Table 2 provides a brief description for each investment program within the System Service narrative along with total expenditures for each program from 2015 onwards to 2019. Individual section numbers for each investment program are also provided in this table.

TABLE 2: DESCRIPTION OF SYSTEM SERVICE INVESTMENT PROGRAMS

Program Index and Name		Description	Total (5 years)
E7.1	Contingency Enhancement	Make improvements to feeders in the existing distribution systems that are currently unable to quickly restore power to affected customers under a contingency situation.	$48.9 M
E7.2	Design Enhancement	Implementing fusing enhancements to resolve the issues of undersized fuses, mis-coordinated fuses and redundant trunk sections that lack fusing. Replacement and strategic location of fuses and the implementation of tree proof conductors to mitigate sustained interruptions caused by tree contact outages.	$7.27 M
E7.3	Feeder Automation	Facilitating faster and less labour intensive system restoration procedures by replacing existing switches with autonomously operating Supervisory Control and Data Acquisition (SCADA) switches, reducing the impact of trunk outages to customers and isolating the faulted section of the feeder in less than a minute.	$54.1 M

Program Index and Name		Description	Total (5 years)
E7.4	**Overhead Momentary Reduction**	Installation of reclosers to provide flexibility to the system, fault protection and improve the distribution feeder reliability performance by limiting outage times and containing the outage to a minimum area.	**$1.91 M**
E7.5	**Handwell Upgrades**	Replacing the remaining legacy handwells with new standard handwells made from non-conducting composite materials to remove the risk of contact voltage to the public.	**$4.98 M**
E7.6	**Polymer SMD-20 Fuses**	Targets SMD-20 switches that were installed between 2006 and 2011, as breakages inhibit these switches from functioning safely as designed. New switches utilize a fiberglass core that has five times the strength of the previous design. Replacement of the switches eliminates the known safety risk to the public and Toronto Hydro employees.	**$4.84 M**
E7.7	**Downtown Contingency**	Providing distribution load transfer capability between stations in the downtown Toronto area by tying feeders from one station with feeders from an adjacent station. This program addresses a risk in the downtown area where no back-up is provided for certain low probability, high impact events.	**$3.36 M**
E7.8	**Customer Owned Station Protection**	Installation of utility-owned protection devices upstream of customer-owned substations to isolate any faults occurring at customer owned substations.	**$4.04 M**
E7.9	**Stations Expansion (including HONI contributions)**	Upgrades to either Toronto Hydro or Hydro One Networks Inc. owned transformer stations. These upgrades address recent trends in customer connection requirements and loading, by mitigating system limitations imposed by existing station equipment.	**$188 M**
E7.10	**Local Demand Response**	Providing medium-term capacity relief to Cecil TS by implementing a targeted and localized demand response strategy which primarily leverages new and existing demand response resources.	**$4.06 M**
E7.11	**Energy Storage Systems**	To provide a conventional support for local capacity constraints and service reliability issues throughout Toronto Hydro's distribution system. These systems are also categorized as a renewable enabling improvement to accommodate the increasing numbers of renewable energy generation (REG) connections.	**$10.8 M**

/C

The following Sections E7.1 though to E7.10 contain the details and justification for each capital investment program within the System Service investment category.

E7.1 Contingency Enhancement

TORONTO HYDRO CREW MEMBER REPAIRING OVERHEAD INFRASTRUCTURE

E7.1.1 Summary

Program Description

The objective of the Contingency Enhancement program is to make improvements to feeders in the existing electrical distribution system that are currently unable to quickly restore power to affected customers under a contingency situation. Distribution feeders can be interrupted due to equipment failure and weather-related events. These interruptions can impact the supply of power along either a portion or the entire feeder. Several feeders in Toronto Hydro's overhead and underground distribution systems lack the ability to restore power to customers in a timely manner during emergencies. The program aims to reduce the risk of long duration outages for customers by ensuring that crews and system controllers have full capability to re-route affected customers to nearby feeders.

Toronto Hydro plans to address the situation by establishing sufficient tie and sectionalizing points, upgrading under-sized loop conductors and upgrading undersized trunk egress cable capacities. These targeted upgrades and installations will equip the distribution system to better meet the needs of customers in contingency scenarios, effectively maximizing the customer value of existing feeders by minimizing unnecessary failure risk.

Table A summarizes the expected benefits related to the Contingency Enhancement Program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduces the length of customer outages. ƒ Increases the number of customers that can be restored during an outage
Reliability	ƒ Enhances reliability through improved load transfers and upgraded equipment. ƒ Faster response with SCADA controlled switches. ƒ Improved system performance during high impact events, including major storms.
Safety	ƒ Eliminates manual switching, which reduces Toronto Hydro crew exposure to energized equipment.
Efficiency	ƒ Eliminates manual switching, allowing Toronto Hydro to utilize resources for other matters.

Program Drivers

The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ Certain feeder configurations and assets on the 27.6 kV distribution systems limit the system controller's ability to restore electrical service to customers when a feeder experiences a fault or requires maintenance. By undertaking this program, Toronto Hydro will reduce the duration of outages during contingency situations, including high impact events such as major storms.
Secondary Drivers	**Reasoning**
System Efficiency	ƒ Manually operated switches require Toronto Hydro crew members to physically travel to the site and perform switching operations during faults, which prolongs the duration of outages for customers. By deploying SCADA-enabled tie point and sectionalizing switches, Toronto Hydro will reduce its need to send crews to perform switching activities. ƒ Undersized conductor restricts Toronto Hydro's ability to transfer load during fault repair or maintenance activities ƒ Aluminum trunk egress cable exists at 10 transformer stations and is not rated to deliver the full capacity of a 27.6 kV feeder circuit, preventing Toronto Hydro from fully utilizing feeder capacity to deliver load to adjacent feeders during a contingency scenario.

Safety	*f* Installation of SCADA enabled switches in the field eliminates manual switching, which reduces Toronto Hydro crew exposure to energized equipment. This is especially important during contingency condition when most of the outages occur during poor weather condition which may result in access to the switch location difficult and crew forced to work near faulty equipment.

Preferred Alternative

Toronto Hydro evaluated the following options for addressing the system design deficiencies considered by this program.

(i) Do nothing and accept the anticipated degradation of reliability due to aging assets and forecasted increases in load growth and the frequency of major storms.

(ii) Increase the contingency capabilities within the system to mitigate anticipated degradation of reliability.

Option II is the preferred alternative as it strengthens Toronto Hydro's distribution system in contingency conditions, thus mitigating a degradation of reliability as the system ages, load growth continues and environmental conditions evolve due to climate change. Enabling feeders to be segmented into smaller sections gives system controllers greater ability to transfer loads and minimize the number of customers impacted during power outages. Upgrading the aluminum egress cable to copper also increases the capacity of feeders, thus allowing them to supply more load, which can benefit reliability under contingency situations.

Timing and Pacing

The Contingency Enhancement program takes into account other renewal projects and will work in conjunction with them to upgrade assets while the renewal project is taking place. This will keep the renewal work costs lower and will reduce the number of planned outages for customers during the renewal process.

Details of the historical and future spending for Contingency Enhancement are outlined below in Table C. There was no historical spending prior to 2015 as these projects were typically undertaken as part of other asset renewal projects.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Total Annual Spend ($M)	0	0	0	0	0	$9.97	$5.88	$9.71	$9.68	$13.53

E7.1.2 Program Description

Distribution feeders can be interrupted by a number of incidents, including equipment failure and weather-related events. A feeder may also need to be taken out of service for scheduled maintenance or repair work. The interruption of a feeder can stop the supply of power along a portion or event the entire feeder. Under either contingency scenario, Toronto Hydro must be able to transfer customers normally supplied by the out-of-service feeder to adjacent feeders to minimize the duration of outages for customers that are dependent on the affected feeder.

A number of feeders in Toronto Hydro's overhead and underground distribution systems lack the ability to restore power to customers quickly during contingency scenarios. The Contingency Enhancement program will make targeted improvements so that customers experiencing an outage can receive re-routed power during contingency scenarios. These investments will help shorten the duration of power outages for customers that are dependent on failing, aging assets. The total cost of the program from 2015 to 2019 is $48.8 million. The program consists of the following distinct but related elements:

(1) Establishing additional tie and sectionalizing points,

(2) Upgrading under-sized loop conductors, and

(3) Upgrading the capacity of trunk egress cable.

E7.1.2.1 Establishing additional tie and sectionalizing points on looped feeders

Toronto Hydro plans to install additional SCADA-enabled[1] tie and sectionalizing points on underground and overhead feeders so that customers can be quickly switched to alternate feeders in the event of a contingency condition, reducing the duration of outages. Initial analysis will be performed on feeders that lack a sufficient number of tie or sectionalizing points to determine the reliability impact. Toronto Hydro will take into account the feeders' configurations and number of customers each serves in determining the optimal location of tie or sectionalizing switches. In addition, overhead line or underground cable extension work will be performed to establish new tie connection points between feeders; this work may involve the installation and removal of poles, lines and switches for the overhead plant. Additional civil infrastructure may be needed for the placement of new pad mounted switches and cable in the underground distribution

[1] SCADA switches are capable of being remotely controlled to perform switching operations from the control room.

system. Also, the utility plans to convert the existing manually operated sectionalizing and tie switches to SCADA-controlled switches where feasible.

Figure 1 shows the locations of feeders in the looped distribution system with insufficient tie points. Toronto Hydro plans to either install new switches or convert existing manually operated switches to SCADA controlled type to address these deficiencies. If the switches are located within the boundary of the rebuild project, they may be included as a renewal project under the System Renewal program. Otherwise, the switches are targeted under this Contingency Enhancement program.

FIGURE 1: MAP OF FEEDERS WITH INSUFFICIENT TIE POINTS

E7.1.2.2 Upgrade existing undersized loop conductors

Toronto Hydro plans to upgrade undersized conductor in lateral loops to ensure that they are properly rated to carry the load of the entire loop under contingency condition. If the existing cable is installed in concrete encased duct, the only work that would be required is the replacement of cable and transformer vault ancillary. However, if the existing cable is direct-buried or if the existing duct structure has collapsed, before replacement work can be undertaken, Toronto Hydro would have to conduct civil construction work to build new concrete encased duct and splice boxes.

Figure 2 shows the location of undersized loop conductors in the distribution system.

FIGURE 2: LOCATION OF UNDERSIZED LOOP CONDUCTOR

E7.1.2.3 Upgrade capacity of trunk egress cable

Toronto Hydro plans to replace existing aluminum cable on feeder trunk egress sections with copper cable to match the 600 A rated capacity of the breaker. The capacity of aluminum cable is limited to 500A/530A in the summer/winter, which means that the full breaker capacity cannot be realized under contingency situations if necessary. The normal rating of copper cable is 630A/680A in the summers/winter, which is sufficient to carry the full continuous load of a 27.6 kV feeder circuit breaker. With the appropriately rated cable, feeders can be used to provide safe and reliable relief to adjacent feeders under a contingency condition. If the existing cable is installed in concrete encased duct, Toronto Hydro will only need to make cable replacements. However, as with the undersized loop conductors, if the existing cable is direct-buried or if the

existing duct structure has collapsed, before replacement work can be undertaken, Toronto Hydro will have to conduct civil construction work to build new concrete encased duct and splice boxes.

The following is a list of Transfer Stations (TS) with under-rated trunk egress cables:

- Leslie TS
- Bathurst TS
- Fairchild TS
- Fairbank TS
- Horner TS
- Runnymede TS
- Finch TS
- Scarborough East TS
- Scarborough West TS
- Sheppard TS

Error! Reference source not found. Table 1 summarizes the assets that are forecast to be replaced through the Contingency Enhancement program during the 2015-2019 period.

TABLE 1: ASSETS TO BE REPLACED (BY ASSET CLASS)

Assets (Units)	2015	2016	2017	2018	2019	Total
Primary cable (meter)	27,397	16,158	26,683	26,600	37,180	134,017
Underground Transformers	23	14	22	22	31	113
Underground switchgear	11	6	11	11	15	54
Poles	157	93	153	152	213	768
Overhead Transformer	28	17	27	27	38	137
Overhead switch	46	27	45	45	62	225

The following table summarizes the anticipated benefits of this program. A detailed discussion of program drivers can be found in the following section.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Reduces the length of customer outages. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $59.79 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.1.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $49.82 million, confirming the economic prudence of the investments (see Section E7.1.7).
Reliability	ƒ Enhances reliability through improved load transfers and upgraded equipment. ƒ Faster response with SCADA controlled switches. ƒ Improved system performance during high impact events, including major storms.
Safety	ƒ Eliminates manual switching, which reduces Toronto Hydro crew exposure to "live" equipment.
Efficiency	ƒ Eliminates manual switching, allowing Toronto Hydro to utilize resources for other matters.

E7.1.3 Why the Program is Needed

Certain sections of Toronto Hydro's distribution network cannot effectively respond to contingency conditions in order to deliver reliable service to customers. The Contingency Enhancement program is needed to minimize the effect maintenance activities and faults have on outages during contingency situations.

E7.1.3.1 Program Drivers

The Contingency Enhancement program is designed to ensure that Toronto Hydro can efficiently and effectively restore power to customers during contingency scenarios. Table 3 presents the trigger and secondary drivers for the Contingency Enhancement program. This program is a System Service initiative because the trigger driver is reliability.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ Certain feeder configurations and assets on the 27.6 kV distribution systems limit the system controller's ability to restore electrical service to customers when a feeder experiences a fault or requires maintenance.

	By undertaking this program, Toronto Hydro will reduce the duration of outages during contingency situations, including high impact events such as major storms.
Secondary Drivers	Reasoning
System Efficiency	ƒ Manually operated switches require Toronto Hydro crew members to physically travel to the site and perform switching operations during faults, which prolongs the duration of outages for customers. By deploying SCADA-enabled tie point and sectionalizing switches, Toronto Hydro expects to reduce its need to send crews to perform switching activities. ƒ Undersized loop conductor restricts Toronto Hydro's ability to transfer load during fault repair or maintenance activities. ƒ Aluminum trunk egress cable exists at 10 transformer stations and is not rated to deliver the full capacity of a 27.6 kV feeder circuit, preventing Toronto Hydro from fully utilizing feeder capacity to deliver load to adjacent feeders during a contingency scenario.
Safety	ƒ Installation of SCADA enabled switches in the field eliminates manual switching, which reduces Toronto Hydro crew exposure to "live" equipment. This is especially important during contingency condition when most of the outages occur during poor weather condition which may result in access to the switch location difficult and crews potentially forced to work near faulty equipment.

(i) Establishing additional tie and sectionalizing points on a looped feeder

When a segment of, or the whole feeder, loses power during a contingency scenario, customers connected to the failed segment receive power from an alternate feeder using feeder tie points and sectionalizing switches. In the underground distribution system, the switching equipment used is SF_6-insulated pad-mounted switches equipped with SCADA capability; the overhead system uses SCADA controlled switches mounted on poles.

If a feeder is not sufficiently equipped with sectionalizing or tie points that can divide the load into smaller sections, re-routing of power may not be possible for all customers during peak loading times. Issues arise because the amount of lost load may be too large for the adjacent feeder to supply without causing an overloading condition. In some cases, load growth and the addition of new developments onto feeders have created this problem. However, this program is not triggered by the challenge of new load added to the system – that driver is addressed in the Load Demand program. The intent of this program is to allow the distribution system to respond adequately to contingency conditions, rerouting affected customers to alternate feeders.

In addition to a lack of tie-points in some areas, an additional issue is that many existing tie and sectionalizing switches in the field that are manually operated, the problems of which are discussed below. Table 4 provides an overview of the switch types found in the distribution system.

TABLE 4: TIE AND SECTIONALIZING SWITCHES

Switch type	Manual	SCADA	Total
Tie	527	395	922
Sectionalizing	3,605	448	4,053

Manual switches were installed before SCADA-controlled devices were available and considered standard equipment by Toronto Hydro. To restore customers using manual switches, a crew must travel to the switch location to perform the switching work on-site. Depending on the location of the fault and accessibility of the switches, it may take anywhere from 30 minutes to a few hours to perform the switching work. On the other hand, with SCADA controlled switches, this switching operation can be performed remotely by system controllers in a matter of minutes. In addition to the time savings, remotely controlling switches is safer than manually performing switching activities because crews are not exposed to live equipment. SCADA controlled switches also send back instant loading information to the control room, enabling controllers to reroute power to adjacent feeders more efficiently and reducing the duration of power outages during a feeder contingency condition.

An illustration of the situation described above is demonstrated in Figure 3 below. Although there are two individual tie points, T1 and T2, connected to the feeder, customers in section C may not have their power restored under a fault condition if section C's load is greater than T1's available spare capacity at the time. As a result, even though tie point T2 has enough capacity to restore power to customers in section B, customers in section C would be without power until repair work is completed and power is restored through the feeder breaker itself.

FIGURE 3: FEEDER WITH INSUFFICIENT NUMBER OF TIE POINTS

Figure 4 illustrates a solution to the problem above. By adding an additional tie point (T3) and a new sectionalizing switch (F) to split the original section "C" into two sections ("C1" and "C2"), an additional source of supply can be used to restore the lost load.

FIGURE 4: AFTER ADDITION OF TIE AND SECTIONALIZING SWITCH

An example of location that required a tie point is project W15391: Bathurst Bridge Tie Point (35M4-35M9), illustrated in Figure 5. Through this project, Toronto Hydro plans to extend overhead 27.6kV conductor on Bathurst St. between Heathdale Rd. and Ridgewood Rd. to connect feeders 35M4 and 35M9 via a new SCADA controlled switch. This project is needed because the south-east most portion of 35-M9 has one of the highest load densities in the area; this section of 35-M9 supplies 3500 residents, including 14 large condominium developments, a 400 resident long-term care facility, and St. Michael's College School. In all, this section accounts for 50% of the total feeder load; however, it is in an isolated corner of the feeder that currently does not possess effective tie points to transfer its load to in the event of feeder failure. As a result, this section had a history of long outages. By installing a new tie switch, this section of the feeder will be able to be supplied by feeder 35M4 in the event of failure, greatly enhancing the reliability of power supply to customers.

FIGURE 5: SCOPE W15391

To provide appropriate backup supply, a feeder should have at least three strategically located tie points connected to three unique back up feeders:

(1) The first tie point connects to another feeder from the same substation bus.

(2) The second tie point connects to another feeder on a separate bus located at the same substation.

(3) The third tie point connects to another feeder from a different substation.

This design is illustrated in Figure 6.

FIGURE 6: THREE TIE POINT DESIGN

By arranging the tie points in such a fashion, a contingency power source is made available for the faulted feeder regardless of whether the fault occurs at the feeder, bus or station level. This increases the flexibility of the switching options available to reroute power quickly to the affected customers from a failed feeders, thus reducing the duration of a power outage. It should be noted that the number of additional sectionalizing switches and tie points that need to be installed for each feeder under this program will vary depending on the amount of load that is connected to the specific feeder and availability of tie feeders in the area.

E7.1.3.2 Undersized loop conductor

In a looped distribution system, a group of transformers is connected in a loop formation from two fused points that are connected to the trunk portion of the feeder, as shown in Figure 7. There is typically an open-point near the middle of the loop so that, under normal operating conditions, about half of the load in the loop is supplied from one lateral or the other. The loop can be a single phase circuit (connecting single phase transformers) or a three-phase circuit (connecting three-phase transformers).

FIGURE 7: LOOPED DISTRIBUTION

If there is an equipment failure at any point along the loop, the faulty asset can be isolated by opening removable connectors in the transformer vault on both sides of the failed equipment. Power to customers on the undamaged portion of the loop can then be restored by closing the open point.

Generally, the conductor on either lateral is, by design, large enough to handle the load of the entire loop if necessary. In a situation where a fault occurs, on the first section downstream of the fuse, the restored load must be supplied entirely from the other side of the loop, as shown in Figure 8. This situation is analogous to the circumstances where Toronto Hydro must electrically isolate an asset for maintenance purposes.

FIGURE 8: POWER RESTORATION IN LOOP AFTER FAULT

Over time, new customers are added to the loop. In some situations, this gradual increase in load has resulted in existing conductors no longer being able to supply the load of the entire loop. A contingency situation in these locations would cause cascading power outages to the entire loop because the conductor is not rated to deliver the total load demand in the loop. This situation is illustrated in Figure 9. In the end, prolonged repair work is required and customers would face long power outages. Although controllers do monitor the conductor size and number of transformers that are transferred to the circuit under contingency, the actual load of each transformer may not be known by the controller. Therefore, even in instances where a conductor withstood a high current during repair work without failing, this overloading situation may have already caused degradation of the integrity of the conductor and could lead to premature failure of the loop conductor and reactive repair work in the future.

Toronto Hydro plans to upgrade undersized conductor in lateral loops to ensure that they are rated to carry the load of the entire loop under contingency conditions.

FIGURE 9: POWER LOST DUE TO UNDERSIZED CONDUCTOR

E7.1.3.3 Insufficient Capacity of Trunk Egress Cable

Feeders in the looped distribution system are connected to one another using tie switches installed at various locations along each feeder. The tie-points are designed to transfer load from one feeder to another under a contingency condition. The initial section of the feeder between the station breaker and the first distribution switch (i.e. the section upstream from any load connections) is called the "egress" section of the feeder. The egress can carry the entire load of the feeder at any time. The trunk egress cable must be adequately sized to be able to supply the load of the feeder as well as additional load from adjacent feeders under contingency, up to the maximum capacity of the feeder breaker.

When stations were initially constructed in the 1960's and 1970's, several factors were considered in choosing which feeders to install, including known or anticipated load, contingency requirements and the material cost of cable. Some existing underground 27.6 kV feeders contain legacy 1000 kcmil aluminum trunk egress cable, a cable that is de-rated (i.e. its current carrying capacity is lowered) when installed in an underground environment to 500 A and 530 A in the summer and winter seasons respectively.

In some areas, demand growth has exceeded the capacity of this existing configuration, so a higher rated trunk egress cable is needed to utilize the full capacity of certain feeders. In addition, the existence of a large quantity of aging assets in the distribution system raises the risk of asset failures, which may ultimately result in multiple feeders in contingency condition at a same time. In some circumstances, a feeder may be forced to carry the load of more than one feeder under contingency. This is a high risk situation, as failure of the load carrying feeder to deliver power to its maximum capacity may ultimately result in loss of power to two other feeders, causing power outages to a very large area for an extended period. It is therefore critical that the egress portion of the feeder be fully rated to effectively utilize the rated capacity of the breaker, which is rated 600A, in order to supply load to customers on its own and to adjacent feeders under contingency. Due to the limitation of current carrying capability of these trunk egress cables, customers that would otherwise be served by those feeders under a contingency condition would experience an outage until the work on their normal feeder has been completed.

Under a contingency condition, controllers may not be able to utilize feeders with 1000 kcmil aluminum egress trunk cable to pick-up load lost on adjacent feeders during fault or planned maintenance. As a result, customers will experience prolonged power outage until the faulty asset is repaired or replaced on the normal supply feeder. Toronto Hydro may also be required to defer important scheduled maintenance work until the load on feeders is low enough to be re-routed, resulting in the deterioration of asset conditions, further reducing reliability.

An example of a project to upgrade undersized trunk conductor is “W11147: Cable Replacement Bathurst Stn M4, M24, M25” (addition details can be found in section E7.1.9). Through this project, Toronto Hydro plans to upgrade existing 1000 kcmil Al trunk egress cable to 1000 kcmil Cu to fully utilize the rated capacity of feeders 85M4, 85M24 and 85M25. Figures 10, 11 and 12 show the loading profile of feeders 85M4, 85M24 and 85M25 from May 2011 to May 2014. The loading charts show that the normal seasonal peak loading for all three feeders is in excess of 450 A. The maximum peak loading that these feeders have experienced, although short in duration, has exceeded the normal rating of the 1000 kcmil Al conductor. While the existing aluminum cable can withstand a small amount of additional load of 80 A, over time, the frequent overloading of cable would eventually cause the cable to fail prematurely, causing power outages to the entire feeder. The small size of the cable and overloading accelerates the physical degradation of the conductor insulation integrity. It is for this reason that the legacy aluminum trunk cable is no longer sufficient to be used as the trunk cable and must be upgraded to Cu conductor

FIGURE 10: FEEDER LOADING 85M4

FIGURE 11: FEEDER LOADING 85M24

FIGURE 12: FEEDER LOADING 85M25

Similar situations also exist in the following stations with aluminum trunk egress cable:

- Leslie TS
- Bathurst TS
- Fairbank TS
- Horner TS
- Runnymede TS
- Finch TS
- Scarborough East TS
- Scarborough West TS
- Sheppard TS

E7.1.4 Timing & Pacing of the Program

Contingency readiness is an essential component of electrical distribution operations. Without it, customers are subject to the risk of lengthy power outages any time there is a disturbance on a feeder. The majority of Toronto Hydro's distribution assets are equipped to properly respond to contingency conditions. In certain areas however, load growth and feeder extension has resulted in sections of the distribution system that are inadequately equipped to handle contingency conditions to restore power to customers in a timely manner. Due to the fact that Toronto Hydro is operating with a large quantity of aged assets in the field, there is an increasing risk of random asset failures that could result in power outages and contingency scenarios. As a result, it is critical that the contingency enhancement work be performed where needed to ensure the impact of feeder failure to customer is minimized.

This program is required to upgrade the distribution system's ability to effectively manage contingency situations in order to minimize customer interruptions. Deferring this program would likely prevent Toronto Hydro from being able to effectively restore power to certain feeder segments that have experienced failure, leading to potentially lengthy power outages. In addition, Toronto Hydro will not be able to perform proactive repair or maintenance work on certain feeders to prevent assets from deteriorating.

Toronto Hydro has taken into account the timing of other planned asset renewal projects that may be taking place in timing the projects under the Contingency Enhancement program. If a switch that needs to be addressed is within the boundary of a renewal project, it will be upgraded in conjunction with the system renewal work since the renewal of overhead lines or underground cable and transformer will usually require that existing switches be temporarily removed to allow for the construction work to be done. As such, it is more efficient and cost effective to upgrade the switch while the renewal project is taking place. If the switch is not located in any planned rebuild project area, Toronto Hydro will assess the urgency to install or upgrade the switch based on the historical reliability, age and condition of the switch and its impact on customer outages. As a result, some projects will be performed from 2015 to 2019 while other, non-urgent projects will take place beyond 2019. Similar logic applies to undersized loop conductor and trunk egress cable.

Contingency readiness is a key element in Toronto Hydro's asset management and engineering function. As indicated in the Table 5 below, there was no historical spending solely dedicated to contingency enhancement prior to 2015. Typically, these projects were undertaken as part of asset renewal or plant upgrade projects and as such, their spending figures can be found under

those respective projects. Although some contingency enhancement projects will continue to be classified under asset renewal projects going, a portion will be performed as standalone work. To align with the new program categorization commencing in 2015, these project are grouped together as part of the Contingency Enhancement program.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	$9.97	$5.88	$9.71	$9.68	$13.53

E7.1.4.1 Ranking & Prioritization

For the tie point and sectionalizing switch work, projects will be ranked and prioritized by feeder loading, reliability and available feeders in the nearby vicinity for new tie switch installations. Some feeders lack a sufficient number of tie points because there is no other feeder in the area that is within reasonable reach. In these cases, work will be required to extend overhead or underground infrastructure to complete the connection and work may need to be staged in phases for completion.

Undersized loop conductor upgrades will be ranked and prioritized based on reliability statistics as well as the age and condition of the existing assets. Aging or unreliable assets can signal a risk of failure, increasing the urgency of the work.

Aluminum to copper conversion of egress cable will primarily be ranked and prioritized based on feeder loading and the reliability of adjacent feeders. A feeder that consistently experiences high loading with insufficient egress trunk cable rating is at risk of not being able to deliver the capacity needed to relief adjacent feeder under contingency. These feeders will be prioritized.

E7.1.5 Program Execution

The underground system uses SF_6-insulated pad-mounted switches equipped with SCADA capability. The overhead system uses SCADA-controlled switches mounted on poles. Installing new switches may require new poles, lines for the overhead plant, or civil infrastructure for the placement of new pad mounted switches in the underground distribution system. Cable replacement may also be required where existing cable must be spliced to accommodate a new switch. Fuses on both the overhead and underground systems may also be replaced.

Replacing undersized lateral loop conductors is required for underground cable only. Cable is either directly buried in the ground or is encased in a concrete duct. In cases where cable is directly buried, concrete duct encasements are also installed.

Feeder trunk cable upgrades are only required on the underground system. Similar to lateral loop conductors, if trunk cable is direct-buried, concrete ducts are installed in advance of the cable replacement. For all underground cable replacement, Tree Retardant Cross Link Polyethylene (TRXLPE) cable is used.

If a planned overhead or underground renewal project overlaps with work from this program, the work to install tie and sectionalizing switches will be included as a part of the larger scale renewal projects (as executing such work together is more cost effective). For locations where work in this program is not associated with any larger-scale renewal work, projects are individually scoped and executed.

E7.1.5.1 Proposed Work Plan

Work in this program covers mainly the 27.6kV looped distribution outside of the downtown core.

E7.1.5.2 Program Risks

Unforeseen site conditions, such as the presence of foreign infrastructure (such as gas, sewer or water pipes), can necessitate scope changes and can result in cost increases and/or delays in the completion of the underground work. In these situations, Toronto Hydro would reprioritize and/or reschedule work after taking all factors into consideration.

As well, Toronto Hydro must take into account city road moratoriums that may be imposed after the scope is issued, which could result in delays. However, Toronto Hydro can mitigate this risk by ensuring that it maintains open communication with the City of Toronto and coordinates its activities with those of the city.

Finally, weather-related events can impact system loading conditions, which may prohibit feeder work (e.g., summer heat wave). In the same way, emergency work may also alter Toronto Hydro's planned work schedule.

E7.1.5.3 Evaluation of Alternatives

E7.1.5.3.1 Quantification/Evaluation of Options

(i) Status Quo

Maintaining the status quo involves forgoing the Contingency Enhancement program. Customers served by troubled feeders would continue to experience lengthy outages during contingency conditions. In addition, Toronto Hydro would incur high costs with respect to performing reactive work to replace equipment that was damaged due to overloading and manual switching work.

For these reasons, the status quo option is not preferable.

(ii) Proposed Program

Executing the proposed program strengthens Toronto Hydro's distribution system in contingency conditions, improving reliability for affected customers. The addition of SCADA controlled tie and sectionalizing switches would enable Toronto Hydro to segment a feeder into smaller sections so that load could transferred to alternate feeders to reduce the duration of power outages. In the end, customers would be expected to experience improved service reliability and Toronto Hydro would gain efficiency advantages by extending the reach of the SCADA system. As well, upgrading aluminum egress cable to copper would allow feeders to utilize the full rated capacity of the circuit in order to deliver power during a contingency condition.

The cost of ownership (COO) and program net benefit (NPV) associated with the Contingency Enhancement program is further detailed in Figure 10 and Figure 11. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities in this program. The cost of ownership (COO) of a state reflects the risk of asset failure including both direct and indirect costs, including the costs of customer interruptions, emergency repairs, and asset replacements associated with that design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NARE) and proposed (NARN) state. Non-asset risks are further explained in Section D3.3. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership ("COO) is compared to the associated program costs (PC) for the first year of activities, the

Contingency Enhancement program produces a net benefit (NPV) value of $49.82 million, as shown in Tables 6 and 7.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo / Existing State of Infrastructure	
Asset Risk [AR_E]	$ 274.66
Non Asset Risk [NAR_E]	$ 719.30
Maintenance Cost [MC_E]	$ 0
Additional Quantifiable Benefits [AQB_E]	$ 0
Cost of Ownership of Existing Assets [COO_E]	$ 993.96

TABLE 7: CONTINGENCY ENHANCEMENT PROGRAM BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Contingency Enhancement (N1)	
Asset Risk [AR_N]	$ 221.67
Non Asset Risk [NAR_N]	$ 712.51
Maintenance Cost [MC_N]	$ 0
Additional Quantifiable Benefits [AQB_N]	$ 0
Cost of Ownership of New Assets [COO_N]	$ 934.17
Option 2: Project Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\Delta COO_1 = (COO_E - COO_N)$]	$ 59.79
Program Cost [PC_1]	$ 9.97
Program Net Benefit [$NPV_2 = (\Delta COO_1 - PC_1)$]	$ 49.82

E7.1.6 Program Projects

Table 8 list the projects that Toronto Hydro plans to execute beginning in 2015. Detail on projects for years 2015 is provided in the following sections.

TABLE 8: PROGRAM SCOPES

Project Number	Project Name	Total Project Cost	Start Date
E14136	E14136 OH Upgrade R43M24 Hollis Milne Birchmount (Electrical) - Map Area 1	$871,476.78	2015

E7.1.6.1 Project Detail

E11637 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: E11637 Civil works for rebuild of NY51M4 Gordon Baker and Hazelnut Crescent

Project Number: E11637

Project Year: 2015

Estimated Cost: $209,013.26

(i) Objective

This project provides necessary civil structures for when direct buried cables are removed from the feeder and replaced with those enclosed concrete encased ducts.

(ii) Scope of Work

TABLE 9: SCOPE OF WORK DETAILS

District Neighbourhood:	Don Valley East
Station(s):	Leslie 1 TS
Feeder(s):	NY51M4

(iii) Justification & Benefits

With respect to reports filed on the ITIS databases, feeder NY51M4 has experienced six outages within the last 12 months. The WPF rank deteriorated from 19 to 16. Aged cable in the loop is the primary cause of failure. This project will upgrade cable to current standard.

E11672 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: E11672 Midland Distribution Re-build/Relocate/VC Ph1 (EJF2 to E5-M27)

Project Number: E11672

Project Year: 2015

Estimated Cost: $109,420.64

(i) Objective

The objective of this project is to rebuild, with voltage conversion, the old distribution at 1710 Midland Ave and to relocate a pad mounted transformer for safety reasons.

(ii) Scope of Work

TABLE 10: SCOPE OF WORK DETAILS

District Neighbourhood:	Scarborough Centre
Station(s):	Canadine Midland (4.16kV)
Feeder(s):	SCEJF2

(iii) Justification & Benefits

The distribution at 1710 Midland Ave is currently operating at 4kV and consists of aged assets. This lateral of EJ-F2 was installed in 1968 according to GEAR.

Routine maintenance inspection determined that assets at this location need to be replaced. This project is needed to upgrade the asset to current standard and supply the customer from 27.6kV distribution in order to improve system reliability.

E11673 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: E11673 Midland Distbn Rebu ild/Relocate/VC Ph2 (EJF3 to E5-M27)

Project Number: E11673

Project Year: 2015

Estimated Cost: $95,988

(i) Objective

The objective of this project is to rebuild, with voltage conversion, the old distribution at 1570 Midland Ave.

(ii) Scope of Work

TABLE 12: SCOPE OF WORK DETAILS

District Neighbourhood:	Scarborough Centre
Station(s):	Canadine Midland (4.16kV)
Feeder(s):	SCEJF3

(iii) Justificat ion & Benefits

The distribution at 1570 Midland Ave is currently operating at 4kV and consists of aged assets. This lateral of EJ-F3 was installed in 1968 according to GEAR.

Routine maintenance inspection determined that assets at this location need to be replaced. This project is needed to upgrade the asset to current standard and supply the customer from 27.6kV distribution in order to improve system reliability.

E13272 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: E13272 Upgrade UG trunk E51M21 Brimley Rd

Project Number: E13272

Project Year: 2015

Estimated Cost: $228,034

(i) Objective

The objective of this project is to replace the old direct buried 750kcmil cable with 1000kcmil Cu cable in CE duct along Brimley Rd from riser OS59873 (at NW of Brimley-Lawrence) to riser OSL51809 (at P882 Brimley).

(ii) Scope of Work

TABLE 14: SCOPE OF WORK DETAILS

District/Neighbourhood:	Scarborough Centre
Station(s):	Scarborough TS (27.6kV)
Feeder(s):	SCN-AE-51M21

(iii) Justification & Benefits

There is a stretch of undersized cable (as per GEAR record), built direct buried, between riser OS59873 (at NW of Brimley-Lawrence) and riser OSL51809 (at P882 Brimley).

Work will upgrade the current carrying capacity of the cable and refresh aged existing direct buried cable with new cable installed in concrete encased duct. In all, this project will improve the reliability of the feeder and contingency readiness.

E14136 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: E14136 OH Upgrade R43M24 – Hollis Milne Birchmount (Electrical)

Project Number: E14136

Project Year: 2015

Estimated Cost: $871,476

(i) Objective

The objective is to replace the undersize conductor (by THESL standard 556kcmil conductors) of the NAR43M24 feeder main in sections on Hollis Ave, Milne Ave, part of Mack Ave and Birchmount Rd.

(ii) Scope of Work

TABLE 16: SCOPE OF WORK DETAILS

District Neighbourhood:	Scarborough Southwest
Station(s):	Warden TS (27.6 kV)
Feeder(s):	SCNAR43M24

(iii) Justification & Benefits

There are some sections of undersize conductor on the feeder OH trunk of feeder NAR43M24 and M28. The sections are on Hollis Ave, Milne Ave, part of Mack Ave and Birchmount Rd. During the transfer of load, especially at peak load time, the weak sections are likely to get overloaded and develop sag and/or melt and burn. Toronto Hydro will replace the weak sections of 336 kcmil conductors with standard 556kcmil conductors. This will establish the full capacity feeder main of R43M24 and transfer tie with NAR43M23 and R43M28

E15460 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: E15460 Morningside Neilson Install SCADA PMH 47M3 SCNT47M3

Project Number: E15460

Project Year: 2015

Estimated Cost: $689,424

(i) Objective

This project will automate four SF6 PMH-11 switches on the trunk of NT47M3 as recommended by Operations.

(ii) Scope of Work

TABLE 18: SCOPE OF WORK DETAILS

District Neighbourhood:	Scarborough Rouge River
Station(s):	Sheppard TS (27.6kV)
Feeder(s):	SCNT47M3, SCNT47M1

(iii) Justification & Benefits

SCNT47M3 was the worst performing feeder from 2005 to 2012; however, there was a gradual improvement because of the replacement of some failing DB cables. The rebuild continued at a faster pace from 2009 to 2011, which further improved reliability. As of October 2013, it is the second worst performing feeder with a FESI ranking of 12.

Converting four underground switches to SCADA controlled type will improve restoration time under contingency and improve reliability of power.

W11147 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: Cable Replacement Bathurst Stn M4, M24, M25

Project Number: W11147

Project Year: 2015

Estimated Cost: $1,181,568

(i) Objective

The objective of this project is to provide adequate capacity in order to maintain the continuity of supply under normal and contingency conditions.

(ii) Scope of Work

TABLE 20: SCOPE OF WORK DETAILS

District Neighbourhood:	York West
Station(s):	Bathurst I TS (27.6 kV), Bathurst II TS (27.6 kV)
Feeder(s):	NY85M4, NY85M24, NY85M25, NY85M31

(iii) Justification & Benefits

An analysis has been done regarding customer's future loads and feeder performance data. It is forecasted that load will rise in 2016 and beyond. New feeders are required to meet growing load.

Program: Contingency Enhancement

Project Title: Cable Replacement Bathurst Station M6, M7, M2, M32

Project Number: W11148

Project Year: 2015

Estimated Cost: $1,911,519 Objective

The objective of this project is to provide adequate capacity in order to maintain the continuity of supply under normal and contingency conditions.

(i) Scope of Work

TABLE 22: SCOPE OF WORK DETAILS

District Neighbourhood:	York West
Station(s):	Bathurst TS (27.6 kV)
Feeder(s):	NY85M6, NY85M7, NY85M2, NY85M32

(ii) Justification & Benefits

An analysis has been done regarding customer's future loads and feeder performance data. It is forecasted that load will rise in 2016 and beyond. New feeders are required to meet growing load.

Program: Contingency Enhancement

Project Title: P03 SCADA Switch Installation on NY55M5

Project Number: W13478

Project Year: 2015

Estimated Cost: $178,176 Objective

The purpose of this project is to replace two existing manual switches to SCADA switches in order to provide more switching flexibility to feeder 55M5.

(i) Scope of Work

TABLE 24: SCOPE OF WORK DETAILS

District Neighbourhood:	Etobicoke York
Station(s):	Finch TS (27.6 kV)
Feeder(s):	NY55M5

(ii) Justification & Benefits

NY55M5 is a feeder located in North York. The feeder possesses SCADA switches at the tie point but no SCADA sectionalizing points. In discussion with Control Room personnel, it was requested that the switches included in this project be installed in order to make the existing sectionalizing switches more useful, improving the feeder's restoration time.

W15228 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: W15228 P01 Canarctic & Wild cat Phase 2 Tie to 55M24 CIVIL NY85M32

Project Number: W15228

Project Year: 2015

Estimated Cost: $427,591

(i) Objective

The primary objective of this scope is the civil portion of providing an adequate tie for 85M32, utilizing 55M24, in the Canarctic and Wildcat area distribution (Phase 2).

(ii) Scope of Work

TABLE 26: SCOPE OF WORK DETAILS

District Neighbourhood:	York West
Station(s):	Bathurst II TS (27.6 kV)
Feeder(s):	NY85M32

(iii) Justificat ion & Benefits

The existing 27.6 kV distribution along Canarctic Dr and Wildcat Rd, near Keele St and Steeles Ave, is supplied from 85M32 and 85M30, and consists of two three-phase loops between PS26636 and PS86071. The area is comprised of commercial customers that are continuing to expand rapidly with emerging loads.

Consumption data using metering suggests that a contingency scenario will result in 201A, which is very close to the continuous rating of the 200K fuse protection scheme. The situation is worsened by the presence of 1/0 STR AL cable, which has a summer emergency ampacity of 180A in a duct bank with three circuits. Through this project, Toronto Hydro will upgrade inadequate assets, which will improve the contingency readiness of the feeder.

Program: Contingency Enhancement

Project Title: W15391 Overhead Tie Point at St.Clair and Spadina RD TO35M6 YK35M9

Project Number: W15391

Project Year: 2015

Estimated Cost: $649,885

(i) Objective

To increase restoration capability to feeder 35M9 by creating a tie point between 35M4 and 35M9.

(ii) Scope of Work

TABLE 29: SCOPE OF WORK DETAILS

District Neighbourhood:	
Station(s):	Fairbanks TS
Feeder(s):	35M4, 35M9

(iii) Justification & Benefits

The south-east most portion of 35-M9 (located on the North-West corner of St. Clair and Spadina) has one of the highest load densities in the area. This section of 35-M9 supplies 3500 residents, including 14 large condominium developments, a 400 resident long-term care facility, and St. Michael's College School, accounts for 50% of the total feeder load and has a history of long outage durations largely due to its lack of tie points.

The section is isolated by surrounding 13.8 kV distribution, and currently has no feeder tie locations. This project will establish additional tie point to enable quicker load transfer under feeder contingency conditions.

Program: Contingency Enhancement

Project Title: W15398 Underground and Overhead ties to 55M30

Project Number: W15398

Project Year: 2015

Estimated Cost: $719,149

(i) Objective

The objective of the scope is to create new tie point between feeder 55M30 and feeder 55M24. In addition to this, the project will replace a manual pad mount switchgear with SCADA to provide operational flexibility to the feeder.

(ii) Scope of Work

TABLE 33: SCOPE OF WORK DETAILS

District Neighbourhood:	York West
Station(s):	Finch TS
Feeder(s):	NY55M30

(iii) Justification & Benefits

Tie points are used to restore power to customers during power outages or planned load transfers. It is important that an adequate number of tie points exist on feeders.

55M30 is a feeder that only had one tie point. Through this project, Toronto Hydro will provide 55M30 with a new tie to 55M24. In addition to this, the project will automate one of the existing Underground ties to provide backup to a section of the feeder.

Program: Contingency Enhancement

Project Title: W15450 P1473 The Queensway - Install Scada OH tie between 38M21 and 38M27

Project Number: W15450

Project Year: 2015

Estimated Cost: $105,504Objective

The objective of this scope is to upgrade the tie switch at location OSL11809 to a SCADA enabled tie-point between feeders 38M21 and 38M27.

(i) Scope of Work

TABLE 37: SCOPE OF WORK DETAILS

District Neighbourhood:	
Station(s):	Manby TS
Feeder(s):	

(ii) Justification & Benefits

Customers serviced by the feeders 38M27 and 38M21 have experienced four outages per year between 2010 and 2013. Outage duration on both feeders combined has exceeded 500 minutes per year in the 2010 - 2013 period, with CI of about 300 per year. Given the high frequency of outages, there is a need for tie switching between 38M27 and 38M21 for temporary reconfiguration. Also, the load break switch OSL11809 has become a highly used switch point; however, it takes a long time to perform switching activities because this is a manual switch. Through this project, Toronto Hydro will install a switch that is automated and can be controlled by SCADA remotely from the control room making.

W15459 Project Description

Portfolio: System Service

Program: Contingency Enhancement

Project Title: W15459 Sectionalizing / Installi ng Tiepoints on the overhead trunk of 38M29

Project Number: W15459

Project Year: 2015

Estimated Cost: $1,063,446 Objective

The objective of this project is to break the trunk of the 27.6kV feeder 38M29 into manageable segments with SCADA enabled sectionalizing switches and to add a new SCADA enabled tie-point with 38M13 on The Queensway.

(i) Scope of Work

TABLE 39: SCOPE OF WORK DETAILS

District Neighbourhood:	Etobicoke Lakeshore
Station(s):	Manby TS
Feeder(s):	38M29, 38M13

(ii) Justification & Benefits

The 27.6kV Manby TS feeder 38M29 currently does not have any SCADA enabled switch located anywhere along its trunk. The DGO control has therefore been 'blind' to the distribution services on the feeder, especially during contingencies. Until now, the feeder had been able to curtail the length of by localizing faulted segments with the 4kV MS stations in its service area. However, the conversion of all the MS stations has led to a necessary and urgent need to sectionalize the feeder.

Installing SCADA enables switches will allow the control room to reconfigure during contingencies and the new tie switch with 38M13 along The Queensway will improve the control centre's ability to provide quick relief during contingencies.

Program: Contingency Enhancement

Project Title: W15517-P05-SCADA for S ectionalization on 88M46, Richview TS

Project Number: W15517

Project Year: 2015

Estimated Cost: $69,509Objective

The objective of this scope is to install a SCADA switch for better sectionalization of feeder 88M46 and to provide operational flexibility for customers east of Centennial Park Blvd on Eglinton Ave W.

(i) Scope of Work

TABLE 41: SCOPE OF WORK DETAILS

District Neighbourhood:	
Station(s):	Richview TS
Feeder(s):	88M46

(ii) Justification & Benefits

There are many large commercial and industrial customers west of Centennial Park Blvd on Eglinton Ave W. These customers can become stranded during certain outage conditions. In the past there have been a number of customer complaints indicating that that outages are long and affects their day to day operations due to them being connected radially, with no other supply method. To combat this issue, Toronto Hydro plans to further sectionalize the trunk to allow a two way method in order to resupply the corner of Centennial Park and Eglinton Ave W. Performing this action will enable restoration upstream and downstream for these customers and will improve the contingency readiness reliability of the system. Furthermore, this project is needed because the Pan Am games will be operating in the area.

E7.2 Design Enhancement

BARE CONDUCTOR IN HEAVY VEGETATION

E7.2.1 Summary

Program Description

The Design Enhancement program targets feeder designs that (1) do not possess effective fusing schemes and/or (2) lack resistance to tree contacts in areas with tree canopy intensification in the City of Toronto.

Fusing enhancements are needed to target issues with respect to undersized fuses, fusing miscoordination and redundant trunks. Undersized fuses can operate prematurely during a transient fault, which leads to unnecessary sustained power interruptions. This issue can be mitigated with the instillation of appropriately rated fuse units. The proper alignment of miscoordinated downstream fuses will reduce the impact of outages on an existing lateral by containing the outage at the sub-lateral level. Unprotected redundant trunk segments, which do not provide a path for tie-points and at the same time, supply loads that are below the interrupting capabilities of fuses, expose the entire feeder to a sustained interruption in the event of an outage on that portion of the trunk. This issue is alleviated with the installation of a fuse at the redundant trunk branch.

In addition to making these fusing enhancements, Toronto Hydro plans to install tree proof conductor in areas of heavy forestation that are susceptible to tree contact outages. The installation of tree proof conductor will help make the circuit more resistant to losing power in the event of a tree contact itself.

Table A summarizes the anticipated benefits associated with the Design Enhancement program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improved service reliability for customers on the targeted feeders; the trunk-related outages that are mitigated can affect up to 7,000 customers ƒ Reduced need to excessively trim trees, thus preserving the aesthetics of existing streetscapes and customer properties
Reliability	ƒ Improved reliability by limiting the frequency and impact of interruptions on the targeted feeders, especially during adverse weather and major storm events. ƒ Installing tree proof conductor can mitigate the frequency of tree contact interruptions, which can cause both momentary and sustained interruptions, especially during adverse weather conditions (e.g. heavy winds).
Safety	ƒ Mitigation of safety risks associated with tree contacts. ƒ Manual switching on trunk portions is minimized and thus, safety risks such as the potential for flashover and injury from breaking parts are managed.
Efficiency	ƒ Prevents complications associated with the restoration of unnecessary trunk outages in terms of switching operations. ƒ Locating faults is made easier. ƒ Prevents the unnecessary replacement of undersized fuses that operate prematurely. ƒ The mitigation of unnecessary load break switch operations extends the life of switches. ƒ The use of tree proof conductor reduces the need for tree trimming cycles.

Program Drivers

At the 27.6 kV primary voltage level, there is a discernable upward trend in the ratio of trunk related outages per year to lateral outages. Similarly, there is an increasing trend of tree related momentary and sustained interruptions on the overhead 27.6 kV system. As trunk related outages impact a much greater number of customers than lateral outages, Toronto Hydro believes it is prudent and necessary to address parts of the system that are vulnerable to trunk related outages by enhancing currently inadequate feeder designs. These types of targeted

investments effectively maximize the customer value derived from existing feeders by minimizing unnecessary failure risk over the life of the assets.

The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ The Design Enhancement program is needed to address negative reliability trends that have emerged due to load growth and the intensification of tree canopy cover in the City of Toronto. These factors have resulted in inadequate fusing and vulnerability to tree contacts. Forecasted increases in the frequency of adverse weather conditions could exacerbate these issues in the future.
Secondary Drivers	**Reasoning**
System Efficiency	ƒ Premature operation of an undersized fuse requires Toronto Hydro crews to be dispatched for an otherwise unnecessary fuse unit replacement. ƒ Redundant trunk portions can result in unnecessary breaker lockouts, which, from an operational perspective, introduce complications associated with the restoration of trunk outages.

Preferred Alternatives

In establishing the Design Enhancement program, Toronto Hydro considered three alternatives:

(i) Do nothing and accept the increasing reliability risk and operational inefficiencies associated with the design deficiencies.

(ii) Eliminate the susceptibility of overhead assets to tree contacts by rebuilding the distribution system away from trees.

(iii) Introduce fusing enhancements and tree proof conductor to mitigate the risk of reliability degradation.

Option III is the preferred alternative as it is the most cost-effective way of ensuring that feeders are well protected, curtailing sustained trunk outages as well as lateral faults. Installing tree proof conductors in critical areas is expected to reduce tree-related outages and may allow Toronto Hydro to scale back its future tree-trimming cycles.

The difference in the cost of ownership between existing and renewed assets (ΔCOO) for the first year of the program is $5.64 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.2.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.23 million, confirming the economic prudence of the investments (see Section E7.2.7).

Timing and Pacing

In terms of program planning and execution, the problem areas will be mapped and grouped together to be addressed in accordance with their respective feeders. Feeders will be prioritized based on the number of sustained interruptions that took place over a five year period and the number of individual locations requiring fusing and bare conductor upgrades.

Toronto Hydro must balance the need to perform feeder enhancements with other necessary renewal work. Accordingly, during the 2015 to 2019 planning period, Toronto Hydro plans to focus on feeders that are in most urgent need and that have the largest impact on the reliability of the system in terms of sustained interruptions. In all, 43 feeders are forecasted for investment in this program.

Table C provides the estimated costs of the program for the 2015-2019 period.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0.4	1.7	1.7	1.7	1.7

E7.2.2 Program Description

The objective of the Design Enhancement program is to mitigate system reliability concerns by: (1) improving fusing configuration to control the impact of sustained outages and (2) installing tree-proof conductor to reduce the frequency of outages. The investments are primarily focused on the 27.6 kV primary voltage level in the horseshoe area of the grid because the issues are most prevalent in this region.

The total estimated cost of the Design Enhancement program is $7.26 million over the 2015-2019 period.

E7.2.2.1 Fusing Enhancements

Toronto Hydro plans to make targeted fusing enhancements to reduce the frequency and impacts of sustained outages. These investments will help ensure that all existing fuses are adequately sized and that all feeder trunk branches are well-protected.

Fuses in Toronto's Distribution System

The key part of a fuse is the "fusible element", which is designed to melt at a predetermined level of current. Fuses are critical distribution system assets that limit the impact of an outage to a specific location along the feeder and associated downstream customers. Fuses prevent sustained feeder-level outage for all customers on the feeder by not allowing an outage to cascade upstream to a circuit breaker.

A typical feeder is comprised of a main, three-phase "trunk" that initiates from the circuit breaker at a station. The trunk is typically routed through arterial streets and will branch off (without a fuse) in several places for the purpose of providing tie-points with adjacent feeders or to supply three-phase loads. The feeder also has multiple branches called "laterals," which are single, two, or three-phase lines that are protected by fuses, limiting the impact of downstream outages to the branch or a sub-section of the branch.

Toronto Hydro's protection scheme is 'fuse-saving' in that fuses and the relay for the circuit breaker are coordinated such that the breaker will trip before the fuse does. This scheme allows a temporary fault to clear itself, at which point the breaker will reclose. If the fault persists beyond this initial operation, the breaker relay delays sending a trip signal to the breaker, which allows the fuses to operate before the breaker trips. If a fuse does not operate properly, the breaker trips and stays open or "locks out." A breaker lockout usually suggests that the fault is located between

the breaker and a fuse, and is therefore deemed a trunk outage. This scheme is typical on overhead systems, where there is a high likelihood of faults that are temporary in nature, such as when tree limbs or animals contact lines. Fuses are strategically placed on "trunks" to create "laterals" and isolate outages downstream of the fuse to reduce impact to the entire feeder. They are sized in accordance with downstream load. Depending on the number of customers, a lateral may be further partitioned using additional sub-fuses.

Fuses Targeted by the Program

The Design Enhancement program targets undersized fuses, mis-coordinated fuses and redundant trunk sections that lack fusing:

- With undersized fusing , downstream loads surpass peak pre-load conditions (i.e. the constant loading that the fuse can sustain without impairing its ability to perform properly) and results in premature operations during a transient fault. The premature operations result in unnecessary sustained power interruptions. This issue is addressed by replacing the existing SMU-20 fuse with the appropriately rated fuse unit. From an operational efficiency standpoint, the premature operation by an undersized fuse is inefficient because it requires a crew to be physically dispatched to the area to perform a fuse unit replacement that otherwise would not have been required had the proper fusing arrangement been in place.

- Mis-coordinated fuses are laterals with a sub-fuse rating. These fuses operate at a slower pace than an upstream fuse for a particular range of fault currents that originate downstream of their location. As a result, customers located in between a lateral fuse and a sub-fuse are unnecessarily affected by outages downstream of a sub-fuse. As with the previous issue, addressing this problem involves replacing the SMU-20 fuse with the appropriately rated fuse units.

- Redundant feeder trunks are branches that (i) do not provide tie points to other feeders, (ii) feature peak loads that are within the threshold of standard fuse ratings and (iii) are not fused. An outage on these unprotected segments results in unnecessary sustained trunk outages to the entire feeder due to the absence of a fuse. This situation is remedied with the installation of a fuse, which includes the entire SMD-20 cut-out switch and its associated accessories, at the redundant trunk branch. In essence, the "trunk" is converted to a fused "lateral", resulting in quicker restoration times for customers who

experience an outage downstream of the newly installed fuses, as complexities associated sustained trunk outages are avoided.

Toronto Hydro's standards specify the use of SMD-20 cut-out switches with SMU-20 fuse units that are rated at 140 K ("K" denotes the speed of the fuse where, in this case, it represents a "fast" fuse, as per ANSI standard requirements in ANSI C37.42)

Figure 1 below illustrates a typical feeder layout with the three types of fusing deficiencies.

FIGURE 1: TYPICAL FEEDER LAYOUT WITH FUSING DEFICIENCIES

E7.2.2.2 Tree Proof Conductor

Overhead bare conductor in close proximity to mature trees is susceptible to tree related interruptions. Tree related outages are typically induced by adverse weather events such as high winds, wet snow or ice loading, particularly where overhanging branches are in close proximity to overhead distribution lines. This was evidenced during the 2013 Ice Storm.

Tree proof primary aerial conductor is an alternative to conventional bare conductor in overhead construction for heavily treed areas. Tree proof cable consists of compact, extra-hard aluminum conductor (ASC or ACSR) and an extruded covering made up of a conductor shield, inner layer and protective outer layer.

The design of tree proof conductor provides resistance to transient faults resulting from tree contacts that would normally cause momentary outages. In addition, sustained interruptions due to phase-to-phase contacts, animal contacts, or tree contacts are eliminated because of the high dielectric strength of the track resistant, high-density polyethylene outer covering. Figure 2 shows a cross-section of tree proof conductor.

Tree proof conductor Bare conductor

FIGURE 2: CROSS-SECTION OF TREE PROOF CONDUCTOR AND BARE CONDUCTOR

In most areas where bare conductor is currently used, the absence of mature trees at the time of installation meant that tree proof conductor was not required. However, tree canopy growth has necessitated the use of tree proof conductor in certain areas.

As shown in Figure 3, excessive tree trimming to protect bare conductors is often not an aesthetically pleasing solution to tree contact problems and is likely to draw customer complaints. Feeders protected by tree proof conductor do not require the same amount of tree trimming due to less stringent clearance requirements. Toronto Hydro construction standards specify minimum clearance of 450 mm from the nearest 16/27.6 kV tree-proof conductor, while bare conductors require 1270 mm of clearance. All clearances must be relative to the estimated position of maximum sag and swing of the nearest conductor.

FIGURE 3: TYPICAL TREE TRIM

Toronto Hydro currently manages tree trimming based on a set maintenance cycle. Regardless of whether the distribution lines that are routed through trees are bare or tree proof conductor, tree trimming is always required to maintain clearances and to comply with the City of Toronto Urban Forestry cycle pruning guidelines. Historical reliability, in terms of tree related contacts, is one of the determining factors in establishing the tree trim cycles for individual feeders. The use of tree proof conductor could reduce the pace of tree trimming cycles by mitigating tree contact outages.

An ancillary benefit to this program is that load-break switching operations, required as part of the restoration of trunk outages on the affected feeders, will be minimized regardless of whether they are switching is done automatically, remotely, or manually. Frequent use of the loadbreak switch subjects the asset to increased degradation due to parts moving against one another, gradually eroding the material, loosening tolerances, and degrading smooth bearing surfaces from increased friction. This wear can lead to the binding of moving parts and ultimately, failure. Thus, the condition and life expectancy of these assets benefits from less usage. Furthermore, the program will protect Toronto Hydro crew members from safety risks associated with manual switching such as flashover, and from being injured by breaking parts while operating aged and poorly conditioned gang-operated switches on the trunk.

Work on fusing deficiencies and bare conductor in areas of heavy forestation will be coordinated on by feeder.

FIGURE 4 DEPICTS PLANNED WORK FOR YEARS 2015 TO 2019.FIGURE 4: FEEDER EXECUTION YEARS OF DESIGN ENHANCEMENT

The following table is a summary of the estimated quantity of assets that Toronto Hydro plans to address during the 2015 to 2019 period as part of this program.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Fuses (units)	45	21	39	31	29	165
Bare Conductor (m)	0	41,099	37,241	43,941	42,395	164,676

The following table summarizes the anticipated benefits of the Design Enhancement program.

TABLE 2: PROGRAM BENEFITS

Customer Value	ƒ Improved service reliability for customers on the targeted feeders; the trunk-related outages that are mitigated can affect up to 7,000 customers and can cause adverse power quality issues for large industrial facilities on the same station bus. ƒ Reduced need to excessively trim trees, thus preserving the aesthetics of existing streetscapes and customer properties

	ƒ The difference in the cost of ownership between existing and renewed assets (ΔCOO) for the first year of the program is $5.64 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.2.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.23 million, confirming the economic prudence of the investments (see Section E7.2.7).
Reliability	ƒ Improved reliability by limiting the frequency and impact of interruptions on the targeted feeders, especially during adverse weather and major storm events. ƒ Installing tree proof conductor can mitigate the frequency of tree contact interruptions, which can cause both momentary and sustained interruptions, especially during adverse weather conditions (e.g. heavy winds).
Safety	ƒ Safety risks associated with tree contacts will be mitigated ƒ Manual switching on trunk portions is minimized and thus, safety risks such as the potential for flashover and injury from breaking parts are controlled.
Efficiency	ƒ Prevents complications associated with the restoration of unnecessary trunk outages in terms of switching operations. ƒ Enhanced fault locating capability. ƒ Prevents the unnecessary replacement of undersized fuses that operate prematurely. ƒ The mitigation of unnecessary load break switch operations extends the life of switches. ƒ The use of tree proof conductor reduces the need for tree trimming cycles.

E7.2.3 Why the Program is Needed

The Design Enhancement program is required to improve system reliability by reducing the frequency and impact of unnecessary service interruptions. At the 27.6 kV primary voltage level, there is a discernable upward trend in the ratio of trunk related outages per year to lateral outages. Similarly, there is an increasing trend of tree related momentary and sustained interruptions on the overhead 27.6 kV system. As trunk related outages impact a much greater number of customers than lateral outages, Toronto Hydro believes it is prudent and necessary to address parts of the system that are vulnerable to trunk related outages by enhancing currently inadequate feeder designs.

E7.2.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for the Design Enhancement program. The program is a System Service initiative, with a trigger driver of Reliability.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ The Design Enhancement program is needed to address negative reliability trends that have emerged due to load growth and the intensification of tree canopy cover in the City of Toronto. These factors have resulted in inadequate fusing and vulnerability to tree contacts. Forecasted increases in the frequency of adverse weather conditions could exacerbate these issues in the future. ƒ As shown in Figure 5, there is an increasing trend of trunk outages, which results in the entire feeder experiencing an outage, and can be mostly attributed to the significant number of redundant trunk locations. ƒ As shown in Figure 6, there has been a steadily increasing trend of tree related outages.
Secondary Drivers	**Reasoning**
System Efficiency	ƒ Premature operation of an undersized fuse requires Toronto Hydro crews to be dispatched for an otherwise unnecessary fuse unit replacement. ƒ Redundant trunk portions can result in unnecessary breaker lockouts, which, from an operational perspective, introduce complications associated with the restoration of trunk outages.

As shown in Figure 5, there is an increasing trend in the ratio of trunk related outages to lateral outages at the 27.6 kV system level. Lateral outages increased by 20% from 2012 to 2013, while trunk outages increased by 53% over the same period.

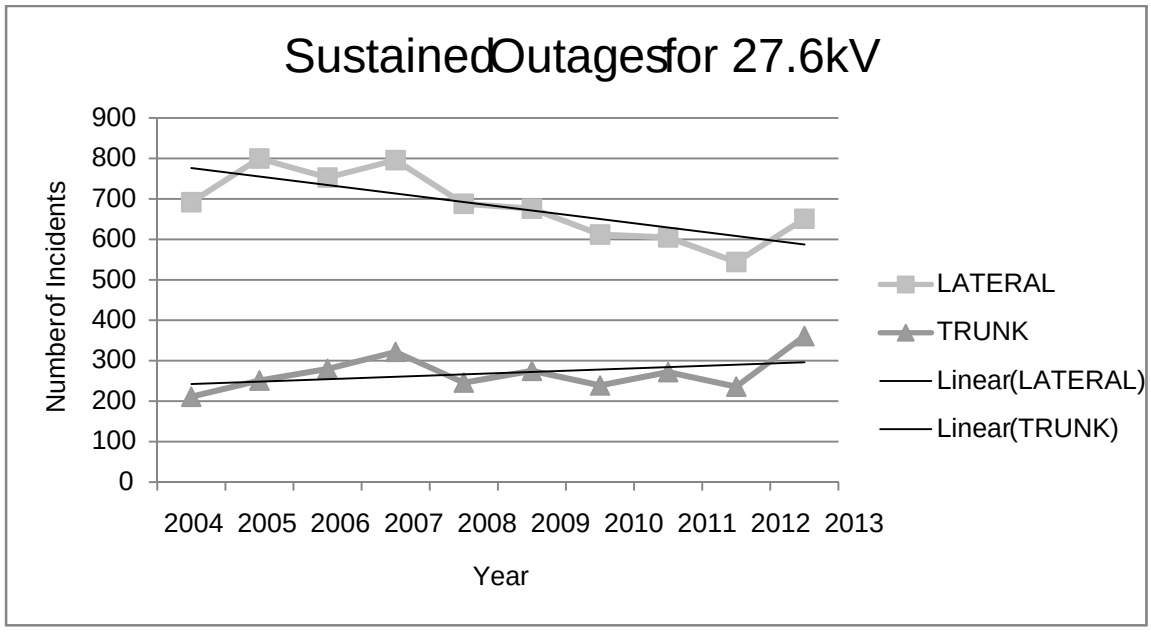

FIGURE 5: HISTORICAL INCIDENTS OF TRUNK AND LATERAL SUSTAINED OUTAGES

Figure 6 shows the five-year historical trend of the outage frequency and impact (in terms of customer interruptions (CI) and customer hours interrupted (CHI)) of tree-related interruptions (including those caused by adverse weather and brush contacts).

FIGURE 6: HISTORICAL TREE-RELATED OUTAGES

The feeders addressed by this program were originally designed and built in accordance with the loading and geographical conditions that existed at the time of construction. As system utilization has increased and vegetation around existing distribution assets has grown, the reliability of some existing feeders has decreased. The following sections discuss these issues in detail.

(i) Fusing and Redundant Trunks

Undersized Fuses

In-service fuses carry an initial load (pre-loading) under normal operating conditions. Excessive pre-loading can inhibit the effective operation of the fuse during an outage and can cause misalignment with the circuit breaker, compromising the "fuse saving" scheme discussed in the Program Description section. Each fuse type/rating can handle a certain amount of emergency peak pre-load without impairing the fuse's ability to properly coordinate and isolate a downstream fault. S&C Electric Company's Data Bulletin 240-195 in Figure 7 tabulates the peak-load capabilities of SMU-20 fuse units. The peak pre-loads represent the maximum loads that each fuse type can sustain (categorized by continuous, daily, or emergency scenarios) before the fuse link is compromised and misaligns with the breaker during fault interruption.

FIGURE 7: S&C ELECTRIC COMPANY'S DATA BULLETIN 240-195 FOR SMU-20 CONTINUOUS, DAILY, AND EMERGENCY PEAK-LOAD CAPABILITY

Misalignment with the breaker can then result in the fuse operating prematurely. The undersized fuses on these laterals expose downstream customers to unnecessary reliability risks. In this scenario, transient faults would cause the undersized fuse to operate faster than the circuit breaker. Contrary to the fuse saving scheme, where the fault would have otherwise been cleared by the upstream circuit breaker, it becomes an unnecessary sustained interruption to customers downstream from the undersized fuse.

There are 17 undersized fuse locations on the 27.6 kV system.

Fuse Mis-coordination

In some areas, fused laterals are further partitioned with sub-lateral fuses to reduce outage impacts on the sub-lateral level. If a sub-lateral fuse is not rated such that it operates and clears prior to an upstream fuse beginning to melt, a fault downstream of the sub-fuse will affect all customers up to the next upstream fuse.

There are 11 mis-coordinated fuse locations on the 27.6 kV system.

Redundant Trunk

In some cases, branches of a feeder trunk do not provide tie points to other feeders, and the loads on these sections happen to be within the threshold of the power interrupting capabilities of Toronto Hydro's highest rated fuse (S&C's SMU-20 140K fuse unit). These redundant branches unnecessarily expose the feeder to breaker lockouts. Installing strategically located fuses at redundant trunk locations can prevent circuit breaker lockouts that lead to sustained trunk outages to the entire feeder.

Redundant trunk portions can result in unnecessary breaker lockouts, which, from an operational perspective, introduce complications associated with the restoration of trunk outages, such as switching operations and longer investigations for the location of the fault. Once a faulted trunk portion is isolated during a circuit breaker lockout (either by means of feeder automation or remote switches), crews must patrol a widespread area on arterial roads or residential streets to identify the source of the outage. In contrast, a blown fuse can typically narrow down the search to a few residential streets.

There are a total of 219 redundant trunk locations on the 27.6 kV system.

Summary

All the above mentioned fusing deficiencies are shown in Figure 1 (in the Program Description section) in a typical feeder layout. These redundant trunk locations can affect up to 7,000 customers on the feeder via a breaker lockout.

Figure 8 displays all undersized fuses, mis-coordinated fuses, and redundant trunk locations at the 27.6 kV primary voltage level. These locations are superimposed with the associated feeders and the average annual sustained outages (based on historical data over the past five years) to illustrate areas that experience the highest number of sustained lateral and trunk outages. As detailed in the Program Description section, undersized fuse locations require fuse upgrades to ensure that unnecessary sustained interruptions are minimized. Mis-coordinated fuse locations also require fuse upgrades for proper coordination and impact reduction. Redundant trunk locations require the installation of a new SMD-20 cut-out switch and fuse link to avoid a sustained trunk outage and minimize the impact to few customers downstream of fuse. Ultimately, investments in these locations will provide reliability improvements in terms of both the frequency and impact of sustained interruptions.

FIGURE 8: LOCATIONS OF FUSING DEFICIENCIES

(ii) Bare Conductor & Tree Contacts

Bare conductors, without elemental barriers, are a common type of overhead wire used to deliver power from supply to consumption points. Toronto Hydro's standard wire gauges for bare overhead conductor operating at 27.6 kV are either 556 kcmil (aluminum stranded conductor) for main trunk lines and #3/0 aluminum conductor steel reinforced for laterals.

System reliability is compromised in areas where bare conductor is currently routed through areas of dense tree canopy. Issues arise because of the bare conductor's susceptibility to tree contacts, which can cause momentary or even sustained interruptions. Tree related outages are typically induced by adverse weather events such as high winds, wet snow or ice loading, particularly where overhanging branches are in close proximity to overhead distribution lines. There has been a steadily increasing trend of sustained and momentary outages due to tree contacts (see section E7.2.5.2 for a detailed discussion of reliability issues).

Figures 9 and 10 show examples of heavy forestation where feeder lines with bare conductor intertwine with mature trees. As was evident during the December 2013 ice storm, one of the most significant contributors to power outages is the weight of ice on tree limbs, which can cause the limbs to fall off or hang and come into contact with power lines in their proximity. This poses an especially severe reliability risk with respect to the trunk portions of feeders, where an outage due to tree contact would affect every customer on that feeder.

FIGURE 9: BARE CONDUCTOR IN HEAVY VEGETATION

FIGURE 10: BARE CONDUCTOR IN HEAVY VEGETATION

Figure 11 shows the location of bare conductors in the horseshoe area (i.e. the former suburbs). The dark red lines and blue lines represent trunk and lateral bare conductors, respectively, in close proximity to mature trees. The lighter green shaded areas indicate tree canopy cover.

FIGURE 11: MAP OF 27.6 KV OH BARE CONDUCTOR

E7.2.4 Timing & Pacing of the Program

As discussed in E7.2.3.1, there are 17 undersized fuses, 11 mis-coordinated fuses, and 219 locations of redundant trunk, and 365,497 m of bare insulated conductor in the proximity of trees. Toronto Hydro must balance the need to perform feeder enhancements with other necessary renewal work, as discussed in Section E2.1. Accordingly, during the 2015 to 2019 planning period, Toronto Hydro plans to focus on feeders that are in most urgent need and that have the largest impact on the reliability of the system in terms of sustained interruptions. In all, 43 feeders will be addressed in this period. More specifically, Toronto Hydro plans to work on a total of 6 undersized fuses, 7 mis-coordinated fuses, 152 redundant trunk locations, and 164,676 m of bare conductor. Feeders that do not require urgent attention will be addressed post-2019.

TABLE 4: HISTORICAL AND FUTURE SPENDING OF DESIGN ENHANCEMENT

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0.4	1.7	1.7	1.7	1.7

In 2015, Toronto Hydro plans on addressing only the most urgent feeders by making fuse enhancements. Also, a validation study will be conducted in 2015 in order to determine the precise circuit lengths of bare conductors that are prone to contact with trees. The sharp increase in spending from 2015 to 2016 is attributed to the rise in investments associated with the initiation of tree proofing upgrades

E7.2.4.1 Ranking & Prioritization

To achieve planning efficiency, Toronto Hydro plans to execute fusing enhancements and tree proof conductor installations simultaneously, organized by feeder. The relative prioritization of these feeders is determined by assessing the following two criteria.

(1) Historical reliability of the feeder: Toronto Hydro plans to target the worst performing feeders first, based on the number of sustained interruptions over the past five years.

(2) Number of locations to be addressed on the feeder: When determining feeder priority, Toronto Hydro will consider the number of distinct laterals that are undersized, laterals that are mis-coordinated, and redundant trunk branches that require fuses. The number of kilometers of bare conductor requiring upgrade will also be considered. Also, feeders with a substantial amount of redundant trunk portions and trunk bare conductor that requires tree proof conductor will be treated with more urgency due to the severe impact that trunk outages can have on the system. The feeders with the greatest number of the aforementioned locations will be executed first.

E7.2.5 Program Execution

Fusing deficiencies and bare conductor that need to be addressed will be grouped together and worked on according to what feeder they are on. By staging the projects under this program on a feeder basis, multiple issues can be attended to while crews are in a certain geographical area, increasing efficiency and reducing travel times.

The typical scope of work of fusing enhancements includes the installation of new fuses in locations that are identified as having undersized fuses, mis-coordinated fuses, and redundant trunk. The devices are sized and coordinated in accordance with circuit rating, existing loading conditions and upstream fuses and/or station circuit breakers. The replacement of the fuse unit requires the use of S&C's portable loadbreak tool, "Loadbuster", which allows the swap under full feeder load without needing isolation. In situations that require the SMD-20 cut-out switches to be replaced, a temporary disconnect tool can be used that allows customers downstream to be energized while the switch is being replaced. In some cases, a circuit reconfiguration of undersized or mis-coordinated laterals will be needed if downstream loads surpass the standard maximum 140 K fuse type interrupting capabilities. The reconfiguration will split laterals and reroute power for the suitability of a 140 K fuse.

Tree proof conductor initiatives involve restringing bare conductors with tree proof overhead conductor. The tree proof overhead conductor is made of a polyethylene covering and the conductor sizes are #3/0 ACSR or 556.5 kcmil ASC, for laterals and trunks, respectively.

E7.2.5.2 Program Risks

A major factor that may inhibit the pace of the Design Enhancement program is the age and condition of assets that are needed to accommodate the new fusing upgrades and tree proof conductors. For undersized and mis-coordinated fuses, Toronto Hydro will replace SMU-20 fuse links that are housed in the SMD-20 cut-out switch. However, before Toronto Hydro can replace certain SMU-20 fuse links, it will have to first replace certain SMD-20 cut-out switches because they have aged, are in poor condition and/or use porcelain insulating material, factors that increase failure risk.

In some locations, Toronto Hydro will need to install new poles and framing for fuse installations or tree proof conductor. Existing poles might have deteriorated to the point that they would compromise the installation of new cut-outs and bolting new framing.

The potential need to perform these additional asset upgrades in order to accommodate the initiatives in this program could inflate the cost of the program and delay construction. Toronto Hydro will study the need for these possible upgrades by conducting field visits to verify the condition of supporting assets (poles, SMD-20 cut-out switch, insulators, etc.) associated with the installation of a fuse or tree-proof conductor.

E7.2.6 Evaluation of Alternatives

E7.2.6.1 Quantification/Evaluation of Options

(i) Status Quo

Maintaining the status quo entails deferring fusing enhancements and tree proof conductor installations past the five year planning horizon of 2015-2019 and maintaining existing configurations. Under this option, capital expenditures would not be made for fusing enhancements and thus, Toronto Hydro would continue to conduct reactive repairs for sustained trunk outages from redundant trunk segments. Complexities involved with restoring sustained trunk outages will persist, contributing to lengthy restoration times. Reactive efforts will also need to be maintained for unnecessary sustained lateral outages due to undersized fuses.

Delaying plans to replace bare overhead conductor with tree proof conductor would result in a continuing pattern of tree related outages. Toronto Hydro currently manages tree trimming based on an aggressive maintenance cycle. However, tree trimming is a temporary solution as it does not permanently remedy the problem of tree related contacts on trunks. As a consequence, tree-related outages will continue to occur

(ii) Fusing Enhancements and Tree proof Conductor

The preferable solution is to install standardized fuses on existing laterals that are undersized, mis-coordinated, or redundant potions of trunk that lack fusing. In some cases, addressing undersized fuses may require reconfiguration work if downstream loading surpasses the standard 140 K fuse threshold. Fusing enhancements and the installation of tree proof conductor would be

expected to provide all of the benefits discussed throughout the narrative, including a reduction in prolonged outages and cost savings with respect to ongoing tree-trimming maintenance.

The cost of ownership (COO) and program net benefit (NPV) associated with the Design Enhancement program is further detailed in Table 6. The cost of ownership is established for both the existing state (COO_E), based on the first year of activities in the program, as well as the new state (COO_N) proposed within the program. The COO of a state reflects the risk of asset failure including both direct and indirect costs, including the costs of customer interruptions, emergency repairs, and asset replacements associated with that design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NARE) and proposed (NARN) state. Non-asset risks are further explained in Section D3.3. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in COO (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Design Enhancement program produces a NPV value of $5.23 million, as shown in Tables 6 and 7. As this is a positive value, it means that there is a net reduction in explicit and implicit costs to customers by transitioning to strategically located and coordinated fused laterals. It means that the benefits of executing the work outweigh the capital expenditures and thus is economically prudent to carry out the program.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	0.18
Non Asset Risk [NAR_E]	5.61

E7.2.7 2015 Project Details

Table 8 lists all projects that will be partially or completed executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred before or after 2015.

TABLE 8: 2015 PROJECTS

Project Number	Project Name	Total Project Cost	Start Date
X14211	35M10 Fuse Coordination	$130,637	2015
W15493	Overhead Design Enhancement on Fairbanks TS 35M1	$192,105	2015
W15495	Overhead Design Enhancement on Finch TS and Jane MS 55M28	$85,670	2015

E7.2.7.1 X14211 35M10 Fuse Coordination

Program: Design Enhancements

Project Title: 35M10 Fuse Coordination

Project Number: X14211

Project Year: 2015

Estimated Cost: $ 130, 637

(i) Objective

Ensure adequate fusing on 35M10 for better improved reliability

(ii) Scope of Work

Nineteen fuses to be replaced or installed along 35M10 in an effort to co-ordinate fusing on this feeder.

TABLE 9: X14211 SCOPE OF WORK DETAILS

Station(s)	FAIRBANK TS
Feeder(s)	35M10

TABLE 10: E12345 ASSETS REPLACED

Assets (Units)	2015
SMD-20	19

(iii) Justification & Benefits

Fusing Enhancements ensure that unnecessary sustained interruptions and their impacts are minimized, improving overall feeder reliability. The chart below depicts the historical reliability of feeders of 35M10 in terms of trunk and lateral outages. The chart shows illustrates the increasing trend of trunk outages that would be addressed by these fusing enhancements.

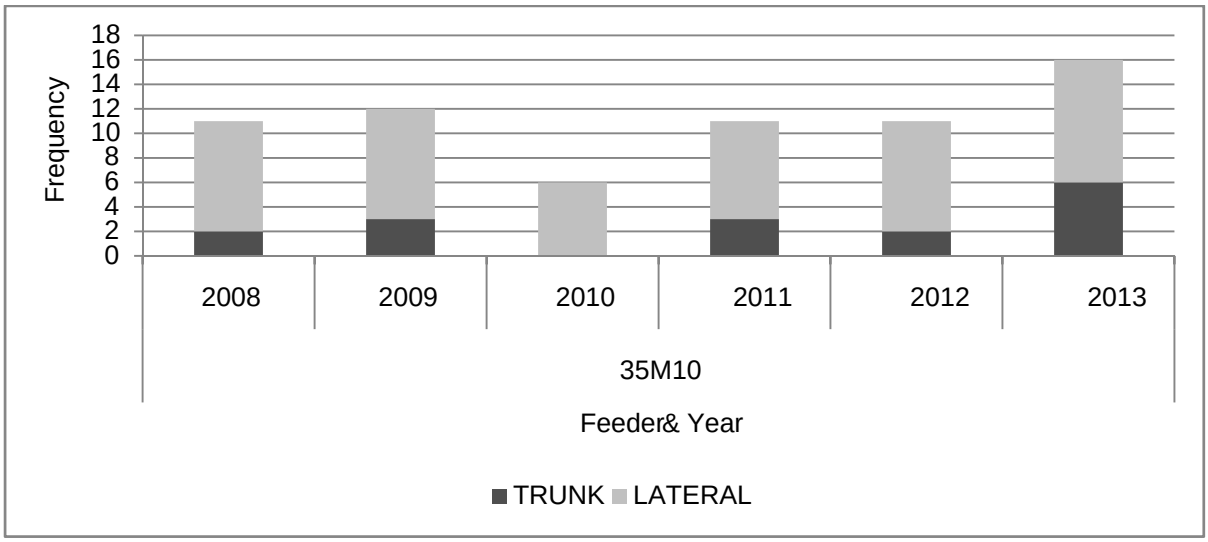

FIGURE 12: HISTORICAL RELIABILITY OF FEEDERS OF 35M10

E7.2.7.2 W15493 Overhead Design Enhancement on Fairbanks TS

Program: Design Enhancements

Project Title: Overhead Design Enhancement on Fairbanks TS

Project Number: W15493

Project Year: 2015

Estimated Cost: $ 192,105

(i) Objective

The objective of this project is to convert portions of the trunk feeder on Fairbanks TS into fused laterals.

(ii) Scope of Work

As part of this project, redundant feeder trunks portions that do not provide tie points and have peak loads that are within the threshold of fuse ratings will be fused. In this case, a new installation of a fuse, which entails the entire SMD-20 cut-out switch and its associated accessories, will be required at the redundant trunk branch. Essentially, the “trunk” is converted to a fused “lateral”.

The following pole locations require the installation of a new fuse (may involve a relocation of an existing asset):

1. Install fuse at pole 28 Trethewey Drive. Also, relocate transformer OT5024 on pole 28 Trethewey Drive to pole 30 on Trethewey Drive
2. Install fuse on Pole 49 Homewood Drive
3. Install fuse on Pole 10 Day Avenue
4. Pole 9 Sellers Avenue. Also, remove OS92387.
5. Pole 38 Holland Park Avenue
6. Pole 192 Glenholme Avenue
7. Pole 35 Stayner Avenue
8. Pole 3 Enid Cres
9. P833 Glencairn Avenue
10. Pole 685 Coldstream Avenue

11. P123 Clenmount Avenue
12. Pole 595 Cranbrooke Avenue and remove OS9482 from pole 563 Cranbrooke Avenue
13. Pole 978 Caledonia Road
14. Pole 14 Hartley Avenue. Also requires the relocations of transformers OT60144 on pole 36 Little Boulevard and install transformer on pole 8 Little Boulevard)
15. Pole 12 Glen Belle Crescent
16. Fuse lateral on Viewmount Avenue
17. Fuse to be installed on Pole 43 Glenmount Avenue
18. Fuse to be installed on Pole 2 Moir Avenue
19. Fuse to be installed on pole 176 Pinewood Avenue. Also, relocate transformer OT61745 from pole 176 at Pinewood Avenue to pole 168 at Pinewood Avenue.

TABLE 11: W15493 SCOPE OF WORK DETAILS

Station(s)	Fairbanks TS
Feeder(s)	35M1, 35M10, 35M11, 35M12, 35M2, 35M3, 35M5, 35M9

TABLE 12: W15493 ASSETS REPLACED

Assets (Units)	2015
SMD-20	19

(iii) Justification & Benefits

An outage on these unprotected segments results in unnecessary sustained trunk outages to the entire feeder due to the lack of a fuse. This project targets improvements to system reliability by will preventing breaker lockouts. In ensuring all redundant trunk portions are fused wherever practical, the number of customers experiencing sustained outages would be limited to customers downstream of the fuse. From an operational perspective, the installation of fuses avoids complications associated with the restoration of trunk outages, such as switching operations and fault locating.

The below chart depicts historical reliability of feeders addressed as part of this job, in terms of trunk and lateral outages.

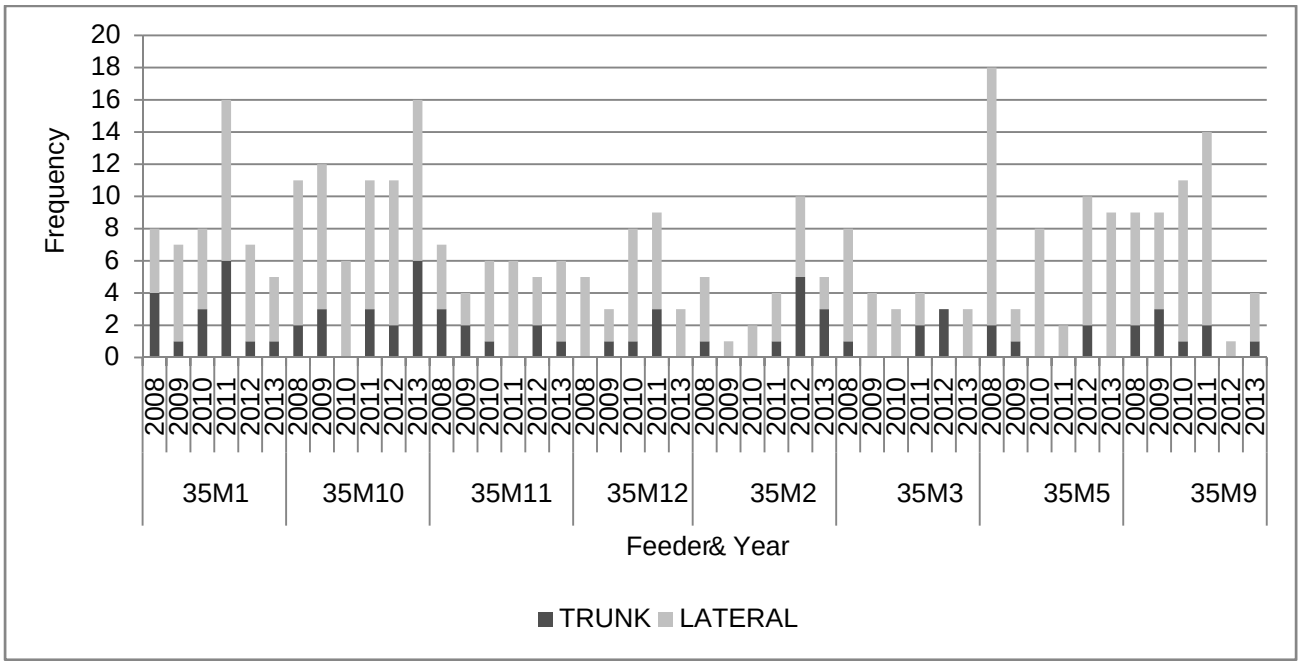

FIGURE 13: HISTORICAL RELIABILITY OF FEEDERS

E7.2.9.2 W15495 Overhead Design Enhancement on Finch TS and Jane MS

Program: Design Enhancements

Project Title: Overhead Design Enhancement on Finch TS and Jane MS

Project Number: W15495

Project Year: 2015

Estimated Cost: $ 85,670

(i) Objective

The objective of this project is to convert portions of the trunk feeder on Fairbanks TS into fused laterals.

(ii) Scope of Work

As part of this project, redundant feeder trunks portions that do not provide tie points and have peak loads that are within the threshold of fuse ratings will be fused. In this case, a new installation of a fuse, which entails the entire SMD-20 cut-out switch and its associated accessories, will be required at the redundant trunk branch. Essentially, the “trunk” is converted to a fused “lateral”.

The following pole locations require the installation of a new fuse (may involve a relocation of an existing asset):

1. Fuse to be installed on pole 22 Gade Drive
2. Fuse to be installed on pole 1 Canton Avenue
3. Fuse to be installed on pole 35 Letchworth Cres
4. Fuse to be installed on pole 36 Deevale Road
5. Fuse to be installed on pole 5 Wheatsheaf Cres
6. Fuse to be installed on pole 5 Checkers Crt
7. Fuse to be installed on pole 89 Laskay Cres

(iii) Justification & Benefits

An outage on these unprotected segments results in unnecessary sustained trunk outages to the entire feeder due to the lack of a fuse. This project targets system reliability improvement by preventing breaker lockouts. In ensuring all redundant trunk portions are fused wherever practical, the number of customers experiencing sustained outages will be limited to customers downstream of the fuse. From an operational perspective, the installation of fuses avoids complications associated with the restoration of trunk outages, such as switching operations and fault locating.

The chart below illustrates the historical reliability of 55M28 in terms of trunk and lateral outages.

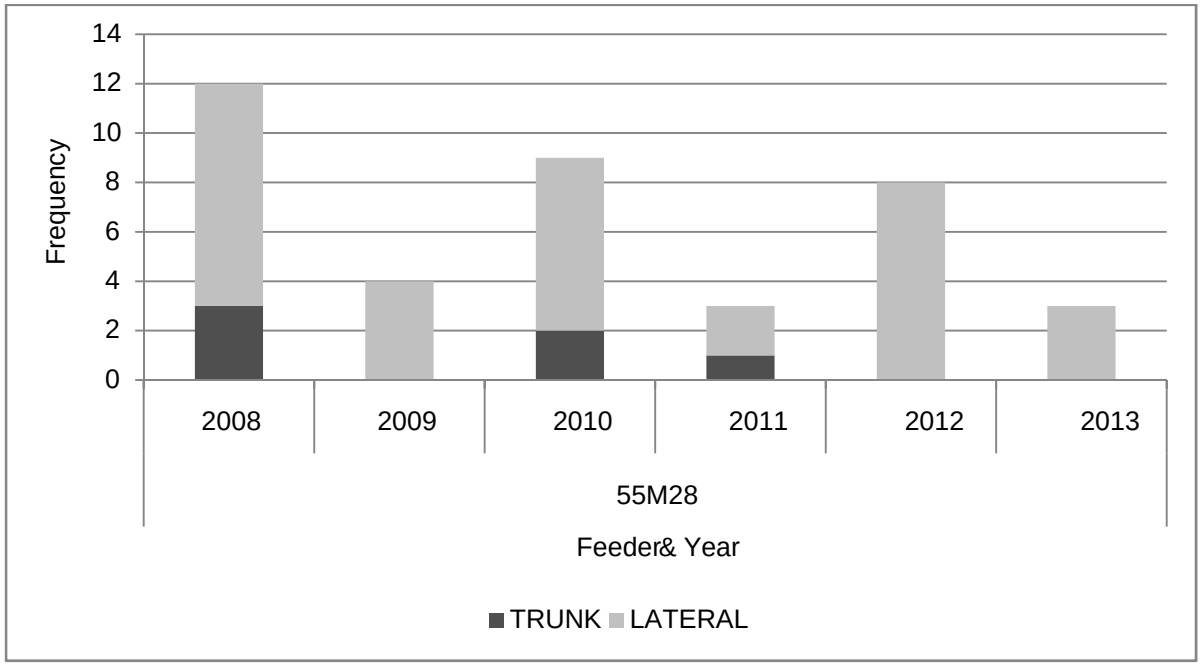

FIGURE 14: HISTORICAL RELIABILITY OF 55M28

E7.3 Feeder Automation

SCADA-MATE SWITCH FOR O/H FEEDER AUTOMATION

E7.3.1 Summary

Program Description

The Feeder Automation program aims to improve system operational efficiency by installing Supervisory Control and Data Acquisition (SCADA) switches that can operate autonomously (i.e. without human intervention). This program focuses on the automation of select feeders in two areas of Toronto Hydro's system: the 27.6 kV open looped system in the "Horseshoe" area and the 13.8 kV underground residential distribution systems in the Downtown area.

In both the Horseshoe and Downtown areas, the switches proposed for automation reside on the main or "trunk" sections of the feeder, which have no protective equipment beyond the station circuit breaker, and which experience outages that generally have the most considerable impacts on customers. The use of automation typically reduces the duration of outages on feeders to under a minute as compared to the typical restoration time of 30 minutes on remote operation SCADA switches and three hours on feeders that require manual switching by crews. These investments are expected to significantly improve SAIDI and SAIFI outcomes, improve

operational efficiency, and help mitigate the impact of certain types of increasingly frequent adverse weather conditions and major storms.

The various other benefits of the Feeder Automation program are further explained in Table A below.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Limits the number of customers affected by a trunk or main loop outage. ƒ Positively impacts power reliability for customers on non-automated feeders as well. Feeder automation decreases the time and effort needed by controllers and switching crews on automated feeders so they can concentrate their attention on non-automated feeders. ƒ Impacts many customers for relatively low cost. While Feeder Automation is not an alternative to asset renewal, the cost of automating a region of the city would typically equal the cost of renewing the asset base of only a section of a targeted feeder. This is further exemplified by the high benefit to cost ratio of the work.
Reliability	ƒ Through automated switching arrangements, restoration following a fault on the feeder trunk occurs in less than a minute. This decreases the number of customers impacted and the outage duration for unaffected customers – resulting in improvements to both SAIDI and SAIFI. ƒ Anticipated benefits of the program include mitigation of impacts from major storms and other adverse weather conditions, which are forecasted to become more frequent as a result of climate change.
Safety	ƒ The new switches have internal grounds, as opposed to the current switches that have external grounds. External grounds are more susceptible to the vault environment and human error during application.
Efficiency	ƒ Feeder automation allows system controllers to make more efficient use of their time. Since switching actions on automated feeders would be able to occur autonomously, crews would be able to focus on other areas requiring restoration. ƒ Enhanced condition monitoring on automated feeders will allow day to day operating decisions and long term asset investment decisions to be made more efficiently and effectively.

Program Drivers

The Feeder Automation program is primarily driven by the system efficiency considerations and is situated in the System Service category. The primary and secondary drivers of the program are detailed in Table B below.

TABLE B: PROGRAM DRIVERS

Primary Driver	Reasoning
System Efficiency	ƒ Significantly improves fault detection, isolation and restoration times during trunk- and/or main loop-related outages. ƒ Potentially mitigates the impact of defective equipment failures on the trunk on reliability, reducing the rate of asset replacements in select cases. ƒ Enables more efficient use of control room and switching crew resources. ƒ By cost-effectively mitigating failure risk costs, Feeder Automation can help maintain a moderate pace of system renewal.
Secondary Driver	**Reasoning**
Reliability	ƒ Decreases the duration of outages on targeted trunk / main loop feeders, facilitating significant reliability improvements for the system and the average customer. ƒ Decreases the number of customers impacted by trunk and main loop-related outages. ƒ Reduces demands on system operators and switching crews during large system outage situations by autonomously restoring power to the unaffected sections of automated feeders, thereby allowing staff to focus on other affected areas.

The lack of automation on trunk portions means that SCADA or manual switching must be used to isolate faults, which increases the duration of outages for customers. In addition, the up to three hour duration for manual switching may be further lengthened if outages occur during times of heavy traffic or in crowded areas. Feeder automation activities, which target the feeder trunk, include the installation or modification of strategically placed SCADA-Mate switches, removing the need for human intervention by automating the switching process to localize the outage in less than one minute.

Preferred Alternative

(1) Toronto Hydro explored three alternatives for mitigating trunk outage failure risk costs:

(2) Maintaining the status quo, foregoing potential improvements.

(3) Install remote operated SCADA-Mate switches: remotely operable SCADA switches bring outage restoration times to approximately 30 minutes during an outage. Lengthy outages

may still result since power controllers may need to manage multiple outages simultaneously.

(4) Install Feeder Automation.

Option 3 is the preferred alternative as it provides significant improvements in system efficiency by automatically isolating faults and thereby improving reliability and restoration efforts, including during major storms. This option effectively reduces the failure risk cost of existing feeder assets, thereby maximizing customer value derived from the existing system. Since the cost of programming SCADA switches and configuring the wireless network for automation is approximately 10% higher than using basic SCADA switch technology, this program is a significantly more cost-effective alternative than Option 2.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $102.74 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.3.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $91.6 million, confirming the economic prudence of the investments (see Section E7.3.7).

Timing and Pacing

Toronto Hydro plans to introduce automation to approximately 130 feeders during the 2015-2019 period. As detailed in Table iii below, this work will cost approximately $54.1 million over this period.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	3.26	0.87	6.24	8.83	0.77	11.1	15.1	9.41	9.99	8.47

The Feeder Automation program will occur alongside Toronto Hydro's proposed renewal work to improve system efficiency and ensure asset replacements are occurring at the most effective time with the most benefit to customers. By implementing automation now, Toronto Hydro has the opportunity to ensure that the cost-effectiveness of the next generation distribution system will be enhanced for current and future ratepayers. The use of modernized equipment and communication infrastructure that supports automation will create a more intelligent grid, one

which provides system operators and planners with high-quality data for future asset management decision making. As such, future asset replacements and planning decisions will be better informed and effective. Toronto Hydro should not postpone these investments beyond 2019, as they are some of the most cost-effective distribution system improvements currently available to Toronto Hydro and its customers.

E7.3.2 Program Description

The Feeder Automation program is designed to improve the process of localizing and isolating faults on the distribution system through the installation and/or refurbishment of SCADA switches with software and sensors that facilitate autonomous operation when faults occur. Automation significantly decreases restoration times for unaffected portions of a feeder that is experiencing a fault. The program's primary objective is to improve the efficiency of the distribution system by reducing the resources and effort required to manage the system during outages. Feeder automation increases the efficiency of the control room by independently locating the fault and performing isolation and power restoration activities that would otherwise have to be performed by a controller.

Automatic restoration occurs when a switch intelligently detects and isolates the fault and restores power to the remainder of the feeder via the station breaker or the tie switches, which connect to other feeders. The use of automatic switches is expected to reduce the duration of outages on automated feeders to under a minute – a drastic reduction as compared to the typical restoration time of 30 minutes on remote operation SCADA switches and three hours on feeders that require a crew to travel to and manually operate switches. The program is also expected to improve operating efficiency in the field by reducing the need for crews to perform manual fault locations and switching activities, freeing up time and resources to focus on the repair of the fault itself. Bypassing the manual fault location and switching activities is expected to reduce the duration of outages on the faulted section(s) of the feeder, since the crews would be able to immediately turn their attention to addressing the outage source. Crew safety would also be enhanced since they would no longer have to manually perform switching on faulted feeders.

The program targets areas of the system that are expected to significantly benefit from expedited fault detection, isolation, and the associated shortened outage restoration times. The program includes plans for the automation of feeders in both the Horseshoe (i.e. the former suburbs) and Downtown areas of Toronto Hydro's system. The automation of these distinct distribution systems requires different technology and equipment, described in more detail in Sections E7.3.2.1 and E7.3.2.2.

Figure 1 shows the areas targeted by the feeder automation program over the 2015 to 2019 period.

FIGURE 1: MAP OF AUTOMATION ZONES AND PLANNED IMPLEMENTATION DATES FOR BOTH HORSESHOE AND DOWNTOWN FEEDER AUTOMATION

The program entails automation of approximately 640 switches located on 130 feeders. The total estimated cost of the program is $54.1 million in the 2015 to 2019 planning period. The following subsections further detail Toronto Hydro's proposal for automating the targeted feeders and explains the distinction between the technical characteristics of feeder automation in the Horseshoe and Downtown systems.

E7.3.2.1 Horseshoe Feeder Automation

Feeder automation in the Horseshoe area targets the 27.6 kV open loop distribution system. Figure 2 provides an example of the typical configuration of an open loop system in this area. Automation of the 27.6 kV system involves the installation of critical tie and sectionalizing switches that can autonomously operate to isolate the problem area and quickly restore power to the unaffected portions of the feeder. Doing so involves the use of software that interprets the data from sensors on SCADA switches to assess the condition of affected feeder segments

during a fault. A switch is then able to determine the state or condition of the feeder segments it connects and operate accordingly.

FIGURE 2: TYPICAL LAYOUT OF 27.6 KV OPEN LOOP SYSTEM. NOTE: THIS DIAGRAM ONLY SHOWS THE FEEDER TRUNK.

An open loop feeder consists of two types of sections, the trunk and the laterals. The trunk is the main portion of the feeder that extends from the station breaker, connects to other nearby trunks and feeds the laterals, which emanate from the trunk to supply side streets. Laterals connect to the trunk by means of fuses and do not connect to any other feeders themselves. When a fault occurs on a lateral, the fuse connecting it to the trunk is blown, isolating the fault area and localizing the outage impact to the customers served by that particular lateral. When a fault occurs on the feeder trunk, all customers connected to the trunk (including those connected via laterals) experience an outage, since the only protective device on the feeder trunk is the station breaker. Accordingly, feeder trunk outages have a significantly larger impact on Toronto Hydro' customers' power reliability than outages on the feeder's laterals. To that end, the proposed

feeder automation program in the Horseshoe area focuses on the feeder trunks. The targeted trunks are typically broken up into segments (this allows them to be resorted in parts) that are connected by automatic switches (referred to as sectionalizing switches) capable of locating and automatically isolating the area experiencing the fault. The automatic switches would also be installed on the ties connecting the targeted feeders with the trunk segments of feeders adjacent to them.

When a fault occurs on the trunk, automation software determines the segment of the trunk it occurred on and proceeds to isolate the faulted section. The software dynamically assesses which adjacent feeders can restore the unaffected sections of the faulted feeder and then carries out the appropriate switching actions to resupply customers. Figure 3 shows the switching actions that would take place in the example system shown in Figure 2. These actions would take place under either manual or autonomous operation; however, they occur more rapidly and without human intervention when automated. When this switching happens autonomously, unaffected customers can be restored within one minute. In addition, automation can localize the fault to a single section of the feeder. If automation is not in place, restoration would require the intervention of the control room to assess where the fault occurred and perform the switching operations remotely via SCADA-Mate switches. In the worst case scenario, a field crew would need to be deployed to locate the fault and manually perform the switching operations. Controllers can typically perform this operation within 30 minutes, while a crew would typically take up to three hours. The timelines of these operations can vary as most Toronto Hydro feeders have a combination of remote switches and manual switches.

FIGURE 3: LAYOUT OF FEEDER OPERATION DURING A FAULT, THESE SAME ACTIONS WOULD OCCUR ON BOTH AN AUTOMATED AND NON-AUTOMATED FEEDER, IT IS TIME IT TAKES THAT IS DEPENDENT ON THE TYPE OF SWITCHES USED. NOTE: THIS DIAGRAM ONLY SHOWS THE FEEDER TRUNK

In the example above, a fault occurred between switches 1 and 2 (S1 and S2) of feeder F1. The feeder automation scheme would detect that a fault occurred between these two switches and open the normally closed switches to isolate the detected fault in that section. Since the remaining sections of the feeder are unaffected by the fault (between S2 to S4) they can be restored through other feeders' supply. In this case, the unaffected portion is resupplied by feeder F3 by closing switch 4 (S4). When outages occur on feeders without automation, this work is done either by system controllers where the switches are remote operable, or via manual switching by field crews where manual switching is required. In either case, automation significantly improves system efficiency by restoring outages multiple times faster than human intervention. This has significant advantages to system reliability for trunk-related outages and can significantly lower outage duration for the benefit of Toronto Hydro's customers. Automation

in the Horseshoe area would reduce total customer interruptions (CI) and customer hours interrupted (CHI) by an anticipated 50%, as shown in Figure 4 below. In all, approximately 75% of the feeder would be able to be restored during trunk related outages following the implementation of automation. The reduction in CI and CHI would also impact the overall SAIDI and SAIFI statistics. In all, the program is expected to significantly improve system reliability in terms of both the frequency and duration of outages. For example, as per the SAIDI graph in Figure 12, over the last five years, the average Toronto Hydro customer experienced an outage lasting over 75 minutes per year (when combining trunk and lateral outage for total system outage). By reducing the number of customers impacted by trunk outages by 75%, the average outage duration would drop to approximately 40 minutes.

FIGURE 4: PROJECTED HORSESHOE RELIABILITY CI AND CHI REDUCTION

Feeder automation in the Horseshoe area requires strategically placed automatic SCADA switches with appropriate communication infrastructure and software. Toronto Hydro positions SCADA switches to optimize the ability of the feeder's trunk to be reconfigured to alternative supply paths during an outage. This design takes into account customer loads and locations and

proximity to, and the loading of, adjacent feeders for each targeted feeder trunk. The SCADA switches utilized in the automation of the Horseshoe area will include overhead and pad-mounted units, depending on whether the segments being tied are overhead or underground. Automation efforts will also include autonomous action of the station breaker in a restoration scenario.

In a number of cases, Toronto Hydro plans to leverage existing overhead SCADA switches, which will only require minor software and communication upgrades to enable desired automation. In cases where existing switches are manually operated, or where the system planners determine that additional new switching nodes are required, new SCADA switches would be installed.

Each SCADA switch requires a remote terminal unit (RTU). RTU's for existing SCADA switches that are currently utilized need to be upgraded so that the switch can operate autonomously. This upgrade consists of a new radio unit, controller faceplate and a software upgrade inside the RTU. The RTUs form an important part of the control and communication infrastructure required for the switches to report remotely and for the automated feeder network to function.

In all, the planned upgrades in the Horseshoe area would improve the operating efficiency of Toronto Hydro's 27.6 kV open loop system and will significantly improve overall system reliability at a low initial investment. Table 1 details the proposed asset installations required for the Horseshoe feeder automation program.

TABLE 1: NEW ASSETS PROPOSED FOR INSTALLATION BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Overhead SCADA Switches	94	63	64	75	63	384
RTU	93	100	64	69	57	383
RTU Upgrade	16	40	34	68	80	238

Underground SCADA Switches	--	31	12	16	12	71

IC

E7.3.2.2 Downtown Feeder Automation

Feeder automation in the Downtown area targets the underground residential distribution (URD) system, which is an underground configuration unique to the former City of Toronto area. The URD is a looped style system with three distinct feeder levels: a main loop, sub-loops and branch circuits (or sub-sub-loops). The main loop does not serve any customers but is equipped with

multiple 600 A switching vaults that allow for the isolation of the sub-loops and branch circuits (which both feed customers) when faults occur. Currently none of these 600 A switches are equipped for remote operation.

Figure 5 is a simplified example of the configuration of a downtown URD feeder.

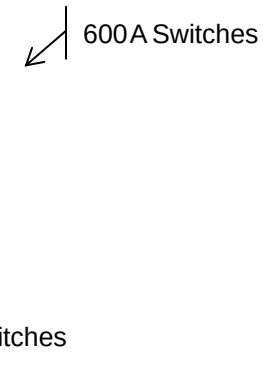

FIGURE 5: TYPICAL LAYOUT OF A DOWNTOWN URD FEEDER; ONLY ONE SUB-LOOP SHOWN FOR SIMPLICITY.

Downtown feeder automation entails replacing existing manual 600 A SF_6 switches in the URD system with new units that can be remotely operated and that are automation-ready. The proposed switches would allow the control room to remotely restore all customers after a fault on the main loop or restore the majority of customers if faults occur on sub-loops or branch circuits. System controllers would be able to remotely operate the new 600 A SCADA switches and gain important fault detection information, improving restoration times. In later years of the program, depending on the success of the original installations, these switches could potentially operate autonomously based on status information available at each switching location. Figure 6 displays the design of the current switch.

FIGURE 6: EXISTING 600 A MANUAL SWITCH INSTALLED IN A SWITCHING VAULT IN THE URD SYSTEM

FIGURE 7: TYPICAL URD FEEDER CONFIGURATION. GREEN DENOTES 600A SWITCH LOCATIONS WHERE NEW SCADA OPERABLE SWITCHES WOULD BE INSTALLED TO ENABLE AUTOMATION OF DOWNTOWN FEEDERS.

As with the Horseshoe feeder automation plan, where automated switches are placed only on the feeder trunk, the Downtown feeder automation plan would only install automated switches on the URD main loop, meaning that fault detection will still be required on the sub-loops. Therefore, the scope of the Downtown area feeder automation work also includes the replacement of existing faulted circuit indicators (FCIs) on the sub and sub-sub loops with new FCIs of a modern design that are capable of communicating with the control room.

An FCI is a device that is installed on a cable segment that can detect whether it has experienced the fault current. The FCIs in the URD system are at the end of their 15-year useful life and often malfunction, leading to interpretation errors by field crews searching for a fault, potentially prolonging the duration of URD system outages. Additional information on the current condition of these assets can be found in section E7.3.3.1. With the proposed automation of the 600 A remote switches and installation of remotely readable FCIs, Toronto Hydro controllers would be able to dispatch crews directly to the location of the fault, thus foregoing the time-consuming fault location procedures, facilitating faster outage restoration timelines on the sub- and sub-sub loops.

FIGURE 8: EXAMPLE OF THE NEW FCIS PROPOSED FOR INSTALLATION, FEATURING A WIRED CONNECTION IN THE VAULT TO COMMUNICATE REMOTELY (NOT PICTURED). DISPLAY COULD BE AS PICTURED OR BE FLASHING OR AUDIBLE FOR ENHANCED MANUAL DETECTION.

Toronto Hydro selected the Harbord Village area (A310CE) as the first feeder to be automated. A discussion of Toronto Hydro's approach and method for selecting and prioritizing which URD feeders will receive automation can be found in Section E7.3.4.1. The A310CE project entails automation of all the 600 A switches and replacement of all the FCIs on the feeder, totaling four switching vaults and approximately 150 FCIs. Each switching vault with a SCADA switch requires an RTU. Fiber optic cable will be used to connect the RTUs in each vault back to an aggregator

at the substation. The FCIs will be connected into the fiber network either by fiber or copper connection, dependent on distance and detailed design.

Toronto Hydro also proposes to automate two additional URD feeders in 2017 in the Little Italy and Palmerstone area (A320CE and A330CE for a total of five 600 A switching vault locations) and two feeders in 2018 in the Rosedale area (A340CS, A360CS for a total of six 600 A switching vault locations). Table 3 details the switching assets and communication infrastructure that will be installed in order to automate the targeted feeders in the Downtown area.

TABLE 2: NEW ASSETS PROPOSED FOR INSTALLATION BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
600A SCADA SF_6 URD Switches	--	4	--	5	6	15
RTU	--	4	--	5	6	15
Fiber Optic Cable (m)	--	3,000	--	3,000	7,000	13,000
Faulted Circuit Indicators (FCI's)	--	150	--	150	150	450

*Length of fiber optic cable necessary is estimated based on the length of primary cable between switching vaults and what fiber would have already been installed. The amount necessary will vary based on detail design.

Toronto Hydro anticipates that the feeder automation program will provide customer value by improving overall system efficiency and reliability by minimizing the duration of outages on targeted feeders. In both the Horseshoe and the Downtown areas, an outage on a feeder's trunk (or main loop) results in a service interruption to all customer on that feeder. By automating the switches on the targeted segments of feeders in the Horseshoe and Downtown areas, a large number of affected customers can be restored swiftly.

Targeted deployment of feeder automation technology is also expected to decrease the overall strain on system controllers during major event days. This can lead to faster restoration times for all customers, including those not located on feeders enabled for automation. In a similar manner, feeder automation is expected to reduce the demand for manual switching from field crews, allowing them to focus on planned switching work or other outages on non-automated feeders. Currently, when field crews need to perform reactive switching, resource limitations result in the postponement of previously scheduled switching work in connection with regularly scheduled maintenance or capital work.

Since feeder automation reduces the magnitude of outages on the feeder's trunk or main loop, it enables Toronto Hydro to postpone planned asset replacement activities scheduled on automated feeders so that other high-priority, critical activities can be completed. In other words,

since the outage impacts and the risk of potential equipment failures on feeder trunks would be diminished through automation, the timing of work on automated feeders can be considered somewhat less rigid. However, feeder automation is not an alternative option nor does it replace the need for asset renewal activities, as it will not prevent faults from occurring and does not deal directly with the growing backlog of end-of-life assets across the distribution system. Feeder automation is intended to improve system efficiency and reliability as Toronto Hydro's critical renewal program continues. The efficiency benefits in particular would be especially valuable to customers over the long-term, as the risks and costs associated with aging assets would be permanently reduced on feeders where feeder automation is installed.

Feeder automation is also expected to improve Toronto Hydro's visibility of system operating conditions, providing the utility with otherwise unobtainable system data. Toronto Hydro can leverage this information to make more informed and efficient asset management decisions in the future. It also will act as a cornerstone for further modernization of the system, since it provides the necessary data acquisition, control, and communication infrastructure (radio network, fiber installations, etc.) necessary for many modernization initiatives (e.g. network vault automation, monitoring of distributed generation, etc).

The following table summarizes the anticipated benefits of the 2015-2019 Feeder Automation program.

TABLE 3: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Limits the number of customers affected by a trunk or main loop outage. ƒ Positively impacts power reliability for customers on non-automated feeders as well. Feeder automation decreases the time and effort needed by controllers and switching crews on automated feeders so they can concentrate their attention on non-automated feeders. ƒ Less streetlights and traffic lights affected by trunk outages, improving public safety and mobility of traffic. ƒ Impacts many customers for relatively low cost. While Feeder Automation is not an alternative to asset renewal, the cost of automating a region of the city would typically equal the cost of renewing the asset base of only a section of a targeted feeder. This is further exemplified by the high benefit to cost ratio of the work. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $102.74 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.3.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $91.6 million, confirming the economic prudence of the investments (see Section E7.3.7).
Reliability	ƒ Automation has resulted in a reduction of 12,389 CHI and 24,778 CI since its installation in 2010. ƒ Through automated switching arrangements, restoration following a fault on the feeder trunk occurs in less than a minute. This decreases the number of customers impacted and the outage duration for unaffected customers – resulting in improvements to both SAIDI and SAIFI.
Safety	ƒ Manual switching is one of the most inherently risky tasks performed by field crews. The use of SCADA operable switches prevents crews from having to manually perform switching. ƒ The new switches have internal grounds, as opposed to the current switches that have external grounds. External grounds are more susceptible to the vault environment and human error during application.
Efficiency	ƒ Feeder automation allows system controllers to make more efficient use of their time. Since switching actions on automated feeders would be able to occur autonomously, crews would be able to focus on other areas requiring restoration. ƒ Enhanced condition monitoring on automated feeders will allow day to day operating decisions and long term asset investment decisions to be made more efficiently and effectively.

E7.3.3 Why the Program is Needed

The Feeder Automation program is needed to improve the system's ability to efficiently detect, isolate and restore power on the feeder' trunk or main loop. In all, automation is needed to significantly reduce outage durations on poorly performing feeder trunks and main loops in the Horseshoe and Downtown area systems, respectively.

Unlike lateral circuits, when a fault occurs on the trunk or the main loop, it trips the station circuit breaker, causing all customers connected to that feeder to experience an outage. Lateral circuits in the Horseshoe area, or sub-loops in the Downtown, have protective devices such as fuses that localize the outage downstream of the breaker and isolate the fault, leaving the majority of the circuit unaffected. The large number of customers affected and the time required to isolate faults make feeder trunks one of the most vulnerable areas on Toronto Hydro's distribution system with respect to outage impacts. Toronto Hydro's ability to isolate an outage quickly and efficiently plays a significant role in mitigating an outage's impact on customers.

E7.3.3.1 Purpose

Table 4 summarizes the primary and secondary drivers for the Feeder Automation program. This program is a System Service initiative, with a primary driver of system efficiency.

TABLE 4: PROGRAM DRIVERS

Primary Driver	Reasoning
System Efficiency	ƒ Significantly improves fault detection, isolation and restoration times during trunk- and/or main loop-related outages. ƒ Potentially mitigates the impact of defective equipment failures on the trunk on reliability, reducing the rate of asset replacements in select cases. ƒ Enables more efficient use of control room and switching crew resources. ƒ By cost-effectively mitigating failure risk costs, Feeder Automation can help maintain a moderate pace of system renewal.
Secondary Driver	**Reasoning**
Reliability	ƒ Decreases the duration of outages on targeted trunk / main loop feeders, facilitating significant reliability improvements for the system and the average customer. ƒ Decreases the number of customers impacted by trunk and main loop-related outages. ƒ Reduces demands on system operators and switching crews during large system outage situations by autonomously restoring power to the unaffected sections of automated feeders, thereby allowing staff to focus on other affected areas.

Horseshoe System

Toronto Hydro plans to implement feeder automation in the Horseshoe system to improve its operational efficiency and decrease outage impact and restoration times on the targeted feeders. As described in Section E7.3.2.1, Horseshoe area automation targets the open loop 27.6 kV system, where feeders are comprised of two main sections: trunks and laterals (also described in section E7.3.2.1).

Current system design utilizes fuses to isolate faults that occur on lateral segments of the feeder, reducing the impact of outages on laterals to just a few hundred customers. This configuration typically results in feeders with shorter trunk segments that supply numerous long laterals in order to minimize the number of circuit kilometers without upstream fusing. As a result, the total circuit kilometers of laterals is greater than the total circuit kilometers of trunk, meaning that more outage incidents occur on the lateral segments, as seen in Figure 9. However, as illustrated in Figure 10, when comparing the impact of outages on lateral segments to those on the trunk segments, trunk outages affect almost three times as many customers because a fault on the trunk section trips the station breaker, affecting all customers on a feeder. The current system design means that human intervention is needed to localize trunk related outages to a small portion of the feeder (i.e. field crews or operators from the control room need to fault locate and perform switching). Feeder automation activities, which target the feeder trunk, include the installation or modification of strategically placed SCADA-Mate switches, removing the need for human intervention by automating the switching process to localize the outage in under one minute.

FIGURE 9: COMPARISON OF TRUNK VS LATERAL OUTAGES

FIGURE 10: LATERAL VS. TRUNK COMPARISON OF CUSTOMERS INTERRUPTED

Since trunk outages affect more customers and usually involve longer restoration times than lateral outages, they also affect Toronto Hydro's SAIFI and SAIDI statistics. As shown in Figure 11, faults on feeder trunks have approximately three times the SAIFI impact on Toronto Hydro's system as compared to faults on the laterals. Figure 12 illustrates a similar relationship in relation to SAIDI. By expanding feeder automation to more feeders in the system, Toronto Hydro anticipates a material improvement of the average system reliability experienced by all customers. More information on the reliability impact and benefits of feeder automation can be found in Section E7.3.5.2.

FIGURE 11: SAIFI COMPARISON BETWEEN TRUNK AND LATERALS

FIGURE 12: SAIDI COMPARISON BETWEEN TRUNK AND LATERALS

Toronto Hydro currently operates the 27.6 kV feeders in the Horseshoe area through a combination of manual switches and remote operated SCADA switches. The number of switches

on a feeder and their placement varies throughout the feeders in the system and is determined based on a feeder's configuration and loading.

Manual switches require field crews to be deployed to the site to isolate the sections upstream and downstream of the fault site. After physically locating the fault, field crews manually operate the necessary tie switches to adjacent feeders to resupply power to the unaffected portions of the feeder. The manual effort to locate the fault, isolate the faulted section and restore the unaffected customers takes an average of three hours to complete. This timeline can be prolonged when outages occur during rush hour, as heavy traffic and downed traffic lights can delay crews' ability to reach the outage and set up their equipment. In a similar manner, outage restoration timelines can increase during multiple outage events, such as adverse weather days. Not only does this increase the duration of the outage, but it also results in additional expenses in the form of fuel costs.

Unlike manual switches, SCADA switches can be opened and closed remotely. When a fault occurs on a feeder with SCADA switches, the system controller can remotely open the switches upstream and downstream of the fault to isolate. They can then remotely close tie switches that connect to adjacent feeders, resupplying the unaffected sections of the feeder. SCADA switches also have current sensors that allow the controller to quickly assess where the fault occurred. Since this can be done remotely, feeder fault detection, fault isolation, and restoration can be done relatively quickly as compared to the manual process. The typical restoration for a feeder with SCADA switches is under 30 minutes.

By replacing the manual and non-automated SCADA switches with switches designed for feeder automation, Toronto Hydro expects to be able to rely on autonomous detection and isolation of affected portions of the feeders, restoring the majority of customers affected in under a minute. As such, the number of customer outage impacts currently associated with trunk outages is expected to be minimized.

By automating feeders with the worst reliability statistics related to trunk outages (the area of the feeder this technology is protecting), Toronto Hydro can target areas that do not justify capital renewal work due to the condition of equipment on the trunk, but that are still problematic due to the risk of the occasional equipment failure or faults induced by weather or foreign interference. This will provide a protection scheme that will automatically localize the outage to a smaller section of the feeder without human intervention and will reduce the impact to customers system wide.

Downtown (URD) System

Similar to the Horseshoe area, feeder automation in the Downtown area is expected to improve the operating efficiency of the system. The URD system is one of Toronto Hydro's downtown underground service distribution configurations that largely supplies residential loads and smaller commercial loads using a series of feeder loops. Determining the source of an outage in the URD system can be time consuming due to the complexity of the loop system configuration. The design of the URD system features FCIs to aid field crews in the fault locating process in this complicated configuration. Due to the corrosive environment in the switching and transformer vaults, many of which are below grade and poorly ventilated, the location of most FCIs exposes them to higher incidence of mechanical failures, resulting in instances of crews misreading FCI indicators while searching for the location of the fault, prolonging the duration of outages. Figure 13 below shows the corrosion damage on FCI units and the effect it can have on the magnetic core of the unit, which is what allows it to sense the fault currents.

FIGURE 13: CORROSION OF FCI CORE AND MECHANICAL FAILURE

In August 2008 an outage occurred on the URD system due to a failed cable. The fault indicators provided incorrect readings, resulting in crews and system operators attempting to restore the outage based on these incorrect readings. This resulted in a significant prolongation of the outage time; a total CHI of 5,458 and CI of 868. The installation of modern FCIs capable of remote communication would have expedited the fault location and isolation efforts, allowing for a large portion of the feeder to be restored a lot quicker.

The outage in August 2008 is prime example of how the complex configuration of the downtown URD system, combined with the reliability issues of currently deployed FCIs, can cause extended outages on this segment of Toronto Hydro's system. Under current conditions, the URD design requires field crews to perform numerous, time-consuming manual fault location work, which includes travel time to the requisite switching vaults. Figure 14 shows that since 2000, the CHI trend for outages on the URD system has been increasing.

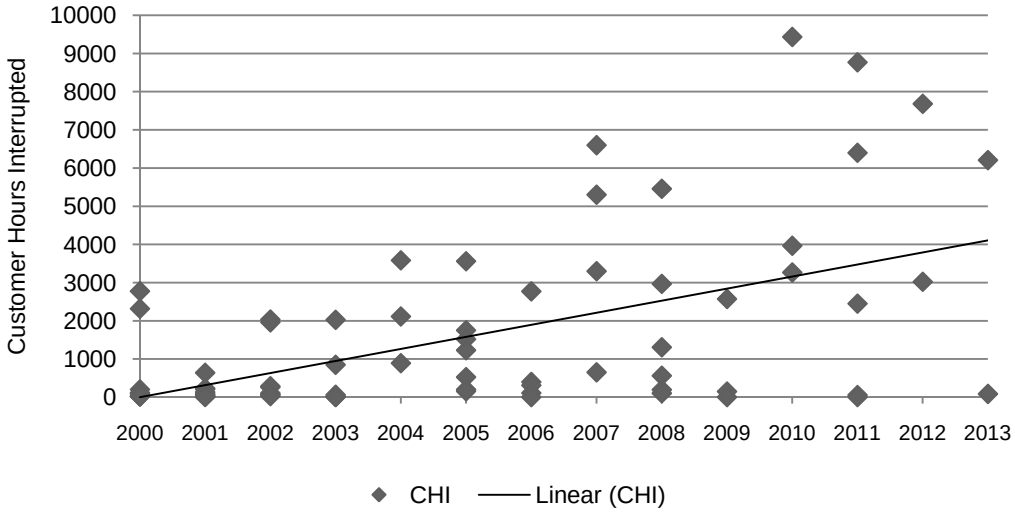

FIGURE 14: CHI OF EACH OUTAGE ON THE URD SYSTEM 2000-2012 (PURE URD FEEDERS ONLY)

The average outage duration on the URD system is historically longer than those on other Toronto Hydro system configurations. This can be seen when examining outage durations for cable faults – the most prevalent fault type on all segments of Toronto Hydro's system. Figure 15 displays the average outage duration for cable faults since 2000 on five different Toronto Hydro systems. The outage duration for cable faults on the URD system has increased on average since 2008. This is consistent with the overall trend of outage time on the URD system, shown in Figure 14.

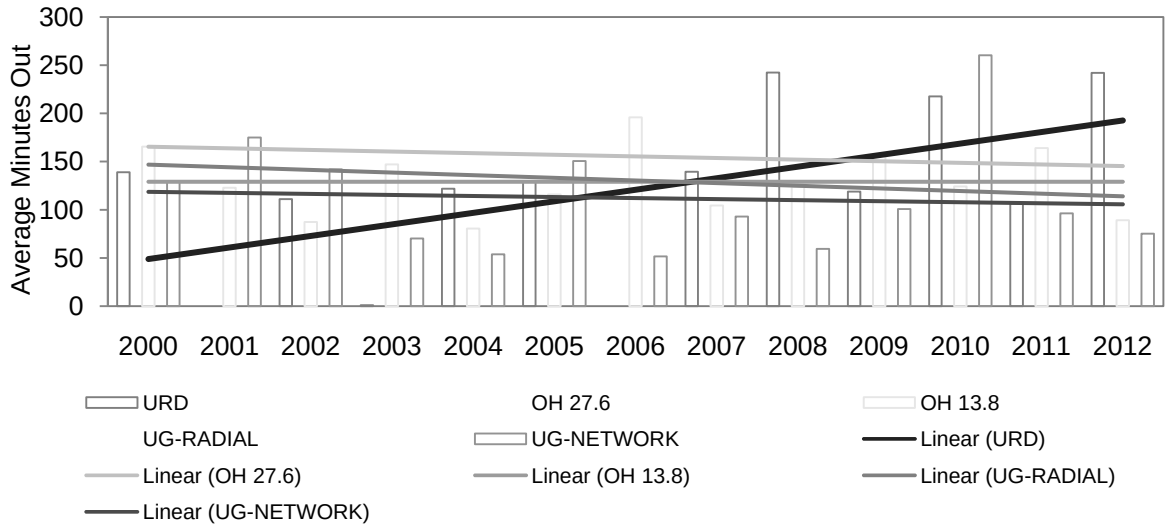

FIGURE 15: YEARLY AVERAGE OUTAGE DURATION FOR UG PRIMARY CABLE FAULTS BY SYSTEM CONFIGURATION TYPE

Table 5 provides the average length of outage durations on each system type from 2000 to 2012 and from 2008 to 2012. The colour of the cell indicates the order of magnitude of the average outage length, with red indicating the longest average outage duration. As with the trend in CHI, it is evident that the URD system has historically experienced the longest outage durations for cable faults, second only to the overhead 27.6 kV system, which is targeted by the Horseshoe automation.

TABLE 5: AVERAGE OUTAGE DURATION FOR DIFFERENT SYSTEM CONFIGURATIONS (FOR OUTAGES CAUSED BY CABLE FAULTS)

	System Average Outage Duration (minutes) 2000-2013	System Average Outage Duration (minutes) 2009-2013 (5yr)
URD	142	142
OH 27.6	165	151
OH 13.8	126	130
UG-RADIAL	123	131
UG-NETWORK	113	125

Figure 15 and Table 6 indicate that URD system warrants improvement when compared to other system types. By installing SCADA operable 600 A switches on the main loop of URD feeders,

Toronto Hydro expects to be able to more quickly restore large portions of customers on the feeder. While SCADA switches are the first step, a further step to make them completely autonomous will further improve restoration times. If the FCIs on the feeder also report remotely, the system operator will be able to dispatch crews to the appropriate switching locations right away, decreasing fault location durations, and subsequently outage durations, dramatically.

E7.3.4 Timing & Pacing of the Program

Toronto Hydro determined the planned pace of feeder automation based on the following considerations:

- Feeder reliability statistics;
- Age of the existing feeder assets;
- Location, and amount, of existing communication infrastructure (e.g. radios, fiber optic cable);
- Staging of work that would allow the company to leverage its existing automated switches and communication infrastructure; and
- Standard testing and acceptance procedures for installation of new equipment.

As per the table below, the total cost of the program over the 2015 to 2019 period is $54.1 million, which includes the automation of approximately 130 feeders. The aggregate yearly budget for the program fluctuate year over year due to the combined effect of the pacing of the Horseshoe and Downtown automation projects.

TABLE 6: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	3.26	0.87	6.24	8.83	0.77	11.1	15.1	9.41	9.99	8.47

The Feeder Automation program will occur alongside Toronto Hydro's proposed renewal work to improve system efficiency and ensure asset replacements are occurring at the most effective time with the most benefit to customers. By implementing automation now, Toronto Hydro has the opportunity to ensure that the cost-effectiveness of the next generation distribution system will be enhanced for current and future ratepayers. The use of modernized equipment and

communication infrastructure that support automation will create a more intelligent grid, one which provides system operators and planners with high-quality data for future asset management decision making. As such, future asset replacements and planning decisions will be better informed and effective. Toronto Hydro should not postpone these investments beyond 2019, as they are some of the most cost-effective distribution system improvements currently available to Toronto Hydro and its customers.

Since the Horseshoe's feeder automation equipment is more mature than Downtown's and has a more established communication infrastructure, the automation work in the Horseshoe area is more front-loaded. Projects in later years make use of some of the assets that will be installed in the earlier years of the program (i.e. adjacent feeder automation zones will be automated sequentially to build off the communication infrastructure of the first zone). As the program progresses, the costs associated with Horseshoe feeder automation will decrease in later years.

Seeing as this is the first time that Toronto Hydro has deployed the type of equipment proposed for installation in the Downtown URD system, Toronto Hydro will follow standard practices for new asset integration. Throughout 2015, the equipment will be tested and impacts of the harsh vault environment (e.g. frequent accumulation of the run-off and ground water) will be assessed. The first URD automation project is planned to take place in 2016 (accounting for a portion of the jump in yearly spend from 2015 to 2016), which is a year after the first installation is made in 2015. Two feeders are planned for automation in 2018 and another two in 2019. The lack of URD automation projects in 2015 and 2017, partially accounts for the year to year variance in program costs.

E7.3.4.1 Ranking & Prioritization

Toronto Hydro assessed whether feeders were suitable for automation based on their reliability history and the utility's knowledge of the location of existing fiber and radio communication infrastructure that could be leveraged to manage overall project costs. Both the Horseshoe and the Downtown feeder automation plans also take into account existing feeder assets, configurations and geography.

Toronto Hydro considered trunk reliability statistics over the past five years in order to prioritize planned work for the Horseshoe area. The frequency of historical outages on candidate feeders provided a good benchmark for how helpful feeder automation would have been and how useful it would be going forward. Higher prioritization was given to feeders that would have most benefitted from automation. Toronto Hydro applied a similar approach for the Downtown feeders,

with particular focus being placed on outages on both the main and sub-loops. For the Downtown feeders, the planners also consulted control room staff to assist in determining which Downtown feeders would benefit most from the automation of the 600A switches.

As mentioned earlier, feeder prioritization also accounted for the feeders' geographic locations. By targeting adjacent feeders, Toronto Hydro can establish a network of automated feeders that will be able to resupply one another in the event of an outage. Automating adjacent feeders provides the basis for project zones, as displayed in Figure 1. Work planned for these zones expands on the existing adjacent network of automated feeders and their switch and communication (radio or fiber) infrastructure. This process of planning automation in zones of geographically proximate feeders heavily impacts the order and prioritization of projects under the Feeder automation program.

E7.3.5 Program Execution

The proposed Feeder Automation program is scoped at a feeder level. The work will be executed based on "automation zones", which each zone being comprised of multiple feeders in proximity to one another. See Figure 1 showing a map of the planned automation zones.

When a zone is planned for automation, all of the switches on the affected feeders are identified (current switch and RTU type). Additionally, the load of existing segments of the feeder will be examined to determine if additional tie points are needed. The switches will be added or replaced one-by-one, coordinated with any other work in the area to ensure minimal switching. Once all switch assets are installed, the switch manufacturer will conduct a radio survey to ensure that the site selected is appropriate given the required communication. Following the completion of switch installation for a given zone, site acceptance testing will be performed to confirm that the automation software installed in each switch controller is functioning properly.

E7.3.5.1 Proposed Work Plan

As mentioned earlier, the work will be executed based on "automation zones", which each zone being comprised of multiple feeders in proximity to one another. Using this approach, adjacent feeders that are connected to one another through tie switches can be automated in the same project year. The installation of the switches themselves will be executed on a feeder basis. Table 7 outlines the feeders planned for automation, their proposed year of execution and the station area they service. The plan presented covers the 2015 to 2019 work period, though feeder automation work is expected to continue beyond 2019.

TABLE 7: 2015-2019 LONG TERM PLAN

Year	Feeder	Station	Area
2015	80M1	Fairchild TS	Horseshoe

2019	Zone 8c	Sheppard/Ellesmere TS	Horseshoe

E7.3.5.2 Program Risks

(i) New Large Customer Loads

The proposed automatic switch locations are determined based on the current optimal feeder configuration, which takes into account the feeder loading levels. Additional loads of new large customers, such as a data centre, industrial facility or a group of new high-rise buildings, could cause some sections of the feeder to be overloaded during power restoration activities, potentially leading to additional outages. As such, Toronto Hydro may be required to reconfigure its automation plans later in the program. Toronto Hydro mitigates this risk by monitoring load forecasts and anticipated developments on an ongoing basis.

Integrity of the Communication Infrastructure

Horseshoe automation requires the installation of a peer-to-peer mesh network that will enable the switching nodes to communicate with one another in the field. The network's functionality is dependent on the sequence of the nodes being built, since nodes need to be able to communicate with one another. As such, a communication design needs to be established between switches and the control room. The sequence of work has been determined by a radio frequency (RF) design to ensure that the integrity of the communication system is maintained. In essence, a delay in the conversion of a single feeder segment can slow down the implementation of a project in a particular zone. Toronto Hydro plans to mitigate this risk by ensuring that the radio design is capable of allowing multiple feeders to have automation infrastructure constructed at the same time, allowing multiple crews to work on different feeders simultaneously.

Premature Asset Failure

In Downtown area automation, approximately 80% of the switches targeted for replacement with new 600 A switches are nearing or are at their end of useful lives. As such, these switches may require reactive replacement before the planned work can be executed due to failure or deteriorating conditions such as low gas levels. In this scenario, Toronto Hydro would have to amend its work schedule. To address this risk, SCADA-ready switches will be installed if reactive replacements are required and the RTUs will then be installed at a later date through the Feeder Automation program.

E7.3.5.3 External Constraints

An external constraint of the Feeder Automation program is the need for Toronto Hydro to coordinate activities with Hydro One Networks Inc. (HONI) so that station breakers, which are owned by HONI, will be updated. While feeder automation can be undertaken without autonomous station breakers (since a system controller could close the breaker as necessary or the automation can seek restoration from tied feeders), a truly automated feeder requires that the breaker also be automated as it is the easiest source to restore power from. Coordination with HONI can delay the complete automation of feeders in the Horseshoe where HONI owns the station breakers. In the Downtown area, breakers are owned by Toronto Hydro and as such, this external constraint does not apply. Toronto Hydro is currently working with HONI to automate station breakers and expects that future automation work will include the update of station breakers. Initially, the update of station breakers may only occur in the year following Toronto Hydro's automation.

Another external consideration is the fact that the installation of the new communications framework required for feeder automation can affect the overall radio performance on the open loop system. Since the feeder automation scheme uses a different communication system, peer-to-peer mesh network as opposed to the traditional point-to-point network, it requires a custom design to ensure that there are enough communication nodes from the switches radio. Where there are shortfalls in coverage, additional repeater radios will have to be installed to act as communication stepping stones to ensure adequate coverage. At the present time, Toronto Hydro relies on an external contractor to perform some of these activities and the timeline or design can be affected if communication cannot be achieved in a cost-effective manner. As the system expands, this issue will become less salient as additional radios are placed in the field, which will provide sufficient coverage.

E7.3.5.4 Standard & Regulation Adherence

The communication system required to enable feeder automation is encrypted and all communication radios (i.e. radios that communicate back to the control room) are located on Toronto Hydro properties or approved private properties. Furthermore, the configuration of the communication network has been designed to ensure that each location has at least one redundant path in the event a radio malfunctions or is put offline.

All switching procedures for automation are in accordance to the Electrical Utility Safety Regulations to ensure that automation does not occur while crew members are within the vicinity of the feeder. Measures have been introduced to ensure that automation times out after an allocated time frame and that feeders with disabled automation cannot be used in the automation process.

E7.3.6 Evaluation of Alternatives

E7.3.6.1 Quantification/Evaluation of Options

(i) Status Quo: Leave the System as is

By maintaining the status quo, Toronto Hydro would not address the prolonged restoration times, which can range from 20 minutes to three hours depending on the mix of manual and SCADA switches on a given feeder. While some Horseshoe feeders use SCADA switches, manual switches in both the Horseshoe and Downtown areas would continue to be used. In all, the considerable issues with respect to system efficiency, reliability and safety will not be addressed.

The continued cost of ownership associated with the Status Quo option (COO_E) is highlighted in Table 10.

(ii) Option 2: Install Remote Operated SCADA-Mate Switches

By installing remote-operated SCADA switches, Toronto Hydro would improve the system by adding data acquisition and control points. This would allow the controller to assess the condition of a feeder using the sensors of the SCADA switch and then remotely operate the switches to isolate the faulted section. A controller can typically restore a Horseshoe area feeder within thirty minutes using remote operable switches.

This option entails an increased investment in the form of installing additional SCADA switches in the Horseshoe and Downtown areas. Under this option, Toronto Hydro controllers would utilize manual intervention of the controller (instead of automated intelligence) to assess the fault and determine the optimal means of restoring it through adjacent feeders. Lengthy outages would likely persist since controllers could potentially be required to manage multiple outages concurrently, as is the case during adverse weather events, and the many substantial benefits of rapid isolation and restoration associated with full automation would not be realized.

The cost of ownership (COO_{N1}) and program net benefit (NPV_1) associated with installation of remote operable switches is further detailed in Table 9.

(ii) Option 3: Install Feeder Automation

Toronto Hydro's preferred option is the Feeder Automation program. With this option, Toronto Hydro would strategically install SCADA switches to either sectionalize a feeder or tie two feeders together for the purpose of restoration. In the Horseshoe area, this would be accomplished by utilizing existing SCADA switches and installing new switches in areas that require them. In the Downtown area, feeder automation would entail the replacement of 600A main-loop switches with SCADA switches. By undertaking the Feeder Automation program, Toronto Hydro would improve the efficiency and reliability of the system while also eliminating safety risks.

The cost of programming SCADA switches and configuring the wireless network for automation is approximately 10% higher than using basic SCADA switch technology. The modest cost increase for automation over a basic remote-operated system is warranted because the investment is expected to significantly improve system reliability for the average customer and improves Toronto Hydro's operational efficiency with respect to trunk outage restoration efforts. Automation modernizes the grid by mitigating the risk of large-impact outages on the most vulnerable part of feeder, the trunk or main-loop. It also provides real-time information to the controller with respect to feeder operation. The software can manage the initial work that would otherwise be required to be undertaken by an operator, freeing the operator and crew to manage the faulted area more quickly.

The COO_{N2} and NPV_2 associated with the Feeder Automation program is further detailed in Table 10. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_{N2}) based on the first year of activities in this program. The COO_{N2} of a state reflects the risk of asset failure including both direct and indirect costs; these costs include customer interruptions, emergency repairs, and asset replacements associated with that design. In

addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_{N2}) state. Non-asset risks are further explained in Section D3.3. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership ($\hat{u}COO_2$) is compared to the associated program costs (PC_2) for the first of activities, the Feeder Automation program produces a net benefit (NPV_2) value of $91.60 million, as shown in Tables 8 and 9.

TABLE 8: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	99.75
Non Asset Risk [NAR_E]	512.64
Maintenance Cost [MC_E]	
Additional Quantifiable Benefits [AQB_E]	
Cost of Ownership of Existing Assets [COO_E]	612.40

The following subsections provide additional details for all 2015 projects.

E7.3.7.1 Feeder Automation Scarborough TS Project Description

Investment Category: System Service

Program: Feeder Automation

Project Title: Feeder Automation Scarborough TS

Project Number: E12679, E14387, E14388, E14389, E14390, E14391, E14392, E14393, E14394, E14395, E14396, E14397, E14398, E14399, E14400, E14401

Project Year: 2015

Estimated Cost: $7.48 million

(i) Objective

The objective of this project is to automate the selected feeders being supplied from Scarborough East TS and expand the network that has been established from Cavangh and Agincourt TS.

(ii) Scope of Work

TABLE 12: SCOPE OF WORK DETAILS

District Neighborhood	SCARBOROUGH
Station(s)	SCARBOROUGH EAST TS
Feeder(s)	5M2, 5M6,5M8,5M10,5M21,5M22,5M23,5M24,5M25,5M26,5M27,5M29,5M30

TABLE 13: ASSETS REPLACED

Assets (Units)	2015
SCADArMate Switches	62
RTU	63
RTU Upgrade	7
Radio & Antenna	71

IC

(iii) Justification & Benefits

Automating this area of the system is expected to mitigate trunk related outages that have occurred in the past.

This project will expand the automated network that will first be established at Cavanagh and Agincourt TS, just north of this area. After automating this area, Toronto Hydro will be able to further expand automation to the east, west and south of this location.

E7.3.7.2 Feeder Automation Fairchild TS Project Description

Investment Category: System Service

Program: Feeder Automation

Project Title: Feeder Automation Fairchild TS

Project Number: W13366, W13368, W13370, W13373, W13484, W13499

Project Year: 2015

Estimated Cost: $1.59 million

(i) Objective

The objective of this project is to automate the selected feeders being supplied from Fairchild TS and expand the network that has been established from Bathurst TS.

(ii) Scope of Work

TABLE 14: SCOPE OF WORK DETAILS

District Neighborhood	NEWTONBROOK & WILLOWDALE
Station(s)	FAIRCHILD TS
Feeder(s)	80M1, 80M4, 80M8, 80M21

TABLE 15: ASSETS REPLACED

Assets (Units)	2015
SCADA-Mate Switch	14
RTU	14
RTU Upgrade	9
Radio & Antenna	23

(iii) Justification & Benefits

Automating this area of the system is expected to mitigate trunk related outages that have occurred in the past.

This project commenced several years ago and is half complete; however, work was halted because of the 2012 IRM decision. The remaining work needs to be completed in order to achieve full automation.

This project will expand the automated network that will first be established at Bathurst TS, just west of this area. After automating this area, Toronto Hydro will be able to further expand automation to east if this location.

E7.3.7.3 Feeder Automation Etobicoke Project Description

Investment Category: System Service

Program: Feeder Automation

Project Title: Feeder Automation Etobicoke

Project Number: W13379, W13381, W13383, W13384, W13483, W13485

Project Year: 2015

Estimated Cost: $1.51 million

(i) Objective

The objective of this scope is to automate the selected feeders being supplied from Manby and Horner TS and establish a new network in Etobicoke.

(ii) Scope of Work

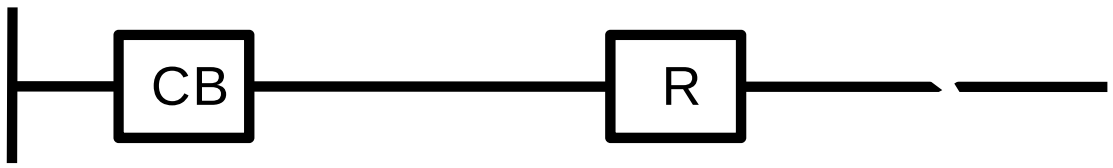
TABLE 16: SCOPE OF WORK DETAILS

District Neighborhood	SOUTH ETOBICOKE
Station(s)	MANBY AND HORNER TS
Feeder(s)	30M9, 38M8, 38M5, 38M4

TABLE 17: ASSETS REPLACED

Assets (Units)	2015
SCADArMate Switches	18
RTU	16
RTU Upgrade	0
Radio & Antenna	18

IC



(iii) Justification & Benefits

Automating this area of the system is expected to mitigate trunk related outages that have occurred in the past.

This project commenced several years ago and is half complete; however, work was halted because of the 2012 IRM decision. The remaining work must be completed in order to achieve full automation.

After automating this area, Toronto Hydro will be able to further expand automation in the Etobicoke area.

E7.4 Overhead Momentary Reduction

TYPICAL RECLOSER CONFIGURATION

E7.4.1 Summary

Program Description

The Overhead Momentary Reduction program involves the installation of reclosers, primarily on the feeder trunk, to address feeders that are experiencing numerous momentary and sustained interruptions. Reclosers are small pole-mounted breakers which would allow Toronto Hydro to better isolate a feeder during a momentary or sustained interruption, thereby limiting the number of customers impacted by an outage.

For a comprehensive explanation of recloser technology and how Toronto Hydro plans to use it, please refer to section E7.4.2 below.

A summary of anticipated benefits from this program is provided in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Limits service outages to the smallest possible segment of the system. ƒ Protect customers' sensitive equipment.
Reliability	ƒ Reduces the impact of temporary and sustained interruptions. • ƒ Reduces the time to locate and clear faults.

Safety	ƒ Eliminates safety hazards due to faults as fast as possible, for example: if energized lines were to fall on a road or highway, the section of the feeder would be isolated. ƒ Crews can safely operate the reclosers from their vehicles using Wi-Fi communication link to a laptop computer. ƒ Reduce the manual switching required for crews; this is considered a high risk task which will translate in positive impact on workers safety.
Efficiency	ƒ Coordination of reclosers, breakers, fuses and sectionalizers is performed to protect the distribution system against all kinds of faults and ensure minimum service interruption to customers. ƒ Benefits Toronto Hydro personnel with respect to patrolling faulted sections of the feeder. Crews will not have to patrol the entire feeder, only the faulted section.

Program Drivers

The trigger and secondary drivers of this program are detailed in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ Momentary interruptions account for 54% of all outages on the Toronto Hydro distribution system ƒ Momentary interruptions can have a substantial negative impact on customers that rely on continuity of service for sensitive equipment. ƒ Certain faults can cause the breaker to open without operating a lateral fuse and with the fault clearing shortly thereafter. Reclosers can limit the impacts of this type of interruption to a smaller section of the feeder.
Secondary Driver	**Reasoning**
System Efficiency	ƒ In the absence of reclosers, breaker-level faults require crews to patrol the entire feeder to locate the fault. Reclosers can reduce the amount of time and resources required to locate a fault.
Safety	ƒ Reclosers are expected to reduce the manual switching required for crews to sectionalize a circuit. Crews can safely operate the reclosers from their vehicles using Wi-Fi communication link to a laptop computer. ƒ Reclosers are expected to provide protection from injury and damage during unforeseen operating events, especially from failures of equipment or faults caused by damaged or objects foreign to the system

Preferred Alternative

Toronto Hydro considered two alternatives for addressing momentary interruptions:

(1) Do nothing beyond existing maintenance (e.g., tree trimming and insulator washing) where momentary interruptions occur frequently. This option would not sufficiently address the reliability concerns posed by momentary interruptions on feeders with especially poor momentary interruption statistics.

(2) Installation of Reclosers to mitigate the high number of momentary interruptions which occur despite the presence of comprehensive maintenance programs

Option 2 is preferred alternative, as it allows Toronto Hydro to put in place a solution designed to effectively limit the impact of momentary interruptions on the system, thereby limiting both the inconvenience and possible damage to sensitive equipment caused by this type of fault.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $6.40 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.4.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $5.76 million, confirming the economic prudence of the investments (see Section E7.4.7).

Timing and Pacing

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0	0	$0.64	$0.64	$0.64

Reclosers are a new technology for Toronto Hydro and the pacing of the program reflects this point. In the first two years of the program, 2015 and 2016, Toronto Hydro will carefully examine how to best integrate reclosers into the system, with consideration given to the coordination of reclosers with other assets. This coordination will involve Hydro One Networks Inc. (HONI) and multiple internal stakeholders. The pacing of the program will, in part, depend on outcomes from these consultations. Studies and planning exercises will provide Toronto Hydro with valuable and detailed information with respect to how to introduce the new technology into the current system and to ensure it is compatible with Toronto Hydro's business processes.

Toronto Hydro plans to install reclosers at a pace of approximately eight units per year over the 2017 to 2019 period. The installation of reclosers follows from Toronto Hydro's general outlook for grid modernization and represents proactive, necessary and timely efforts to reduce the impact of momentary interruptions in the system. The program will continue beyond 2019, targeting stations that are experiencing a high number of momentary interruptions.

E7.4.2 Program Description

The Overhead Momentary Reduction program involves the installation of reclosers on feeders that have experienced a high number of momentary and sustained interruptions. The objective of the program is to help minimize the number of customers affected by these interruptions across the system.

A momentary interruption is a single operation of an interrupting device that results in a voltage of zero that lasts less than one minute. A sustained interruption is any interruption not classified as a momentary interruption, that is, any interruption that lasts more than one minute.

Reclosers are small circuit breakers located at the top of distribution poles and are typically used on very long distribution feeders. Reclosers isolate a section of the feeder during momentary and sustained interruptions or overload conditions, thereby minimizing the number of customers experiencing service loss. Since reclosers act as small circuit breakers, they have the capability to restore power automatically in temporary or permanent fault situations, hence the name "recloser". See Figure 1 for an image of a recloser.

FIGURE 1: RECLOSER INSTALLED ON A POLE

Reclosers are set to trip at a lower fault current than the breaker at the station so that the fault can be isolated downstream. In other words, a single event on the feeder will only cut off power to the section handled by a recloser, long before the feeder breaker at the station would notice a problem. This is beneficial to customers, especially those that are particularly sensitive to momentary interruptions such as manufacturers, where a momentary outage can shut down production.

The benefits of reclosers can be understood by comparing the current Toronto Hydro distribution system without reclosers to one in which reclosers are installed. In the current distribution system, feeders are protected with circuit breakers at each station. In the event of a fault, the circuit breaker at the station activates and opens to turn-off power, which prevents damage from occurring to station and feeder assets. As a result, all customers on the circuit experience a momentary interruption. Afterwards, the circuit breaker closes to restore power to the entire

feeder. If the fault persists on the feeder, the circuit breaker will activate once again, creating a permanent fault on the feeder.

Reclosers function in a nearly identical fashion to the station breakers described in the previous scenario. However, instead of being positioned at the station and protecting the entire feeder at once, reclosers are strategically placed along the feeder downstream from the breaker in order to reduce the number of customers affected by momentary and sustained interruptions. In a Toronto Hydro distribution system with reclosers, the circuit breaker, reclosers and downstream fuses would be coordinated. If a temporary fault occurred downstream of the recloser, the recloser would activate before the circuit breaker, leaving the breaker uninterrupted and limiting the momentary loss of power to the circuit downstream of the recloser instead of the entire feeder. In the case of sustained interruptions on the feeder, the recloser time delay curve allows the fuse to clear (in the same manner that a station breaker allows the downstream fuses to clear), resulting in an interruption only to the lateral on which the fault occurred.

Figure 2 illustrates a basic feeder arrangement with the circuit breaker (labeled as “CB”) functioning as station-level/trunk-level protection and a downstream lateral protected by a fuse that is coordinated with the breaker. Approximately 3,000 customers can be affected in the event of a momentary or forced interruption that affects the entire trunk portion of a feeder. Figure 3 demonstrates how reclosers improve reliability indices by mitigating both momentary and sustained interruptions.

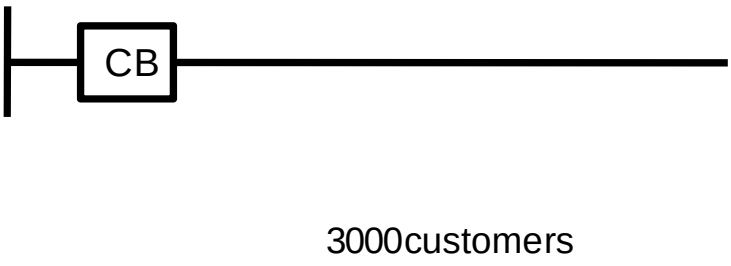


FIGURE 2: BASIC FEEDER ARRANGEMENT WITH A CIRCUIT BREAKER AND DOWNSTREAM FUSE

Figure 3 shows a feeder with a circuit breaker and a recloser. The recloser (labeled as “R”) is strategically placed on the feeder to minimize the impact of a fault to customers. In the event of a momentary or forced interruption on section B (which includes all load downstream of the recloser), the recloser senses the fault and opens, isolating section B of the feeder. As a result,

customers on section A (which includes all load between the breaker and recloser) will not be impacted by the fault or experience an interruption. If the fault were to happen on section A, momentary or sustained, the entire feeder would experience an outage.

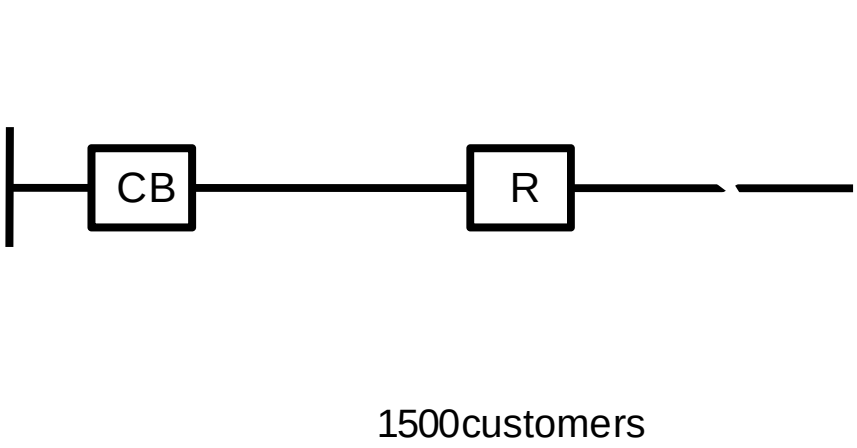

FIGURE 3: FEEDER WITH CIRCUIT BREAKER AND LINE RECLOSER

To address its reliability challenges, discussed in section E.7.4.3, Toronto Hydro plans on installing reclosers on overhead feeders (13.8 kV and 27.6 kV). The installation will take place at the feeder trunk, which will help minimize the effects of a fault on the main feeder and help divide the feeder into smaller sections. Reclosers will not be installed on the downtown core area, which is supplied by the secondary network system.[1] The 4.16 kV systems will also not be part of the program since the infrastructures is reaching end-of-life and the assets will be replaced using a higher voltage level like 27.6 kV.

By adding a midpoint recloser and providing trip coordination with the circuit breaker, temporary faults downstream of the recloser will no longer be expected to affect customers upstream. This technology is relatively low cost and will benefit all customer classes on feeders that experience a high number of momentary interruptions. In particular, reclosers have the potential to deliver significant value to critical customers in commercial or industrial areas or who otherwise rely on sensitive electronics to generate revenue or to maintain operational continuity.

Preventive maintenance measures such as tree trimming, animal guard installation and lightning arrestor replacement do not fully prevent momentary interruptions to distribution feeders, and certain feeders tend to experience a disproportionate number of momentary interruptions that

[1] The network system is designed in such a way that customers do not experience momentary outages if one feeder, and associated network units, are taken out of service.

they experience. Using reclosers, in combination with Toronto Hydro's maintenance programs, will help: (a) reduce the impact of outages on the feeders; (b) reduce the average amount of time required to restore service to customers located on the faulted section of the feeder; (c) minimize the required time (and therefore cost) to find and remove faults, and (d) reduce the need to perform manual switching.

The implementation of reclosers will also have a positive impact on worker safety. Without reclosers, Toronto Hydro crews are required to manually operate switches along the trunk in order to sectionalize the feeder. Manual switching is considered a high risk task for field crews. The installation of reclosers would entail a reduction in manual switching activities that would be required to restore power.

Table 1 shows the number of assets that Toronto Hydro plans to install during the 2015 to 2019 period. In 2015 and 2016, Toronto Hydro will examine and evaluate the integration of reclosers with existing feeder technology and protection schemes. Coordination with other protection devices is important to ensure that, when a fault occurs, the smallest section of the circuit is disconnected to minimize disruption of power to customers. Without this coordination, the recloser would not provide intended benefits; instead, they would act as a regular switch and would not reduce the impact of both momentary and sustained interruptions experienced by a feeder.

TABLE 1: ASSETS TO BE INSTALLED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
Reclosers	0	0	8	8	8	24
Poles	0	0	8	8	8	24

Toronto Hydro plans to spend an estimated $1.92 million on the Overhead Momentary Reduction program during the 2015 to 2019 period.

Table 2 summarizes the anticipated benefits of the Overhead Momentary Reduction program. The program is a grid modernization initiative that is expected to provide greater system reliability and outage management, increase operational efficiencies, improve levels of service and reduce economic losses caused by outages to sensitive customers.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Helps limit service outages to the smallest possible segment of the system. ƒ Facilitates protection of customer-owned sensitive equipment. ƒ The difference in the cost of ownership between existing and renewed assets (ΔCOO_1) for the first year of the program is $6.40 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.4.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV_1 of $5.76 million, confirming the economic prudence of the investments (see Section E7.4.7).
Reliability	ƒ Reduces the impact of temporary and sustained interruptions. • ƒ Reduces the time to locate and clear faults.
Safety	ƒ Addresses safety hazards due to faults as fast as possible, for example: if energized lines were to fall on a road or highway, the section of the feeder will be isolated. ƒ Crews can safely operate the reclosers from their vehicles using Wi-Fi communication link to a laptop computer. ƒ Reduces the manual switching required for crews, which is considered a high risk task. Addressing this issue is expected to have positive impact on worker safety.
Efficiency	ƒ Coordination of reclosers, breakers, fuses and sectionalizers is performed to protect the distribution system against all kinds of faults and ensure minimum service interruption to customers. ƒ Benefits Toronto Hydro personnel with respect to patrolling faulted sections of the feeder. Crews will not have to patrol the entire feeder, only the faulted section.

E7.4.3 Why the Program is Needed

E7.4.3.1 Program Drivers

Table 3 presents the trigger and secondary drivers for the Overhead Momentary Reduction program. The trigger driver of reliability situates this program in the System Service investment category.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ Momentary interruptions account for 54% of all outages on the Toronto Hydro distribution system (Figure 4). ƒ Momentary interruptions can have a substantial negative impact on customers that rely on continuity of service for sensitive equipment. ƒ Certain faults can cause the breaker to open without operating a lateral fuse and with the fault clearing shortly thereafter.
Secondary Drivers	**Reasoning**
System Efficiency	ƒ In the absence of reclosers, breaker-level faults will require crews to patrol the entire feeder to locate the fault. Reclosers can reduce the amount of time and resources required to locate a fault.
Safety	ƒ Reclosers will reduce the manual switching required for crews to sectionalize a circuit. Crews can safely operate the reclosers from their vehicles using Wi-Fi communication link to a laptop computer. ƒ Reclosers will provide protection from injury and damage during unforeseen operating events, especially from failures of equipment or faults caused by damaged or objects foreign to the system

Momentary interruptions account for 54% of the interruptions affecting Toronto Hydro's distribution system, as shown in Figure 4. These interruptions are of particular concern for customers that rely on continuous uninterrupted service for their sensitive equipment, such as high-precision manufacturing equipment, computers, digital clocks, and others. Power interruptions can result in customer inconveniences such as having to reset clocks and reprogram the equipment. The impacts can be most severe for businesses, manufactures and other organizations using computers, digital controls and automatic systems. For these customers, momentary interruptions can result in the crashing of electronic devices and lost production, retail sales, and inventory.

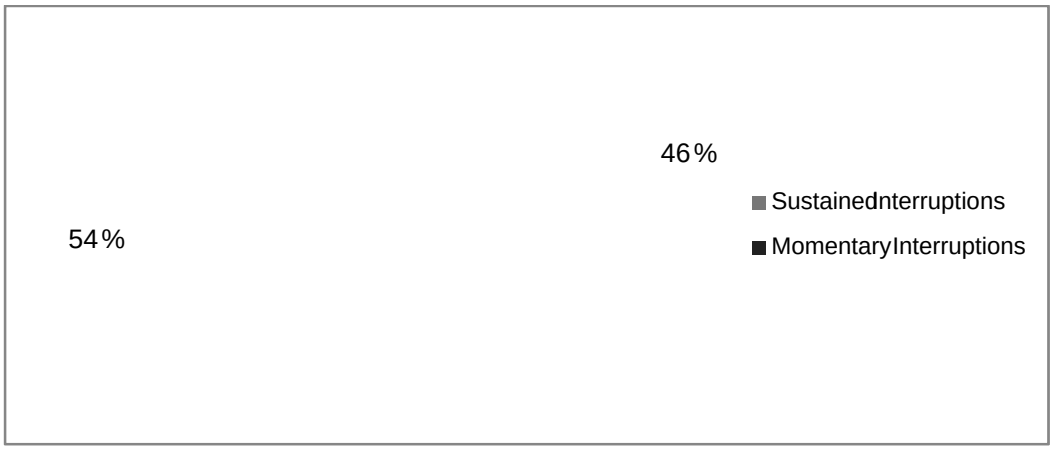

FIGURE 4: PERCENTAGE OF MOMENTARY INTERRUPTIONS BASED ON THE TOTAL NUMBER OF OUTAGES FROM 2009-2013

Figure 5 highlights the areas of the system that experience a high frequency of momentary interruptions. This map relates to Figure 6, which shows the stations with highest number of momentary interruptions. For the 2017-2019 timeframe, Toronto expects to target the following stations: Richview Station, Warden Station, Leslie Station and Dufferin Station. Some of the areas highlighted in red are not targeted in the 2015-2019 planning horizon because they currently fall under the implementation of the Feeder Automation program (refer to Section E7.3). In the future, Toronto Hydro expects to eventually integrate recloser technology with existing Feeder Automation technology in order to provide a fully optimized protection scheme on feeder trunks throughout the system.

FIGURE 5: MOMENTARY FREQUENCY BREAKDOWN BY FEEDER FROM 2011-2013

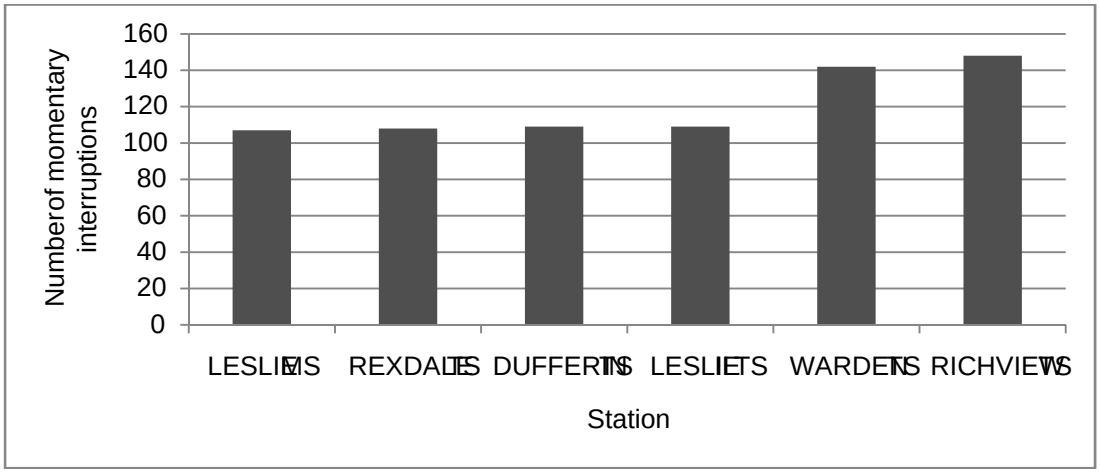

FIGURE 6: TOTAL NUMBER OF MOMENTARY INTERRUPTIONS BY STATION

E7.4.4 Timing & Pacing of the Program

Table 4 provides the estimated costs for the program and the timing of spending.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	0	0	$0.64	$0.64	$0.64

Reclosers are a new technology for Toronto Hydro and the pacing of the program reflects this point. In the first two years of the program, 2015 and 2016, Toronto Hydro will carefully examine how to best integrate reclosers into the system, with consideration given to the coordination of reclosers with other assets. This coordination will involve Hydro One Networks Inc. (HONI) and multiple internal stakeholders from Toronto Hydro. The pacing of the program will, in part, depend on outcomes from these consultations. Studies and planning exercises will provide Toronto Hydro with valuable and detailed information with respect to how to introduce the new technology into the current system and to ensure it is compatible with Toronto Hydro's business processes. Specific issues and initiatives that will be considered include the development of safety, control and operating practices, as well as a determination as to what is the optimal design, location, specifications and controls for the integration of reclosers.

Toronto Hydro plans to install reclosers at a pace of approximately eight units per year over the 2017 to 2019 period. The installation of reclosers follows from Toronto Hydro's general outlook for grid modernization and represents proactive, necessary and timely efforts to reduce the impact of momentary interruptions in the system. The program will continue beyond 2019, targeting stations that are experiencing a high number of momentary interruptions.

Figure 7 provides a map of the areas of the city that are the proposed focus of this program over the 2017 to 2019 period; these areas were selected because of the high frequency of momentary outages experienced on these feeders.

FIGURE 7: RECLOSER INVESTMENT FOR 2017-2019

E7.4.4.1 Ranking & Prioritization

The prioritization of work in the Overhead Momentary Reduction program will take into account both the historic performance of feeders and results of the study that will be performed in 2015 and 2016. The study will determine the capability of existing stations circuit breakers to be coordinated and work together with reclosers. It is Toronto Hydro's intention to target feeders with the highest number of momentary interruptions in the past three years in order to minimize outages.

Assuming a successful completion of the technology study, Toronto Hydro will eventually introduce recloser technology across the entire distribution system, but will first target feeders that experience the highest number of momentary interruptions over the 2015 to 2019 period.

E7.4.5 Program Execution

The installation of reclosers will include the replacement of poles onto which reclosers will be installed. The installation of new poles may require pole framing and conductor replacement. As

well, the coordination of reclosers with both upstream and downstream equipment will have to be performed.

Protection coordination is crucial for the proper operation of the reclosers within the time-current curves of the breaker and downstream fuses. Coordination with other protection devices is important in order to ensure that the faults are localized into small sections to minimize disruptions of supply to customers. Without this coordination, a recloser will operate as a regular switch instead of the using its full capabilities, thereby failing to reduce the number of momentary and sustained interruptions.

E7.4.5.1 Proposed Work Plan

Table 5 represents the 2017-2019 Long Term Plan investment on the Toronto Hydro Stations.

TABLE 5: 2015-2019 LONG TERM PLAN

Year	Station
2017	Richview TS
2017	Warden TS
2018	Warden TS
2018	Leslie TS
2019	Leslie TS
2019	Dufferin TS

E7.4.5.2 Program Risks

The following are risks to program completion that Toronto Hydro considers when planning and executing the installation of reclosers.

One potential risk is stakeholder coordination. Timely communication and coordination with HONI will be crucial for the completion of the recloser installation. Toronto Hydro owns 61% of the circuit breakers within the City of Toronto. The remaining 38% are owned by HONI. To establish communication between breaker and reclosers, the settings at the station breaker must be adjusted, and Toronto Hydro will rely on HONI's cooperation to establish coordination with their breakers. This risk will be mitigated by engaging HONI early in the process, specifically while the study is performed.

E7.4.6 Evaluation of Alternatives

E7.4.6.1 Quantification/Evaluation of Options

(i) Status Quo

By maintaining the status quo, Toronto Hydro would continue to monitor and evaluate feeders that experience many momentary interruptions and will perform maintenance work to help mitigate the number of outages. This work includes tree trimming, insulator washing, the installation of animal guards, infrared scans and other activities. While maintenance activities can help prevent some momentary interruptions, Toronto Hydro anticipates that interruptions will continue to be a significant reliability concern.

(ii) Installation of Reclosers

Introducing reclosers into the feeder circuit will give Toronto Hydro the flexibility to sectionalize and isolate permanent faults to drastically minimize the effect of interruptions. This option is recommended because it is the only course of action that provides the benefits discussed throughout the narrative and addresses the serious issues facing customers with respect to momentary and sustained interruptions.

The cost of ownership (COO) and program net benefit (NPV) associated with the Overhead Momentary Reduction program is further detailed in Table 6. The cost of ownership is established for both the existing state (COO_E), and the proposed new state (COO_N) based on the first year of activities within this program. The cost of ownership (COO) of a state reflects the risk of asset failure including both direct and indirect costs. These costs including customer interruptions, emergency repairs, and asset replacements associated with that design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_N) state. Non-asset risks are further explained in Section D3.3. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ΔCOO_1) is compared to the associated program costs (PC_1) for the first of activities, the Overhead Momentary Reduction program produces a net benefit (NPV_1) value of $5.76 million, as shown in Table 6 and Table 7.

TABLE 6: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E]	63.54
Non Asset Risk [NAR_E]	375.69
Maintenance Cost [MC_E]	
Additional Quantifiable Benefits [AQB_E]	
Cost of Ownership of Existing Assets [COO_E]	439.23

TABLE 7: OVERHEAD MOMENTARY REDUCTION BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: Overhead Momentary Reduction (N)	
Asset Risk [AR_N]	60.90
Non Asset Risk [NAR_N]	371.93
Maintenance Cost [MC_N]	
Additional Quantifiable Benefits [AQB_N]	
Cost of Ownership of New Assets [COO_N]	432.83
Option 1: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	6.40
Program Cost [PC_1]	0.64
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	5.76

E7.5 Handwell Upgrades

E7.5.1 Summary

Program Description

The Handwell Upgrades program completes the activities previously described in the Ontario Energy Board (OEB) approved Handwell Replacement segment as part of Toronto Hydro's 2012-2014 rate filing. Toronto Hydro's Handwell Upgrades program replaces (i) existing legacy handwells made of conductive material (i.e., a concrete body and metal cover) with new non-conductive handwells, and (ii) secondary conductors between handwells. Using these new composite handwells removes the risk of handwells becoming energized due to defective conductor connections within. Replacing secondary conductor between handwells and reconnecting conductors with water tight connectors renews the old conductors that are operating beyond their useful lives. It also helps protect the connection point from roadside contaminants

Table A summarizes the benefits associated with the Handwell Upgrades program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Reliability	ƒ The non-conductive handwell, together with new secondary conductor and water tight connections, will mitigate the risk of interruptions to the street lighting secondary supply source caused by contact voltage or corroded/loose connections.

Efficiency	ƒ Toronto Hydro will able to reduce the frequency of scheduled contact voltage scans across the city.
Safety	ƒ Minimizes the risk of contact voltage harming individuals, pets and wildlife.

Program Drivers

The Handwell Upgrades program is primarily driven by the safety issues associated with the risk of contact voltage. As established in previous rate filings, Toronto Hydro considers handwells to be a critical safety issue, and as such, this program has been positioned within the System Service category. The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Safety	x Contact voltage on handwells, poles, street fixtures and sidewalk surfaces poses a safety risk to the public. In the City of Toronto, on both November 20, 2008 and January 13, 2009, pet fatalities occurred because the animals came into contact with energized assets. Toronto Hydro also received reports of children and pets receiving contact voltage shocks in early 2009.
Secondary Driver	**Reasoning**
Functional Obsolescence	x Older legacy handwells that are made of conductive material are not able to safely house secondary conductors. x The handwell body is conductive and wire connections inside were made using connectors that, due to corrosion and water damage over time, may become exposed and come into contact with the handwell lid or body. This results in contact voltage on the handwell, pole, street fixtures or the sidewalk surface.

Preferred Alternative

The Handwell Upgrades program analyzed and evaluated the following options:

(i) Do nothing and accept the safety risks associated with metallic, conductive handwells

(ii) Proactive Replacement of metallic handwells with new non-conductive ones

Option II is the preferred alternative as it mitigates the existing public safety hazard.

Timing and Pacing

The number of units replaced and project costs have varied over the years because, in some locations, Toronto Hydro needed to undertake civil construction in order to address collapsed ducts or the fact that some existing conductors are direct-buried (i.e., they were not installed in ducts); these activities delay completion times and introduce additional expenses.

In terms of project execution, secondary conductors between handwells are replaced at the same time as the handwells themselves, unless additional civil construction is required to install or rebuild conduits. Where additional civil construction is needed, the conductors are replaced after the civil work is completed. Table C provides the estimated costs of the program for the 2015-2019 period.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	21.1	32.9	12.6	11.7	16.2	4.98	-	-	-	-

E7.5.2 Program Description

Handwells are used to supply 120 V power to street lights, bus shelters and signs, etc. Toronto Hydro began replacing all existing handwells following the Level III emergency in 2009, after children and pets received shocks from contact voltage originating from faulty handwells. At the start of the handwell replacement program in 2010, Toronto Hydro estimated that there were approximately 11,700 handwells in the field. However, during program execution, Toronto Hydro determined that, as of the end of 2013, there are more than 13,000 handwells. These additional locations were found by crews while performing handwell replacement work.

The replacement work that began in 2010 continued as part of the Incremental Capital Module (ICM) within Toronto Hydro's 2012-2014 IRM Filing. This work was subsequently approved by the Ontario Energy Board (OEB). Toronto Hydro forecasts to have replaced all but 723 existing handwells with new, non-conducting composite handwells by the end of 2014. Toronto Hydro iplans to complete replacement of those remaining 723 existing handwells not addressed in prior years.

Most of the remaining 723 locations are in the downtown area. Work will involve replacing existing handwells with new handwells made of non-conducting composite material. Any existing handwells that are found to be empty are physically removed and the vacated space filled.

FIGURE 1: NON-CONDUCTIVE HANDWELL

Existing secondary conductors between handwells will be replaced if possible. If the site condition does not allow for the replacement of conductors during the handwell replacement work

(due to a collapsed conduit or existing direct buried conductor), the location will be marked for follow-up work where civil construction will likely be needed to install new conduit between handwells. All new electrical connections in the handwell will be made using a water tight connector as shown in Figure 2.

FIGURE 2: NEW HANDWELL WATER TIGHT CONNECTOR

The following table summarizes the expected benefits of this program.

TABLE 1: SUMMARY OF PROGRAM BENEFITS

Reliability	ƒ The non-conductive handwell, together with new conductor and water tight connections, reduces interruptions due to contact voltage or corroded/loose connections.
Efficiency	ƒ Removes need for Toronto Hydro to allocate significant amount of resources for contact voltage mitigation after the program is completed. ƒ Allows for adjustment to the frequency of scheduled contact voltage scans across the city, which potentially reduces maintenance costs.
Safety	ƒ Minimize the risk of contact voltage on city property from handwells

E7.5.3 Why the Program is Needed

Handwells made of conductive materials, including concrete bodies and metallic lids, have been shown to be a potential a source of contact voltage. Compromised electrical connections inside a handwell can energize the handwell and surrounding area through either direct contact with the handwell or through salt water accumulated in the handwell, which acts as a conducting medium. During the contact voltage emergency, all handwells were inspected for damage and wiring connections in handwells and hand holes in street lighting poles were re-connected where possible using new water tight connections to mitigate the immediate risk.

Contact voltage may appear on the following locations on the street:

- Sidewalk surface
- Metallic or concrete poles installed on energized sidewalk
- Signs mounted on energized sidewalk
- Handwells made of a concrete body or with a metallic cover

Following the Level III emergency, Toronto Hydro launched a citywide program to replace all existing handwells with non-conductive material as well as replacing conductors between handwells to ensure long term risk from contact voltage due to existing obsolete hardware is removed. To further enhance the integrity of the electrical connection from water seepage into the live conductor, all new electrical connections in handwells are made using water tight connectors as shown in Error! Reference source not found. The lug with wires connected is fully inserted into a gel filled pouch to ensure full blockage of any water contact with the live conductors.

E7.5.3.1 Program Drivers

Table 2 presents the trigger and secondary drivers for Secondary Upgrades program. This program is primarily driven by the safety issues associated with the risk of contact voltage. A secondary driver is functionally obsolete due to the design of these assets. As established in previous rate filings, handwells are a critical issue to Toronto Hydro, and as such, this program has been positioned within the System Service category.

TABLE 2: PROGRAM DRIVERS

Tigger Driver	Reasoning
Safety	Potential Public Safety Risk: ƒ Contact voltage on handwells, poles, street fixtures and sidewalk surfaces is a safety risk to the public. In Toronto, there were pet fatalities caused by contact voltage on November 20, 2008 and January 13, 2009. Toronto Hydro also received reports of children and pets receiving contact voltage shocks in early 2009. ƒ There has been a reported case of human fatality as a result of contact voltage in the city of New York.
Secondary Driver	**Reasoning**
Functional Obsolescence	ƒ Older legacy type handwells that are made of conductive material such as metal lid or concrete body are not able to safely house secondary conductors. ƒ The handwell body is conductive and wire connections inside were made using connectors that, over time, due to corrosion and water damage, may become exposed and come in contact with the handwell lid or body. ƒ This results in contact voltage on the handwell, pole, street fixtures or the sidewalk surface.

Saltwater enters handwells during the winter season where salt is spread on the sidewalks to melt the snow.

Between 2008 and 2009, two dogs were fatally shocked and incidents of risk to children by contact voltage in the City of Toronto. In response, Toronto Hydro declared a level III emergency in early 2009 to study and mitigate the safety risks associated with contact voltage across the city. During the contact voltage emergency, all handwells were inspected for damage, and wiring connections in handwells and hand holes in street lighting poles were re-connected where possible using new water tight connections to mitigate the immediate risk.

Contact voltage may occur at the following locations on the street:

- ƒ sidewalk surface,
- ƒ metallic or concrete poles installed on energized sidewalk,
- ƒ signs mounted on energized sidewalk, and
- ƒ handwells made of a concrete body or with a metallic cover.

Following the Level III emergency, Toronto Hydro launched a city-wide program to replace all handwells with ones made of non-conductive material and to also replace conductors between handwells in order to eliminate the long-term safety risks associated with the obsolete hardware. To further protect the electrical connection from water seepage into the live conductor, all new electrical connections in handwells are made using water tight connectors as shown in Figure 2.

(i) Safety

Handwells installed on city sidewalks are used as junction boxes to safely contain electrical connections that supply power to street lights or road fixtures such as crosswalk signs, bus shelters and advertising signs. Historically, electrical connections in handwells were made using a split bolt wrapped in layers of polyvinyl chloride tape and self-amalgamating plastic in order to protect the connections from coming into contact with the handwell body or the metal lid, which could produce contact voltage on the surface.

Toronto Hydro discovered that over time, seasonal freezing and thawing cycles of water in the handwells can damage the tape and loosen the electrical connection inside, eventually exposing the live conductor (as shown in Figure 3 below). As previously mentioned, the live conductor can energize the handwell. The energized handwell may in turn, energize the pavement and fixtures in the area, creating a serious safety hazard.

FIGURE 3: EXPOSED CONDUCTOR

(ii) Functional Obsolescence

Toronto Hydro determined that existing handwells with concrete bodies and/or metal lids were functionally obsolete because these assets are unable to reliably and safely house sidewalk secondary connections. The typical useful life for concrete handwells is approximately 50 years. These assets degrade thorough exposure to road contaminants such as water, dirt and salt, which leads to corrosion of reinforcing steel, spalling of concrete and rusting of covers. Independent of whether an existing handwell has exceeded this life expectancy, as previously described, Toronto Hydro has determined that all existing handwells composed of a concrete body and metal lid present a safety concern and are functionally obsolete.

Secondary conductors installed underground are constantly exposed to water and soil contaminants that degrade their insulation strength. Over time, insulation jackets can break down and result in short-circuit and failure of the conductor. The normal useful life of these secondary conductors is 20 to 25 years. Toronto Hydro plans on renewing secondary conductors at the same time as it replaces remaining handwells.

E7.5.4 Timing & Pacing of the Program

As noted previously, Toronto Hydro has been replacing legacy handwells with new non-conductive handwells since 2009. By the end of 2014, Toronto Hydro expects to replace almost all of the existing handwells with the new design. The remaining 723 handwells are scheduled to be replaced by the end of 2015.

TABLE 3: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	21.1	32.9	12.6	11.7	16.2	4.98	-	-	-	-
Number of handwells replaced	3,127	2,476	2,127	1,828	2,500	723	-	-	-	-
Number of handwells removed	534	637	319	126	0	0	-	-	-	-

The number of units replaced and project costs have varied over the years because in some locations, Toronto Hydro needed to undertake civil construction in order to address collapsed ducts or the fact that some existing conductors are direct-buried (i.e., they were not installed in ducts); these activities delay completion times and introduce additional expenses. The cost for 2010 and 2011 are higher because after the cessation of Level III emergency, Toronto Hydro started to replace existing metallic handwell covers with Tiercon plastic lids as an immediate measure to remove the risk of contact voltage hazard to the public. In addition there was followup repair work that needed to be performed on defects that were identified during the Level III emergency. Some of these items involved: Installation of street lighting fuse; repair faulted underground cable; and replacement of defective street lighting poles.

The forecasted number of handwell removals (as opposed to replacements) for 2014 and 2015 is currently zero, as Toronto Hydro is unable to determine whether a handwell has been abandoned until crews physically open the unit in the field. Therefore, Toronto Hydro assumes that all remaining handwells will require replacement.

E7.5.4.1 Ranking & Prioritization

Toronto Hydro expects to replace all remaining legacy handwells by the end of 2015.

E7.5.6 Program Execution

Toronto Hydro will organize the work to be conducted through this program by location. In each location, Toronto Hydro will need to excavate a small portion of the sidewalk in order to remove the existing handwell before the new handwell is installed. Conductors between handwells are also expected to be replaced at the same time if they can be easily removed. In cases where the conductor between handwells is directly buried in-ground or the conduit between handwells has collapsed, the conductor replacement will occur after the necessary civil construction work is completed.

Where follow-up civil construction is required to install new conduits between handwells, design work and city approval will be required before the construction takes place. Any handwell found to be abandoned and empty will be physically removed from the sidewalk and the vacated space will be filled.

As these conductors primarily supply power to street lights, bus shelters or street banner signs, interruption of power during construction will not have a significant impact on the public.

E7.5.6.1 Program Risks

The timing and costs of replacements will be impacted by the amount of civil work that is required. Follow-up civil work will require additional design and approval time, and may also be impacted by City moratoriums.

E7.5.7 Evaluation of Alternatives

E7.5.7.1 Evaluation of Options

Toronto Hydro considered two alternatives, maintain the status quo or proactively replace handwells.

(i) Option 1: Status Quo

By maintaining the status quo, Toronto would take a reactive approach to handwell replacements. More specifically, it would respond to contact voltage incidents as they occur and would only replace units following a reported incident of contact voltage. Toronto Hydro does not recommend using this reactive approach because it introduces potential public safety risks.

(ii) Option 2: Proactive Replacement

Under this option, Toronto Hydro would proactively replace metal handwells with non-conductive handwells, and would replace the conductors between handwells and connections with water tight connectors. Proactive replacement of handwells is the preferred option as this approach will mitigate existing potential public safety hazards.

APPENDIX A: Execution CHALLENGES

As previously discussed in Section B of this schedule, when executing its capital program Toronto Hydro must be prepared to respond to circumstances "on the ground" in order to make the most efficient use of resources and ultimately deliver the best value for its customers. From a planning point of view, this means that the utility must be able to substitute, defer and add projects in the annual work program in any given year to accommodate the operational realities that it experiences in the course of its work program.

This appendix describes aspects of Toronto Hydro's services territory that add complexity to the execution of large capital projects.

1. Weather and the natural environment

A number of unpredictable work execution challenges arise due to severe weather and conditions that exist in the natural environment. These challenges are difficult to assess in advance of undertaking projects and planned work.

Weather

Unpredictable weather events have the potential to impact work execution in two ways. One is that extreme weather (e.g. very cold or very hot temperatures) over a prolonged period can cause projects to be delayed. Second, severe weather such as extreme wind, ice, and rain events can cause wide-spread damage to Toronto Hydro's distribution system and necessitate the redirection of crews from planned work to emergency storm restoration activities.

An example of a prolonged weather pattern that impacted Toronto Hydro's ability to execute planned work was the cold experienced during the 2013-2014 winter. Due to frost, snow, and ice, utilities are generally challenged to conduct civil and pole installation work during winter months. To manage this reality, Toronto Hydro conducts significant amounts of civil work in the lead up to winter and then does not schedule much civil work until winter conditions subside. Given that the 2013-2014 winter was particularly long and cold, resulting in frost settling deep into the ground, civil work was substantially delayed in 2014. The long winter not only impacted capital projects but also maintenance programs such as insulator washing that cannot be conducted in cold temperatures.

Examples of severe weather events causing damage to Toronto Hydro's distribution system occurred on October 29, 2013 (i.e. Hurricane Sandy) and December 21, 2014 (i.e. the 2013 Ice

Storm). In response to the damage caused by these severe weather events, Toronto Hydro redirected all available crews, including crews working on planned projects and programs, to emergency storm restoration activities. In any given year, the amount of time and delay caused by severe weather can vary but can equate to weeks of construction time across all projects as evidenced in 2013, where planned work was delayed due to flooding in July, strong winds in August and October, and the ice storm in December. Some of the delays were overcome by working overtime at an increased cost to individual projects.

The Natural Environment

The natural environment can create challenges due to issues that may involve soil conditions, ground water, and vegetation. Prior to work execution, Toronto Hydro attempts to plan for the natural environment and mitigate associated risks. However, it is not uncommon for even the most prudently planned projects to be delayed due to challenges associated with the natural environment.

One set of challenges that are encountered are related to the soil conditions found on sites where planned projects are being conducted. For example, it is not uncommon for Toronto Hydro to encounter shale while installing poles. When identified, shale must be removed using a jackhammer causing delays and increased costs. Toronto Hydro tries to mitigate the risk of unexpected shale using test pits prior to commencing work. These test pits require additional site visits and are costly. As a result, it is prudent for Toronto Hydro to only undertake such costs if there is a reason to believe that soil conditions are abnormal.

Another risk related to soil conditions is soil contamination. The removal and disposal of contaminated soil can be particularly costly and can delay projects if identified during work execution. An example of a where this did occur is the Strachan TS Civil Egress project. This project was required to construct cable chambers and underground conduits from Hydro One's Strachan TS to Manitoba Drive. When construction commenced, contaminated soil was discovered and the additional cost for soil testing, removal, and disposal was $400,000.

A second set of challenges associated with the natural environment is excessive ground water. Although de-watering needs are anticipated for many projects including those that are undertaken close to Lake Ontario, these needs can significantly exceed estimates and contingencies. In some cases, de-watering specialists need to be called in during work execution as excessive and unanticipated water levels delay the project and increase costs. Further complications can arise if soil is contaminated and de-watering is required. Finally, Toronto Hydro may need to obtain a

permit from the City of Toronto to pump water out and to release it in the City's sewer system. An example of excessive de-watering needs occurred during the civil construction work associated with the Copeland TS project. Some of the conduits and cable chambers being built as part of this project resulted in an additional $375,000 for excessive de-watering.

Beyond the de-watering challenges described above, complications can also arise with de-watering that is required following heavy rains. For example, the heavy rain on July 9, 2013 and the flooding that ensued caused work at a number of Toronto Hydro's construction sites across the City to stop until de-watering could be completed. Project schedules as a result were generally delayed for approximately four days each.

A third set of challenges associated with the natural environment is related to vegetation, specifically trees. Many of Toronto Hydro's overhead and underground construction projects have the potential to negatively impact trees and as part of the design and estimating process, Toronto Hydro takes into consideration precautions to protect trees. These precautions are often conditions of obtaining permits and approvals from the City of Toronto. These conditions are enforced by City inspectors that may visit sites during construction. In many cases, precautions must be expanded upon or altered during work execution based on conditions that are identified at the time. For example, Toronto Hydro may need to dig deeper, alter trench routes, or construct unplanned tree tunnels during work execution to avoid damaging a tree. These requirements can and do result in delays and additional costs.

2. External Stakeholders

Work execution challenges often arise as a result of external stakeholder needs, preferences, requests, and actions. External stakeholders include the City of Toronto, Toronto Hydro's customers, Hydro One, and a wide variety of other organizations and individuals that have an interest in the work that Toronto Hydro undertakes. Challenges that are related to external stakeholders can greatly impact project and program schedules and costs as illustrated by the examples that follow.

The City of Toronto

A significant stakeholder in all work that Toronto Hydro undertakes is the City of Toronto. The vast majority of Toronto Hydro's assets are located on City road allowances and co-exist with City (e.g. water and sewer systems, roads, sidewalks) and other utility (e.g. telecommunications, gas lines) and non-utility (e.g. TTC) infrastructure. To enable the efficient management of road

allowances, the City has implemented a number of co-ordination, permitting, and approval processes that have the potential to influence work execution, schedules, and budgets.

An example of how the City's processes can impact work execution is road moratoria that are implemented following City road improvement projects. (Moratoria are implemented pursuant to the City's Municipal Consent Requirements for the Installation of Plant Within City of Toronto Streets.) Depending on the type of road (e.g. road, curb, sidewalk) improvement that the City undertakes, utilities such as Toronto Hydro will not be granted permits to conduct subsequent construction work for a period of three to 10 years.

In situations where the City advances or provides short notice for road improvements, Toronto Hydro must re-prioritize work to ensure that projects that are planned in the short and medium terms are completed before a moratorium goes into place. A specific example of this is work that Toronto Hydro planned in the Hogg's Hollow area of Toronto. Plans were to initially execute the work in five sequential phases. When the City announced that it was moving forward with road improvement work, Toronto Hydro brought forward the execution of the fifth phase to avoid a road moratorium after 2013. Re-prioritizing projects in this manner can force the deferral of another project and has the potential to increase costs depending on whether the project must be undertaken by a different contractor or resource group.

Another example is work that Toronto Hydro had to conduct as a result of a series of City projects (e.g. granite sidewalk retrofit; water main replacement) in the vicinity of Bay and Bloor Streets. During one project, Toronto Hydro was given only three months to complete its work and during another project, Toronto Hydro had to rebuild an overhead pole line during the Christmas season. Typically, work in this area is constrained as restrictions to only work certain hours of the day, to only occupy a certain length of street at a time, to minimize disruption to local business, and to eliminate work during rush hour are in place. Given the tight timelines imposed, Toronto Hydro had to obtain noise exemptions from City and crews had to work overtime resulting in costs that would not otherwise have been required. Another project on Asquith Avenue in the same vicinity needed to be delayed entirely and was only completed in 2014 as a result of City work in the area.

On many occasions, challenges that arise as a result of City requests do not result in delays or additional costs, but instead result in a need to advance costs from one year to the preceding year. One example is a voltage conversion project south of Bloor Street. Initially, Toronto Hydro had planned to finish the project by May 1, 2014 when the City asked for the project to be

completed by March 31, 2014 due to a planned water main and sewer replacement project. To accommodate the City's request, Toronto Hydro started construction in the last quarter of 2013 and advanced more than $200,000 of expenditures into 2013. Another example is a project to replace direct buried cable on Starview Lane and Rockbank Crescent in the Weston Road and Sheppard Avenue area. To avoid a scheduling conflict with other City's water main and sewer work, Toronto Hydro advanced an additional $250,000 into 2013.

Customers

A second set of stakeholders that can introduce unexpected challenges during work execution are customers and members of the public. Although Toronto Hydro undertakes significant customer engagement activities (e.g. informational letters, town hall meetings, responses to requests for accommodation) before and during planned work, and although the vast majority of Toronto Hydro's customers are supportive and very reasonable when work is being undertaken in proximity to their homes and businesses, incidents and challenges do arise.

One example is the aforementioned set of projects at Bay and Bloor Streets in downtown Toronto. During one project, pedestrian control in the area became so challenging that Toronto Hydro had to increase the budgeted number of paid duty police officers from one to two. In addition, one of the buildings along the project route started renovations at the same time that Toronto Hydro's project was to be executed. The building's contractors installed scaffolds outside the building for two months and this prevented Toronto Hydro from commencing its project during this time.

Hydro One Networks

Toronto Hydro is supplied by Hydro One Networks and owns equipment at 34 transformer station sites that are owned by Hydro One Networks. The equipment at station sites is tightly integrated and the two companies must closely coordinate planned work. At times, even the best efforts and plans cannot fully mitigate the risk that challenges will arise and delays will occur.

3. Operating Environment

Work execution challenges that are brought on by the Operating Environment relate to issues that arise as a result of working within congested underground utility corridors that are shared with other service providers such as the City of Toronto's Water Division, natural gas and telecom companies. This includes past tenants or users of the space that now makes up the corridors.

These challenges, as illustrated below, can greatly influence Toronto Hydro's ability to execute work on schedule and on budget.

Ageing Infrastructure

Challenges often arise due to the need to work around ageing infrastructure that is often owned by third parties (or Toronto Hydro). One example of this is water and sewage lines. Around these lines, Toronto Hydro utilizes specialized excavation techniques such as vac-truck digging to mitigate the risk of damage. However, ageing lines have at times broken open despite the use of these techniques and have caused water or sewage spills that delay projects and increase costs.

A particular example of the unexpected failure of water and sewage lines during the execution of a Toronto Hydro project occurred on Laird Drive in East York. As illustrated in Figure 1, a sewer line was uncovered and during the project, the line began to leak as a result of a defective fitting. The fitting needed to be replaced and the line needed to be supported during the construction of the duct bank.

FIGURE 1: SEWAGE LINE UNCOVERED DURING DUCT BANK CONSTRUCTION

As part of the same project, a water line was also uncovered while constructing a new cable chamber. This water line began to leak and water migrated into the chamber as shown in Figure

2. These two issues caused weeks of delays in the construction schedule of the Laird Drive project.

FIGURE 2: WATER LINE LEAK FLOODING CABLE CHAMBER DURING CONSTRUCTION

Another particular example occurred where Toronto Hydro needed to construct a duct structure well below an old existing water main. This main can be seen at the bottom of the trench in Figure 3. During excavation, the water main broke. (Water can be seen running in the trench in Figure 3.) The main had to be repaired and supported by chains, which caused delays and additional costs in the project.

FIGURE 3: WATER MAIN LEAK AT THE BOTTOM OF A TRENCH

Beyond ageing water and sewer infrastructure, challenges also arise during work execution in the vicinity of telecommunication infrastructure and even Toronto Hydro's own infrastructure. For example, older telecom cables were buried directly into the ground without concrete encasings as found during a recent project on Toresdale Avenue in North York. Precautions to mitigate the risk of damage to in-service cables during the Toresdale Avenue project added to costs and if damage had occurred, would have resulted in delays. Precautions must also be taken with Toronto Hydro's own infrastructure, which often must be supported and maintained in functional condition throughout a project. The following figures illustrate live cables being supported during construction projects.

FIGURE 4: IN-SERVICE CABLE BEING SUPPORTED AS A LARGE CABLE CHAMBER WAS RE-CONSTRUCTED IN THE AFOREMENTIONED LAIRD DRIVE PROJECT.

FIGURE 5: IN-SERVICE CABLES BEING SUPPORTED DURING A VAULT RE-BUILD AT WELLINGTON AND EMILY STREETS IN DOWNTOWN TORONTO.

FIGURE 6: IN-SERVICE CABLES BEING SUPPORTED DURING A VAULT RE-BUILD AT 390 BAY STREET IN DOWNTOWN TORONTO.

The complexity of some of these work sites and the necessity to support at times ageing and deteriorated assets can lead to issues arising, delays in work schedules, and increased costs.

Undocumented Sites and Infrastructure

During work execution, it is not uncommon for Toronto Hydro to encounter sites and infrastructure that are not documented or difficult to anticipate. Some of these discoveries can be accommodated within the scope of a project. However, some are particularly unique and result in unavoidable delays and costs. Discoveries often cause projects to be placed on hold as they necessitate investigations, project redesigns, and new permits.

One example of a unique discovery during work execution is an unregistered archaeological site that was found on Scenic Hill Court in Scarborough. The discovery was made during an underground civil construction project and resulted in a four-month delay in the project.

A second example of a unique discovery is an old undocumented gas pipe that was found during a system expansion project to supply new customer load. The project was replacing an overhead single circuit steel pole line with a new double circuit wood pole line. When an old cast iron pipe was discovered, pole installation was halted and a subsequent investigation revealed that the pipe was an abandoned gas main. Enbridge was contacted and approval to break out the

abandoned gas main at the proposed new wood pole locations was obtained. The impact of the abandoned pipe, which included breaking out the pipe at 28 pole locations, resulted in an addition $120,000 expenditures and approximately three weeks of delay.

E7.6 Polymer SMD-20 Switch Renewal

FAILED SMD-20 SWITCH

E7.6.1 Summary

Program Description

The Polymer SMD-20 Switch Renewal program completes the SMD-20 replacement program that was created as part of the incremental capital module (ICM) and approved under the 2012-2014 IRM filing submission.

Polymer SMD-20 switches are used to mount SMU-20 fuse units onto distribution poles. SMU-20 fuse units protect the upstream circuit and equipment from faults that occur on the circuit downstream of the fuse units. SMD-20 switches must be manually operated by Toronto Hydro with a loadbreak tool, which necessitates the use of a significant amount of manual force. In 2011, there were two incidents of SMD-20 switches breaking while being operated by Toronto Hydro crew members. These incidents prompted Toronto Hydro to conduct a comprehensive failure analysis study. Based on the results of this study and the manufacturer's own analysis, it was determined that a defect in the switch weakens the insulator, which leads to failure of the asset. Consequently, Toronto Hydro concluded that its SMD-20 switches installed from 2006 to 2011 are defective and require immediate replacement.

Table A summarizes the anticipated benefits associated with the Polymer SMD-20 Switch Renewal program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improves restoration times ƒ Reduces the potential for property damage from broken switches
Reliability	ƒ Reduces the need to install a switch when a fault occurs, reducing outages by two hours per switch **ƒ** Potential mitigation of 33,564 CHI
Safety	ƒ Reduces the risk of injury to field crew due to falling broken pieces ƒ Reduces the risk of arcing and flashover **ƒ** Reduces the risk of injury to the public and property from falling pieces
Efficiency	ƒ Can open and close on load without the need to de-energize ƒ Field crews can focus on refusing and fault location without the added task of replacing the SMD-20 switch

/C

Program Drivers

Polymer SMD-20 switches manufactured between 2006 and 2011 are defective and require replacement for safety and reliability reasons. The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Safety	**ƒ** The high probability of SMD-20's failing poses safety hazards for Toronto Hydro crews. **ƒ** When switches break, pieces of the unit can fall on Toronto Hydro crews operating the loadbreak tool underneath. As well, Toronto Hydro crews are exposed to flashover. **ƒ** The safety issues listed above can also extend to the public, as the fracture of the switch can occur without direct contact if there is a substantial load applied to it. Similarly, pieces can fall and injure the public and property that are in close proximity.
Secondary Drivers	**Reasoning**
Substandard Performance	**ƒ** The asset has been identified by the manufacturer, S&C Electric Ltd., as being inherently defective. ƒ The switch has a high probability of breaking apart under normal operating conditions and within its own technical specifications.
Reliability	**ƒ** When an outage occurs causing the fuse to blow on a defective SMD-20, the entire unit must be replaced instead of just the fuse, prolonging the outage to affected customers by two hours for single phase switches and by 3.5 hours for three phase switches.

Preferred Alternative

The Polymer SMD-20 Switch Renewal program analyzed and evaluated the following options:

(i) Replace the Defective SMD-20 Switches Reactively

(ii) Replace the Defective SMD-20 Switches Proactively

Option II is the preferred alternative as it will eliminate all safety and operational risks that are associated with defective SMD-20 switches and improve reliability seen to customers.

Timing and Pacing

All necessary replacements will be made in 2015. The aggressive replacement schedule is necessary so that Toronto Hydro can alleviate the safety and reliability risks that the system is currently exposed to in a timely manner. Without immediate action, operational difficulties will continue because switches will continue to fail. Table C provides the estimated costs of the program for the 2015-2019 period.

E7.6.2 Program Description

The Polymer SMD-20 Switch Renewal program will continue the replacement activities that were initiated as part of the Ontario Energy Board (OEB) approved Polymer SMD-20 Switches segment of Toronto Hydro's 2012-2014 ICM application. The projects to be undertaken under this program are identical in nature to the jobs included in the 2012-2014 filing. Toronto Hydro plans to complete the replacement of defective SMD-20 switches by the end of 2015 at a total cost of $4.84million. The program will first target switches on feeders with the worst reliability and will then replace the remaining switches. Table 1 shows the number of assets to be replaced by asset class.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS

Asset (Units)	2015	2016	2017	2018	2019	Total
1-Phase Units	407	-	-	-	-	407
3-Phase Units	751	-	-	-	-	751

IC

The 1,158 defective switch locations that remain in Toronto Hydro's distribution system are made up of 407 single phase locations and 751 three phase locations (which consist of three switches clustered together). As such, a total of 2,660 discreet SMD-20 switching units is targeted for replacement as part of this program.

IC

The locations of switches that are scheduled to be replaced are illustrated in Figure 1 below.

/C

FIGURE 1: MAP OF THE REMAINING DEFECTIVE SMD-20 SWITCH LOCATIONS IN THE SYSTEM

As illustrated in Figure 2, Polymer SMD-20 switches are used to mount SMU-20 fuse units on overhead distribution poles. The SMU-20 fuse is designed to interrupt fault current caused by equipment downstream of the fuse on the distribution system, and is necessary to protect assets from the impacts of fault current, overloading, and to isolate faulted equipment from the feeder. The SMD-20 switches are used as isolation and restoration devices to the lateral section of the circuit by opening and closing the switch. In order to operate these switches for isolation, restoration or to access or replace a fuse on the switches, Toronto Hydro crews must manually operate the switches using an eight foot loadbreak tool. The SMD-20 switch is comprised of an insulator, latch and hinge assembly and the SMU-20 fuse unit. The insulator isolates the live components of the circuit from the pole. The latch and hinge assembly holds the SMU-20 fuse unit and is designed to allow the fuse to swing open if blown. The SMU-20 fuse unit houses the fuse and allows it to interface with the SMD-20 switch by the latch and hinge assembly.

FIGURE 2: SMD-20 SWITCH

In 2011, there were two incidents of SMD-20 switches breaking apart while being operated by field crews. An investigation concluded that the switches had a manufacturing defect, causing them to fail by breaking apart under the stress applied during normal operation. It was determined that switches manufactured from 2006 to 2011 were defective and require replacement (section E7.6.3.1 provides further details on the switching defects and investigation).

A proactive replacement program was approved by the OEB as part of the incremental capital module (ICM) within the 2012-2014 rate filing to replace the defective SMD-20 switches with newly designed SMD-20 switches that utilize a fiberglass core with five times the breaking strength of the old design (Figure 3). These switches can endure the physical load that is placed on them when operated. Installation of the new switches mitigates the functional, safety and reliability issues posed by the defective switches.

FIGURE 3: COMPARISON OF NEW DESIGN AND OLD DESIGN

Program Benefits

Replacing defective SMD-20 switches provides value to Toronto Hydro customers by improving reliability and mitigating safety risks with respect to individuals and property. As well, by proactively replacing these switches, Toronto Hydro is able to mitigate the risk of extended customer outages associated with the reactive replacement of defective switches. Failure risks associated with SMD-20 switches are further detailed in section E7.6.3.1.

The installation of the new generation SMD-20 switches provides several efficiency advantages for fuse coordination and isolation and restoration. The switch was designed to open and close while the circuit is loaded; it can safely break an energized circuit using the loadbreak tool and can close back onto load using a hotstick tool. A properly operating switch can be operated immediately after a fault is repaired while the defective switch requires removal and replacement with a new switch. The opening and closing of a switch is shown in Figures 4 and 5.

FIGURE 4: LOADBREAK TOOL OPENING AN SMD-20 SWITCH

FIGURE 5: HOTSTICK CLOSING SMD-20 SWITCH

Crews are able to quickly isolate and restore the circuit downstream of the SMD-20 switch whereas other technologies might require another method of isolation. Also, the SMD-20 switch makes fuse replacement simple, since a crew on the ground can unhook it from the switch using the loadbreak tool, as opposed to other fuse designs where crews must physically uninstall the entire switch via a bucket truck. A properly operating SMD-20 switch also automatically opens when the fuse is blown. This not only provides additional protection to clear a fault, but also

provides a visual cue to Toronto Hydro crews when patrolling to assist in determining fault location. Crews are able to limit their fault search to downstream of the fuse location. Finally, the newly designed SMD-20 switch features alternating diameter sheds that helps prevent bridging in wet and polluted environments. The watersheds help prevent contamination from building up which can cause a flashover.

A summary of benefits is provided below in Table 2. A number of these benefits are discussed in further detail in Section E7.6.3.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ	Improves restoration times
	ƒ	Reduces the potential for property damage
	ƒ	The difference in the cost of ownership between existing and renewed assets ($\hat{u}COO_1$) for the first year of the program is $11.5 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.6.7).
	ƒ	Accounting for capital program costs, the first year's activities deliver a positive NPV_1 of $6.7 million, confirming the economic prudence of the investments (see Section E7.6.7).
Reliability	ƒ	Reduces the need to install a switch when a fault occurs, reducing outages by two hours per switch
	ƒ	Potential mitigation of 33,564 CHI
Safety	ƒ	Reduces the risk of injury to field crew due to falling broken pieces
	ƒ	Reduces the risk of arcing and flashover
	ƒ	Reduces the risk of injury to the public and property from falling pieces
Efficiency	ƒ	Can open and close on load without the need to de-energize
	ƒ	Field crews can focus on refusing and fault location without the added task of replacing the SMD-20 switch

E7.6.3 Why the Program is Needed

Polymer SMD-20 switches manufactured between 2006 and 2011 are defective and require replacement for safety and reliability reasons.

E7.6.3.1 Program Drivers

Table 3 summarizes the trigger and secondary drivers for the Polymer-SMD-20 Switch Renewal program. This program is a System Service initiative with a trigger driver is safety.

TABLE 3: PROGRAM DRIVERS

Trigger Driver	Reasoning
Safety	ƒ The high probability of SMD-20s failing poses safety hazards for Toronto Hydro crews. ƒ When switches break, pieces of the unit can fall on Toronto Hydro crews operating the loadbreak tool underneath. As well, Toronto Hydro crews are exposed to flashover. ƒ The safety issues listed above can also extend to the public, as the fracture of the switch can occur without direct contact if there is a substantial load applied to it. Similarly, pieces can fall pose a risk to the public.
Secondary Drivers	**Reasoning**
Substandard Performance	ƒ The asset has been identified by the manufacturer, S&C Electric Ltd., as being inherently defective. ƒ The switch has a high probability of breaking apart under normal operating conditions and within its own technical specifications.
Reliability	ƒ When an outage occurs causing the fuse to blow on a defective SMD-20, the entire unit must be replaced instead of just the fuse, prolonging the outage to affected customers by two hours for single phase switches and by 3.5 hours for three phase switches.

In order to open the SMD-20 switch safely under load, a loadbreak tool that attaches to the switch and is manually pulled open by a field crew is required. The SMD-20 switch can be closed using a standard hotstick. Its design guides the switch closed within several inches and the switch is finally closed with a purposeful thrust. The force of the operation, in combination with the defect inherent in SMD-20s manufactured between 2006 and 2011, has caused a high probability of failure when these switches are used.

A failed switch can be seen in Figure 6. After the two failure incidents occurred in 2011, a failure analysis was initiated to investigate the cause. Fourteen SMD-20 switches were randomly selected from the Toronto Hydro warehouse for testing. Out of the 14 random switches selected, 13 failed in less than 10 operations. Details of the study can be found in Phase 1 of Toronto Hydro's 2012-2014 rate filing[1]. The manufacturer, S&C Electric Ltd., also conducted a study on their own, reaching the same conclusions as Toronto Hydro, that the SMD-20 switches are defective.

[1] EB-2012-0064, Application and Evidence (May 10, 2012), at Tab 4, Schedule B7, Page 7.

FIGURE 6: FAILED SMD-20 SWITCH

Figure 7 shows a failed switch prior to and after operation. The root cause of the SMD-20 failures was determined to be a small crack located internally in the polymer core material. This crack creates a weak point in the insulator core, causing it to break when force is applied, such as when the loadbreak tool is used. The crack was determined to be due to a manufacturing defect and could have resulted from improper mold temperature, mold fill speed or improper core handling prior to silicon over-molding during the manufacturing process.

FIGURE 7: BEFORE AND AFTER SWITCH OPERATION DURING TESTING

The crack in the polymer core is covered by the outer silicon housing, which prevents the defect from being detected in the field. Figure 8 shows the outer silicone housing over the core where a potential crack could be covered.

FIGURE 8: FAILED SMD-20 SWITCH

Since the first incident in September 2011, awareness of the issue has grown among utilities within the province. Bulletins have been published by the distributor of the switches (November

28, 2011), Toronto Hydro (November 9, 2011), Electrical Safety Authority (December 9, 2011) and the manufacturer (November 30, 2011) (See Appendix A). The insulator of the SMD-20 is bolted onto the pole and serves to isolate the live circuit from the pole and to maintain the switch's structure so that it can be operated safely. The nature of the defect causes the insulator to shear while the operating force is applied the switch, meaning that if when switch breaks, pieces of the switch could fall below onto a crew member or could be projected onto property nearby, such as parked cars.

Defective SMD-20s may also arc as the switch breaks apart, potentially causing a flashover – a safety hazard that could subject Toronto Hydro crews to risk of injury. These hazards also extend to any members of the public in the area. As well, the failure of a switch extends outage restoration time as the entire switch must be replaced in order to correct the problem instead of simply replacing the fuse.

As of 2015, Toronto Hydro expects that there will be 2,660 defective switches remaining in the distribution system at 1,158 locations. These defective switches can potentially cause interruptions for up to 26,455 customers, resulting in up to 40,809 CHI as shown in Table 4. On average, each location has the potential to interrupt 23 customers, contributing to 35 CHI. An SMD-20 on a single phase lateral can add an additional two hours of outage time to a lateral fault, while an SMD-20 on a three-phase lateral can add an additional three-and-a-half hours. ***IC***

TABLE 4: TOTAL ACCUMULATED RELIABILITY

E7.6.4 Timing & Pacing of the Program

As per the table below, this program is expected to cost $4.84 million in 2015.

TABLE 5: HISTORICAL AND FUTURE SPENDING

Toronto Hydro has been proactively removing defective SMD-20 switches since 2013, targeting feeders that have historically experienced a large number of outages since they are more likely to experience faults going forward. This program continues replacement of the SMD-20 switches through the final year of the three year program, such that, by the end of 2015, Toronto Hydro expects all defective SMD-20 switches will be replaced. The aggressive replacement schedule is necessary so that Toronto Hydro can alleviate the safety and reliability risks that the system is currently exposed to in a timely manner. Without immediate action, operational difficulties will continue because switches will continue to fail.

E7.6.4.1 Ranking & Prioritization

Toronto Hydro continues to prioritize the replacement of defective SMD-20 switches by giving weight to the number of outages that had occurred historically on the relevant feeders in order to minimize the risk that a defective switch would need to be operated or replaced reactively.

E7.6.5 Program Execution

The switches that need to be replaced have been grouped by geographical location in order to make replacement efforts more efficient and easier to coordinate. This form of grouping allows the control room to more effectively manage the replacement work as opposed to having to manage multiple locations scattered throughout the distribution system. Addressing defective switches in clustered locations improves the cost-efficiency of the program by allowing crews to spend more time on actual replacement rather than travel time.

In order to replace the defective switches, a field crew will disassemble the defective switches using the load disconnect tool, which allows the crews to bypass the SMD-20 switch being replaced. Using this approach, crews can install a new switch and transfer over the customer load without requiring an outage to connected customers.

E7.6.5.1 Program Risks

This program will address 1,103 switch locations system-wide. In some locations, it may be difficult to obtain permits if other work is being done by other city utilities at the same time. In addition the Pan Am Games set to take place in 2015 have introduced certain restrictions with respect to working on areas that are being used as a route for the games. These issues could delay the scheduling of certain portions of this program. Toronto Hydro will take these issues into account when scheduling the replacements.

Another program risk is that some poles may be in worse condition than indicated in Toronto Hydro's records and may require replacement – including re-installation of all attached equipment – while changing out the SMD-20 switch. Replacing the poles would increase costs and further strain resources that are needed to complete this program; however, Toronto Hydro does not anticipate that this would prevent the successful completion of the program.

E7.6.5.2 Standard & Regulation Adherence

The manufacturer has developed a new polymer insulator design that incorporates a fiberglass core that provides greater flexibility and has an ultimate bend strength that is five times greater than the old SMD-20 switch design. The manufacturer also improved their production testing and quality assurance policies and procedures. Toronto Hydro has also initiated a quality assurance and vendor management program for this product by increasing the audit count, introducing vigorous test report reviews and revising construction standards, specifications, and quality procedures. These measures will significantly reduce the probability of future defective switches being installed into the system.

The testing criteria of the Institute of Electrical and Electronics Engineers (IEEE) C37.41, which is the standard for design testing on disconnecting cut-out type switches, is to operate the switch 67 times at the manufacturing stage to ensure quality of operation. Ten of the newly designed SMD-20 switches were randomly selected and each one successfully operated 70 times without failure, indicating that they are not defective.

E7.6.6 Evaluation of Alternatives

E7.6.6.1 Quantification/Evaluation of Options

(i) Option 1: Replace the Defective SMD-20 Switches Reactively

Under this option, the defective SMD-20 switches would be replaced reactively after they fail in the field. This alternative involves lower capital expenditures in the short-term as compared to proactively replacing all of the switches. However, this course of action would delay the replacement of all defective SMD-20 switches currently in the field, subjecting Toronto Hydro crews and the public to safety risks associated with this equipment. Furthermore, customers will continue to experience prolonged outages when a defective switch fails and requires replacing.

(ii) Option 2: Replace the Defective SMD-20 Switches Proactively

Under this option, Toronto Hydro would continue the previously approved program to proactively replace all defective switches. This recommended course of action will eliminate all of the safety and operational risks that are associated with defective SMD-20 switches.

The cost of ownership (COO) and program net benefit (NPV) associated with the Polymer SMD-20 Switch Renewal program is further detailed in Table 6. The cost of ownership is established for both the existing state (COO_E) and the proposed new state (COO_N) based on the first year of planned activities within this program. The cost of ownership (COO) of a state reflects the risk of asset failure including both direct and indirect costs. These costs include customer interruptions, emergency repairs, and asset replacements associated with a given design. In addition, the risk that non-asset failures contribute to a particular design is included in both the existing (NAR_E) and proposed (NAR_N) state. Non-asset risks are further explained in Section D3.3. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3.

TABLE 6 : COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

When the difference in cost of ownership ($\hat{u}COO_1$) is compared to the associated program costs (PC_1) for the first of activities, the Polymer SMD-20 Switch Renewal program produces a net benefit (NPV_1) value of $6.7 million, as shown in Table 7. /C

TABLE 7: POLYMER SMD-20 SWITCH RENEWAL BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (Millions)	
Difference in Asset Risk **[$\hat{u}AR = AR_E - AR_N$]**	$9.2	/C
Difference in Non Asset Risk **[$\hat{N}AR = NAR_E - NAR_N$]**	$2.3	/C
Difference in Cost of Ownership **[$\hat{C}OO_1 = (COO_E – COO_N) = \hat{u}AR + \hat{N}AR$]**	$11.5	/C
Program Cost [PC_1]	$4.8	/C
Program Net Benefit [$NPV_1 = (\hat{C}OO_1 – PC_1)$]	**$6.7**	/C

E7.6.7 2015 Projects

Table 8 shows the total program cost for 2015. The costs are broken into capital expenditure amounts associated with:

- previously filed projects that appeared as jobs in the OEB approved Polymer SMD-20 Switches segment as part of Toronto Hydro's 2012-2014 Incremental Capital Module (ICM) filing; and
- projects appearing for the first time as part of the 2015-2019 Customer Incentive Rate-setting (CIR) application.

TABLE 8: 2015 PROGRAM COSTS

2015 CAPEX ($M)	
ICM Projects	CIR Projects
1.56	3.28

E7.7 Downtown Contingency

FEEDER TIES

E7.7.1 Summary

Program Description

The objective of the Downtown Contingency program is to provide load transfer capability between stations in the downtown area. There are currently 15 stations and 557 13.8 kV feeders spread out throughout the downtown area, and only 15 of these feeders, or about 3%, have inter-station feeder ties. The lack of inter-station feeder ties in Toronto's downtown area means that there is currently a significant and unmitigated risk that a large number of customers could experience long duration outages due to station loss of supply, which can be caused by events such as station flooding and catastrophic equipment failure, as well as loss of supply from the transmitter. Mitigation of this risk will effectively enhance the customer value derived from existing assets by minimizing failure risks of the existing downtown dual-radial configuration.

Toronto Hydro plans to establish inter-station feeder ties for all 557 13.8 kV feeders in the Toronto downtown area. This is accomplished by tying feeders from one station to adjacent feeders from another station.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improved outage restoration times ƒ Reduces likelihood of business customer monetary losses due to loss of supply ƒ Reduces likelihood of business closure due to loss of supply

Reliability	ƒ Provides alternate power supply to customers where none presently exists.
Safety	ƒ Provides alternate power supply to customers that depend on it for their health and safety, such as those relying on life-support equipment.
Efficiency	ƒ Ability to remotely transfer the load from one station to another.

Program Drivers

Between August 2003 and July 2013, there were 17 major station outage events in the downtown area, with an average interruption time of 8.2 hours per event. These outages resulted in an average annual customer interruption cost (CIC) of $12.4 million. If inter-station feeder ties had been installed and available to pick-up these customer loads, the number customer hours interrupted (CHI) would have been reduced by 86%.

The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVER

Trigger Driver	Reasoning
Reliability	ƒ Significant and unmitigated risk of customers experiencing long outages due to station loss of supply.
Secondary Drivers	Reasoning
Operational Constraints	ƒ During station outage conditions, Toronto Hydro is unable to efficiently and quickly restore power to customers. ƒ Inability to transfer load between adjacent stations on temporary or permanent basis.
Safety	ƒ The loss of power supply can put certain customers at risk, such as those that rely on life-support equipment. ƒ The loss of power supply during extreme weather events can put customers at risk.

Preferred Alternative

Toronto Hydro considered the following alternatives for addressing the contingency risks associated with feeders lacking inter-station feeder ties downtown.

(i) Maintaining the status quo: Toronto Hydro would not resolve issues which are imminent and therefore leave customers with excess risk and potentially reduced reliability.

(ii) Purchase mobile equipment: An alternative to the status quo includes the use of mobile generators/switchgears or inter-feeder ties. The use of mobile equipment is not feasible due to its high capital and maintenance costs as well as unsuitability for fully resolving contingency issues.

(iii) Downtown Contingency program: install inter-station feeder ties across the downtown area where they are currently lacking.

The use of inter-station feeder ties is recommended because it is the only option that will provide Toronto Hydro with the capability to restore supply to most of its downtown customers under outage conditions, thereby fully mitigating loss-of-supply risk to the extent feasible.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $3.07 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.7.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $2.33 million, confirming the economic prudence of the investments (see Section E7.7.7).

Timing and Pacing

The timing of the Downtown Contingency program was established to ensure continuing progress on this long-term program while balancing resource usage with other system investment priorities during the 2015 to 2019 period.

The proposed program would allow transfer of customer loads on feeders between:

- Dufferin TS & Cecil TS
- Dufferin TS & Strachan TS
- Dufferin TS & Wiltshire TS
- Basin TS & Carlaw TS

Investments begin in 2016 to allow for necessary HONI transformer replacements.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	1.09	4.66	0.05	1.09	1.04	0	0.74	0.74	1.00	0.88

E7.7.2 Program Description

The Downtown Contingency program involves the installation of inter-station feeder ties between distribution feeders located in various stations in the downtown area of Toronto. At the present time, there are 15 stations and 557 13.8 kV feeders spread out throughout the downtown area. Only 15 of these feeders, or about 3%, currently have inter-station feeder ties. Table 1 lists the six inter-station feeder-ties that will be established through the Downtown Contingency program during the 2015 to 2019 planning period.

TABLE 1: SIX INTER-STATION FEEDER-TIES

Feeder	Station
A204BN & A250E feeders	Basin & Carlaw stations
A273DN & A57W feeders	Dufferin & Wilshire stations
A256DN & A34W feeders	Dufferin & Wilshire stations
A257DN & A230T feeders	Dufferin & Strachan stations
A530DN & A390CE feeders	Dufferin & Cecil stations
A254DN & A390CE feeders	Dufferin & Cecil stations

Typically, the downtown area is setup so that 500 kVA to 10 MVA load customers are supplied by two 13.8 kV radial feeders from the same transformer station (TS) switchgear. One feeder acts as the primary feeder while the other operates on a stand-by basis. During an outage to a normal feeder, the stand-by feeder supplies power to the affected customers. Figure 1 illustrates the downtown dual radial distribution feeder design. As the figure shows, each TS supplies its customers independently, and none of the station feeders have ties with the adjacent station's feeders. As a result, under some contingency conditions, such as complete or partial station outages, this configuration leads to lengthy customer outages while Toronto Hydro repairs the station.

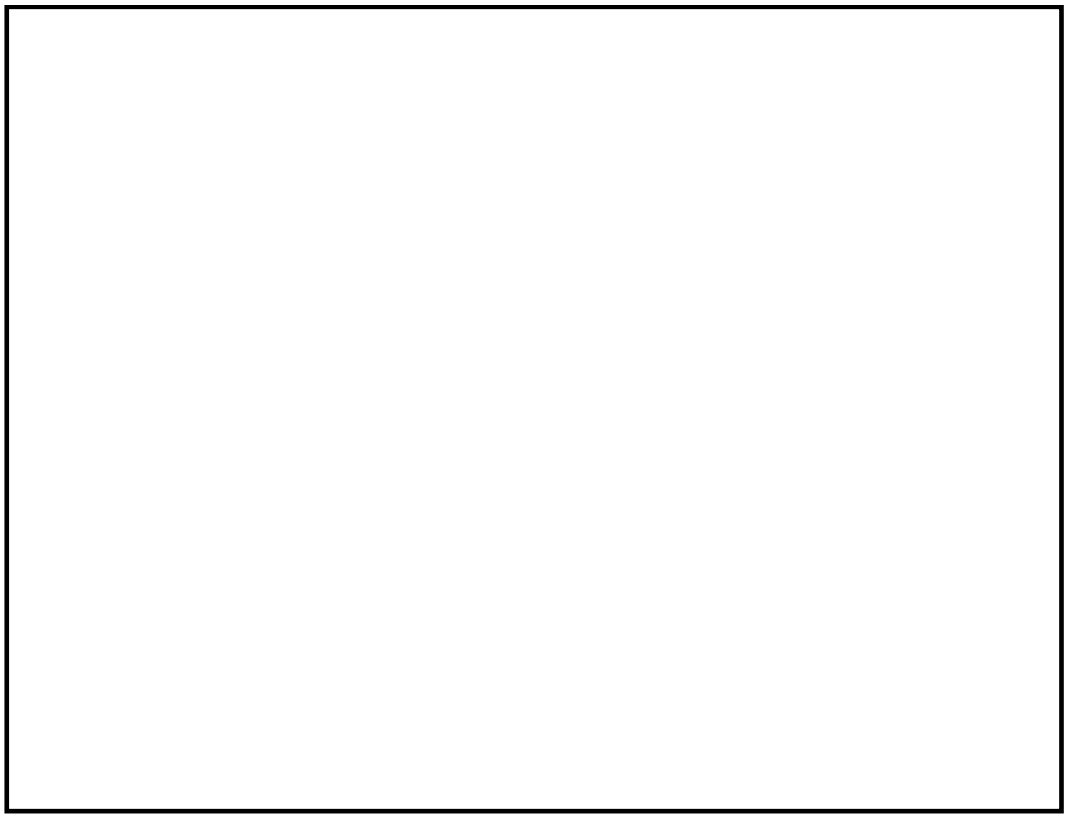

FIGURE 1: DUAL RADIAL DISTRIBUTION DESIGN UTILIZED IN TORONTO DOWNTOWN AREA

In contrast, outside of the downtown Toronto, the distribution system is configured as an open loop design. An open loop system incorporates many ties between feeders; in particular, it includes ties between feeders housed in different stations. As a result, contingency situations do not typically lead to lengthy outages because most areas can be quickly re-supplied by an alternative station when necessary. Figure 2 illustrates how the downtown Toronto example can be modified to gain the benefits of the design used outside of the downtown core.

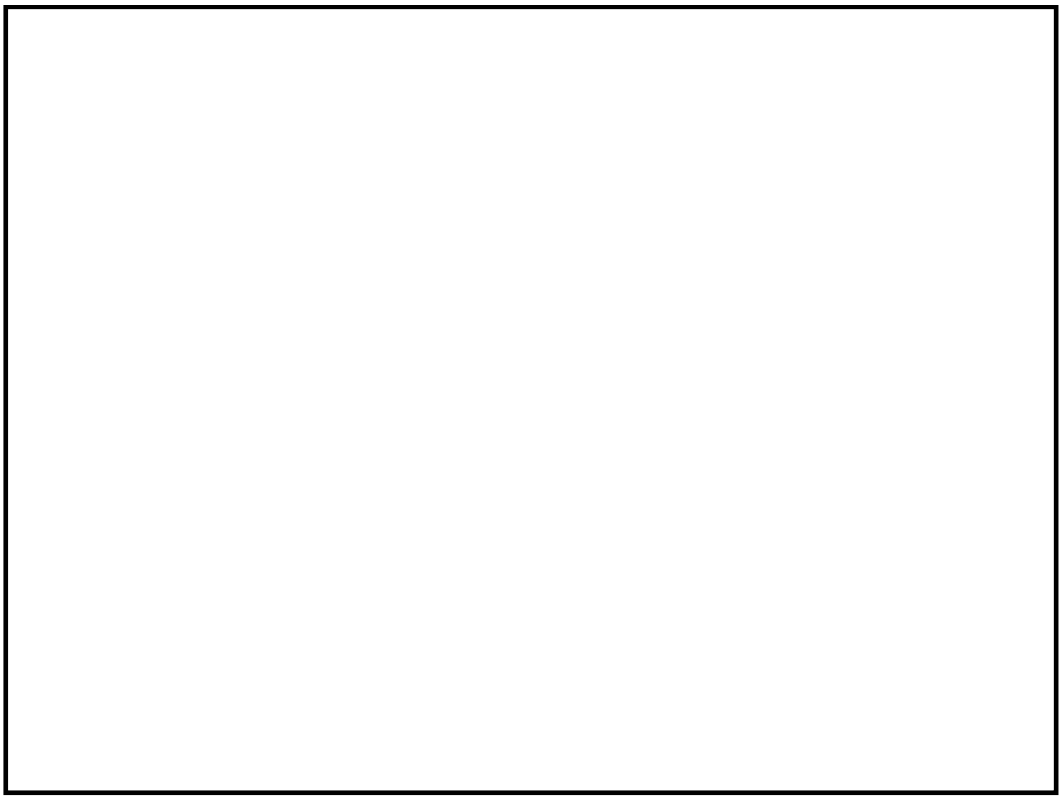

FIGURE 2: DOWNTOWN AREA INTER-STATION FEEDER –TIES DESIGN WITH REMOTE CONTROLLED SWITCHES

Toronto Hydro plans to execute six discrete Downtown Contingency projects between 2015 and 2019, similar in nature to the example above, between the following transformer stations (TS) and municipal stations (MS):

- Basin TS and George & Duke MS (one project)
- Dufferin TS and Cecil TS (two projects)
- Dufferin TS and Strachan TS (one project)
- Dufferin TS and Wiltshire TS (two projects)

Toronto Hydro plans to spend an estimated $3.36 million on the Downtown Contingency program between 2015 and 2019. Figure 3 shows the locations of the six proposed feeder tie projects.

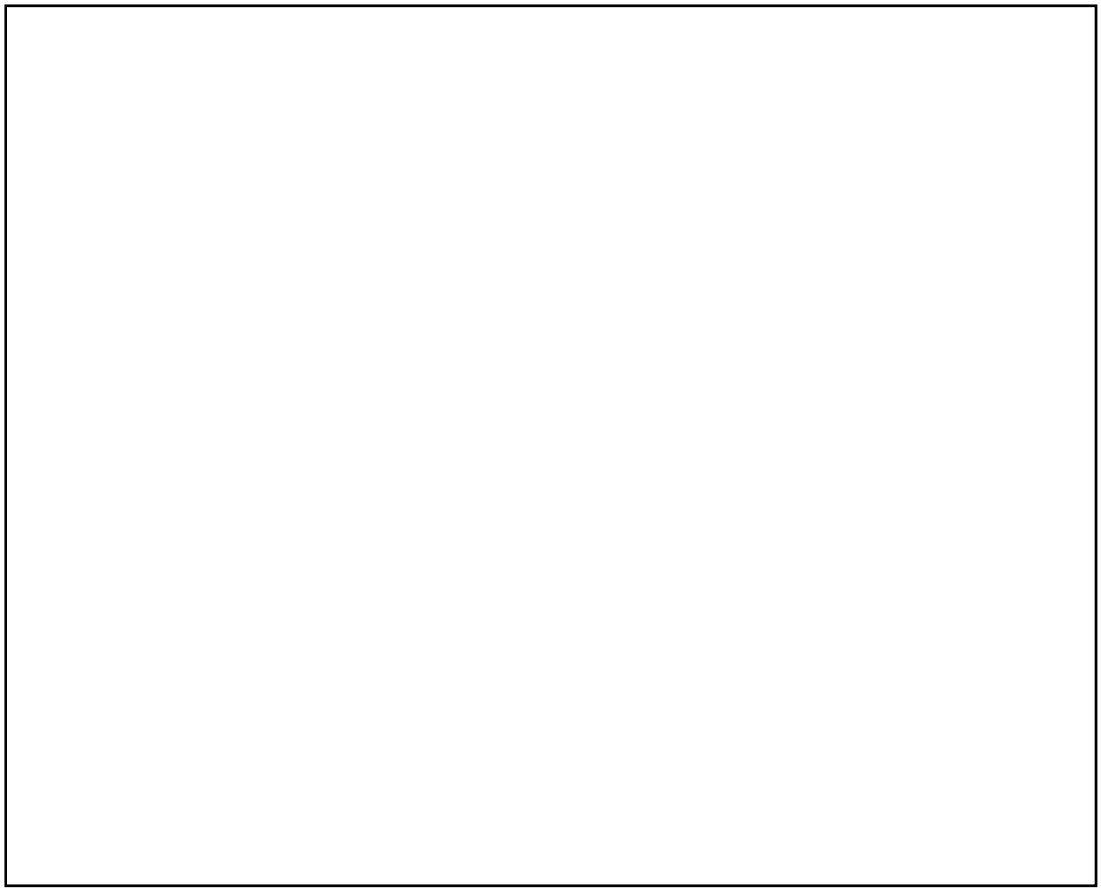

FIGURE 3: INTER-STATION FEEDER-TIE PROJECTS

This program involves the use of new assets and/or the replacement of existing assets in order to provide load transfer capabilities between the adjacent stations. The major assets of the program are tabulated in Table 2 below and include underground (UG) and overhead (OH) switches as well as UG cable and OH conductor.

TABLE 2: ASSETS ADDED / REPLACED BY ASSET CLASS

Assets (Units)	2015	2016	2017	2018	2019	Total
UG Switch	0	0	0	1	0	1
OH Switch	0	4	2	2	2	10
UG Cable (km)	0	0.1	0.6	1.3	3.0	5
OH Conductor (km)	0	0.35	0.2	1.3	0.02	1.87

The Downtown–Contingency program is expected to improve overall system efficiency through optimized distribution system management. With the installation and commissioning of inter-station feeder ties, power system controllers will have the ability to remotely transfer the load from one station to another in the downtown area of Toronto, optimizing management of the distribution system during planned work and unplanned emergency situations. Through this program, inter-station feeder ties will be provided remote operable switches that are under the control of the power system controllers. Using this configuration, the expected service restoration time would drop from an average of 8.2 hours to approximately one hour, providing a significant benefit to affected customers.

A summary of the program's benefits is provided below.

TABLE 3: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Improved outage restoration times for downtown customers ƒ Reduces likelihood of inventory losses due to loss of supply (eg: frozen good, perishables). ƒ Reduces likelihood of business closure due to loss of supply. ƒ The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $3.07 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.7.7). ƒ Accounting for capital program costs, the first year's activities deliver a positive NPV of $2.33 million, confirming the economic prudence of the investments (see Section E7.7.7).
Reliability	ƒ Provides alternate power supply to customers where none presently exists. ƒ Provides the ability to address virtually any station loss of supply incident, including flooding, equipment failure, HONI loss of supply, damage caused by third parties and environmental impairment.
Efficiency	ƒ Improves overall system efficiency through optimized distribution system management. Ability to remotely transfer the load from one station to another.
Safety	ƒ Provides alternate power supply to customers that depend on it for their health and safety, such as those relying on life-support equipment.

E7.7.3 Why the Program is Needed

The Downtown Contingency program is needed to mitigate the loss of supply risks related to partial or complete station outages in the downtown area of Toronto. Toronto Hydro plans to mitigate these risks by executing inter-station feeder-tie projects that will provide sufficient distribution load transfer capability during partial or complete station outages.

E7.7.3.1 Program Drivers

Table 4 provides the trigger and secondary drivers of the Downtown Contingency program, with the trigger driver being the need to mitigate critical risks to system reliability.

TABLE 4: PROGRAM DRIVERS

Trigger Driver	Reasoning
Reliability	ƒ There is significant, unmitigated risk of customers experiencing long outages due to station loss of supply incidents.
Secondary Drivers	**Reasoning**
Operational Constraints	ƒ During partial or complete station outage conditions, Toronto Hydro is unable to efficiently and quickly restore power to customers. ƒ Toronto Hydro is currently unable to transfer load between adjacent stations on temporary or permanent basis.
Safety	ƒ The loss of power supply for an extended time can put certain customers at risk, such as those that rely on life-support equipment. ƒ The loss of power supply during extreme weather events can put customers at risk.

(i) Reliability

The primary objective of the Downtown Contingency program is to address the risk of customers in the downtown area facing lengthy service disruptions caused by low probability, high impact events such as partial or complete station failure. All six inter-station feeder tie projects in the 2015 to 2019 program are expected to allow Toronto Hydro to remotely transfer loads to adjacent station feeders within one hour, resulting in reliability improvements for customers on these feeders.

While major downtown contingency incidents are infrequent, the occurrence of one would have a significant impact on system reliability if feeder ties are not out into place. In the past decade, seventeen partial and complete station outages have occurred in the downtown area, which have resulted in a total CHI of 1,369,668 (see Table 5). These represent a significant portion of all of the major loss of supply incidents that have ever occurred in downtown Toronto.

For example, in January of 2009, Dufferin TS was completely shut down because HONI's fire suppression system flooded the station; this incident was responsible for 626,692 CHI that year (62% of all downtown CHI) and 34,308 CI. Some customers were left without electricity for up to

24 hours. In all, this outage incident ranks as the worst loss of supply incident in the last ten years.

The most recent downtown contingency incident took place in July of 2013. Flooding at Richview station triggered an outage in Manby station, which in turn caused HONI supply failures at Strachan, Wiltshire, and Windsor stations. The incident resulted in a total of 33,875 CI and 50,777 CHI.

TABLE 5: DOWNTOWN CONTINGENCY OUTAGES AUGUST 2003 THROUGH JULY 2013

DATE	CMO (Customer Minutes Out)	CHI (Customer Hours of Interruption)	CI (Customers Interrupted)	OUTAGE DURATION (Minutes)	STATION NAME	OUTAGE CAUSE
14-Aug-03	22,272,720	371,212	9,010	2,472	Dufferin TS	Loss of supply -TS flooding
01-Dec-03	1,573,297	26,222	10,021	157	Main TS	Loss of supply - Raccoon on Main TS Transformer - T3

04-Dec-04	9,960	166	60	243	Windsor TS	Loss of supply - TS Equipment failure
23-Jan-05	2,304,288	38,405	3,556	632	Terauley TS	Flooding of T S basement - City water main broken
26-Jul-05	4,603,904	76,732	24,005	1,850	George & Duke MS	Loss of supply - TS Equipment failure
23-Aug-07	1,625,517	27,092	4,971	327	Glengrove TS	Defective Station Equipment
27-Nov-07	1,023,984	17,066	6,564	156	George & Duke MS	Loss of supply - Outage on HONI J1-J2 Ring bus @ Esplande TS
15-Jan-09	37,601,491	626,692	34,308	1,418	Dufferin TS	Adverse Environment
09-May-09	2,443,452	40,724	18,511	132	Dufferin TS	Loss of supply - Raccoon contact with T2 transformer

DATE	CMO (Customer Minutes Out)	CHI (Customer Hours of Interruption)	CI (Customers Interrupted)	OUTAGE DURATION (Minutes)	STATION NAME	OUTAGE CAUSE
09-May-09	1,104,831	18,414	8,307	133	Dufferin TS	Loss of supply - Raccoon contact with T2 transformer
05-Jul-10	4,022,761	67,046	36,984	138	Strachan TS	Loss of supply - Explosion @ Manby TS
08-Jul-13	1,083,808	18,063	15,271	76	Strachan TS	Loss of Supply - Manby & Richview TSs flooding
08-Jul-13	1,721,744	28,696	14,851	134	Wiltshire TS	Loss of Supply - Manby & Richview TSs flooding
08-Jul-13	241,052	4,018	3,753	68	Windsor TS	Loss of Supply - Manby & Richview TSs flooding
Total	82,180,054	1, 369,668	196,447	8,369		

In the incidents above, if inter-station feeder ties were available to transfer loads within one hour, the CHI would have been reduced from 1,369,668 to 196,447, an 86% improvement as illustrated in Figure 4 below.

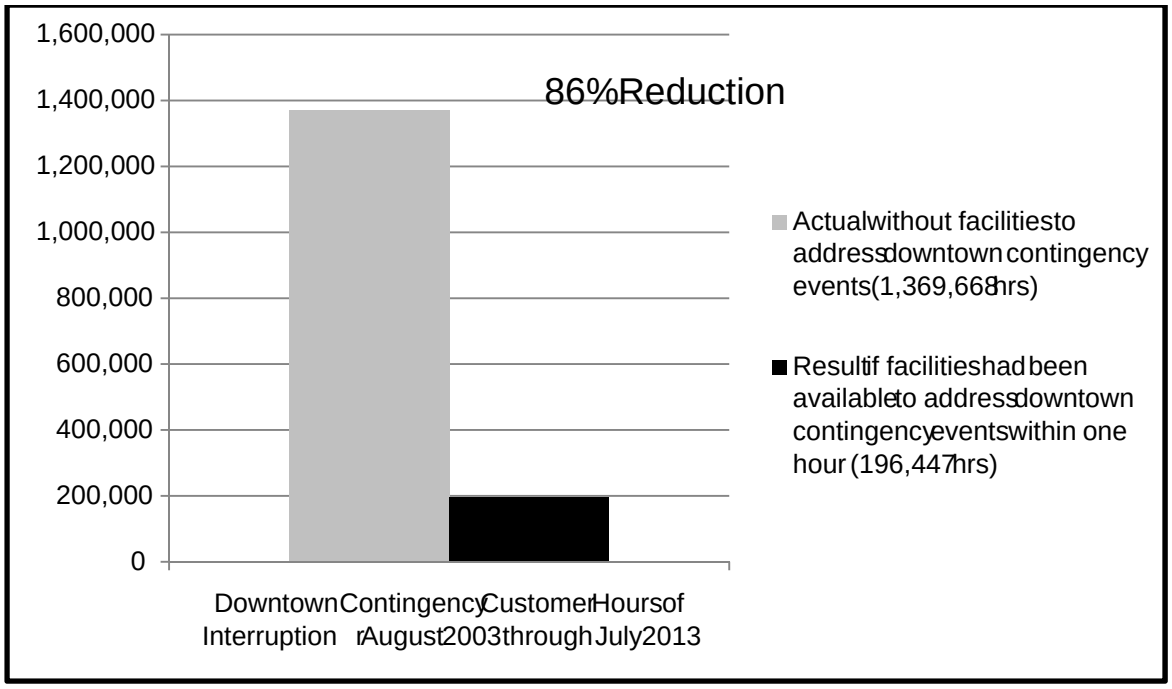

FIGURE 4: RELIABILITY IMPACT OF DOWNTOWN STATION LOAD TRANSFER IMPLEMENTATION

The fact that virtually all of the major loss of supply incidents have occurred in the last decade indicates that conditions in and around the 15 downtown stations are worsening as time progresses. Most of these incidents are due to flooding incidents, which are largely random and unpredictable, but can have considerable impacts. Historically, most flooding incidents were due to failure of man-made water systems. However, the three flooding incidents that occurred in 2013 were all due to extreme weather events. Climate change models for the Toronto area suggest that extreme weather conditions are likely to occur more frequently in future years, increasing the urgency to mitigate this risk. The only method of ensuring that such failures in the downtown area do not affect downtown customers is to introduce back-up supply through inter-station feeder ties.

(ii) Operational Constraints

The provision of inter-station feeder ties will provide new operational capabilities in the downtown area of Toronto, similar to what already exists in other parts of Toronto Hydro's system. Improvements to system operational efficiency and power restoration time will be enabled through the use of remote operable switches under the control of power system controllers, and

field crews will not need to be dispatched to perform switching operations for contingencies. Service restoration times are forecast to improve from a historic average of 8.2 hours interruption following a loss of supply event, to approximately one hour.

The Downtown Contingency program is also expected to enable Toronto Hydro to respond to both station and feeder capacity constraints that are not associated with loss of supply incidents. An example is urgent reactive maintenance work that must be performed on station equipment. Such work typically requires a portion of station equipment to be taken out of service, and may result in overloading the remaining equipment or feeders. Downtown Contingency inter-station feeder ties provide the ability to offload station equipment under such conditions.

(iii) Safety

The Downtown Contingency program is expected to improve the overall safety of the distribution system. In the event of a feeder fault, controllers would have the ability to remotely isolate and transfer a feeder load to another station and quickly re-supply customers with power. This will mitigate the consequence of long term outages to customers. Over the last ten years, Toronto Hydro's longest station outage was over 41 hours.

The customers most at risk from long term service interruptions are those electronic medical support equipment. Such equipment generally has battery back-up that can sustain service for several hours following a service interruption. A lengthy outage would almost certainly result in the failure of such equipment and could potentially put customers' health at risk.

The utility keeps track of life-support customers in a master list and, during service interruption situations, takes special actions to ensure their continued wellbeing, such as providing emergency generators. However, as enrollment in this program is voluntary, Toronto Hydro may not be aware of all affected customers.

Similarly, hospitals have many patients that could be put at risk in the event of lengthy power outages. Although hospitals have back-up generators, they typically have no more than one day's supply of fuel on hand. Finally, the loss of power during the winter and summer months can potentially pose safety risks to customers, as they depend on heating and cooling systems to moderate the temperate. In particular, seniors, infants, the disabled and people who are ill may face heightened risk.

Downtown Contingency inter-station feeder ties provide is expected to enable Toronto Hydro to restore service in about one hour during contingency situation. This outage duration is generally short enough to mitigate the majority of the above noted safety risks.

E7.7.4 Timing & Pacing of the Program

As per the table below, the total cost of the program over the 2015-2019 period is $3.36 million.

TABLE 6: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	1.09	4.66	0.05	1.09	1.04	0	0.74	0.74	1.00	0.88

Over the last five years, work has been conducted between several feeders of Dufferin TS and adjacent stations to provide inter-station feeder tie capabilities. This has resulted in the ability to transfer customer loads between adjacent stations in the downtown Toronto area. The timing of the Downtown Contingency program was established to ensure continuing progress on this long-term program while balancing resource usage against other system investment priorities during the 2015 to 2019 period.

The proposed program will allow remote, rapid transfer of customer loads on feeders between:

- Dufferin TS & Cecil TS
- Dufferin TS & Strachan TS
- Dufferin TS & Wiltshire TS
- Basin TS & Carlaw TS

The load transfer capabilities that would become available represents roughly 6% of Basin TS loading, 4% of Carlaw TS loading, 2% of Cecil TS loading, 20% of Dufferin TS loading, 6% of Strachan TS loading, and 6% of Wiltshire TS loading. In all, this program is expected to improve reliability issues at six of the 15 downtown stations, and provides backup supply to approximately 9,000 customers, or 53 MVA of load.

Originally seven Downtown Contingency projects were planned for the 2015 to 2019 period. However, two projects that were originally planned for 2015 have been rescheduled. One was advanced to 2014 because the critical path for this project permitted this change. The second

requires the prior installation of new A10-11E switchgear at Carlaw station and has been rescheduled for 2016. Replacement of this switchgear has been delayed to accommodate HONI transformer replacement constraints associated with the Pan Am Games. It is impractical to advance the other 2016 project to 2015, and, as a result, the two projects will be undertaken in 2016 and none in 2015.

E7.7.4.1 Ranking & Prioritization

The ranking and prioritization of the work within this program is predominantly based on the following factors:

- Historical Outages Data : Historical station outage data for the 15 downtown area stations has been assessed to determine the priority for inter-station feeder ties. Only supply related outages were considered (e.g. transmission system loss of supply, station equipment failure, external infrastructure failure, extreme weather events, etc.). Stations with a higher outage history received higher priority.

- Execution Complexities: Projects within the program that are easier to implement because they are associated with fewer technical and implementation difficulties will be completed first; OH feeders have fewer technical challenges as compared to UG feeders. For example, Toronto Hydro will have to ensure that downtown stations with underground feeders have sufficient space for feeder tie switches in UG vaults near stations and along the feeder tie locations. In addition, Toronto Hydro will have to undertake substantial civil work to upgrade UG vaults and cable chambers before underground inter-station feeder ties can be installed.

Based on these factors, six overhead feeder tie projects are planned for 2015 through 2019. Five out of the six inter-station feeder ties involve Dufferin station feeders.

E7.7.5 Program Execution

The projects to be completed under the Downtown Contingency inter-station feeder tie program are not associated with high program execution risks. For instance, Toronto Hydro is afforded flexibility as to where it places switching and tie locations, resulting in more design and construction options than is typically available for downtown program projects.

As shown in Figure 2, inter-station feeder tie projects involve the installation of new switches near each station and at feeder tie locations, and feeder extensions to the proposed feeder tie

locations. Depending on the complexity of project, it is expected to take 10 to 15 months to complete one inter-station feeder tie.

Typically, the following steps are considered in the planning and execution of an inter-station feeder tie project:

- Review the station outages history to find out which stations experience the most loss of supply outages;
- Review the adjacent stations buses to identify compatible bus configurations (e.g. low / high impedance or three-wire / four-wire bus);
- Review adjacent station feeder types (e.g. overhead / underground or normal / stand-by), routes, locations and loadings;
- Begin technical planning and design;
- Use the typical project planning scope process for developing and executing the inter-station feeder ties project.

Inter-station feeder tie operation is based on the "break then make" principal. With reference to Figure 2, this means that before tying a station (TS1) feeder to an adjacent station (TS2) feeder, the remote controlled load break switch on the tying station's (TS1) feeder must be opened first. Then, the remote controlled load break switch of the adjacent station's (TS2) feeder may be closed. This is required to avoid paralleling of two different stations.

While the 2015 to 2019 program mostly addresses the overhead (OH) distribution system, one underground switch will be installed to tie an OH feeder to an underground residential distribution (URD) feeder. Figure 5 is a photo of a SF_6 load break switch, which is used for underground residential distribution (URD) feeder. Figure 6 is a pole-mounted SCADA mate switch, which is used for overhead feeders.

FIGURE 5: 600A SF6 LOAD BREAK SWITCH

FIGURE 6: SCADA MATE – POLE MOUNTED SWITCH

E7.7.5.1 Proposed Work Plan

Under the Downtown Contingency program, six inter-station overhead feeder tie projects are proposed to be completed from 2015 to 2019. Five of the six inter-station projects involve Dufferin Station. Table 7 lists the proposed projects.

TABLE 7: 2015-2019 LONG TERM PLAN

Year	Feeder	Station
2015	-	-
2016	A204BN & A250E feeders-	Basin & Carlaw stations
2016	A273DN & A57W feeders	Dufferin & Wilshire stations
2017	A256DN & A34W feeders	Dufferin & Wilshire stations
2018	A257DN & A230T feeders	Dufferin & Strachan stations
2018	A530DN & A390CE feeders	Dufferin & Cecil stations
2019	A254DN & A390CE feeders	Dufferin & Cecil stations

E7.7.5.2 Program Risks

The following are program risks that Toronto Hydro plans on mitigating:

- The City of Toronto is expected to perform work in the next few years along some major and minor corridors in the downtown area. Road construction moratoriums and the difficulty of obtaining city permits for civil work will potentially create issues for the downtown contingency program. Toronto Hydro will coordinate its work with the city in line with its requirements and schedule work accordingly to mitigate these risks.

- Toronto Hydro is required to co-ordinate with HONI with respect to the addition or replacement of station switchgear (buses) and the replacement of high impedance neutral reactors of power transformer with low-impedance reactors. Toronto Hydro cannot use the bus until HONI completes their work, which puts the program schedule at risk. Toronto Hydro will mitigate this issue by coordinating with HONI to create a jointly planned schedule with work that be completed in phases.

E7.7.5.3 External Constraints

External third parties may affect the Downtown Contingency Program. Some of the program's projects depend on equipment and plant that is not owned by Toronto Hydro. In such cases, work will need to be coordinated with the applicable third party, and may need to be postponed or re-designed. Examples of third party infrastructure include HONI equipment, wired and wireless telecommunications infrastructure, wired and wireless television services, and Toronto Hydro infrastructure located on private property.

E7.7.6 Evaluation of Alternatives

E7.7.6.1 Quantification/Evaluation of Options

Three alternatives were considered for this program:

- Maintain the status quo,
- Use mobile generators and switchgears, and
- Introduce inter-station feeder ties.

(i) Status Quo

By maintaining the status quo, Toronto Hydro would not introduce load transfer capability by tying feeders from one station to an adjacent feeder. This option is not recommended because customers would continue to be exposed to the risk of prolonged outages under partial or complete station outage conditions.

(ii) Mobile Generators and Switchgear

Mobile Generator units can be used during the construction and maintenance of the distribution system, or to supply emergency loads during a feeder failure. Figure 7 below is a mobile generator.

FIGURE 7: MOBILE GENERATOR

Mobile generators

Mobile generators are not suitable for low probability, high-impact station outage scenarios (e.g. HONI loss of supply, station equipment failure, external infrastructure failure, extreme weather events, etc.) due to the high initial capital and high maintenance costs.

Typically no more than twelve 2 MVA generators are available within a 24 hour notice period to pick up customer loads following a major station incident. Three to five generators would be

required per feeder for peak loading, with an average of about 35 feeders per station. This represents less than 10% of a typical downtown station's maximum capacity and therefore the use of this equipment can only be considered a partial, inadequate solution.

Mobile switchgear

Mobile switchgear is not suitable for low probability, high-impact station outage scenarios (e.g. HONI loss of supply, etc.)

If HONI supply is operating normally, but Toronto Hydro's 13.8kV station switchgear fails and is not repairable, then the feeders connected to this switchgear will be unable to provide power to downstream customers. Under such conditions supply to the downstream customers can be maintained by:

- Transporting and installing a mobile switchgear near the affected station,
- Connecting mobile switchgear to the 13.8kV secondary of the HONI existing 115/13.8kV, power transformer at the station, and
- Re-cabling and connecting feeders from the affected station switchgear's to the mobile switchgear,

Under such scenarios, following a switchgear failure, customers can expect to experience a day to week long service interruption depending on which station is affected. Toronto Hydro has no history of such types of station failures occurring in the downtown area that have resulted in the permanent loss of station switchgear.

(iii) Inter-Station Feeder ties

The use of inter-station feeder ties is recommended because it is the only option that will provide Toronto Hydro with the capability to restore supply to most of its downtown customers during partial or complete station outages conditions and any loss of supply incident.

The cost of ownership (COO) and program net benefit (NPV) associated with Downtown Contingency is further detailed in Tables 8 and 9. The cost of ownership is established for both the existing state (COO_E), and the proposed new state (COO_N) based on the first year of planned activities in this program. The cost of ownership (COO) of a state reflects the risk of asset failure, including both direct and indirect costs; these costs include customer interruptions, emergency repairs, and asset replacements associated with that design. Costs in maintenance activities are

also included for both states. All of these factors combine to form the COO for a particular design. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first of activities, the Downtown Contingency produces a net benefit (NPV) value of $2.33 million as shown in Tables 8 and 9.

TABLE 8: COST OF OWNERSHIP OF EXISTING ASSETS/STATUS QUO

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Asset Risk [AR_E] customer outage cost	$4.48
Non Asset Risk [NAR_E]	$0
Maintenance Cost [MC_E]	$0
Additional Quantifiable Benefits [AQB_E]	$0
Cost of Ownership of Existing Assets [COO_E]	$4.48

TABLE 9: STATION-TO-STATION FEEDER TIES BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: Station-to-Station Feeder Ties	
Asset Risk [AR_N] customer outage cost	$1.38
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0.03
Additional Quantifiable Benefits [AQB_N]	$0
Cost of Ownership of New Assets [COO_N]	$1.41
Option 1: Program Net Benefit (NPV_1)	
Difference in Cost of Ownership [$ûCOO_1 = (COO_E - COO_N)$]	$3.07
Program Cost [PC_1]	$0.74
Program Net Benefit [$NPV_1 = (ûCOO_1 - PC_1)$]	$2.33

E7.8 Customer-Owned Substation Protection

AGING CUSTOMER-OWNED SUBSTATION EQUIPMENT

E7.8.1 Summary

Program Description

The Customer-Owned Substation Protection (COSP) program is designed to address customer-owned substations which may have an effect on the larger grid. These are defined as customer-owned civil structures that accommodate customer-owned electrical equipment and that connect to Toronto Hydro's distribution system. There are currently 2,110 customer-owned substations in the Toronto Hydro network; 1,417 substations are located in the Horseshoe area (i.e. the former suburbs) and 693 are in the vicinity of downtown Toronto.

The customer-owned protection devices associated with these substations do not alone offer sufficient protection. It is important that utility-owned protection devices be installed upstream from the customer-owned substations, except in situations where the customer-owned device is located in Toronto Hydro's underground network in the downtown area of Toronto. There are several instances in which the current configuration is non-compliant with Toronto Hydro standards, either because: (1) Toronto Hydro-owned protection devices are absent altogether or need to be replaced; or (2) customer-owned protection devices do not meet required standards. Proper coordination between the protection devices and the station breaker is necessary to localize the negative impact of a fault at the customer-owned substation. Therefore, non-

compliance can lead to a lack of adequate protection, which, historically, has resulted in service disruptions.

To remedy this situation, Toronto Hydro proposes to install or replace Toronto Hydro-owned high voltage protective devices and will coordinate them with station breaker relays and the customer-owned protection devices.

The COSP program is made up of two phases. In the "Audit Phase", Toronto Hydro plans to audit all of the customer-owned and Toronto Hydro-owned protection devices to assess their coordination, condition and operability, including their ability to provide protection. This phase will begin in early 2015 and is scheduled to be completed by the end of 2018.

The second phase of the program, the "Implementation Phase", will commence on a rolling basis once audit results become available. As such, Toronto Hydro expects the Implementation Phase to commence by the third quarter of 2015. It will involve a mix of equipment upgrades to be completed by customers and the installation by Toronto Hydro of high-voltage protection devices upstream from customer-owned substations. During this phase, Toronto Hydro plans to also address previously identified issues associated with poorly maintained assets.

The anticipated benefits of this program are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Helps prevent customers from experiencing power outages. ƒ Increases the quality of power, providing customers with a better service and experience.
Reliability	ƒ Reduces the impact of interruptions (CI and CHI) by isolating outages. ƒ Anticipated reduction in interruptions would reduce stress to equipment on the grid.
Safety	ƒ Improves the safety of distribution system for both the general public and Toronto Hydro employees.
Efficiency	ƒ Information obtained regarding customer-owned substations through this program could also be used to verify and update the data captured in the GIS. ƒ Verifying and updating data regarding customer-owned equipment would also add flexibility for existing or future programs and avoid the additional work needed for other teams to collect this data. ƒ Controllable costs could be reduced because the high voltage protection devices will be coordinated with circuit breakers and act accordingly to prevent wide-spread outages

Program Drivers

The trigger and secondary drivers for this program are outlined in Table B.

TABLE B: PROGRAM DRIVERS

Primary Driver	Reasoning
Reliability	ƒ The failure of customer-owned equipment resulted in approximately 17 interruptions per year. ƒ If customer-owned protective devices fail to clear the fault at the customer-owned substations and the Toronto Hydro-owned protection devices are not in place or coordinate properly, there is likelihood of a larger outage affected a broad base of customers. In absence of the proper upstream high voltage protective devices, station breakers will operate, interrupting all customers on the feeder. ƒ Aged and/or unmaintained customer-owned protection devices pose significant reliability issues because of their risk of failure.
Secondary Driver	**Reasoning**
Safety	Currently, 22% of the visited customer-owned substations in Horseshoe area were identified as being poorly maintained or past their useful life. These substations can create safety hazards for both the general public and Toronto Hydro employees: ƒ Heavily rusted electrical equipment within the substation can be a fire hazard. ƒ Poorly maintained transformers and glass-made lightning arresters could fail and cause damage to their surroundings. ƒ Poorly maintained civil structures within the customer-owned substation (e.g., heavily rusted substation tower, pole and fence/door) can collapse.

Preferred Alternative

Toronto Hydro considered the following options for addressing the potential impact of poorly maintained customer-owned stations and inadequate protection equipment.

(i) Status Quo – Continue to perform repairs reactively, after equipment has failed and/or following an outage event. Reliability challenges and safety risks are expected to continue to worsen over time.

(ii) Proposed Program – Execution of this program, whereby inspections are performed and protection is enabled at customer-owned substations over the next five-year period wherever necessary.

The proposed program is preferred as it mitigates the safety, reliability and operational flexibility issues related to deteriorating and poorly coordinated customer-owned equipment.

Timing and Pacing

The total estimated cost for the COSP program over the 2015 to 2019 period is forecasted to be approximately $4.04 million. This estimation is based on costs of inspection, analysis, design and construction of Toronto-Hydro-owned protective devices for an estimated 210 customer-owned substations. There is no historical spending for the COSP program as there has not been a systemic program-based approach to this issue to date.

The installation of utility-owned protection devices is expected to occur at a rate of 50 substations a year, completing 200 substations from 2016 to 2019. Toronto Hydro plans to address the remaining 10 substations during the 3rd and 4th quarters of 2015. The estimated costs of the COSP program for the 2015-2019 period are provided in Table C below.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Total Annual Spend ($M)	0	0	0	0	0	$0.59	$1.03	$1.03	$0.78	$0.61

E7.8.2 Program Description

The Customer-Owned Stations Program (COSP) is designed to address customer-owned substations which may have an effect on the larger grid. These are defined by Toronto Hydro's Conditions of Service as customer-owned civil structures that accommodate customer-owned electrical equipment and that connect to Toronto Hydro's distribution system. Figure 1 shows the locations of the 2,110 customer-owned substations in the Toronto Hydro network; 1,417 substations are located in the Horseshoe area (i.e. the former suburbs) and 693 are in the vicinity of downtown Toronto.

FIGURE 1: MAP OF ALL CUSTOMER-OWNED SUBSTATIONS IN THE TORONTO HYDRO NETWORK

Customer-owned substations are used by commercial and industrial customers who tend to have significant power usage. Customer-owned substations include both civil assets (e.g. substation overhead steel structures) and electrical assets (e.g. high voltage transformers, high voltage protective devices, and primary switchgear). Figure 2 shows the typical structures of both open and enclosed high voltage customer-owned substations.

FIGURE 2: EXAMPLES OF OPEN AND ENCLOSED CUSTOMER-OWNED SUBSTATIONS

Customer-owned protection devices do not alone offer sufficient protection. It is important that utility-owned protection devices be installed upstream from the customer-owned substations, except in situations where the customer-owned device is located in Toronto Hydro's underground network in the downtown area of Toronto. The redundancy in protection and coordination is necessary to ensure the failure of a customer-owned protection device to clear a fault does not trigger the station breaker and interrupt other customers on the same feeder.

There are several instances in which the current configuration is non-compliant with Toronto Hydro standards, either because: (1) Toronto Hydro-owned protection devices are absent altogether or need to be replaced; or (2) customer-owned protection devices do not meet required standards. Proper coordination between the protection devices and the station breaker is necessary to localize the negative impact of a fault at the customer-owned substation. Therefore, non-compliance can lead to a lack of adequate protection, which, historically, has resulted in several service disruptions. For example, in July 2010, the failure of a customer-owned arrester within the substation at 40 Titan Road caused a power outage. Feeder 38-M3's circuit breaker auto-reclosed and immediately tripped, resulting in 1,090 Customers Interrupted (CI) and 281 Customer Hours Interrupted (CHI). The lack of an upstream Toronto Hydro-owned protection device is partly responsible for this outage (please refer to Section E7.8.3.1 for additional details regarding reliability issues).

In addition to the reliability issues in connection with non-compliance with standards, customer-owned substations also pose several safety risks to the general public and to Toronto Hydro crew members working in close proximity to the equipment. Safety risks include fire hazards (if electrical components are unmaintained and heavily rusted), environmental hazards (if equipment is leaking oil), and other types of damage (please refer to Section E7.8.3.1 for additional details regarding reliability issues).

Toronto Hydro crews are required to operate and be in proximity to customer-owned equipment to off-load customers under the following circumstances:

(1) A fire at the customer's premises;

(2) To control backfeed caused by damaged Toronto Hydro-owned conductors;

(3) To disconnect customer-owned equipment when there is customer related issues (e.g., damaged customer-owned conductors); and

(4) When the customer-owned equipment or vegetation has an impact on the reliability of Toronto Hydro's distribution system.

If customer-owned equipment and upstream Toronto Hydro-owned protection devices are not coordinated with each other and with the applicable station breaker, there is a risk that in the event of a fault, all customers on the applicable feeder would experience a power interruption because the station breaker would operate before the protection devices do. As well, in some cases, Toronto Hydro-owned protective devices may not be in place because legacy standards did not require them at the time of construction. Finally, in other situations, current customer-owned protection devices may be absent or inadequate, details of which is discussed in section E7.8.3.1. To remedy these issues and ensure that faults at customer-owned substations are isolated, Toronto Hydro proposes to install or replace Toronto Hydro-owned high voltage protective devices and will coordinate them with station breaker relays and the customer-owned protection devices.

The COSP program is made up of two phases. In the "Audit Phase", Toronto Hydro plans to audit all of the customer-owned and Toronto Hydro-owned protection devices to assess their coordination, condition and operability, including their ability to provide protection. This phase will begin in early 2015 and is scheduled to be completed by the end of 2018.

The second phase of the program, the "Implementation Phase", will commence on a rolling basis once audit results become available. As such, Toronto Hydro expects the Implementation Phase to commence by the third quarter of 2015. It will involve a mix of equipment upgrades to be completed by customers and the installation by Toronto Hydro of high-voltage protection devices upstream from customer-owned substations. During this phase, Toronto Hydro plans to also address previously identified issues associated with poorly maintained assets.

One of the following two options will be implemented to address any problems identified through the engineering analysis of customer-owned substation equipment and associated protection devices:

(1) If Toronto Hydro-owned protective devices are no longer adequate because of changes to the customer-owned equipment, or such devices are not in place where needed, Toronto Hydro would install or replace its protection devices.

(2) If the condition of customer-owned equipment is an issue, Toronto Hydro would advise the customer to upgrade their equipment to ensure compliance with the utility's standards, as determined by equipment's physical conditions and protection settings (please refer to section E7.8.5.2 for details).

The COSP program will first address sites on Toronto Hydro's overhead distribution system, as they are simpler to access and address. With respect to the underground system, Toronto Hydro will primarily focus on reviewing existing customer protection and coordination schemes and will undertake construction only where necessary, as identified by thorough analysis (please refer to section E7.8.3.1 for guidelines for customer-owned substation protection and connections to distribution system). This planning decision was made in light of the unique structures and connections of customer-owned substations on the underground distribution system, and the relative complexity of the system itself.

Toronto Hydro plans to invest an estimated $4.04 million in the COSP program during the 2015 to 2019 period. This investment involves the construction of an estimated 630 Toronto Hydro-owned single-phase protection devices at 210 customer-owned substations, as shown in Table 1. Toronto Hydro expects to install protection devices at these substations because they are currently missing upstream, Toronto Hydro-owned protection devices, as determined by Toronto Hydro's GIS platform (refer to section E7.8.3.1, subsection: Program Asset Demographic). If more substations are identified through the completion of the GIS review and the actual site inspections and analysis, Toronto Hydro plans to address these locations beyond the 2015-2019

timeline. Toronto Hydro will notify the customer if deficiencies are identified at the customer-owned substation. The repairs or upgrade of the customer-owned equipment shall be carried out by the customer at their expense (refer to section E7.8.5.2 Standard & Regulation Adherence).

TABLE 1: ASSETS TO BE INSTALLED

Assets (Units)	2015	2016	2017	2018	2019	Total
High-voltage protection device (single-phase)	30	150	150	150	150	630

The costs for this program were calculated based on the cost of installing in-line fuse products as required by Toronto Hydro standards (10-1300C fused disconnect in-line switches for primary voltage of 13.8 and 27.6 kV). In addition, Toronto Hydro added 25% for contingency cost purposes (15% standard project contingency and 10% risk contingency), as the utility may need to remove or replace other assets or perform other activities to complete the construction and installation of a protection device. In all, the average unit cost is forecasted to be approximately $6,410 per high voltage protection device (single-phase). A detailed list of estimated project spending for 2015 can be found in Table 7, "2015 Projects", in section E7.8.7.

A summary of anticipated program benefits is provided in the table below.

TABLE 2: PROGRAM BENEFITS

Customer Value	ƒ Helps prevent customers from experiencing power outages, which could otherwise lead to monetary losses (e.g., potential revenue loss from retail sales). ƒ Helps improve the quality of power, which would provide customers with a better service and experience.
Reliability	ƒ Power reliability would be enhanced through the upgrade and maintenance of customer-owned equipment. ƒ Reduces the impact of interruptions (CI and CHI) by isolating outages. ƒ A reduction in interruptions will reduce stress to equipment on the grid.
Safety	ƒ Improves the safety of distribution system for both the general public and Toronto Hydro employees.
Efficiency	ƒ Information obtained regarding customer-owned substations through this program could also be used to verify and update the data captured in the GIS. ƒ Verifying and updating data regarding customer-owned equipment would also add flexibility for existing or future programs and avoid the additional work needed for other teams

	to collect this data. ƒ Controllable costs could be reduced because the high voltage protection devices will be coordinated with circuit breakers and act accordingly to prevent wide-spread outages

E7.8.3 Why the Program is Needed

The COSP program is needed so that Toronto Hydro can ensure that customer-owned protection devices are properly maintained and that appropriate safeguards are in place, including Toronto Hydro-owned protection devices. In doing so, Toronto Hydro expects to minimize existing reliability issues (refer to section E7.8.3.1) and enhance the protection of other customers from interruptions that would otherwise be caused by the failure of customer-owned equipment at a specific substation. In addition, this program will enhance the safety of the system.

E7.8.3.1 Purpose

Table 3 presents the trigger and secondary drivers for the COSP program. This program's primary driver is reliability.

TABLE 3: CUSTOMER-OWNED SUBSTATI ON PROTECTION PROGRAM DRIVERS

Trigger Drivers	Reasoning
Reliability	ƒ The failure of customer-owned equipment has resulted in approximately 17 interruptions per year. ƒ If customer-owned protective devices fail to clear the fault at the customer-owned substations and the Toronto Hydro-owned protection devices are not in place or coordinate properly, there is likely to be a larger outage affected a broad base of customers. In absence of the proper upstream high voltage protective devices, station breakers will operate, interrupting all customers on the feeder. ƒ Aged and/or unmaintained customer-owned protection devices pose significant reliability issues because of their risk of failure.
Secondary Drivers	**Reasoning**
Safety	Currently, 22% of the visited customer-owned substations in the Horseshoe area were identified as being in need of maintenance or past their useful life. These substations can create safety hazards for both the general public and Toronto Hydro employees: ƒ Heavily rusted electrical equipment within the substation can be a fire hazard. ƒ Poorly maintained transformers and glass-made lightning arresters could fail and cause damage to their surroundings. ƒ Poorly maintained civil structures within the customer-owned substation (e.g., heavily rusted substation tower, pole and fence/door) can

	collapse.

The trigger driver for this program is reliability. During a fault, an uncoordinated upstream protection device is a device that fails to act after the customer-owned protection device operates, but before the station breaker comes into action. If the Toronto Hydro-owned protection devices are improperly set, or if they are absent altogether, the inability for a customer-owned protection device to isolate a fault will lead to the station breakers triggering, which would interrupt the entire feeder.

While Toronto Hydro has protection devices in most places in the Horseshoe area, in some instances, these devices are inadequate or absent altogether. There are several explanations as to why this issue might exist:

(1) At the time of original construction, the impact that a customer's load could have on the system may have been negligible. However, over time, a customer's load may have risen considerably. Given the increase in customers and associate loads, these substations can now have a significant impact on the reliability of power supply and can no longer be neglected.

(2) Some customers could be large enough for the substations to not have its upstream protection setup at the time of original construction (e.g., substation is too large to have upstream fuses). Today, the gang-operated load-break SCADA switches could be used to connect this type of large substation to the feeder trunk as specified in Toronto Hydro's current standards.

(3) At the time of construction, the manufacturers might not have had the preferred protection devices available (e.g., fuse sizes were limited) for the specific customer-owned substations and loading requirements. As technology evolved, more options are now available (e.g., fuses at higher rating), which would provide better protection to the system.

As discussed above, in addition to issues with respect to customer-owned protection devices, Toronto Hydro must also address its own assets. Toronto Hydro plans to further investigate and minimize the existing and potential impacts associated with its upstream protective devices. More specifically, Toronto Hydro must ensure that such devices are in-line with the utility's most recent standards.

The previously discussed situation that took place at 40 Titan Road in July 2010 illustrates the issues that can arise when utility-owned protection devices are not in place. The current standards require the in-line fused switches to be put in as a second line of defense. Regardless of the physical condition of the customer-owned equipment at this location, redundancy in protection and coordination of equipment was necessary to prevent outages to other customers on the same feeder in the event the customer-owned protection device failed to clear the fault.

As specified in Toronto Hydro Requirements for The Design and Construction of Customer-Owned High Voltage Substations Toronto Hydro requires its protection devices to be in place, upstream from the high-voltage customer-owned substations. This is consistent with the industry standards and good utility practice. It is designed to prevent interruptions to other customers when customer protection device fails to clear the fault at one substation. The following summarizes the current three main options and provides further guidelines for customer-owned substation protection and connections to the distribution system.

1. Lateral fuses are used:
    1.1. Lateral feeder with aggregate transformer MVA under 11 MVA (27.6 kV network).
    1.2. Maximum single transformer or aggregate MVA of 5 MVA at the customer-owned substation. (27.6 kV network).
    1.3. Lateral feeder with aggregate transformer MVA under 5 MVA (13.8 kV overhead network only).
    1.4. Maximum single transformer or aggregate MVA of 1.5 MVA at the customer-owned substation. (13.8 kV overhead network only).
2. A three-phase, gang-operated load-break SCADA switch may be used to connect the customer to the feeder trunk for customers with a maximum load of up to 10 MVA (27.6 kV network)
3. Connect directly to the main underground feeder (13.8 kV underground network).

Absent or uncoordinated protection devices continue to cause sustained interruptions at the feeder level. According to Toronto Hydro's Interruption Tracking Information System (ITIS), there have been 83 interruptions that were caused by the failure of customer-owned equipment from 2009 to 2013. Figure 3 shows the outage distribution across the City of Toronto. Approximately

53% of the interruptions occurred in Toronto Hydro's overhead distribution system while 47% were in the underground network.

FIGURE 3: HISTORICAL RELIABILITY EVENTS 2009-2013

In 73 of the events mentioned above, the customer-owned and upstream utility-owned protective equipment failed to minimize the faults, which impacted many upstream customers. In all, these events led to 58,382 CI and 24,665 CHI. On average, if the impacts were limited to the faulted customer, each interruption would have only cause two CHI and one CI. Instead, each outage produced an average of 800 CI and 338 CHI. These figures illustrate the importance of verifying that customer-owned protection devices are in compliance with Toronto Hydro's current standards, and that Toronto Hydro-owned protection devices are installed and properly functioning upstream.

It should be noted that the outage figures mentioned above do not take into account 10 of the 83 outages in which the fault was successfully isolated at the customer's location. These faults produced a total CHI and CI of 20 and 10 respectively.

Figure 4 illustrates the number of interruptions that have occurred since 2009 as a result of faults on customer-owned substations, which impacted upstream customers. The restoration of service following each interruption can take anywhere from a few minutes to hours, which can ultimately result in thousands of hours in total CHI.

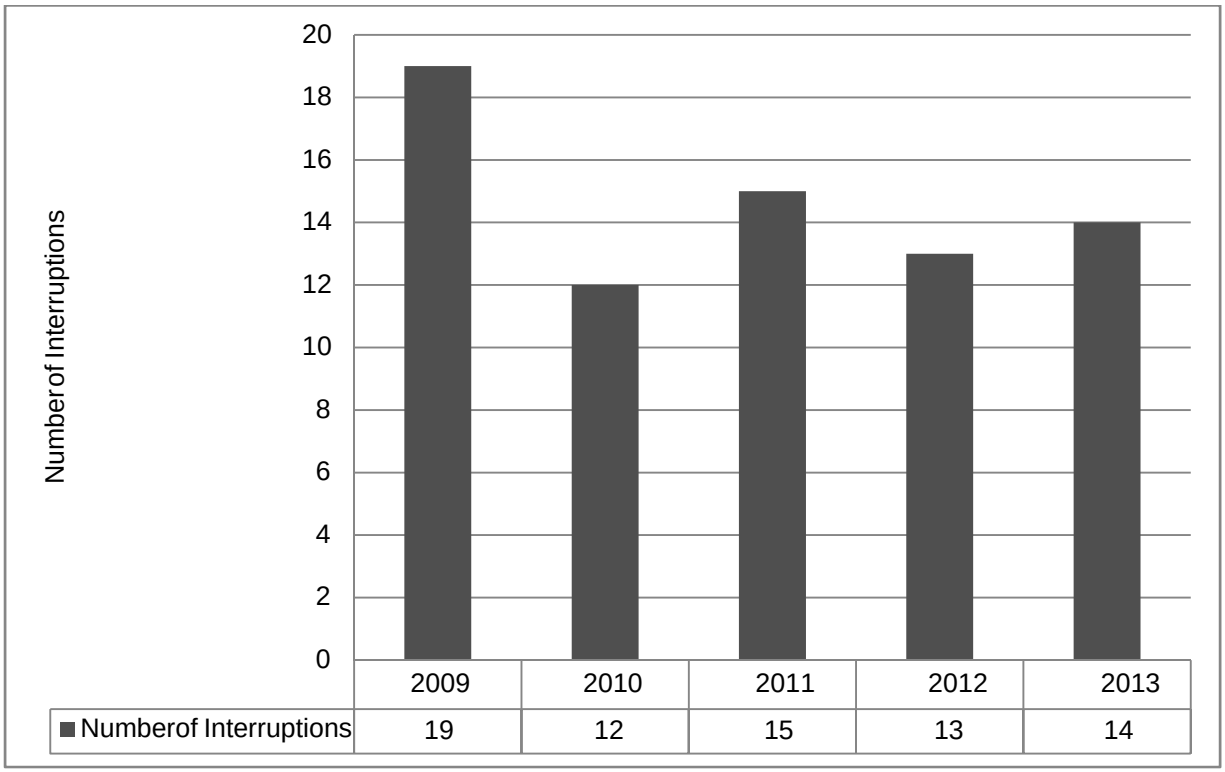

FIGURE 4: INTERRUPTIONS DUE TO FAILURE OF CUSTOMER-OWNED ASSETS

In addition to the issues caused by absent or inadequate utility-owned protection devices, poorly maintained customer-owned substations also cause reliability and safety issues. Customer-owned assets have a much higher chance of failure due to age or improper maintenance. In particular, electrical equipment can cause short circuits and fire hazards if it is heavily rusted. As well, faults can occur if the customer fails to remove vegetation located inside of a substation or close to the overhead incoming feeder. In addition, aged or unmaintained civil structures are at risk of failing and collapsing, which can damage the surrounding area and create faults.

Figure 5 shows customer-owned assets that have been poorly maintained. Severe rust is visible on all the electrical equipment. This equipment is extremely dangerous and can cause injury. For

example, an overloaded transformer with poorly maintained dielectric fluid is more likely to fail and can lead to an electrical fire.

FIGURE 5: EXAMPLES OF AGED AND POORLY MAINTAINED EQUIPMENT

Without proper isolation and protections in place, customer-owned asset failures will cause reliability issues for the grid, interrupting many upstream customers and putting stress on Toronto Hydro's assets. As well, these issues create safety issues for the general public and Toronto Hydro crew members. Accordingly, through the proposed program, Toronto Hydro plans to identify the poorly maintained substations and will advise the asset owner that equipment upgrade, repair or replacement is necessary (refer to section E7.8.5.2).

Based on data collected from the site inspection of 256 substations (185 are in the Horseshoe area and 71 are in the Downtown area), Toronto Hydro determined that 21 of 185 customer-owned substations visited in the Horseshoe area (which is primarily overhead) were identified as

having power transformers past their useful lives. Table 4 provides the useful lives of equipment that is typically found in customer-owned substations.

TABLE 4: USEFUL LIFE FOR CUSTOMER-OWNED SUBSTATION

Assets (Units)	Asset Size	Useful Life (years)
Power Transformer	5 MVA, 27.6 kV	44
Station Steel Structures and Overhead Bus Work	Bus Structure for 27.6 kV	67
Outdoor Station Disconnect Switch	600 A, 27.6 kV	40

The following example illustrates the issues associated with inadequate or missing Toronto Hydro-owned protection devices and non-functioning customer-owned protection devices. In August 2012, the customer-owned load break switches on both A72WR and A73WR feeders flashed over and faulted. As a result, the circuit breakers of feeders A72WR, A73WR, A26WR and A43WR automatically operated to open the circuit. The outage lasted six hours and affected four of Toronto Hydro's large customers: 18 York Office Tower, Famous Players, Ice Condo Temp and Maple Leaf Square. Proper upstream Toronto Hydro-owned protection devices would have isolated the fault to the substation at 16 York Street and minimized the impact to other customers.

Program Asset Demographics

Toronto Hydro is currently in the process of reviewing the Geographic Information System (GIS) for missing utility-owned protection devices for customer-owned substations in the overhead distribution system. This exercise is the first step in identifying the customer-owned substations in Toronto Hydro's distribution system that should be targeted by this program. Up to May 31, 2014, 210 customer-owned substations without upstream utility-owned protection devices had been identified within the overhead distribution network. Toronto Hydro expects this total to grow upon the completion of the review process in GIS. The accuracy of the above data will be improved through physical inspections of customer-owned substations.

In some instances, the proper utility-owned protective devices may not be installed upstream either due to the legacy standards that existed at the time of construction (as was the case in the 40 Titan Road example in the Program Description) or because customers upgraded or replaced their equipment and failed to communicate these changes to Toronto Hydro. In the latter case, the existing protection settings may not be effective or in alignment with the upgraded/replaced equipment.

A sample including 214 customer-owned substations (approximately 10% of the total population) was initially planned for preliminary inspection and analysis. Analysis of the remaining substations will be carried out upon completion of the sample population. As of May 31, 2014, Toronto Hydro has visited 256 customer-owned substations (214 sample locations and an additional 42 substations). Of those 256 customer-owned substations, 185 are in Horseshoe and 71 are in Downtown. The analysis of the visited substations is in progress, which includes asset assessment of the substation as well as protection and coordination.

During the sample substations inspections in the Horseshoe area, 64 of the 185 visited substations were found to be missing upstream utility-owned protection devices. All 64 of these substations are amongst the substations first identified in the GIS. All 71 substations visited in the downtown Toronto area are located in Toronto Hydro's underground network. All of these substations are missing upstream Toronto Hydro-owned protection devices located in between customer-owned protection devices and the station breakers.

The site visits are conducted by way of visual inspections. 40 out of 185 (22%) customer-owned substations that were visited in the Horseshoe area have been identified as either aged or poorly maintained, while three out of 71 substations (5%) in the downtown area of Toronto were deemed aged or poorly maintained. However, Toronto Hydro expects the number for downtown area of Toronto to be higher due to the missing manufacture date of the customer-owned equipment in most of the inspected substations. If the current ratios hold for the entire population, about 312 of the 1,417 substations in Horseshoe area and 35 of the 693 substations in the downtown area of Toronto will have similar issues. Based on the current findings, through the COSP program, Toronto Hydro plans to first inspect and analyze the remaining customer-owned substations in the Horseshoe area (mainly overhead network) and the substations in the downtown area of Toronto (underground network).

TABLE 5: STATUS OF CUSTOMER-OWNED SUBSTATION INSPECTIONS

	Number of Customer-owned Substations	Number of Sample Substations (Initially Planned for Inspection)	Number of Inspected Substations as of May 30, 2014 (Actual)	Number of Substations without utility-owned protection devices	Number of Substations that identified as aged or poorly maintained
Horseshoe	1,417	144	185	64	40
Downtown	693	70	71	71	3
Total	2,110	214	256	135	43

As discussed earlier in the Program Asset Demographic section, Table 6 illustrates the findings of the sample substations inspection. Please note that the sampling and the GIS review are two separate processes and the candidates were all randomly chosen. The inspection work of the 214 sample substations was completed in May 2014, at which point an additional 42 substations were inspected to increase the available dataset.

E7.8.4 Timing & Pacing of the Program

As per the table below, the total estimated cost for the COSP program over the 2015 to 2019 period is $4.04 million. Program spending was derived based on the costs of the inspection, analysis, design and construction of Toronto-Hydro-owned protective devices upstream for the estimated 210 customer-owned substations.

TABLE 6: HISTORICAL & FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	$0.59	$1.03	$1.03	$0.78	$0.61

The Implementation Phase will commence on a rolling basis once audit results become available. As such, Toronto Hydro expects the Implementation Phase to commence by the third quarter of 2015. That phase will involve a mix of equipment upgrades to be completed by customers and the installation by Toronto Hydro of high-voltage protection devices upstream from customer-

owned substations. During this phase, Toronto Hydro will also address previously identified issues associated with poorly maintained assets.

Toronto Hydro plans to install 150 Toronto Hydro-owned protection devices at 50 customer-owned substations per year through 2016-2019, for a total of 200 substations. The remaining 10 customer-owned substations will be addressed with the use of 30 Toronto Hydro-owned protective devices (single-phase) in the 3rd and 4th quarters of 2015. This timeline will allow Toronto Hydro to complete the construction work for all 210 substations within the 2015-2019 period.

E7.8.4.1 Ranking & Prioritization

As discussed earlier, inspection and analysis work is currently in progress to determine the condition of assets and the current protection scheme. The 10 customer-owned substations that have been identified as missing upstream utility-owned protection devices have already been inspected are scheduled to be addressed in 2015. Three out of the 10 substations have been identified as being aged and/or poorly maintained. As discussed earlier in the narrative, customer-owned substations in the overhead distribution system will be targeted first followed by the ones within the underground system. Specific substations will be determined to have a higher prioritization in the program execution phase based on the physical condition of the inspected assets and absence of utility-owned protection devices. With that in mind, sequencing of work with the COSP program is based on the following four factors:

(1) Customer-owned substations that are in Toronto Hydro's overhead distribution system will be analyzed first. Overhead connections are more susceptible to reliability issues such as faults caused by trees and animals, as the electrical components are exposed to the elements. An estimated 210 substations on the overhead system are currently missing Toronto Hydro-owned protection devices.

(2) The number of interruptions caused by a fault at the customer-owned equipment. According to ITIS data for 2009-2013, the Horseshoe region has experienced the greatest number (45 out of 83) of interruptions that were caused by a fault at customer-owned equipment. This area is given higher priority.

(3) Condition of the equipment - Customer-owned equipment that has aged and/or is poorly maintained will be given higher priority because it represents the greatest safety risks.

(4) Protection and Coordination - Changes/modifications may have been made to customer-owned equipment that was never communicated to Toronto Hydro. As a result, improper coordination between the customer-owned equipment and that of Toronto Hydro may be in place. In addition, there may be an absence of necessary Toronto Hydro-owned protection devices. Priority will be given to both the aforementioned situations because they present significant reliability risks to the system.

Additional factors may affect the pace of implementation for the program. One such factor is the time required to gather customer data, which may vary significantly for reasons such as multiple site visits required to collect the data. In addition, Toronto Hydro cannot control the pace at which its customers respond to requests for additional information.

E7.8.5 Program Execution

Through the COSP program, Toronto Hydro plans to first assess the physical condition of customer-owned high voltage substations, as well as the current protection and coordination scheme, which includes both customer high-voltage protection devices and associated Toronto Hydro-owned upstream protection at all 2,110 customer-owned substations. Six to nine months into this assessment phase, Toronto Hydro plans to begin implementing solutions to the issues discovered during the assessment.

The proposed work for the years 2015-2019 will involve analysis of the assessment data to determine if Toronto Hydro owned protection devices are missing or if their settings are appropriate. Assessment of equipment for safety and maintenance purposes will be performed on the transformer, switches, fuses and other electrical equipment and civil structures at the customer-owned substation. Based on the outcome of the technical analysis for each individual customer-owned substation, the implementation phase will be conducted. This phase may require that the customer perform equipment upgrades, and/or the installation of Toronto Hydro upstream high voltage protection devices.

The execution of the proposed program for each customer-owned substation location may involve the following four stages, described in detail below, following the list:

(i) Customer-Owned Substation Inspection

Site inspections will be performed to verify the existence of utility-owned protection devices, evaluate the physical condition of the substation, and to gather information on customer-owned equipment (e.g., customer-owned electrical and civil assets within the substation). In the previous

example at 40 Titan Road, the substation would have been identified as missing upstream Toronto Hydro protection devices.

(ii) Customer-Owned Substation Analysis & Report

Asset assessment, protection and coordination analysis needs to be performed to determine the best solution and protection settings for each substation. If customer-owned equipment is identified as non-compliant with Toronto Hydro's standards, then the customer will be advised to upgrade and apply appropriate changes (refer to section E7.8.5.2). In the example, the current customer-owned substation is outdoors with a 750 kVA transformer and overhead connection. According to Toronto Hydro's latest construction standards, disconnect in-line fused switches should be put in place to isolate the fault at the customer-owned substation. In instances where existing protection is adequate, Toronto Hydro plans to take no action.

(iii) Design for Construction of Toronto Hydro High-Voltage Protection Devices

Design for construction will be conducted by Toronto Hydro's designers. They will prepare drawings and further specify the exact equipment and associated work required to install the required protection devices for each substation. In addition, the design process will indicate the additional work that must be done prior to the completion of the construction (i.e. if a pole needs to be replaced and/or if tree trimming required for the construction work).

(iv) Construction of High-Voltage Protection Devices

Once the previous processes are completed, the final task of asset construction would commerce on each individual substation. Asset construction work may involve coordinating switching arrangement with the customer and Toronto Hydro, installing or replacing the necessary equipment and other support services. At the current stage, due to the reactive/dynamic nature of the proposed work and lack of data and analysis regarding customer-owned substations, detailed project-by-project information cannot be produced until further investigations are completed.

E7.8.5.1 Program Risks

One of the chief risks of the COSP program is related to the reactive/dynamic characteristic of the implementation phase. The total number of stations that require new or replacement protective devices has yet to be determined. As well, the costs associated with the installation of new or replacement protective devices will differ depending on the results of the assessment. For

example, some locations may already have a switch in place but may be missing a fuse. In this case, as long as the condition of the currently installed equipment is adequate, Toronto Hydro will only be required to install a fuse. In the same vein, if Toronto Hydro determined that a pole is too low or corrupted, it may have to install a new poll. Since it is impossible to predetermine all of these costs, Toronto Hydro has built in a 25% contingency (15% standard project contingency and 10% risk contingency) budget to the cost of this program.

Acquiring all necessary data and documentation is another risk of the program. Some equipment data is not readily available to Toronto Hydro because it is associated with customer-owned substations (e.g., primary protective devices or damaged transformer nameplate). In these instances, Toronto Hydro will need to contact the asset owner to obtain the required information. Since Toronto Hydro has no control over the customer's response time, this process may result in delays. However, Toronto Hydro will follow-up with the customer periodically for the requested information to try to keep this program risk at minimal.

E7.8.5.2 Standard & Regulation Adherence

As specified in Toronto Hydro Requirements for The Design and Construction of Customer-Owned High Voltage Substations, customers shall satisfy the required standards to coordinate with Toronto Hydro upstream protective devices. Based on the primary voltage and rating of the transformer, customer-owned protection and utility-owned protective devices shall be as per Toronto Hydro guidelines. System studies will be performed to confirm coordination with the feeder's circuit breaker at the terminal station. In short, these documents contain detailed information regarding the responsibilities of owners and the latest standards for customer-owned substations.

As specified in Conditions Of Service (revision 13), Section 1.7.5 – Customer-Owned Equipment, Infrastructure and Property, where Toronto Hydro indentifies, through an inspection or other activity, deficiencies relating to the equipment, infrastructure, or property owned by the customer, such as deficiencies to walls, ceilings, floors, doors, vents, drains, electrical devices or other elements, Toronto Hydro may:

- Notify the customer of the deficiencies
- Provide a reasonable time for the customer to correct the deficiencies; and
- If circumstances merit, request that the customer to correct the deficiency in a manner that brings the equipment, infrastructure, or property up to current standards even if the

equipment, infrastructure, or property was designed, installed, or constructed to an older standard. Examples of circumstances that may merit the application of a current standard include, but are not limited to, the existence of health or safety hazards, legal or regulatory requirements, and conditions that may impact the integrity, reliability, or operability of the distribution system or any equipment that supplies the customer.

If notified of deficiencies, or requested to correct deficiencies in a particular manner, the customer shall correct the deficiencies and comply with any requests. If the customer does not correct the deficiencies within the reasonable time, or if the corrections are not considered adequate by Toronto Hydro or an inspection authority, Toronto Hydro may disconnect the supply of electricity to the customer or may correct the deficiencies at the customer's expense, and Toronto Hydro shall not be liable to the customer for any damage arising as a result of or in the course of disconnecting supply or correcting the deficiencies other than physical damage to facilities arising directly from entry on the customer's property.

E7.8.6 Evaluation of Alternatives

E7.8.6.1 Quantification/Evaluation of Options

(i) Status Quo

The status quo would have Toronto Hydro continue to perform repairs reactively, after equipment has failed and/or following an outage. The considerable reliability challenges and safety risks currently posed by the status quo would continue and potentially worsen. The inspection of sample substations has indicated that over 22% of customer-owned substations in the Horseshoe area are either aged or poorly maintained. With regular maintenance of the customer-owned substations often being neglected, this equipment is increasingly likely to fail and cause reliability (e.g., outages to upstream customers) and safety (e.g., vault fire) problems on or near Toronto Hydro's distribution system. The failure of customer-owned equipment has already resulted in approximately 17 interruptions per year during the 2009-2013 period. This number is likely to increase in the near future if the proposed program is not implemented. For these reasons, Toronto Hydro does not recommend this option.

(ii) Proposed Plan

By undertaking the COSP program (i.e. the preferred option), Toronto Hydro expects to improve the safety, reliability and operational flexibility of its system. More specifically with respect to reliability, the program will enable Toronto Hydro to isolate faults at customer-owned substations, which will minimize the likelihood that an entire feeder would be affected by a fault at a customer-owned substation; thus, reducing the number of customers that will experience power outages.

E7.8.7 2015 Projects

Toronto Hydro must first inspect and analyze the specific circumstances surrounding each problem area before designing and constructing a solution that addresses all deficiencies. To gather the necessary data and analysis regarding customer-owned substations, further research and additional site visits are required.

Table 7 lists projects that are planned for completion in 2015.

TABLE 7: 2015 PROJECTS

Estimate Number	Quantity	Task	Cost	Year
E30476	522	Customer-owned Substation inspections	$248,000	2015
E30476	428	Customer-owned Substation analysis & report	$174,000	2015
E30476	20	Design for construction of Toronto Hydro owned high voltage protection devices (3 phase)	$87,000	2015
E30476	30	Construction of Toronto Hydro owned high voltage protection devices (per phase)	$87,000	2015

E7.9 Station Expansion

13.8 KV METAL CLAD SWITCHGEAR IN THE CENTRAL TORONTO AREA.

E7.9.1 Summary

Program Description

The Stations Expansion program involves upgrades to station infrastructure located at Toronto Hydro supply points where Toronto Hydro receives power from Hydro One Networks Inc. (HONI). The upgrades aim to address ongoing trends in customer connection requirements and loading by addressing system limitations imposed by existing stations equipment. The system limitations fall into one of three categories: capacity shortfalls, short circuit current limitations and support for a large new customer connection.

In order to address the issues described herein, Toronto Hydro plans to pursue the following projects in the 2015-2019 period:

- Expansion of Copeland TS, which will provide an additional 144 MVA of capacity to the area as well as a significant number of new feeder positions. This expansion is referred to as “Phase 2” of Copeland TS. The scope of Phase 2 is incremental to what has previously been presented to the OEB, and includes installation of two additional 72 MVA busses, three gas insulated power transformers and installation of a transfer bus to allow

for utilization of the spare transformer to back up Copeland TS and/or other stations through the installation of ties.

- Construction of a new Toronto Hydro owned transformer station in the Manby TS area, as well as an expansion of Runnymede TS to include one additional bus. This work will provide sufficient capacity to the area to allow for rebalancing of loads and facilitate development in the area.

- Incremental upgrade of HONI's T12 at Strachan TS from 75 MVA to 100 MVA to leverage HONI's asset renewal program.

- Installation of a four position, outdoor, open air bus structure at Basin TS rated for up to 750 MVA of short circuit current. Additionally, the installation of two new circuit breakers at Bathurst TS to enable construction of a dedicated feeder to a large customer will be required. As HONI owns the bus at this location, both parties will be required to collaborate.

Table A summarizes the anticipated benefits associated with the Station Expansion program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	- Ensure Toronto Hydro continues to meet its obligations to current and future customers with respect to providing a reliable supply of electricity. - Ensure that capacity and feeder positions are available to connect new customers to the most technically appropriate station based on location, reducing connection costs to individual customers. - Facilitate redevelopment of potential high growth areas of the city of Toronto (waterfront, south Etobicoke, Portlands, etc.). - Facilitate the connection of renewable resources by upgrading short circuit limitations of existing infrastructure.
Reliability	- Enable Toronto Hydro to maintain the basic design principles upon which the distribution system was constructed (i.e. N-1 design). - Facilitate renewal of aging 13.8 kV switchgear, which are critical links in the distribution of electricity to customers. - Installation of additional capacity near load centers will enable reduced feeder lengths, which generally results in a more reliable system.
Safety	- Overloading equipment reduces the remaining equipment life, thereby increasing failure risk. Depending on the equipment and the failure mode, a failure could result in an explosion, fire or other potential safety hazard. This program reduces the likelihood of overloading equipment, which reduces equipment failure risk.
Efficiency	- Increased capacity will allow for more flexibility in scheduling planned

	outages for maintenance at the effected stations. Currently, Toronto Hydro and Hydro One maintenance may be deferred because of system loading. ƒ New customers who are located within the impacted areas are more likely to be serviced from the station that is geographically closest, reducing connection costs. ƒ Completion of the Strachan TS transformer upgrade would prevent Toronto Hydro from having to pay the full cost to replace the transformer again when additional capacity is required. It would also reduce the overall future cost to fully utilize the 72 MVA rating of the A1-2T or A9-10T busses.
Other	**ƒ** Supports the continued economic development in Toronto by ensuring that electrical capacity is sufficient to support ongoing growth. ƒ Supports other important Toronto Hydro programs such as transformer station switchgear renewal and station-to-station ties.

Program Drivers

The Stations Expansion program is primarily driven by capacity constraints, due to the fact that several stations within Toronto Hydro's service territory will exceed rated peak capacity in the near term (i.e., next five to ten years). The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Capacity Constraints	**ƒ** Several stations within Toronto Hydro service territory are forecasted to exceed rated peak capacity in five to ten years. ƒ Several stations are running low on spare station bus feeder positions, which are required to connect large new customers (including large office towers, condos or data centres). ƒ Some stations are at risk of being unable to accommodate DG connections ƒ With station load exceeding capacity, Toronto Hydro would need to operate the system outside of design parameters, leading to: o reduced reliability, o costly short-term load transfer projects, o suboptimal connection points for new customers, o reduced flexibility to schedule outages for maintenance, and o compromised ability to restore power under contingencies.
Secondary Drivers	**Reasoning**
Reliability	**ƒ** System capacity under an N-1 contingency (where any single system

	component is out of service) is defined based on the element with the lowest rating. ƒ Additional capacity will support planned switchgear renewal, where space limitations prevent direct load transfers from old to new equipment. ƒ Lack of spare capacity limits Toronto Hydro's ability to complete maintenance (which in turn increases failure risk) and increases the likelihood of customer outages in the event of an equipment failure.

Preferred Alternative

Toronto Hydro has identified alternative options to address several issues and evaluated the options based on current and future needs of the system. As an alternative to undertaking capital work, the potential for Conservation and Demand Management (CDM) was evaluated. However, the potential peak reduction achieved through CDM is not sufficient to materially defer or eliminate the need for the capital projects included in this program. Toronto Hydro does plan to undertake a demand reduction program to address future capacity needs at Cecil TS. The details of this program are provided in E7.10 Local Demand Response.

Timing and Pacing

Station Expansion projects generally require material capital investment, involve significant coordination with HONI and are extremely complex to execute. For these reasons, detailed project execution scheduling and feasibility is difficult to estimate until the project is underway.

The timing for projects is driven by system need (i.e., when the forecasted capacity shortfall is expected to materialize) and anticipated project lead times. Delay of the program could result in rotating blackouts, voltage reductions, inability to execute planned work (maintenance or capital) and reduced reliability (due to long feeder lengths that would be required for load transfers).

Table C provides the estimated costs of the program for the 2015-2019 period.

/C

E7.9.2 Program Description

The objective of the Station Expansions program is to address limitations and constraints placed on the distribution system by existing transformer station infrastructure. These constraints fall into one of three categories:

(1) Forecasted thermal capacity shortfalls due to increasing electricity demand,

(2) Short circuit current limitation/shortfalls due to forecasted distributed generation (DG) connections, and

(3) Requirements for additional feeder positions to connect very large customers.

In each case, Toronto Hydro has identified specific projects to mitigate these issues and ensure that the utility can continue fulfilling all of its obligations under the Distribution System Code (DSC). Each issue is described in further detail in the sections below. A summary of the projects included as part of the Stations Expansion program is provided in Table 1.

TABLE 1: SUMMARY OF STATIONS EXPANSION PROJECTS

Description	Station(s) Impacted	Need	Anticipated Project Start	Anticipated Project Finish	Cost ($M)
Copeland TS – Phase 1 (carry over)	Copeland TS	Capacity	2013	2016	192.9
New Transformer Station in Manby TS area	Horner TS, Manby TS	Capacity	2016	2019	72
Expansion of Runnymede TS	Runnymede TS, Fairbank TS	Capacity	2016	2017	33
Copeland TS - Phase 2	Windsor TS, Esplanade TS (George and Duke MS), Copeland TS	Capacity	2019	2020	46
HONI T12 replacement and upgrade	Strachan TS	Capacity	2018	2018	0.5
Basin TS short circuit upgrades	Basin TS	Short Circuit	2015	2015	2
Bathurst – New Feeder Positions	Bathurst TS	Feeder Positions	2018	2018	1.5

IC

A summary of the anticipated benefits associated with completion of the Station Expansion program are provided in Table 2.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Ensure Toronto Hydro continues to meet its obligations to current and future customers with respect to providing a reliable supply of electricity. ƒ Toronto Hydro will be able to continue to serve customers under first contingency, without the need for rolling blackouts or voltage reduction. ƒ Enable completion of maintenance and planned capital work without requiring significant customer outages. ƒ Ensure that capacity and feeder positions are available to connect new customers to the most technically appropriate station based on location, reducing connection costs to individual customers. ƒ Facilitate redevelopment of potential high growth areas of the city of Toronto (waterfront, south Etobicoke, Portlands, etc.). ƒ Facilitate the connection of renewable resources by upgrading short circuit limitations of existing infrastructure.
Reliability	ƒ Enable Toronto Hydro to maintain the basic design principles upon which the distribution system was constructed (i.e. N-1 design). ƒ Facilitate renewal of aging 13.8 kV switchgear, which are critical links in the distribution of electricity to customers. ƒ Enable Toronto Hydro's long term vision to install station-to-station ties for back up and contingency support purposes. Sufficient capacity would be required to make effective use of these ties. ƒ Installation of additional capacity near load centers is expected to enable reduced feeder lengths, which generally results in a more reliable system.
Safety	ƒ Overloading equipment reduces the remaining equipment life, thereby increasing failure risk. Depending on the equipment and the failure mode, a failure could result in an explosion, fire or other potential safety hazard. This program reduces the likelihood of overloading equipment, which reduces equipment failure risk.
Efficiency	ƒ Increased capacity would allow more flexibility in scheduling planned outages for maintenance at the effected stations. Currently, Toronto Hydro and HONI maintenance may be deferred because of system loading. ƒ New customers located within the impacted areas are more likely to be serviced from the station that is geographically closest, reducing connection costs. ƒ Additional capacity would enable system reconfiguration to optimize the supply to customers who are currently supplied in a sub-optimal manner (i.e. from station other than the one that is closes to them). This may occur when there is not sufficient capacity to connect a customer to the closest station. This will serve to reduce line losses and improve reliability.

	ƒ Completion of the Strachan TS transformer upgrade would prevent Toronto Hydro from having to pay the full cost to replace the transformer again when additional capacity is required. It will also reduce the overall future cost to fully utilize the 72 MVA rating of the A1-2T or A9-10T busses.
Other	ƒ Overloading equipment reduces the remaining equipment life, thereby increasing failure risk. Depending on the equipment and the failure mode, a failure could result in an oil spill, fire or other potential environmental hazard. This program reduces the likelihood of overloading equipment and associated failure risk, which reduces the associated potential environmental risks. ƒ Supports the continued economic development in Toronto by ensuring that electrical capacity is sufficient to support ongoing growth. ƒ Supports other important Toronto Hydro programs such as transformer station switchgear renewal and station-to-station ties.

E7.9.2.1 Capacity Shortfalls

Toronto Hydro completes a ten-year station bus load forecast on an annual basis. The purpose of this forecast is to identify long term station and station bus capacity adequacy to meet existing and future peak load demand. The outputs of this forecast trigger the proactive investigation of investment options for mitigating potential station-level system constraints. The goal is ultimately to inform short-term investment decision making such that it aligns with long-term system needs. This is a critical part of Toronto Hydro's planning process. The exhaustion of all available capacity would have an enormous impact on overall system performance, and the lead times associated with some of the potential solutions are much longer than the average distribution system investment project.

Toronto Hydro is also an active participant in the OPA-led Central Toronto Integrated Regional Resource Planning (IRRP) process. As a contributing member of the IRRP Working Group, along with the OPA, HONI and the IESO, Toronto Hydro has supported the IRRP Working Group efforts to assess the adequacy of the transmission system in serving current and future needs. Through the assessment phase, the IRRP Working Group has identified certain near-term needs that require action on the part of Toronto Hydro (along with HONI coordination), needs that are addressed by projects within the Stations Expansion program. More specifically, the needs include an additional step-down relief in the Windsor / Esplanade / George and Duke / Copeland and the Manby / Horner / Runnymede / Fairbank areas. The OPA has requested that Toronto Hydro pursue development of options to address these needs. In general, these options include

station or bus expansion, permanent station-to-station load transfers and/or improving system capability for inter-station load transfers.

Based on Toronto Hydro's 2014 load forecast (and other considerations described throughout this document), there are three areas for which it is prudent and necessary for Toronto Hydro to undertake projects to add capacity within the 2015 to 2019 period:

(1) South-west Toronto (service territory of Horner TS, Manby TS, Fairbank TS and Runnymede TS), shown in Figure 1.

FIGURE 1: SERVICE AREA OF SOUTH-WEST TORONTO AREA (HORNER TS, MANBY TS, RUNNYMEDE TS AND FAIRBANK TS)

(2) Downtown core (service territory of Windsor TS, Esplanade TS, George and Duke MS and, once in service, Copeland TS), shown in Figure 2.

FIGURE 2: SERVICE TERRITORY OF DOWNTOWN CORE TRANSFORMER STATIONS

(3) Service territory of Strachan TS, shown in Figure 3.

FIGURE 3: SERVICE TERRITORY OF STRACHAN TRANSFORMER STATION

In each case, Toronto Hydro has identified and evaluated the practical options for satisfying the short term and/or long term needs of the system. Planned projects are expected to enable the utility to continue providing reliable service – specified as N-1 design (refer to section E7.9.3.1) – to current and future customers in a cost-efficient manner. It should be noted that some of the projects in this program, in particular those involving addition of entirely new infrastructure, require extensive collaboration and coordination with third parties to validate project costs, feasibility and overall prudence in the context of the overall electricity system serving the Greater Toronto Area. This collaboration is ongoing as part of the OPA-led Regional Planning Process. Toronto Hydro expects to continue to work with its partners at the OPA, HONI and the IESO to

develop the complete scope of such projects, in particular any upstream transmission level work required to enable the project benefits, and move forward towards implementation.

South-West Toronto

For the south-west Toronto area, Toronto Hydro plans to pursue implementation of two independent solutions. The first solution involves the installation of an additional 27.6 kV load serving bus at Runnymede TS. As this station is owned by HONI, Toronto Hydro has submitted a connection application to HONI to formally identify the need for additional capacity and to request a study to determine feasibility, requisite transmission upgrades and detailed project costs. This request is expected to be addressed once the first phase of the Toronto Regional Plan exercise is complete. The preferred option is the Runnymede TS expansion option as it is expected to provide relief to both Runnymede TS and Fairbank TS load, which is isolated from adjacent stations by the Humber River, Highway 401 and 13.8 kV distribution areas. In parallel, Toronto Hydro also plans to pursue an entirely new transformer station in the existing Manby TS service territory. This transformer station is expected to provide direct capacity relief to Manby TS and Horner TS. Both areas continue to experience the redevelopment of previously vacant land with large condo projects and energy intensive data centres. This new transformer station would be supplied from the 230 kV transmission system, which would reduce the load on the 115 kV lines currently supplying Runnymede TS, Fairbank TS and much of the 13.8 kV distribution system in central Toronto.

Downtown Core

For the downtown core area encompassing the current (and planned) service territories of Windsor TS, Esplanade TS, George and Duke MS (which is supplied from Esplanade TS) and Copeland TS, Toronto Hydro plans to introduce additional bus and feeder capacity, additional feeder positions and enhanced reliability through Phase 2 of the Copeland TS project. Phase 1, which includes construction of the station facility, installation of the high voltage transmission connections, two power transformers and two busses, is expected to be completed in 2016. Towards the end of the 2015 to 2019 time period, Toronto Hydro anticipates needing Phase 2 to address emerging and future capacity and feeder position shortages anticipated as a result of current growth and planned intensification of currently vacant lands in the area. Toronto Hydro proposes that Phase 2 involve the installation of three power transformers (two load serving, one back up), a transfer bus to enable station to station ties and utilization of the backup transformer, ***/C***

and two load serving busses. This project will enable full utilization of the station site and transmission system connection work that is being completed under Phase 1.

Strachan TS

HONI has informed Toronto Hydro that they will be replacing their existing 75 MVA T12 transformer at Strachan TS due to end-of-life. This transformer is one of a pair of 115 kV to 13.8 kV transformers supplying Toronto Hydro's A5-6T and A7-8T busses. As this is a HONI asset, HONI is obligated to pay the entire replacement cost to maintain the current capacity of the system. Instead of a like-for-like replacement, Toronto Hydro has requested that HONI replace the existing unit with a standard 100 MVA transformer. Under these circumstances, Toronto Hydro is obligated to make a capital contribution to HONI equal to the incremental cost associated with installing a 100 MVA unit rather than a 75 MVA unit as is installed today. Once both existing transformers have been replaced with 100 MVA transformers, the capacity available to Toronto Hydro will be increased by a total of 64 MVA. This is desirable, as the capacity of this station is forecasted to reach 96% by 2023. Alternatively, Toronto Hydro can allow HONI to replace T12 with a 75 MVA unit, and then request that both transformers be replaced (again) and upgraded to 100 MVA in 5 to 10 years when required due to loading. Under these circumstances, where HONI upgrades their assets solely at the request of Toronto Hydro, Toronto Hydro is obligated to make a capital contribution equal to 100% of HONI replacement cost. Therefore, upgrading the transformer at this time is a more cost effective alternative.

E7.9.2.2 Short Circuit Limitations

In order to facilitate connection of DG projects to the distribution system, Toronto Hydro must ensure that there is sufficient short-circuit capacity available at the connection point. Short-circuit capacity refers to the ability of equipment to withstand the maximum short-circuit current that could arise in the event of a phase-to-phase or phase-to-ground fault. In particular, circuit breakers have a maximum current that they are designed to interrupt and the system must be designed so that this maximum current value is not exceeded. The available short-circuit current is determined by the impedance of the upstream transformers, the short-circuit contribution of any connected rotating loads (i.e., synchronous or induction motors, which release energy back out to the grid under fault conditions) and the short-circuit contribution of any connected generation.

When Toronto Hydro receives a DG connection request, it completes a connection impact assessment. As a result of these connection impact assessment processes, Toronto Hydro has identified that Basin TS is at its short-circuit capacity of 470 MVA (18 kA at 15 kV). There is

currently a 5-MW DG source connected to this station, which is forced to operate under constraints due to short circuit considerations. Also, Toronto Hydro is currently developing a generation project (to be connected to the distribution system at Basin TS) that would be prevented from connecting because it would result in the short-circuit rating being exceeded. Toronto Hydro is proposing to eliminate these short-circuit constraints. Discussions with HONI are ongoing, and the proposed solution is to implement changes to the normal operating state of the existing transformers and protection circuits supplying the A7-8BN bus. Implementation of these modifications will require collaboration and agreement with HONI as their upstream equipment (circuit breakers, transformers and protection) would likely require modification as well.

E7.9.2.3 Additional Feeder Position Requirements

Toronto Hydro has received notice from a large customer currently being supplied from Bathurst TS indicating that they plan to expand their operation significantly over the next several years, from 11.5 MW to 14.5MW in 2018, with an ultimate long term load of 22 MW at a yet to be determined date. Given the amount of load required by this customer, Toronto Hydro anticipates that a dedicated feeder will be required. To address this need, Toronto Hydro will make a formal request to HONI to install of a new pair of feeder breakers on the HONI-owned bus. The design of Bathurst TS requires two circuit breakers to be installed at the same time to provide backup for each other while under contingency. Since HONI owns the bus at this station, the requisite work would be shared between HONI and Toronto Hydro; Toronto Hydro would purchase and install the circuit breakers and HONI would be asked to complete the necessary work to connect the new circuit breakers to their bus. Toronto Hydro would be obligated to make a capital contribution to HONI to complete this work pursuant to the requirements of the Transmission System Code (TSC). As well, the customer would be required to make a capital contribution to Toronto Hydro to cover the distribution costs (as required by the DSC); however the station upgrade costs covered under this project are not recoverable from the customer.

Table 3 provides some illustration of assets that will be impacted through the execution of this program.

TABLE 3: EXAMPLES OF STATION ASSETS

Picture	Description
	13.8 kV metal clad switchgear in the central Toronto area. Owned by Toronto Hydro and contains the bus and circuit breakers.
	HONI-owned power transformer.

Picture	Description
	A Toronto Hydro-owned outdoor 27.6 kV oil circuit breaker used in the Horseshoe area.
	Outdoor open air 27.6 kV bus and associated oil circuit breakers. The bus (located behind the screening) is owned by HONI and the circuit breakers are primarily owned by Toronto Hydro.

E7.9.3 Why the Program is Needed

The projects comprising the Stations Expansion program stem from Toronto Hydro's need to mitigate forecasted system constraints as set out in Section E7.9.3.1. As described throughout this narrative, Toronto Hydro has experienced a significant amount of load growth in recent years. This growth is concentrated in specific areas of the city where there is a large amount of densification and redevelopment – a trend which is expected to continue in the future. Toronto Hydro continues to receive connection requests that require incremental distribution system capacity. The direct effect of this trend is that the existing system is approaching capacity at several locations, making necessary to ensure that Toronto Hydro is able to manage the distribution system in an efficient and responsible manner. As a result, Toronto Hydro has developed this program to address forecasted system constraints (capacity, feeder positions, short circuit capacity, etc). The projects that Toronto Hydro has planned are expected to mitigate the short-term and long-term forecasted capacity shortfalls, support future system needs (such as load transfers to enable switchgear renewal work in the downtown core), and enable the introduction of backup capabilities (station-to-station ties). It will also proactively facilitate connection of new load and generation customers.

E7.9.3.1 Program Drivers

The Stations Expansion program is primarily driven by capacity constraints, due to the fact that several stations within Toronto Hydro's service territory are expected to exceed rated peak capacity in the near term (i.e., next five to ten years), as further explained in Table 4. Due to the critical system capacity issues that this program is intended to address, this program is positioned as part of the System Service category.

TABLE 4: PROGRAM DRIVERS

Trigger Driver	Reasoning
Capacity Constraints	***f*** Several stations within Toronto Hydro service territory are forecasted to exceed rated peak capacity in five to ten years. *f* Several stations are running low on spare station bus feeder positions, which are required to connect large new customers (including large office towers, condos or data centres). *f* Some stations are at risk of being unable to accommodate DG connections *f* With station load exceeding capacity, Toronto Hydro would need to operate the system outside of design parameters, leading to: o reduced reliability, o costly short-term load transfer projects,

	o suboptimal connection points for new customers, o reduced flexibility to schedule outages for maintenance, and o compromised ability to restore power under contingencies.
Secondary Driver	**Reasoning**
Reliability	***f*** System capacity under an N-1 contingency (where any single system component is out of service) is defined based on the element with the lowest rating. *f* Additional capacity will support planned switchgear renewal, where space limitations prevent direct load transfers from old to new equipment. *f* Lack of spare capacity limits Toronto Hydro's ability to complete maintenance (which in turn increases failure risk) and increases the likelihood of customer outages in the event of an equipment failure.

Toronto Hydro receives power from the IESO-controlled grid at 35 individual TS located throughout the City of Toronto. At each station, the voltage is converted from either 230 kV or 115 kV to 27.6 kV or 13.8 kV. From these delivery points, Toronto Hydro distributes power to its end-use customers.

Each station in the system has a specific maximum capacity that it is capable of delivering. This limit is derived from the ten-day limited time rating of the lowest rated element at the station, allowing the system to operate with any specific element out of service for up to ten days without permanently compromising the life of the remaining equipment. This is a long-standing industry practice and is typically referred to as "N-1" design. In addition to providing redundancy in the event of unplanned outages, it also enables Toronto Hydro to undertake planned outages for equipment upgrades or repairs. In order to maintain this redundancy (and ensure that the system is being operated within its design parameters), the peak load supplied from a station must be equal to or less than this capacity rating. "N-1" design is a distribution industry best practice that is employed throughout Ontario. Without a backup supply for first contingency situations, any equipment failure is likely to result in a prolonged outage to customers (essentially until replacement equipment could be located, delivered to site and installed). Given the lead time associated with procuring major stations equipment (typically eight to 24 months), the risk of equipment failure and prolonged outages is not tolerable to Toronto Hydro and its customers.

Every year Toronto Hydro completes a ten-year station bus load forecast, based on the following methodology:

(1) Toronto Hydro identifies the summer and winter peak loads for each bus supplying Toronto Hydro feeders (regardless of which utility owns the actual bus).

(2) Peak loads are normalized to the average historical temperature at which the peak has occurred.

(3) Five-year historical growth rates are calculated. Different growth rates are calculated for the six distinct areas of the system. These areas are defined by shared distribution system characteristics, demographics, historical growth and potential for future growth.

(4) Customer connection requests are added based on the desired in service date of the customer and the amount of load requested.

(5) An adjustment factor of 70% is applied to the load requested by customers to reflect past experience of load being overstated at the application phase.

(6) For larger customers, new customer load is added to future years according to either the load build up profile provided by the customer, or in absence of that information, in accordance with a standard build up profile of 60% in year one, 20% in year two and the remaining 20% in year three. Historically, Toronto Hydro has observed that it takes several years for a large customer's full load to materialize.

The historical growth rates (as calculated in part 3) are applied to forecast load for years four to 10.

FIGURE 4: TEN-YEAR STATION BUS LOAD FORECAST PROCESS

The purpose of this forecast is to provide distribution system planners with an outlook of spare capacity available at each station bus and to inform planning decisions such that they are aligned with long-term system needs. As Toronto Hydro receives new connection requests following the issuance of the annual forecast, Toronto Hydro assesses and monitors their potential impact on bus capacity. These connection requests are formally included in the following year's load forecast.

DG and CDM initiatives are not explicitly addressed by the station bus load forecast, as they could serve to mask incipient capacity shortages and their impact on peak demand is often difficult to predict. Rather, the historical impacts on peak load of these initiatives are accounted for in the growth rate calculation. In order to ensure delivery of electricity in a reliable manner, Toronto Hydro must design its system to serve the peak demand, and thus any generation, load shifting or demand response initiative that is not guaranteed to be in operation at the system peak must be disregarded for capacity planning purposes. If not, the utility could be in position where rotating blackouts or load shedding are necessary. That said, DG that is known with certainty to be available at system peak, or CDM initiatives which are certain to reduce peak demand, can both be considered practical alternatives to adding capacity. The relative merits of these generic alternatives depend on the specific circumstances being assessed.

When Toronto Hydro identifies that the load on a station bus is forecasted to exceed capacity, planners identify and assess the available options. This assessment considers the magnitude of the problem, the timeframe, and the long-term needs of the area. A summary of typical solutions is provided in Table 5.

TABLE 5: TYPICAL CAPACITY RELIEF OPTIONS

Option	Prerequisites	Comments
Transfer load to a different bus within the station	Requires an existing bus at the same station with sufficient capacity and feeder positions to accept the new load.	*f* Generally the most cost effective option when available. *f* Some technical restrictions (3-wire vs. 4-wire busses, ability to segment existing load, etc).
Transfer load to a bus at a different station	Requires an existing bus at a nearby station with sufficient capacity and feeder positions to accept the new load. Must be feasible to construct the necessary distribution infrastructure to permanently transfer the load (for example,	*f* Can require significant amount of new infrastructure. *f* Can be very expensive. *f* Technical limits on feeder length must be respected in order to maintain system within design parameters.

Option	Prerequisites	Comments
	there must be spare civil infrastructure between the new station and the load to be transferred).	*f* Investment does not actually result in an increase in capacity – rather, it simply means available capacity is being utilized sooner than it would have been otherwise.
Permanent peak reduction through conservation, demand management or distributed generation initiatives	Potential for peak reduction must be sufficient to mitigate shortfall. Must be persistent. There must be a guaranteed funding mechanism (i.e. the load or generation customer has signed an agreement and paid the requisite deposit to connect to the system).	*f* Reductions must be realized before forecasted overload of bus. *f* Only impact on peak demand is relevant. Impact on energy consumed is irrelevant.
Replace and upgrade limiting component at station	Typically requires coordination with HONI. There must be a specific component or set of components that is exclusively limiting capacity (i.e. a cable section, a transformer, etc).	*f* Some elements can be replaced at relatively low cost and result in incremental capacity. *f* Some Toronto Hydro switchgear replacement projects will result in additional capacity. *f* Toronto Hydro often requests that HONI upgrade transformer ratings to provide additional capacity when they renew their assets.
Expand an existing station by installing a new bus and/or new transformation and/or new transmission infrastructure	Requires sufficient physical space at the station to facilitate expansion. Requires sufficient upstream (transmission) capacity.	*f* Can be very costly. *f* Requires coordination with HONI. *f* Existing ownership of these assets (HONI vs. Toronto Hydro) varies throughout the city. *f* Costs highly dependent on requisite transmission upgrades.
Build a new station	Requires a suitable site located sufficiently close to serve the new load of offload the existing station.	*f* Can be very costly. *f* Requires coordination with HONI. *f* Costs highly dependent on requisite transmission upgrades. *f* Generally lengthy approvals and lead times.

Toronto Hydro's 2014 station bus load forecast identified two general areas of the city where station infrastructure is approaching rated capacity. Each area is discussed in detail below.

(i) Windsor TS / Esplanade TS (George and Duke MS) / Copeland TS

For planning purposes, Toronto Hydro reviews station loading across groups of stations that serve areas with similar demographics. Loading at four stations located in the downtown core of the City of Toronto are of particular concern. These stations encompass a total of 11 busses. Toronto Hydro forecasts that five of these busses will be at or above 95% capacity by 2020 and six of these busses will be above 95% capacity by 2023. To date Toronto Hydro has been able to accommodate the load growth by utilizing existing spare capacity and through the construction of a new transformer station (Copeland TS, which is included in the analysis). From 2008 to 2013, the peak load weather-independent growth rate for the downtown transformer stations identified here is approximately 1.3%. This is less than the weather dependant growth rate quoted in past rate filings (2%, which applied to the entire 13.8 kV system), as starting with the 2014 load forecast Toronto Hydro has normalized historical peaks to correct for weather effects prior to calculating growth rate. This approach is conservative in that it results in a lower growth rate, but it does not account for potential peak demand growth that might result from climate change. Using raw 2008 to 2013 peak data to calculate historical growth rates results in a growth rate of 2.0%, which is consistent with past findings. This indicates that recent weather trends – ostensibly peak summer temperatures – have resulted in an increase in peak electricity demand. If peak temperatures continue to increase, as is predicted by many climate change studies, it can be expected that this will provide upward pressure on peak demand. Toronto Hydro's 2014 summer load forecast for this area is provided in Table 6.

For planning purposes, Toronto Hydro considers a bus at a 13.8 kV station in the former City of Toronto area to be overloaded when it reaches 95% of the rated capacity. This is to account for the lead time required to offload a bus and implement a permanent solution, as well as the fact that the utility must keep sufficient spare capacity on each bus to accommodate any new customer connection requests. Typically, customers request connection anywhere from one to three years in advance, whereas a load relief solution can take anywhere from one to four years to implement, depending on the nature of the existing configuration. It is possible for a customer to request more load than is available on a bus in a shorter timeframe than Toronto Hydro can respond. As shown in the load forecast, within ten years, six of the busses supplied from Windsor TS, Copeland TS and Esplanade TS are forecasted to require capacity relief.

An important indicator of load growth is the number of new connection requests that are received from customers. These requests are submitted by existing and potential customers seeking to

increase their load and/or requiring entirely new connection points. The number of new connections requested for the past several years is shown in Table 7.

TABLE 7: NUMBER OF NEW CUSTOMER CONNECTION REQUESTS BY STATION BY REQUESTED IN SERVICE YEAR

Year	2006	2007	2008	2009	2010	2011	2012	2013
Esplanade TS	1	3	1	2	3	1	6	0
George and Duke MS	4	8	8	9	5	7	12	2
Windsor TS	7	18	10	14	13	13	16	14
Area Total	**12**	**29**	**19**	**25**	**21**	**21**	**34**	**16**

The total number of new connections requested for this specific area is shown in Figure 5.

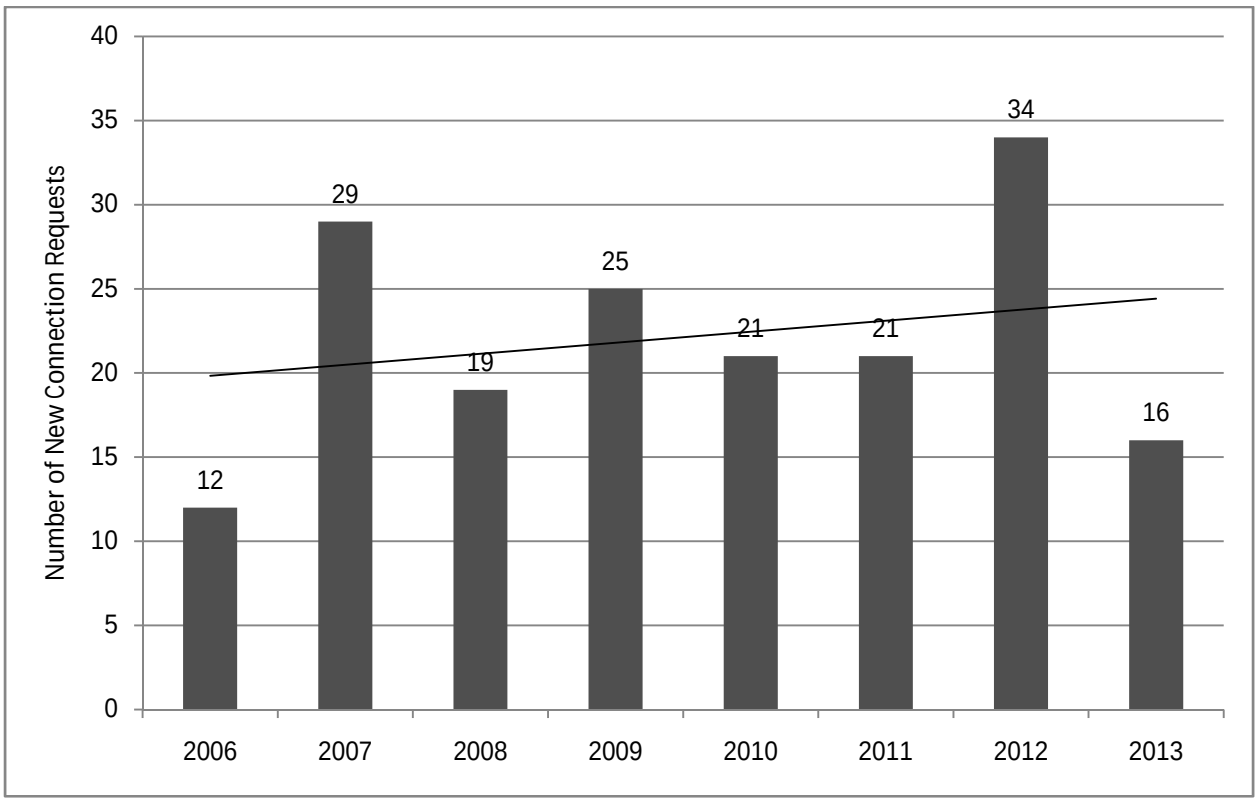

FIGURE 5: TREND OF TOTAL NUMBER OF NEW CUSTOMER CONNECTION REQUESTS FOR ALL AREAS BY REQUESTED IN SERVICE YEAR (WINDSOR / ESPLANADE / GEORGE & DUKE / COPELAND AREAS)

As depicted in the graph, for several years the Windsor, Esplanade, George and Duke and Copeland areas have shown a generally increasing trend in the number of connection requests in

a given year. While a stable trend would indicate that load can be expected to continue to grow at the current rate, an increasing trend strongly suggests that load growth may accelerate in the future.

The impact of various CDM initiatives has been considered as well. For each station, Toronto Hydro's CDM team has forecasted peak load reductions that are achievable over five and ten years based on 2014 OPA targets, energy efficiency initiatives, demand response initiatives and codes and standards changes. For the purposes of this assessment, these station level estimates have been averaged across the number of busses at each station to provide an indication of how much capacity relief can be expected as a result of CDM initiatives. This information is shown in Table 8.

TABLE 8: FORECASTED PEAK REDUCTION THROUGH CDM INITIATIVES

Station	Number of Busses	Cumulative Peak Reduction in MW (2014-2019)	Cumulative Peak Reduction in MW (2019-2024)	Average Cumulative Peak Reduction per Bus in MW (2014-2019)	Average Cumulative Peak Reduction per Bus in MW (2019-2024)
Copeland TS / Windsor TS	8	7.7	8.5	1.0	1.1
Esplanade TS / George and Duke MS	3	3.7	4.0	1.2	1.3

Comparing the forecasted peak load reduction through CDM at the bus level to the forecasted capacity shortfalls shows that CDM initiatives would be insufficient to defer or offset the need for additional capacity. Furthermore, the peak reduction achievable through CDM initiatives is likely to be overstated here as Toronto Hydro's load forecasting methodology intrinsically assumes that CDM, demand response and DG impact on peak demand growth rates will persist for the entire forecast period, and therefore the forecast is offset based on the assumption that peak reductions will continue to be realized at the same rate as past years.

As discussed in Section E7.9.3.1, the first option for relieving bus capacity is generally to transfer load to an adjacent bus at the same station, or even a nearby station. For the downtown core, where these stations are located, this is often more technically complex and costly. The distribution system in downtown Toronto operates at a primary voltage of 13.8 kV and is operationally unique compared to the utility's service territory served by the 27.6 kV system, known as the "Horseshoe" area. The 13.8 kV area – the oldest part of Toronto Hydro's system –

is comprised of feeders radiating from 17 (soon to be 18 with Copeland TS) central Toronto stations that supply customers located in their geographic service areas. There are very few interconnections between different stations, meaning that load transfers between stations typically require construction of new civil and electrical infrastructure. These load transfers can be extremely costly and challenging to implement given the space limitations and the congested nature of the existing utility infrastructure in the area. Load transfers also require available spare feeder positions on the bus receiving the load transfer. Spare feeder positions are increasingly scarce at certain stations as Toronto Hydro continues connecting new customers.

A typical 13.8 kV station arrangement is shown in Figure E7.96 below. The numbers along the bottom of the figure indicate the feeder number or connected station equipment (such as a station service transformer or potential transformers for voltage measurement). “SP” designates a spare feeder position. The bus in Figure 6 depicts a bus with only two remaining feeder positions; once these positions are assigned, the ability of this bus to accept load transfers or supply additional large customers is severely restricted.

FIGURE 6: TYPICAL DOUBLE BUS SINGLE BREAKER STATION CONFIGURATION

Another limitation to load transfers is imposed by the distribution system design. 13.8 kV feeders can be either 3-wire or 4-wire, referring to the electrical configuration of the transformer secondary windings supplying the bus and the resulting number of wires running from the station. A 3-wire system generally supplies three phase load, and connections are made between phases. There is no neutral wire. A 4-wire system has three wires plus a fourth for the neutral connection and supplies both single phase (line to neutral) and three phase (line to line to line) load. At the station, a bus is designed to support either 3-wire load or 4-wire load. A 4-wire bus can supply 3-wire load; however, a 3-wire bus cannot supply 4-wire load unless the switchgear and neutral grounding system at the station is upgraded/replaced. Unlike the Horseshoe area, the downtown system is not designed with the capability to transfer load through switching operations. Lastly, the nature of the load itself affects whether or not it can be transferred to a

different bus or station. In the downtown core, the majority of customers are made up of either large commercial or residential buildings or secondary networks. In these cases, the load is actually comprised of discrete, indivisible "chunks". Even if there is spare capacity on a nearby bus, there may not be enough capacity to transfer an entire customer, thus preventing utilization of the remaining bus capacity. For example, if Bus A is overloaded and Bus B has 10 MVA in spare capacity, and the smallest discrete chunk of load on Bus A is >10 MVA, Bus B cannot be utilized to off load Bus A. A summary of some of the characteristics impacting load transfer feasibility for Esplanade TS, Windsor TS, George and Duke MS and Copeland TS is provided in Table 9.

TABLE 9: BUS CHARACTERISTICS

Station	Bus	Spare Feeder Positions (2016)[1]	Bus Type	Amount of Large Discrete Customer Load	Amount of Network Load
Copeland TS	A1-2CL	4	4-wire	High	Low
Copeland TS	A3-4CL	2	4-wire	High	Low
Windsor TS	A3-4WR	4	3-wire	High	High
Windsor TS	A5-6WR	0[2]	3-wire	High	High
Windsor TS	A11-12WR	0	3-wire	High	Minimal
Windsor TS	A13-14WR	4	3-wire	High	Minimal
Windsor TS	A15-16WR	0	3-wire	High	Low
Windsor TS	A17-18WR	12	3-wire	High	Low
Esplanade TS	A1-2X	6	3-wire	High	Medium
George and Duke MS	A1-2GD	2	4-wire	High	Low
George and Duke MS	A3-4GD	0	3-wire	High	High

1. 2016 forecasted spare feeder positions is shown to reflect benefits of completion of Copeland TS Phase 1.
2. A5-6WR will be out of service for replacement in 2016.

Some additional considerations outlining the need for additional capacity in this area are summarized in Table 10.

/C

TABLE 10: ADDITIONAL STATION-BY-STATION CONSIDERATIONS

Station	Considerations
Esplanade TS and George and Duke MS	ƒ George and Duke MS is supplied by medium voltage express feeders from Esplanade TS. ƒ GD supplies some network load – limits ability to install feeders back to back and thus limits overall availability of feeder positions. ƒ Prime location for new condo or office developments. ƒ Significant potential for redevelopment and load growth – the City of Toronto has developed long term "Precinct Plans" for area near Esplanade TS (West Don Lands, East Bayfront). ƒ Space is available for station expansion. ƒ A1-2GD is a four wire busses approaching 95%, which requires capacity relief in the near future. A1-2X at Esplanade TS is a 3- wire bus and therefore cannot be used to provide relief (although it is nearing 95% capacity as well).
Strachan TS	ƒ Prime location for new condo developments (King West, Liberty Village, etc.). ƒ Potential for generation connections (Exhibition Place, Island MS). ƒ Significant potential for redevelopment and load growth (Exhibition Place). ƒ Replacements of Strachan A5-6T planned, A7-8T in progress. ƒ Space is available for station expansion. ƒ A5-6T and A7-8T are 3-wire busses and cannot accommodate 4-wire load.
Windsor TS	ƒ Current plan is to replace all six switchgear one after another o 2015: A5-6 : 2017: A3-4 : 2019: A11-12. o This will reduce overall capacity at the station by 39 to 65 MVA for the foreseeable future. ƒ Station is effectively at capacity due to switchgear replacements, additional loads likely to be connected to Copeland. ƒ Prime location for new condo or office developments. ƒ Capacity on A3-4WR and A5-6WR revised downward by HONI (from 68 to 59 MVA) as a result of an analysis of LTR rating of series reactors. ƒ No space is available for station expansion. ƒ Currently only three of six busses can accommodate new feeder positions.
Copeland TS (Phase 1, 144MVA)	ƒ Will provide support for Windsor TS switchgear replacements. ƒ Energization date of 2016. ƒ Station built with provisions for expansion to 244 MVA. ƒ Transmission connection work completed with Phase 1. ƒ Will primarily service load currently supplied by Windsor TS and new customers (some load will be transferred from Esplanade TS and Terauley TS as well).

/C

As new load and customers materialize, Toronto Hydro anticipates having to undertake a number of load transfer projects to maintain all 11 busses located in the Windsor / Esplanade / Copeland area that are below 95% of their rated capacity. Based on the load forecast and the system limitations described throughout this section, Toronto Hydro anticipates that after 2023, there will be no feasible options to supply future load/customers. Therefore, additional capacity must be installed and available in the area no later than the end of 2023. Should peak demand growth

outpace the historical rate in this area over the next several years, this need will be accelerated. Thus, it is crucial that Toronto Hydro begin implementing a solution towards the end of the 2015-19 filing period.

Toronto Hydro's objectives for this program are to ensure that the utility is able to continue to fulfill its obligations under the DSC to connect new customers in its service territory, to enable replacement of aging infrastructure (i.e. switchgear replacements where no space currently exists to stage the construction without transferring load to an adjacent station), and to do so in such a way that maximizes value to ratepayers. In order to provide sufficient system capacity to meet these objectives Toronto Hydro is proposing to expand Copeland TS to its full design capacity. Project details are as follows:

Installation of three power transformers (two directly supplying busses, one backup on potential), installation of two load serving busses rated at 72 MVA each and installation of a transfer bus to facilitate station-to-station and intra-station load transfers for contingency purposes.

This would add capacity to the downtown core which would be utilized to provide additional capacity support for adjacent stations and additional feeder positions to support Windsor TS.

Toronto Hydro's total high level estimated incremental cost is $46 million, a small portion of which is expected to be a capital contribution to HONI. $24 million of these costs are anticipated to occur in 2019, with the remaining project costs carried over to 2020.

Toronto Hydro estimates that this project will require two years to complete, plus at a minimum one to two additional years to transfer load to the new infrastructure. Based on the above-mentioned critical "need" date of 2023, the project is scheduled to commence in 2019 for completion of the station work in 2020. Load transfers and system reconfiguration would take place between 2021 and 2022, in time to address the 2023 need date. Note that this timeline may need to be accelerated depending on the actual peak demand growth rate observed in the near future.

Toronto Hydro plans to pursue this project with its partners at the OPA, HONI and the IESO as part of the Regional Planning process. Any decision to proceed would be undertaken only after consultation with these stakeholders.

(ii) Strachan TS

Strachan TS, located at Strachan Avenue and Fleet Street, supplies much of the south-west portion of central Toronto, including Exhibition Place, BMO Field and Ontario Place. The station is comprised of four load service busses, each supplied from two windings from two of four different HONI transformers located on site (designed as T12, T13, T14 and T16). HONI has indicated to Toronto Hydro that they plan to replace the 75 MVA T12 transformer because it has reached its end-of-life. This transformer supplies Toronto Hydro's A5-6T and A7-8T busses. Toronto Hydro is proposing to request that HONI upgrade the size of the replacement transformer from 75 MVA to 100 MVA. Under these circumstances, Toronto Hydro would be responsible for paying the incremental difference in cost relative to a like-for-like replacement. This will provide additional capacity and flexibility to the area at a fraction of the cost should such an upgrade be completed solely at Toronto Hydro's request. Currently, the A1-2T and the A9-10 busses are rated for 72 MVA; however their actual capacity is limited to 56 MVA by the transformer size. Once both transformers supplying a bus are upgrade to standard 100 MVA units, the full rating of the bus can be utilized.

The 2014 load forecast for the Strachan TS area is shown in Table 11.

TABLE 11: 2014 SUMMER LOAD FORECAST FOR STRACHAN TS

STATION / BUS	FIRM CAPACITY(MVA)		YEAR										
	100%	95%	2013*	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023
STRACHAN (115KV/13.8KV) TS													
A1r2	56	53	46	50	52								
A9r10 (Formerly A3r4)	50	48	37	41	42	43	43	44	44	45	46	46	47
A5r6	40	38	23	25	29	31	32	33	33	34	34	34	35
A7r8	40	38	36	37	33	34	35	35	36	36	36	37	37
Total of all Buses	192	182	142	153	156	162	164	167	169	172	173	175	178
Surplus MVA			50	39	36	30	28	25	23	20	19	17	14
% Loading (Load/2013 Firm Cap)			74	80	81	84	85	87	88	90	90	91	93

By 2023, the station is forecasted to reach 93% loading overall. At that point in time, Toronto Hydro will have the option to request replacement of the other transformer(s) supplying the A1-2T or the A9-10T, which will result in a capacity increase to 72 MVA. This represents an opportunity to leverage HONI's planned asset renewal program to benefit Toronto Hydro ratepayers. Toronto Hydro estimates that its cost to complete this work will be $0.5M.

(iii) South-West Toronto (Horner TS, Manby TS, Runnymede TS, Fairbank TS areas)

There are currently four stations in the south-west part of Toronto Hydro's service territory that are forecasted to be at capacity in the near future. These stations are Horner TS, Manby TS, Runnymede TS and Fairbank TS.

FIGURE 7: MANBY TS

FIGURE 8: HORNER TS

FIGURE 9: RUNNYMEDE TS

FIGURE 10: FAIRBANK TS

This location in the Horseshoe area distributes electricity at a primary voltage of 27.6 kV. There is generally some dynamic load transfer capability built in to move load between stations through

operational switching, although it is limited by technical considerations such as voltage drop and reliability, as longer feeders, such as those connecting these stations, generally have a negative impact on reliability. At these stations, the demarcation point between HONI and Toronto Hydro is the feeder breaker. HONI owns everything up to and including the secondary side of the feeder breaker, while Toronto Hydro owns everything electrically downstream from that point. The 2014 load forecast for these stations is provided in Table 12.

TABLE 11: 2014 SUMMER LOAD FORECAST (SOUTH-WEST TORONTO)

% Loading (Load/2013 Firm Cap)			90	91	92	94	96	97	98				

As can be seen in Table 13 above, Toronto Hydro is forecasting that the total capacity for the entire area will be exhausted by 2020. The load forecast utilizes a growth rate of 1.1% for Runnymede TS and Fairbank TS, and a growth rate of 2.3% for Manby TS and Horner TS. These growth rates were determined based on weather corrected historical peak loads. Actual peak load can vary significantly on a year-over-year basis if there is an abnormally large (or small) volume

of customer connection requests, and based on the size of said requests. Generally, Toronto Hydro tries to balance loading between area station busses through load transfers. However, this is becoming increasingly difficult in this area of the system given that all four stations are reaching capacity. Over the past few years, Toronto Hydro has seen an increasing number of requests for connection in the areas served by these stations. This is illustrated in Table 13 and Figure 12, respectively.

TABLE 12: NUMBER OF CONNECTION REQUESTS BY STATION

Year	2006	2007	2008	2009	2010	2011	2012	2013
Fairbank TS	2	4	3	2	4	5	6	8
Horner TS	11	7	3	8	5	4	12	7
Manby TS	8	3	4	5	3	4	8	6
Runnymede TS	1	3	0	4	1	0	7	0
Area Total	**16**	**17**	**18**	**10**	**19**	**16**	**30**	**29**

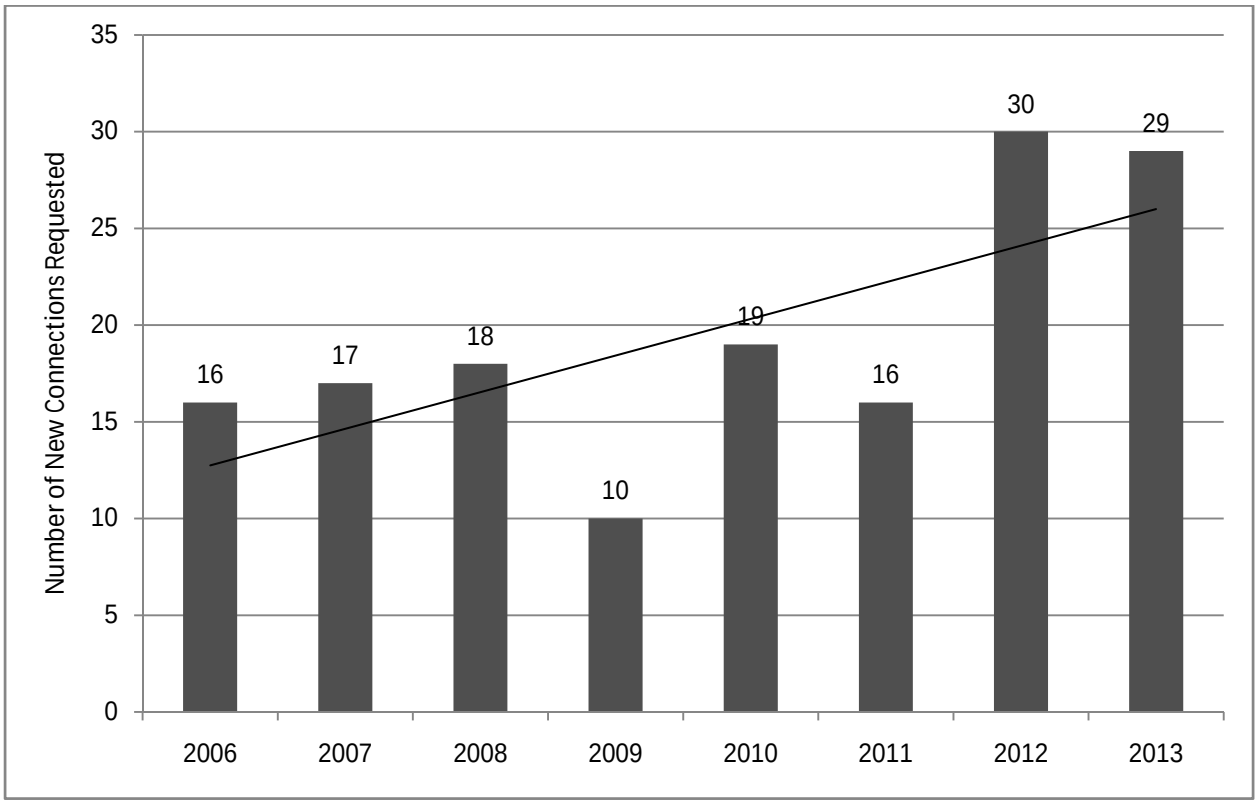

FIGURE 11: TOTAL AREA CONNECTION REQUESTS (HORNER / MANBY / FAIRBANK / RUNNYMEDE AREAS)

The increasing trend in connection requests received across the area strongly implies that peak demand is expected to continue growing at historical levels. Toronto Hydro has also observed a corresponding increase in the aggregate amount of new load to connect. This is illustrated in Table 14 and Figure 12, respectively.

TABLE 13: TOTAL LOAD OF CUSTOMER CONNECTION REQUESTS (MVA)

Year	2006	2007	2008	2009	2010	2011	2012	2013
Fairbank TS	1.3	0.6	0.9	0.1	0.3	1.7	9.7	3.5
Horner TS	9.3	7.4	7.9	14.8	5.2	7.3	9.7	24.6
Manby TS	7.1	1.4	3.0	9.2	3.7	5.6	5.5	3.4
Runnymede TS	0.7	1.9	0.0	1.0	0.0	0.0	23.6	0.0
Area Total	**18.4**	**11.3**	**11.9**	**25.1**	**9.2**	**14.5**	**48.5**	**31.6**

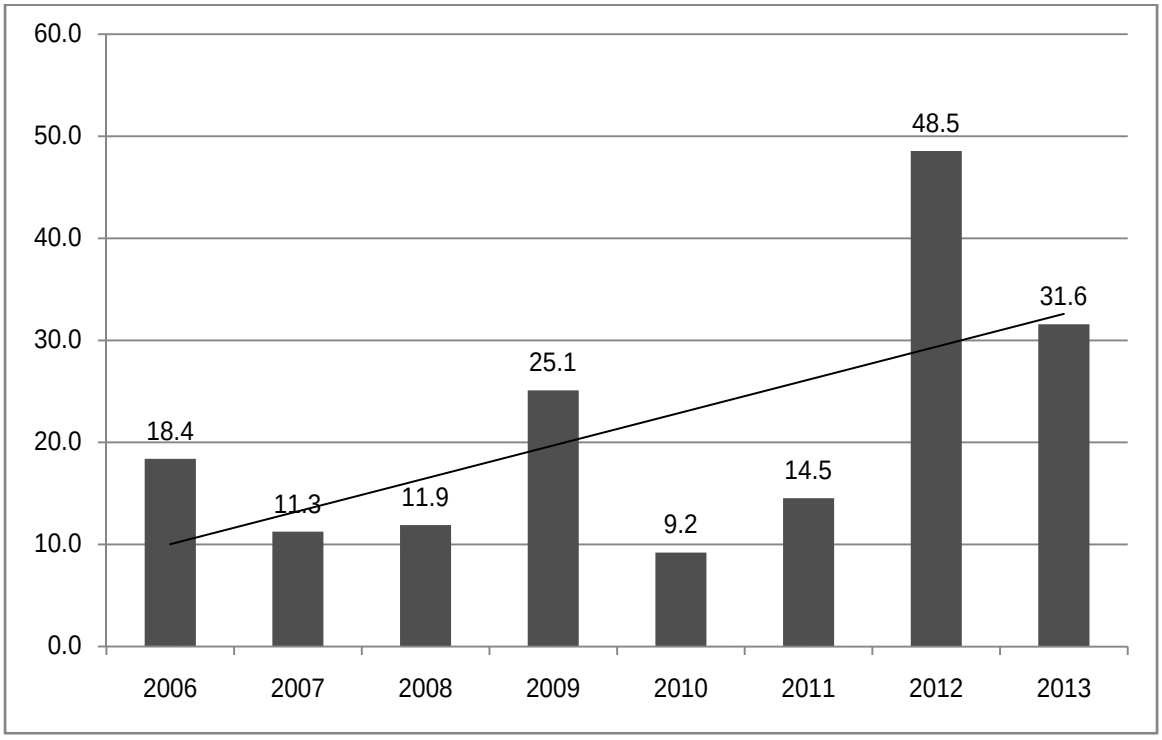

FIGURE 12: TOTAL LOAD (MVA) OF AREA CONNECTION REQUESTS (HORNER / MANBY / FAIRBANK / RUNNYMEDE AREAS)

The connection data presented in these figures is incorporated in to the 2014 load forecast. While not all the load will materialize, this data serves as a useful indicator of the level of customer connection activity Toronto Hydro is facing.

An additional consideration for Runnymede TS and Fairbank TS is the Eglinton Crosstown LRT project currently being undertaken by Metrolinx.

FIGURE 13: EGLINTON CROSSTOWN LRT (SOURCE: WWW.THECROSSTOWN.CA)

The proposed transit stations from Bathurst Station West to Mt. Dennis are located in the Fairbank TS or Runnymede TS service territory. Toronto Hydro is involved with ongoing discussions with Metrolinx regarding their power requirements, and preliminary information indicates that up to 33 MVA of permanent power will be required for this segment of the line, adding to the overall load demand in this area. Long term, it stands to reason that development (and thus electricity demand) will intensify along the Eglinton corridor once the new LRT line is in full service.

As was the case with for Windsor TS, Copeland TS and Esplanade, Toronto Hydro has also assessed the impact of various CDM initiatives. Toronto Hydro's CDM team has forecasted peak

load reductions that are achievable over five and ten years based on 2014 OPA targets, energy efficiency initiatives, demand response initiatives and codes and standards changes. For the purposes of this assessment, these station level estimates have been averaged across the number of busses at each station to provide an indication of how much capacity relief can be expected as a result of CDM initiatives. This information is shown in Table 15. This level of reduction is insufficient to address the need for additional capacity in these areas.

TABLE 14: FORECASTED PEAK REDUCTION THROUGH CDM

Station	# of Bus Pairs	Cumulative Peak Reduction in MW (2014-2019)	Cumulative Peak Reduction in MW (2019-2024)	Average Cumulative Peak Reduction per Bus Pair in MW (2014-2019)	Average Cumulative Peak Reduction per Bus Pair in MW (2019-2024)
Horner TS	1	5.2	5.6	5.2	5.6
Manby TS	3	7.3	7.8	2.4	2.6
Runnymede TS	1	4.2	4.8	4.2	4.8
Fairbank TS	2	8.1	9.4	4.0	4.7

Some additional considerations pertaining to system need in this are summarized in Table 16.

TABLE 15: LIST OF STATION-BY-STATION CONSIDERATIONS

Station	Considerations
Horner TS	***f*** Station is surrounded by physical barriers (Lake Ontario, Enersource service territory, the Gardiner Expressway and the Humber River), which make load transfers more challenging and expensive. *f* In addition to the information contained in the load forecast, and the connection requests not included in the forecast, Toronto Hydro received an inquiry in early 2013 from a customer claiming to require up to 60 MVA by 2019. While no official request has been received, Toronto Hydro will be challenged significantly to supply this customer should they formally indicate their intention to proceed. *f* Toronto Hydro has submitted a connection application to HONI to confirm a cost, schedule and feasibility for installation of a new bus and the requisite transmission capacity.
Manby TS	***f*** Station is adjacent to Richview TS (which has spare capacity). Toronto Hydro has reviewed load transfer options in detail; however, the cost is significant and the load relief would only be temporary. These stations are separated by Highway 401, which presents a challenge to transferring load between stations. *f* Toronto Hydro understands that there is no physical space on the HONI-owned site for a new bus.

Station	Considerations
Runnymede TS	ƒ Toronto Hydro has submitted a connection application to HONI to confirm a cost, schedule and feasibility for installation of a new bus and the requisite transmission capacity. ƒ This station is supplied from the 115kV lines originating at Manby TS. HONI has indicated that installation of new capacity at this station would have a negative impact on the overall supply capacity of those lines (in excess of the amount of capacity added). ƒ This station is separated from Richview TS and Manby TS by the Humber River, making load transfers complicated and costly. It also borders the 13.8kV system (no load transfers possible between different voltage classes) and Fairbank TS, which is also overloaded. ƒ Toronto Hydro's CDM team is targeting this area for future demand response programs. Once the impact of this program is defined, Toronto Hydro will review its impact on capacity expansion plans.
Fairbank TS	ƒ Toronto Hydro understands that there is no physical space on the HONI owned site for a new bus. ƒ Toronto Hydro's CDM team is targeting this are for future demand response programs. Once the impact of this program is defined, Toronto Hydro will review its impact on capacity expansion plans.

As is the case with the previously discussed downtown station expansion program, Toronto Hydro's objective for the South West Toronto portion of the program is to ensure that it is able to continue fulfilling its obligations under the DSC by connecting new customers in its service territory in a manner that maximizes ratepayer value. To accomplish this objective, Toronto Hydro is currently proposing to undertake two projects:

(1) Installation of a new HONI owned bus at Runnymede TS (minimum 60 MVA).

This project would involve the installation of two power transformers with a minimum 60 MVA LTR rating and a bus pair. It is assumed that no transmission upgrades are required.

This would add capacity to the area east of the Humber River and south of highway 401 which would provide support to Fairbank TS and Runnymede TS without requiring any river or highway crossings.

A formal Connection Application has been submitted to HONI. HONI is required to respond with a cost and schedule to address the forecasted shortfall.

Toronto Hydro's high level estimated cost is $33 million, which would be a capital contribution to HONI.

Toronto Hydro's estimated project schedule is to commence construction in 2016 for completion in 2017.

(2) Construction of a new Toronto Hydro-owned station in the Manby TS area (minimum 100 MVA).

This project would involve the purchase and preparation of a suitable site, high voltage connection work, installation of two power transformers and a bus pair and construction of the necessary civil egress infrastructure.

This would add capacity support to the Horner TS and Manby TS areas.

Toronto Hydro is currently working to identify potential areas to site a new transformer station, preferably within two kms from the existing 230 kV transmission system (which would simplify project execution).

Would ideally be supplied from the 230kV system and provide direct relief to Manby TS, Runnymede TS and the 115 kV transmission system supplying the western portion of central Toronto.

Toronto Hydro's high level estimate is $72M, part of which would likely be a capital contribution to HONI.

Toronto Hydro's estimated project schedule is to commence construction in 2016 for completion in 2019.

Toronto Hydro plans to pursue these options with its partners at the OPA, HONI and the IESO as part of the next phase of the Regional Planning process. Any decision to proceed will be made upon agreement that these projects are prudent and appropriate solutions from a transmission system planning perspective in addition to a distribution system planning perspective.

(iv) Basin TS Short Circuit Upgrades

Basin TS is located in the "Portlands" area of Toronto, south-east of the downtown core. The station is comprised of two dual winding HONI owned power transformers (designated T3 and T5) and two Toronto Hydro owned busses (designate A5-6BN and A7-8BN). One characteristic of power distribution systems that limit connection of DG resources is the "short circuit level". Essentially, this refers to the system's ability to withstand the current generated by a short circuit on the system. Large currents generate significant amounts of heat, induce strong magnetic fields

and are more difficult to interrupt compared to normal operating currents. As a result, power system equipment has a maximum rated amount of short circuit current that it can withstand. This is particularly important for circuit breakers as they are the devices whose purpose it is to interrupt said current and isolate faults. The amount of short circuit current available at a given point in the system is calculated based on the impedances of the power lines and equipment (high impedance serves to limit fault current), the size and location of rotating loads (large industrial motors, which in the event of a fault release energy out into the distribution system) and the amount and location of connected DG resources (which will also supply energy in to a fault).

As part of the connection process for generation projects, Toronto Hydro regularly assesses the short circuit capacity available at the station. In the case of Basin TS, Toronto Hydro has identified that short circuit levels are presently at the station capacity of 470 MVA. Toronto Hydro is currently developing a generation project at the Ashbridges Bay Wastewater Treatment Plant which will add an additional 60 MVA of short circuit current. This connection cannot currently be made. As a solution, Toronto Hydro is proposing to take action and work with HONI to upgrade the short circuit rating of the station by modifying the configuration of the bus supply. This will likely also involve installation of some additional equipment (circuit breakers and short current limiting devices) at Basin TS, the need for which will be established upon completion of a detailed technical analysis in conjunction with HONI. This job will also require upgrades to protection settings and may involve reconfiguration of the existing transformer connections. A high level estimate of the total cost for this work is $2 million, of which $0.5 million is anticipated to be a capital contribution to HONI. Any solution pursued by Toronto Hydro will require extensive cooperation and collaboration with HONI.

(v) Bathurst TS – New Feeder Positions

Bathurst TS is a HONI owned station located in the Bathurst Street and Finch Avenue area. The ownership arrangement is such that Toronto Hydro owns the feeder circuit breakers and HONI owns the bus and all assets upstream from that point. Toronto Hydro has received notice from a large customer that it anticipates the need for a dedicated feeder in the coming years to support expansion plans. In order to respond to this need, Toronto Hydro will be required to request a pair of bus positions at Bathurst TS to install two new feeder circuit breakers to support this request. Based on the standard design of the station, two circuit breakers would be required for reliability purpose as they are designed to back each other up in contingency situations.

TABLE 17: SPENDING BY PROJECT

Project	2015	2016	2017	2018	2019	Future
Copeland Phase 1	$41.8M	$13.1M	-	-	-	-
New Transformer Station in Manby TS area	-	$12.0M	$20.0M	$20.0M	$20.0M	-
Expansion of Runnymede TS	-	$16.5M	$16.5M	-	-	-
Copeland TS - Phase 2	-	-	-	-	$24.0M	$22.0M
HONI T12 replacement and upgrade	-	-	-	$0.5M	-	-
Basin TS short circuit upgrades	$2.0M	-	-	-	-	-
Bathurst – New Feeder Positions	-	-	-	$1.5M	-	-

/C

Construction on Copeland Transformer Station (TS) began in 2013 and is expected to be completed in 2016. Copeland TS is a uniquely challenging project located in the dense urban core of the city. The station design places most of the equipment underground and includes a tunnel connection to HONI's Front Street tunnel. Excavation of the main site began in 2013 and was completed before the end of that year. Presently, civil construction is under way on the project. Cable tunnel mining is complete and concrete placement is ongoing. Major equipment orders were placed in 2013. Manufacturing, factory acceptance testing and delivery of most of the major equipment occurred in 2014 and it is now in secure storage awaiting station readiness for installation.

/C

Initially, Toronto Hydro estimated the Copeland TS (Phase 1) project would be completed by the end of 2014. However, due to several unforeseen events and factors, Toronto Hydro now expects the construction to be completed in the second quarter of 2016. The project's overall cost is expected to remain within the OEB-approved amount; however, the timing of certain portions of those expenditures will shift given the delay to the construction completion date (i.e. some of the 2014 forecast spend is now deferred to 2015 and 2016). The delay is attributable to a variety of factors, including the effect of unusually adverse weather events, a generally harsh winter in 2014, challenging site conditions and contractor performance. Other causes of delay include unforeseen obstructions found on site (not known at time of the RFP or identified in engineering reviews of site records), and delays in securing appropriate permits for certain on-site activities (i.e. lane closure permit for tunnel boring subcontractor).

/C

In addition to Copeland Phase 1, the majority of the remaining historical spending over the 2010 to 2014 time period on Station Expansion type work can be attributed to the Leaside-Birch transmission reinforcement project, which involved upgrades to the 115 kV transmission lines between Leaside TS and Wiltshire TS, and installation of additional feeder breakers at various 27.6 kV stations to support load growth due to new customer connections. It should also be noted

that the 2010 and 2011 historical spending includes capital contributions made to HONI for transformer station switchgear replacement projects. While these costs would normally be categorized under the Station Switchgear Renewal program, for these years Toronto Hydro is unable to delineate between contributions made for renewal projects and contributions made for expansion projects.

E7.9.4.1 Ranking & Prioritization

Toronto Hydro prioritized the projects comprising this program based on the following criteria:

- Forecasted year of capacity shortfall,
- Magnitude of forecasted capacity shortfall, and
- Lead time required to complete each individual project and degree of complexity

A complete list of projects that Toronto Hydro plans to undertake, including their timing and prioritization is provided in Table 19.

TABLE 18: PROJECT TIMING

Project	In Service Year	Timing and Prioritization
Basin TS Short Circuit Upgrades	2015	*f* Timing based on forecasted short circuit capacity shortage and planned in service year of Ashbridges Bay generation project.
Copeland Phase 2	2020	*f* Toronto Hydro forecasts that through a combination of small scale load transfers, the need for additional capacity in the Copeland/Windsor/Esplanade area can be deferred to 2023 at the absolute latest. *f* Upon completion of this project, Toronto Hydro will require one to two years to transfer load to the new busses and rebalance load in the area.
Strachan TS Transformer Upgrade	2018	*f* Timing is contingent on HONIs asset renew programs.
Runnymede TS Expansion	2017	*f* Based on the 2014 summer load forecast, Toronto Hydro requires immediate capacity relief as one bus at Fairbank TS is already overloaded. Short term measures (small load transfers) can be implemented to buy time but additional capacity is required as soon as possible. *f* In service year of 2017 for additional capacity reflects anticipated project lead time.
New Transformer	2019	*f* Toronto Hydro is in need of immediate capacity relief at Manby TS as the station has already exceeded capacity in

E7.9.6 Program Execution

A generalized overview of the steps and prerequisites required to implement each type of job contained in this program is provided in the table below. This summary is intended to provide a high level overview of the key steps involved with each job. It does not represent the exact scope of work for each project.

TABLE 19: TYPICAL STATION CAPACITY RELIEF OPTIONS

Job Type	Steps	Execution Risks	External Coordination
Load transfer	1. Distribution Planner assesses feasibility and issues scope to construct new infrastructure. 2. Station planner issues scope to prepare new feeder position on receiving bus (if required). 3. Scopes are issued to designers. 4. Scopes are issued for construction.	x Given the complex nature of these projects, there are inherent planning challenges/risks that can impact overall project cost and feasibility. x Road moratoriums can cause permitting complications.	x Standard Toronto Hydro customer engagement for construction projects in their area.
Upgrading of HONI equipment (i.e. a transformer)	1. Toronto Hydro submits connection application to HONI requesting additional capacity through equipment upgrade. 2. HONI reviews request and if acceptable, provides cost and schedule. 3. Toronto Hydro and HONI	x If a HONI owned asset is being replaced and it is not at the end of its life useful, Toronto Hydro is required to compensate HONI. x Schedule depends	x Formal agreement with HONI required for study and completion of work.

Job Type	Steps	Execution Risks	External Coordination
	sign Connection Cost Recovery Agreement (CCRA). 4. HONI completes work.	on HONI's ability to execute the work. x Overall project cost highly dependent on HONI estimates.	
Expansion of a Toronto Hydro-owned station	1. Toronto Hydro station planner identifies need. 2. Toronto Hydro submits connection application to HONI to assess feasibility, cost and schedule for requisite transmission connection work. 3. Scope issued to Toronto Hydro execution groups. 4. HONI reviews request and if acceptable, provides cost and schedule. 5. Toronto Hydro and HONI sign CCRA. 6. Toronto Hydro executes its work. 7. New infrastructure energized upon completion of HONI and Toronto Hydro work.	x Schedule depends on HONI's ability to execute the work. x Overall project cost highly dependent on HONI estimates. x Requires significant coordination with distribution planners to ensure load transfers occur in an optimized manner.	x Standard Toronto Hydro customer engagement for construction projects in their area. x Additional communication with the community is necessary if expansion is observable during or after construction. x Formal agreement with HONI required for study and completion of work.
Expansion of a HONI-owned station	1. Toronto Hydro station planner identifies need. 2. Toronto Hydro submits connection application to HONI to assess feasibility, cost and schedule for requisite transmission connection work. 3. HONI reviews request and if acceptable, provides cost and schedule. 4. Toronto Hydro and HONI sign CCRA.	x Schedule depends on HONI's ability to execute the work. x Overall project cost highly dependent on HONI estimates. x Requires significant coordination with distribution planners to ensure load transfers	x Toronto Hydro would support HONI with community engagement as required.

Job Type	Steps	Execution Risks	External Coordination

Construction of a new Toronto Hydro-owned station	1. Toronto Hydro station planner identifies need. 2. Toronto Hydro submits connection application to HONI to assess feasibility, cost and schedule for requisite transmission connection work. 3. Scope issued to Toronto Hydro execution groups. 4. HONI reviews request and if acceptable, provides cost and schedule. 5. Toronto Hydro and HONI sign CCRA. 6. Toronto Hydro executes its work. 7. New infrastructure energized upon completion of HONI and Toronto Hydro work.	x Schedule depends on HONI's ability to execute the work. x Overall project cost highly dependent on HONI estimates. x Requires significant coordination with distribution planners to ensure load transfers occur in an optimized manner.	x Toronto Hydro will support HONI with community engagement as required.

E7.9.7 Evaluation of Alternatives

E7.9.7.1 Quantification / Evaluation of Options

Toronto Hydro has identified alternative options to address several issues and evaluated the options based on current and future needs of the system. The impact of forecasted peak reductions through CDM has been included in the plan.

(i) Windsor / Esplanade / George & Duke / Copeland

Issue: As described in detail in Section E7.9.3, Toronto Hydro requires additional capacity in the area served by Windsor, Esplanade, George and Duke and Copeland stations to serve both near and long term system needs. In summary:

- By 2019 Toronto Hydro forecasts that two busses will be overloaded at George and Duke MS and two busses overloaded at Windsor TS.
- By 2025 Toronto Hydro forecasts that one bus will be overloaded at Copeland TS, two busses overloaded at George and Duke MS and three busses overloaded at Windsor TS.
- Currently at Windsor TS, four out of six busses have no spare feeder positions to connect new customers. One bus has a single spare feeder position and one bus has two spare feeder positions.
- Currently at George and Duke MS, one bus has no spare feeder positions and one bus has six spare feeder positions.
- Currently at Esplanade TS, the sole bus has only three spare feeder positions.
- Once in service, Copeland TS is forecasted to have six and three spare positions on each its two busses, respectively.

Toronto Hydro anticipates that at the current pace of development in these areas, both bus and feeder position will be at or near capacity within five to ten years. In identifying solutions to these issues, Toronto Hydro considered the following options.

Chosen Option: Expansion of Copeland TS

- Completion of Copeland TS Phase 2, which includes the purchase and installation of three power transformers (two on load, one on potential spare), two distribution 72 MVA busses and one transfer bus to facilitate integration of the spare transformer and inter-station ties with Windsor TS. While not entirely non-discretionary, installation of the second 72 MVA bus, the spare transformer and the transfer bus at this time is considered the more prudent option. This would allow Toronto Hydro to fully utilize the space and infrastructure installed in phase 1 while eliminating the need and cost associated with re-entering the station (roof removal and redoing the landscaping). Additionally, the spare transformer is required given the uniqueness of the SF_6 transformers that will be installed

at the station and the long lead times to procure replacement units. Should a transformer fail before a spare is available, the station load would be under contingency for an extended amount of time. Adds 144 MVA and a significant number of feeder positions to allow for bus rebalancing in the area and to facilitate future switchgear replacements, particularly at Windsor TS. Installing two 72 MVA busses will enable utilization of all additional transformation capacity (installing one bus would still require installation of two transformers for contingency purposes).

- Provides additional security of supply to critical downtown customers.
- Would provide additional support for adjacent stations Terauley TS, Strachan TS and Cecil TS through load transfers (if necessary).
- Provides additional capacity to facilitate potential development of West Donlands area, east Waterfront and the Portlands.
- Minimal additional high volta$_g$e connection work will be required beyond what was completed as part of Copeland phase 1.
- This option involves no permanent visual disturbance to the area.
- Estimated total cost of $46M.

Alternative Option 1: CDM

- Toronto Hydro forecasts that cumulative incremental peak reductions of approximately 1.2 MW per bus at Esplanade TS and George and Duke MS and peak reductions of 1.1 MW per bus at Windsor TS and Copeland TS are achievable over the 2014 to 2019 timeframe.
- This level of reduction is insufficient to meet short and long term needs.
- Furthermore, the forecasted peak reductions include considerations for factors outside of Toronto Hydro's control, such as reductions through program which are as of yet unfunded and codes and standards initiatives which are driven by third parties.
- Given that there is currently no clear funding mechanism for this work, and the fact that it is inadequate as a stand-alone solution, this option is not preferred.

Alternative Option 2: Expansion of Esplanade TS

- This option would involve working with HONI to construct a new building on the existing Esplanade TS site, perform necessary transmission upgrades (as determined by HONI), install two new power transformers, installed two new 72 MVA distribution busses and complete the requisite high voltage connection work.
- This option is better positioned to serve areas of potential future development (West Donlands area, east Waterfront and the Portlands), it is located further from the existing load centre compared to Copeland TS.
- This project would involve construction on a new facility and could encroach on parkland that is adjacent to the station.
- Estimated cost of $48M, including necessary contributions to HONI. As this project could require as of yet undetermined work on the transmission system, the costs and schedule associated with this option would be subject to a significant amount of uncertainty.

Alternative Option 3: Load Transfers

- From a practical perspective, there are several technical barriers that would make this a costly and extremely complex exercise.
- This would require a very significant amount of investment in order to build the necessary infrastructure. This investment may be sufficient for five to ten years, yet it does not provide any relief for additional capacity needs in the longer term.
- Much of the load that would need to be transferred comes in indivisible, discrete chunks and requires dedicated feeder positions (i.e. secondary network load and large office or condo buildings). The busses that have capacity generally will not have sufficient feeder positions available to provide the dedicated feeders needed to supply these discrete loads.
- Load transfer potential is further limited by the 3-wire vs. 4-wire configuration issue described earlier in this narrative. For example, George and Duke busses A1-2GD and A3-4GD both require relief and Esplanade bus A1-2X has capacity. But, since A1-2X is a 3-wire bus and the George and Duke busses are 4- wire, load transfers are not possible.

- The stations immediately adjacent to Windsor, Copeland and Esplanade are approaching capacity as well and in the long term, will require capacity relief. Load transfers will not provide any long term support to relief of these stations.

- It should be noted that assuming it is feasible, Toronto Hydro anticipates the need to undertake some load transfer projects in order to defer the need for new area capacity to 2023.

(ii) Horner, Manby, Runnymede & Fairbank

Issue: As described in detail in Section E7.9.3, Toronto Hydro requires additional capacity in the area served by Horner TS, Manby TS, Runnymede TS and Fairbank TS stations to serve both near and long term system needs. In summary:

- In 2013 both Manby TS busses exceeded their peak ratings.

- Fairbank TS bus B&Q is forecasted to exceed its peak in 2014.

- Horner TS bus B&Y is forecasted to exceed its peak in 2019.

- Runnymede TS is currently at 92% capacity and is forecasted to reach 94% capacity in 2019 and 99% capacity in 2023.

- The combined capacity of all four stations is expected to be entirely exhausted by 2020.

- Toronto Hydro has observed significant redevelopment of some areas served by these stations. Further development is anticipated based on upcoming projects (the Eglinton Crosstown LRT) and the increased growth in annual connection requests and the gross MVA requested.

Toronto Hydro plans to pursue two projects to address these issues.

Chosen Option 1: Construct a New Toronto Hydro-Owned Transformer Station in the Manby TS Area

- This option involves construction of a transformer station in the Manby area (100 MVA) and purchase of the requisite land.

- Toronto Hydro is currently investigating potential areas for locating the proposed new transformer station. The preferred location would be within two kilometers of the existing 230 kV transmission lines (subject to availability) to simplify project approvals.
- This will provide sufficient capacity to relieve Horner TS, Manby TS and partially relieve Runnymede TS. It will also provide a number of new feeder positions to add redundancy to the system.
- This station would be supplied from the 230 kV system, which will provide relief to the 115kV circuits running from HONI's Manby East switchyard to Bridgman TS. This will improve restoration ability in the event of a major transmission event.
- Estimated cost is $72M.

FIGURE 14: 115KV LINES CURRENT SUPPLYING FAIRBANK AND RUNNYMEDE FROM MANBY EAST

Chosen Option 2: Install a New Bus at Runnymede TS

- This option would involve installation of a new bus and requisite transformation at Runnymede TS.
- As this is a HONI owned station, this work would most likely be completed by HONI and funded by Toronto Hydro.
- In 2012, Toronto Hydro submitted a formal Connection Application to HONI to study this option.

- This option is best suited to provide relief to Runnymede TS and Fairbank TS. Fairbank TS has no room for expansion and is adjacent to a 13.8kV area, making Runnymede TS the only practical load transfer option.
- This option may require significant transmission system upgrades – to be determined by HONI.
- Estimated cost to Toronto Hydro is $33 million.

Alternative Option 1: CDM

- Toronto Hydro forecasts that cumulative incremental peak reductions of approximately 2.4 to 5.2 MW over the 2014 to 2019 timeframe and 2.6 to 5.6 MW per bus over the 2019 to 2024 timeframe.
- This level of reduction is insufficient to meet short and long term needs.
- Furthermore, the forecasted peak reductions include considerations for factors outside of Toronto Hydro's control, such as reductions through program that are unfunded and codes and standards initiatives that are driven by third parties.
- Given that there is currently no clear funding mechanism for this work, and the fact that it is inadequate as a stand-alone solution, this option is not preferred.
- In parallel, Toronto Hydro is investigating targeted demand response initiatives in the Runnymede and Fairbank TS areas to provide interim support for the area between now and when a long-term permanent solution can be implemented.

Alternative Option 2: Expansion of Horner TS

- This option involves expansion of Horner TS to install a new 100 MVA bus and associated transformation supplied from the 230kV transmission system.
- Toronto Hydro submitted a formal Connection Application to HONI in 2013 to study the cost and feasibility of this option. Preliminary discussions indicate that the option is technically feasible.
- As this is a HONI owned station, the work would most likely be completed by HONI.

- The Horner TS service area is bordered by Lake Ontario to the south and Mississauga (Enersource) to the west and Manby TS to the north (separated by the Gardiner Expressway). Manby TS is the only station which borders the service territory of Horner TS to facilitate direct load transfers. a result there is only one station service area that it borders for direct load transfers (Manby TS).

- Should this option be undertaken, Toronto Hydro would look to relieve Manby TS through direct load transfers.

- Runnymede TS and Fairbank TS are located a significant distance away from Horner TS and the Gardiner Expressway and the Humber River are also located between Horner and these stations. These physical barriers significantly increases the complexity, cost and long term reliability risk associated with potential transfers load transfers, assuming that it is even feasible.

- Estimated cost to Toronto Hydro is $33M.

Alternative Option 3: Load Transfer to Richview TS

- Richview TS, located north of highway 401 near Highway 27 and Dixon Road, is a HONI owned station. Currently there is a significant amount of spare capacity available.

- Toronto Hydro has considered the option of utilizing this capacity to provide relief to Manby TS and Horner TS.

- The estimated cost to address the capacity issues is approximately $148 million, consisting of $38 million in electrical work and $110 million in civil work.

- Such a load transfer would be costly and complex. It would not result in any permanent incremental capacity and the infrastructure may eventually be abandoned once new capacity is added on a permanent basis.

- Richview TS is located approximately eight kilometers from Manby TS. This is a significant distance to run 27.6 kV distribution feeders and presents potential issues with voltage drop and reliability.

- A portion of this work would be considered as a short term mitigation action should Toronto Hydro receive a committed large customer request in the area which could not be served through other means.

(iii) Bathurst TS New Feeder Positions

Issue: A large customer has requested a dedicated feeder at Bathurst TS

Chosen Option: Request that HONI Expand the Bus

- This option involves paying a capital contribution to HONI to install a pair of new circuit breakers at Bathurst TS to provide a dedicated feeder position to supply the customer.
- Estimated cost is $1.5M.

Alternative Option: Connect Customer to an Existing Feeder

- Based on information provided by the customer with respect to anticipated load, reliability requirements and potential DG resources, connecting to an existing or shared feeder may not meet their requirements.

(iv) Basin TS Short Circuit Upgrades

Issue: Short circuit capacity limitation at Basin TS is preventing connection of proposed DG resources.

- Currently, the A7-8BN at Basin TS is rated to interrupt 470 MVA of short circuit current.
- A customer recently connected a set of mobile generators. When these generators are in service and connected to the grid, the available short circuit current at Basin A7-8BN is 470 MVA.

No further DG resources can be connected. Toronto Hydro is proposing to connect a new generator (located at Ashbridges Bay) in 2015, which would contribute approximately 60 MVA of short circuit current and exceed the short circuit rating of the bus.

Chosen Option: Reconfigure supply to Basin TS

- It is technically feasible to overcome short circuit capacity issues by reconfiguring the normal operating state of the transformer windings at Basin TS. This would involved protect and control upgrades and potentially installation of auto-transfer switches and protective relates to enable the bus to be operated in auto-transfer mode.
- This option may impact the reliability of the bus.

- Toronto Hydro plans to pursue this option with HONI.
- Estimated cost to Toronto Hydro is $2 million.

Alternative Option 1: Install a four position outdoor open air bus with a (750 MVA short circuit rating)

- This will involve a tap off of the secondary winding of one of the Basin TS power transformers.
- Toronto Hydro would install a four position bus rated with the ability to interrupt 750 MVA of short circuit current and work with HONI to make the requisite protection and control changes.
- Preliminary discussions with HONI indicate that this option is not feasible.

Alternative Option 2: Expand Basin TS

- This option would involve installation of a new 72 MVA bus and the required transformation, rated to interrupt 750 MVA of short circuit current.
- This bus would provide thermal capacity and feeder positions to the area as well.
- Basin TS bus A5-6BN will be at 95% capacity in 2022. Additionally, there is potential for significant redevelopment of the surrounding area (Portlands).
- At this point in time additional capacity at Basin TS is not justified.
- Estimated cost to Toronto Hydro is $35 million.

Alternative Option 3: Do nothing

- This option would require Toronto Hydro to reject the DG connection, and is not considered an acceptable or prudent approach.

(v) Strachan TS Transformer T12 Upgrade

Issue: HONI is planning to replace their T12 transformer at Strachan TS due to asset condition and age. Toronto Hydro forecasts a long term need for additional capacity at Strachan TS. By 2023, Strachan TS is expected to be at 96% capacity.

Chosen Option: Request that HONI replace the existing 75 MVA T12 with a standard 100 MVA unit and contribute the incremental cost, rather than allow HONI to replace like-for-like.

- Toronto Hydro would be responsible for the incremental cost difference between a 75 MVA unit and a 100 MVA unit.
- Given the long term need for additional capacity, this represents an opportunity to align Toronto Hydro plans with HONI plans.
- Capacity would be increased when the other transformer paired with the T12 is upgraded as well at some point in the future.
- Estimated cost to Toronto Hydro in 2018 is $0.5 million.
- Upon determining that additional capacity is required at Strachan TS, Toronto Hydro would request that HONI upgrade the remaining transformer (assuming they have no prior plans based on asset condition/age) at an estimated cost of $5.5 million. Total cost to Toronto Hydro to increase capacity by 64 MVA is $6.0 million.

Alternative Option: Allow HONI to replace its transformer like-for-like.

- No cost to Toronto Hydro at this time.
- When Toronto Hydro determines that additional capacity is required, Toronto Hydro would be responsible for the entire replacement cost of both transformers supplying the bus. Based on the load forecast, this is expected to occur 5 to 10 years from now. At that time, Toronto Hydro would request that HONI replace both transformers (one of which would be very new, having been installed in 2018) with 100 MVA units. Toronto Hydro would be responsible for the entire project cost which is estimated at $10.0M.

E7.10 Local Demand Response

E7.10.1 Summary

Program Description

The objective of the Local Demand Response (Local DR) program is to support Toronto Hydro's Stations Expansion activities. Toronto Hydro has identified limitations and constraints imposed upon the distribution system by Cecil transformer station (Cecil TS). The utility has identified a capacity relief requirement in the Cecil TS service territory because peak load is expected to approach infrastructure capacity in the medium-term (five to ten years), first at the individual bus level, and then at the total station thresholds. Providing capacity relief normally entails major capital investment in new and/or upgraded assets. However, this situation is somewhat unique because the load duration curve of Cecil TS generates short-run capacity concerns; issues are apparent for only a few hours over the summer months. Under these conditions, typical DR actions would address the need with minimal impact on affected customers.

The Local DR program consists of a targeted and localized demand response strategy – primarily leveraging new and existing DR resources – to reduce peak demand, and extend the planning and implementation timelines associated with future system upgrade projects. Through the Local DR program, Toronto Hydro expects to be afforded greater flexibility in assigning system upgrade resources. The program is expected achieve approximately 9.5 MVA of peak demand reduction over the course of the investment. Using strategic load balancing, the capital investment required

to address bus relief that would have otherwise been required in 2020 can be delayed to approximately 2025-2026. Total costs for the Local Demand Response program are estimated to be $4.1 million over the period of 2015 to 2019. Table A summarizes the benefits associated with the Local Demand Response program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Facilitates long-term service reliability at Cecil TS. ƒ Participant energy cost savings, financial incentives, and equipment upgrades. ƒ Positive long-term impact on customer rates.
Reliability	ƒ Enhances spare capacity to facilitate replacement of aging switchgear. ƒ Supports long term plan to install inter-station ties in downtown core. ƒ Increasing station capacity in downtown core load centre reduces feeder lengths.
Safety	ƒ Operating station equipment within design parameters increases equipment life, lowers failure rates, and associated physical risks to personnel .
Efficiency	ƒ Facilitates flexibility in scheduling planned outages for maintenance purposes. ƒ Enables system reconfiguration to optimize supply to customers situated in Cecil service area, but who are currently supplied from other stations. ƒ New customers in station area more likely to be served from closest station, reducing connection costs.
Other (e.g. cyber-security, environment)	ƒ Environmental benefits, including reduced emissions associated with offsetting generation and transmission of electricity through DR load curtailment. ƒ Provides insights into new capacity relief alternative. ƒ Wider applicability based on project outcome. ƒ Public policy responsiveness: Ministry of Energy's new CDM framework directs LDCs to consider demand management alternatives to capacity expansion

Program Drivers

The Local DR program is driven by capacity constraints at Cecil TS, which directly impact system reliability and efficiency. Constraint issues are forecast to begin affecting system operation and planned maintenance by 2020. The trigger and secondary drivers for this program are provided in Table B.

TABLE B: PROGRAM DRIVER

Trigger Driver	Reasoning
Capacity Constraints	ƒ Bus capacity shortfalls anticipated by 2020; total station shortfall anticipated as early as 2025. ƒ Limited capacity available to connect large new customers (including large office towers, condos and data centers). ƒ Potential to be forced to operate outside of design parameters.
Secondary Driver	**Reasoning**
Reliability	ƒ System capacity under an N-1 contingency (where service is maintained when any single system component is out of service) is compromised if all remaining system components are already at capacity. ƒ Limited capacity to support planned switchgear renewal, where space limitations prevent direct load transfers from old to new equipment. ƒ Lack of spare capacity limits Toronto Hydro's ability to complete maintenance (increasing failure risk) and increases the likelihood of customer outages in the event equipment failure. ƒ Reduced ability to effectively manage contingency situations

Preferred Alternative

Toronto Hydro considered the following options for addressing the capacity constraints at Cecil TS:

(i) No Action

(ii) "Status Quo" Capacity Expansion

(iii) Local DR Program

The Local DR program is the preferred option due to its strong financial case in comparison to the station expansion alternative and the difficulties anticipated with respect to the only feasible station expansion option at Cecil TS.

Financial analysis of the deferral demonstrates that the Local DR program will produce a positive net present value from the point of view of affected stakeholders, including the province, Toronto Hydro, program participants, and rate-payers. Toronto Hydro finds current policy support in the recently released and updated provincial CDM framework, "Conservation First – A Renewed

Vision for Energy Conservation in Ontario"[1], which notes that Local Distribution Companies (LDCs) will be able to make rate applications to the Ontario Energy Board (OEB) for local targeted DR if cost-effective/deferring infrastructure investments.

Timing and Pacing

The Local DR program is based on a system need at Cecil TS that is expected to produce a number of operational and reliability risks by 2020 if not addressed. The implementation of the Local DR solution in 2015 is justified by the amount of lead time required to minimize program risk and produce the intended outcome. Currently, the conventional station expansion solution is not considered an optimal option due to feasibility issues, and failure to address system constraints at Cecil TS entirely could result in Toronto Hydro being forced to undertake costly, complex and impractical load transfer projects, or to operate the system in violation of its design parameters. This could result in rotating blackouts, voltage reductions, inability to execute planned work (maintenance or capital), and reduced reliability. Regardless, whether considering a conventional station expansion solution – which will require longer lead time than usual due to the need for property/facility procurement and the corresponding extensive approvals and construction processes – or the Local DR project, which carries longer capacity procurement realization, the planning stages for future relief must begin now.

The timing, pace, and magnitudes of the annual program investments are appropriate considering the nature of the strategy. Capital spending is largely incremental to procured DR capacity, and therefore, the pace of the investment is directed by the level of anticipated program success. Historical CDM program analysis suggests that typical uptake should slowly increase from the first year to the next 2-3 years, where it is expected to peak, and then market saturation would result in a certain level of decline. The projected program potential has been modeled with this uptake curve as the main guideline. The noteworthy spending exception is the considerable anticipated increase in 2016, relative to the other program years. The majority of the 2016 capital spend is allocated for the battery storage unit planned for installation at Cecil TS. The components of this unit are anticipated to cost over $2 million. This strategy is planned for year two of the program due to the length of time it may take to procure, design, install, and commission the system: it is unlikely to be in place and energized for 2015.

E7.10.2 Program Description

Demand Response Overview

Demand Response (DR) typically refers to any program that induces a change in electricity usage by end-use customers, in response to changes in the price of electricity or other economic incentives. The purpose of DR programs is generally to encourage a shift in electricity consumption from on-peak periods – when electricity demand is highest and therefore the generation and delivery systems are most likely to approach the capacity of supply – to off-peak periods when grid capacity is less of a concern.

Since the size of generation, transmission, and distribution equipment needed to serve a customer base is dictated by peak demand rather than the overall consumption of energy, DR programs can play an important role in managing the reliability of power supply. This is particularly true in instances where system peaks only occur for short intervals a few times each year. Choosing to increase peak demand can be expensive and typically entails providing permanent additional capacity, even if the additional capacity is only required for a limited time throughout the year. Conversely, an effective DR program can address small and infrequent intervals of system stress so that permanent expansions can be delayed and reserved for when a more permanent solution is warranted.

Toronto Hydro has identified some regions within its overall service territory where peak load will approach infrastructure capacity in the medium-term (five to ten years), either at the individual bus or total station thresholds. This condition typically results in the planning and implementation of a major capital investment in new and/or upgraded assets. Toronto Hydro expects the proposed Local DR program to allow the utility to defer these system upgrade projects by introducing a targeted and localized DR strategy – primarily leveraging new and existing DR resources – to reduce peak demand. The deferral assists medium- and long-term capacity relief efforts because it is forecasted to extend the timeline for projected station upgrade investments at locations where the need for additional capacity is projected for 2020 and beyond. This would provide Toronto Hydro with greater flexibility in assigning system upgrade resources, and as is demonstrated in this program's financial analysis, is expected to help optimize Toronto Hydro's capital allocation strategy by deferring the need for capital expenditure and facilitating alternative short to medium-term investment considerations. The combination of deferring work and avoiding costs is a fiscally prudent approach that will benefit ratepayers. However, it should be noted that this program will not replace near-term capacity relief efforts, since the lead time associated with

targeted reductions under the Local DR program extends beyond the period by when these near-term needs must be addressed.

In Ontario, DR programs have traditionally been offered province-wide to address any provincial peak demand constraints. However, Toronto Hydro understands that sufficient provincial capacity exists into the medium-term as a result of existing and committed CDM activities and investments in generation. As such, the relief needs that do exist are primarily regional, as are the cases in the Toronto Hydro service areas. These DR utilization trends have encouraged Toronto Hydro to assess the potential for targeted DR efforts to mitigate localized capacity constraints currently projected in transformer station load forecasts. So, while DR solutions have been extensively proven to effectively reduce peak demand for the province – as well as many other jurisdictions, worldwide – this program presents an instance where DR resources can produce a significant benefit when directed at a singular distribution point and its corresponding service area, relative to immediate system renewal investments.

Local DR Program – Cecil TS

The objective of Toronto Hydro's Local DR program is to complement the work of the utility's Stations Expansion program by addressing the distribution system's increasing capacity constraints. Local DR provides an approach to relieving demand on Transformer Station (TS) by extending the period in which the station can safely operate within intended design limitations, making it possible to defer otherwise necessary (and more costly) infrastructure renewal at Cecil TS. This program is expected to reduce the risk of future contingency situations which, in turn, mitigates critical constraints and security-of-supply concerns.

The Local DR program targets the area served by Cecil TS (Figure 1). Cecil TS serves a relatively confined geographical space, affording a smaller scale site that can increase the efficiency of localized efforts. Cecil TS is located in the downtown core, and serves as a strategic centre for inter-station load balancing as it is largely surrounded by TS service areas projecting shorter-term constraints. Finally, it offers little to no room for physical expansion. All of these factors strengthen the case to apply a strategic alternative at Cecil TS rather than a conventional station upgrade.

FIGURE 1: MAP OF CECIL TS SERVICE AREA

This program targets to help control and reduce peak demand. The annual load profile for Cecil TS demonstrates short and infrequent system peaks. These temporary "spikes" in customer demand typically occur during the hottest weekday afternoons in summer when maximized cooling loads amplify the normal daily peaks that result from electrical building system and operational end-uses. The vast majority of historical and current applications of DR programs have been dedicated to the reduction of these summer peaks; as a result, the solutions for achieving the targeted peak load relief in summer are already well-developed, including both the technologies and implementation guidelines. The Local DR program is currently positioned to defer a permanent infrastructure improvement at Cecil TS.

Currently, Toronto Hydro's capacity forecasts project a need for load relief in up to 14 of 35 TS service areas by 2025, with the majority of these falling within the short-term planning horizon, i.e. by 2019. Figure 2 identifies candidate station areas based on their need for relief. While the application of the Local DR program is limited to Cecil station for the purpose of this application, any success and/or program lessons will be directly applicable to other locations within Toronto

Hydro's service area as new TS load constraint projections materialize. The impact of this program may also serve as a useful reference for other LDCs faced with similar constraint issues.

FIGURE 2: MAP OF LOAD RELIEF FORECASTS

When the load on a station bus is forecasted to exceed capacity, planners identify and assess the available options, giving consideration to the magnitude of the problem, the timeframe, and the long-term needs of the area. A summary of typical solutions is provided in Table 1.

The Local DR program includes targeted DR resource procurement, focusing on customers served by Cecil TS. Toronto Hydro also intends to assess utility-side load relief options, and to develop locally targeted marketing and sales programs to further promote existing and new DR technologies and energy storage applications.

The following table sets out the options that a utility typically considers when responding to capacity constraints, as well as the Local DR approach proposed in this program.

TABLE 1: TYPICAL CAPACITY RELIEF OPTIONS

Option	Prerequisites	Comments
Transfer load to a different bus within the station	ƒ Requires an existing bus at the same station that possesses sufficient capacity and feeder positions to accept the new load.	ƒ Generally the most cost effective option when available. ƒ Technical restrictions may arise: 3-wire vs. 4-wire busses, ability to segment existing load, etc.
Transfer load to a bus at a different station	ƒ Requires an existing bus at a nearby station with sufficient capacity and feeder positions to accept the new load. ƒ Must be feasible to construct the necessary distribution infrastructure to permanently transfer the load (for example, there must be spare civil infrastructure between the new station and the load to be transferred).	ƒ Can require significant amount of new infrastructure ƒ Can be very expensive ƒ Technical limits on feeder length must be respected in order to maintain system within design parameters. ƒ Investment does not actually result in an increase in capacity – rather, it simply means available capacity is being utilized sooner than it would have been otherwise.
Replace and upgrade limiting component at station	ƒ Typically requires coordination with Hydro One Networks Inc. (HONI). ƒ There must be a specific component or set of components which is exclusively limiting capacity (i.e. a cable section, a transformer, etc.).	ƒ Some elements can be replaced at relatively low cost and result in incremental capacity. ƒ Some Toronto Hydro switchgear replacement projects will result in additional capacity. ƒ Toronto Hydro often requests that HONI upgrade transformer ratings to provide additional capacity when they renew their assets.
Expand an existing station by installing a new bus and/or new transformation and/or new transmission infrastructure	ƒ Requires sufficient physical space at the station to facilitate expansion. ƒ Requires sufficient upstream (transmission) capacity.	ƒ Can be very costly. ƒ Requires coordination with HONI. ƒ Existing ownership of these assets (HONI vs. Toronto Hydro) varies throughout the city of Toronto. ƒ Costs highly dependent on requisite transmission upgrades.
Build a new station	ƒ Requires a site located sufficiently close to serve the new load of offload the existing station.	ƒ Can be very costly. ƒ Requires coordination with HONI. ƒ Costs highly dependent on requisite transmission upgrades. ƒ Generally lengthy approvals and lead times.

Option	Prerequisites	Comments
Peak reduction through demand management or distributed generation initiatives	ƒ Potential for peak reduction must be sufficient to mitigate shortfall. ƒ Must be persistent. ƒ There must be a guaranteed funding mechanism (i.e. the load or generation customer has signed an agreement and paid the requisite deposit to connect to the system).	ƒ Reductions must be realized before forecasted overload of bus. ƒ Only impact on peak demand is relevant. Impact on energy consumed is irrelevant.

The Local DR program provides a compelling financial case for supporting and strengthening station expansion investment. In addition, from an operational perspective, DR resources which are known with certainty to be available at system peak are practical alternatives to adding capacity. Of course, in order to ensure the desired outcome and demonstrate the full benefit of the DR solution, the program must cost-effectively procure the maximum amount of peak load reduction. Moreover, since the area served by Cecil TS comprises a diverse combination of residential, commercial & institutional (C&I), and industrial customers, the project must include a suite of alternative DR initiatives to deliver maximum area uptake. As such, the following combination of programs has been chosen based on its collective ability to attract all customer sectors and sizes.

PeaksaverPLUS®

Target Market : Single Family Residential & Small C&I Customers

The peaksaverPLUS® program is open to residential and small commercial consumers. These customers participate by allowing a one-way paging network to control either a programmable communicating thermostat (PCT) or a load control switch to curtail electricity demand for central air conditioners, electric water heaters or pool pumps during the peak period on high electricity demand days. PeaksaverPLUS® also offers consumers an in-home display (IHD), which enables participants to monitor their electricity consumption and associated cost in real-time. Ontario's LDC's are responsible for procuring the equipment offered and for the marketing of the program (jointly with the OPA); however, it should be noted that Toronto Hydro currently does not contribute any capital expenditures: the purchase of all physical assets is fully refunded by the Ontario Power Authority (OPA). As of December 2012, approximately 180,000 control devices

have been installed on central air conditioners in Ontario, nearly all in residential premises. Participants in the Toronto Hydro service territory accounted for over 70,000 of these devices. In addition, nearly 50,000 IHDs had been installed at participant premises.

Often, the appliances contributing to afternoon summer peak demand operate in unoccupied homes and can be managed by direct load control without significant customer disturbance. Currently, typical penetration rates by TS service areas in the city of Toronto are approximately 20-25%. According to Freeman, Sullivan & Co., the OPA's PeaksaverPLUS® evaluation contractors, achievable penetration rates for well-established residential DR programs can reach nearly 50%, suggesting that there is ample room for growth using a geographically-specific initiative.

Multi-Unit Residential DR (MURB) – SuiteSaver

Target Market : Multi-Unit Residential Buildings

The MURB DR program is designed to offer MURBs the opportunity to participate in DR initiatives. This sector presents a provincial peak demand of approximately 1 GW, and a considerable demand reduction potential of more than 20 MW in the Toronto Hydro service region alone. The installation of load control devices on common area systems and programmable communicating thermostats in individual suites would facilitate savings during activation periods, and in turn, building and suite owners would receive payment for their load control availability. Also included in the program is a comprehensive energy efficiency strategy, made up of system audits and retrofit incentives that further increase the demand reduction and annual energy savings impact in the MURB sector. With the increasing number of MURBs being constructed in the city of Toronto and in the province more generally, this program offers a complimentary load relief strategy through increased load densification that can have a positive impact on local service constraints.

This program was piloted in the summer of 2013 and is currently being considered for additional testing this summer. The Total Resource Cost (TRC) analysis submitted with the initial proposal assumed a 4% penetration in the MURB sector and 40% suite penetration in participating buildings. These projections were derived from current Peaksaver participation evaluations and took into account the more attractive incentives being offered to both building owners and participating suite owners.

Toronto Hydro projects that the thermostat and occupancy setback controls would provide between 0.3 – 0.5 kW/suite in curtailment and approximately 65-80 kW in curtailment for common area load controls. The targeted uptake in the MURB sector is 25% or approximately 19 buildings over the course of the 5-year plan.

Commercial Energy Management & Load Control (CEMLC) – GridSaver

Target Market : C&I and Industrial Customers (> 50KW)

The CEMLC pilot is designed to produce peak demand reductions in the 50-999 kW commercial, retail, institutional, and hospitality sectors, where facility heating, ventilation, and air-conditioning (HVAC) systems include rooftop units (RTUs). The strategy involves the installation of load control devices on RTUs and programmable communicating thermostats that offer the opportunity for energy and demand reductions during DR events. The provincial peak cooling load in these sectors is nearly 2000 MW, and contributes a reduction potential of approximately 60 MW in the Toronto Hydro service area alone. The program design also recommends a facility energy management strategy, incorporating occupancy sensors to further improve the peak demand reduction and annual energy savings impacts.

Savings projections were developed with the use of the U.S. Department of Energy setback calculator and resulted in an estimated 12% reduction in cooling load. It is proposed that facilities in this load class could produce an average of approximately 24 kW of summer peak reduction. Though anticipated penetration is relatively low at 5-10%, this market is virtually untapped, with the previous DR opportunity consisting solely of the OPA's DR3 program, discussed below. Therefore, the potential DR resource that these customers represent is considerable.

Demand Response Three (DR3)

Target Market : C&I and Industrial Customers (>50 kW)

For customers capable of meeting the minimum availability commitments of the OPA's DR3 program, the flexibility to choose a curtailment strategy and the level of incentive payment may make this program the most favourable option. DR3 is a contractual DR program that offers large C&I and industrial consumers reserve payments for making themselves available to provide load reductions when requested by the OPA. Participants are required to meet contractual reductions when instructed, or payments are reduced or eliminated. In addition, DR3 participants must notify the OPA and Independent Electricity System Operator (IESO) of any short-term fluctuations in

load reduction capability due to facility maintenance or down-time. Scheduled non-performance days lead to reductions in the participant payments. Unscheduled non-performance – failure to deliver scheduled load reductions during events leads to even larger payment reductions.

Current DR3 penetration rates are virtually non-existent in the Toronto Hydro service territory, with less than 100 customers having opted to participate to date. However, the anticipated changes to the DR3 program should lead to higher customer uptake and considerable load curtailment. With almost the entire segment of large C&I and industrial customers available for enrolment, and in a situation where a relatively small number of these participants can have a major impact during a curtailment event, this program is expected represent a key focus in the local DR strategy. While there is currently a level of uncertainty regarding the availability of DR3 participants for localized events, if available, Local DR could maximize the contracted hourly availability currently under-utilized by provincial DR3 event frequency.

Energy Storage [2]

The Local DR program will include energy storage initiatives, which will be implemented at participant facilities, in the form of thermal storage units integrated into RTUs, and in the form of battery storage units. Energy storage applications optimize the supply and demand of distribution system energy by loading the energy accumulator (storage device) during off-peak times when supply is cheaper and more readily available, and then releasing that stored energy during high demand, thereby relieving the equivalent amount of system stress. Sizes and capacities of energy storage systems vary; however, the units planned for Local DR are expected to offer four continuous hours of peak demand relief, at approximately 4-kW/unit for the thermal storage applications, and 50 – 250-kW/unit for the battery storage installations.

An overview of the planned capital assets is included in Table 2.

[2] The planned implementation of energy storage mentioned in this narrative is not accounted for in the Energy Storage program section of the DSP. The thermal storage devices which will be promoted in the Local DR project are separate technologies not used in the Energy Storage program; and the battery storage units proposed are accounted for only in this section of the DSP. The Local DR program is interested in leveraging the technology used by the Energy Storage program to the same desired effect, but in the case of Local DR, battery storage is simply one strategy incorporated into the suite of proposed measures.

TABLE 2: A BASIC OVERVIEW OF CAPITAL ASSETS

	Number of Installations						Cost
	2015	2016	2017	2018	2019	Total	($M)
PeakSaver	84	336	589	420	253	1,682	$0.3
Load Control Devices In-Home Displays							
SuiteSaver	2	4	6	5	3	20	$1.2
Communicating Thermostats Door Contacts Network Infrastructure Load Control Devices							
GridSaver	2	6	11	8	5	32	$0.1
Communicating Thermostats							
Thermal Storage	2	2	2	2	2	10	$0.3
Ice Storage Units							
Battery Storage	-	1	-	-	-	1	$2.0
Battery Storage Unit Inverter							

Toronto Hydro is developing the Local DR program in parallel with the ongoing Toronto Integrated Regional Resource Plan (IRRP), an exercise which Toronto Hydro is also engaged as an active participant. Any outputs or conclusions from the IRRP which directly or indirectly impact this program will be incorporated in this program's scope. Toronto Hydro understands that the Toronto IRRP will primarily focus on system adequacy at the transmission level. While Toronto Hydro's stations relief plan is driven primarily by the urgent nature of the issues Toronto Hydro faces with respect to distribution system capacity constraints, Toronto Hydro expects that it will be aligned with the conclusions of the Toronto IRRP.

Toronto Hydro recognizes that by undertaking a collaborative design effort and a strategic approach that serves both local and provincial system needs, there is a valuable opportunity to maximize existing DR assets and program impact.

The following table provides a high-level summary of the Local DR program benefits:

TABLE 3: PROGRAM BENEFITS

Customer Value	ƒ Ensure long-term service reliability at Cecil TS. ƒ Participant energy cost savings, financial incentives, and equipment upgrades. ƒ Positive long-term impact on customer rates.
Reliability	ƒ Enhances spare capacity to facilitate replacement of aging switchgear. ƒ Supports long term plan to install inter-station ties in downtown core. ƒ Increasing station capacity in downtown core load centre reduces feeder lengths.
Safety	ƒ Operating station equipment within design parameters increases equipment life, lowers failure rates, and associated physical risks to personnel.
Efficiency	ƒ Ensures flexibility in scheduling planned outages for maintenance purposes. ƒ Enables system reconfiguration to optimize supply to customers situated in Cecil service area, but who are currently supplied from other stations. ƒ New customers in station area more likely to be served from closest station, reducing connection costs.
Other (e.g. cyber-security, environment)	ƒ Environmental benefits, including reduced emissions associated with offsetting generation and transmission of electricity through DR load curtailment. ƒ Provides insights related to new capacity relief alternative. ƒ Wider applicability based on project outcome. ƒ Public policy responsiveness: Ministry of Energy's new CDM framework directs LDCs to consider demand management alternatives to capacity expansion

The Local DR program enhances the reliability of Cecil TS as follows:

- ƒ Helps secure spare capacity necessary to facilitate future replacement of aging switchgear at a location where there is currently no physical space to install new switchgear next to the existing one.

- ƒ Securing available capacity in the form of reduced existing peak load at Cecil will support Toronto Hydro's long term plan to install inter-station ties. In order to make effective use of these ties, the "back-up" stations would need to have sufficient capacity to support both their normal load as well as the temporary load from the stations taken out of

service. Currently, with many stations close to 100% utilization – including stations adjacent to Cecil – ties would not be as effective as they could be if there was more available capacity.

- Increasing station capacity near/within the downtown core load centre will enable reduced feeder lengths and more straightforward network configurations; in general, this results in a more simple and reliable system.

Execution of this program is also expected to result in certain operational efficiencies, including the following:

- New customers located within the station area are more likely to be served from the station that is geographically closest.

- Maintaining or increasing station capacity will enable system reconfiguration to optimize the supply to customers who are situated in the Cecil service area, but who are currently supplied from other stations. This occurs when there is not sufficient capacity to connect a customer to the closest station. This is expected to reduce line losses and improve reliability.

While this program is not expected to have a direct impact on worker or public safety, there are inherent safety benefits associated with operating station equipment within their respective design capacities:

- Overloading equipment reduces equipment life and increases failure rates, which, in the extreme cases, can lead to events that can impact public or worker safety.

- Equipment wear and tear on a capacity-constrained station, expected to be mitigated by the proposed program leads to higher potential for events such as arc flashes during switching operations and racking out breakers, which are among the highest operational risks under normal conditions.

Thus, continuing to operate Cecil under its standard operating N-1 contingency design standard as contemplated by this program helps mitigate physical risks to the personnel responsible for the operation and maintenance of the assets.

E7.10.3 Why the Program is Needed

The Local DR program is needed to mitigate forecasted system constraints in the Cecil TS service area and acts as an alternative to undertaking immediate expansion. Toronto Hydro has experienced a significant amount of load growth in recent years, growth that is generally concentrated in areas of the city where densification and redevelopment are the primary drivers of increased electrical load. The projected impact of Toronto Hydro continuing to receive connection requests requiring incremental distribution system is that the existing system is approaching its limit at several locations, including the area served by Cecil TS. Either load relief or expansion is necessary to help ensure that Toronto Hydro is able to operate the distribution system in a safe and reliable manner.

E7.10.3.1 Program Drivers

The Local DR program is driven by capacity constraints at Cecil TS, which directly impact system reliability and efficiency. Constraint issues are forecast to begin affecting system operation and planned maintenance by 2020. A summary of program drivers is presented in Table 4.

TABLE 4: PROGRAM DRIVERS

Trigger Driver	Reasoning
Capacity Constraints	ƒ Bus capacity shortfalls by 2020; total station shortfall as early as 2025. ƒ Limited capacity available to connect large new customers (including large office towers, condos and data centers). ƒ Potential to be forced to operate outside of design parameters.
Secondary Driver	**Reasoning**
Reliability	ƒ System capacity under an N-1 contingency (where service is maintained when any single system component is out of service) is compromised if all remaining system components are already at capacity. ƒ Limited capacity to support planned switchgear renewal, where space limitations prevent direct load transfers from old to new equipment. ƒ Lack of spare capacity limits Toronto Hydro's ability to complete maintenance (increasing failure risk) and increases the likelihood of customer outages in the event equipment failure. ƒ Inability to effectively manage contingency situations

The following is a discussion of the station and service area risks that are addressed by this program:

Medium and long term forecasted capacity shortfalls at Cecil TS

By the year 2020, it is expected that two of the four existing buses at Cecil will surpass 95% of firm capacity, as illustrated in Table 5.

TABLE 5: CECIL STATION LOAD FORECAST

STATION:	CAPACITY (MVA)										
	100 %	95%	2015	2016	2017	2018	2019	2020	2021	2022	2023
A1-2			32	32	32	33	33	34	34	35	35
A3-4			41	43	43	44	44				
A5-6			60	61	62	63	64	64	65	66	67
A7-8			64	64	65	66	67				
Total Station (No CDM)	238	226	197	200	202	206	208	211	214	217	220

Bus A1-2 is a dedicated bus that supplies load to the University of Toronto, and therefore is not an option for accepting load from other buses as they reach capacity. Buses A3-4 and A7-8 will reach their load capacity by 2020, at which point the load from these buses can be shared with A5-6 bus. However, A5-6 is projected to approach 90% of its rated capacity in the same year. Excluding the dedicated bus A1-2, the remaining load will approach 93% of station capacity in 2020. So despite the fact that total station threshold concerns are not projected to materialize until 2026, the status quo scenario – including maintaining bus A1-2 as dedicated University of Toronto capacity – is troublesome and demonstrates a need for earlier load relief.

Generally, the first option considered to relieve bus capacity is to transfer load to an adjacent bus at the same station. The second option is to find relief at a nearby station. For the downtown core, where Cecil TS is located, the second option is often more technically complex and costly than in other circumstances. The distribution system in downtown Toronto operates at a primary voltage of 13.8 kV and is operationally unique compared to the rest of Toronto Hydro's service territory, which is served by the 27.6 kV system. The 13.8 kV area – the oldest part of Toronto Hydro's system – is currently comprised of feeders radiating from 18 central Toronto stations that supply customers located in their geographic service areas. There are very few interconnections between the stations in the area; in the case of Cecil, there are currently no effective inter-station ties, meaning that load transfers to another station would require construction of new civil and electrical infrastructure. These load transfers can be extremely costly and challenging to implement given the space limitations and the congested nature of the existing utility infrastructure in the area. Load transfers also require available spare feeder positions on the bus

receiving the load transfer. Spare feeder positions are increasingly scarce in the vast majority of downtown stations given that Toronto Hydro continues connecting new customers.

Inability to facilitate load transfers to enable switchgear renewal work in the downtown core

Cecil TS has a maximum capacity of 238 MVA. This limit is derived from the 10-day limited time rating of the lowest rated element at the station. The 10-day limit signifies that the station can operate with any specific element out of service for up to 10 days without permanently compromising the life of the remaining equipment. This is a long standing industry practice and is typically referred to as "N-1" design. Failure to maintain this arrangement may significantly lengthen the time required to restore power after a station outage, as Toronto Hydro could be forced to wait until the failed equipment can be procured and replaced. In addition to providing redundancy in the event of unplanned outages, it also enables Toronto Hydro to undertake planned outages for equipment upgrades or repairs. In these situations, Toronto Hydro will need to transfer existing load elsewhere for the duration of the project. Thus, the Local DR program is required to ensure sufficient spare capacity is available to facilitate these future replacements of aging switchgear, where there is currently no physical space to install a new switchgear next to the existing one. Without this investment, planned outages would likely pose significant issues at Cecil TS as the total station load begins to approach threshold capacity. Faced with limited spare capacity and a planned equipment outage, Cecil could compromise the N-1 contingency design standard; the result would be risking permanent damage to the existing assets by accepting station design overload conditions, while the alternative would be to force customers to endure planned outages in the form of brownouts (intentional drops in supplied voltage which negatively impact the functionality of customer end-uses) or rolling blackouts (complete power outages scheduled to rotate throughout the service area, impacting all customers for pre-determined periods of time) .

Inability to support installation of backup capabilities

Toronto Hydro's long term capital plan will help ensure greater system reliability by enhancing the backup capabilities of the distribution grid. This is a particularly critical concern in the downtown core where station inter-connections are at a minimum. In correcting this issue, "back-up" stations – where load can be temporarily redirected – would need to have sufficient capacity to support both their normal load as well as the additional load from the buses and/or stations taken out of service. Currently, the majority of the stations adjacent to Cecil TS exhibit either more immediate

capacity relief needs, or, at a minimum, similar capacity relief projections. The Local DR program is expected to produce additional capacity relief at Cecil TS in order to provide the spare capacity in which to potentially allocate adjacent station loads during the construction of critical inter-station ties.

Inability to accommodate new customer connections

An important indicator of load growth is the number of new connection requests that are received from customers. These requests are submitted by existing and potential customers who will be increasing their load and/or require entirely new connection points. The number of new connections requested for Cecil TS over the past several years is shown in Figure 3[3]:

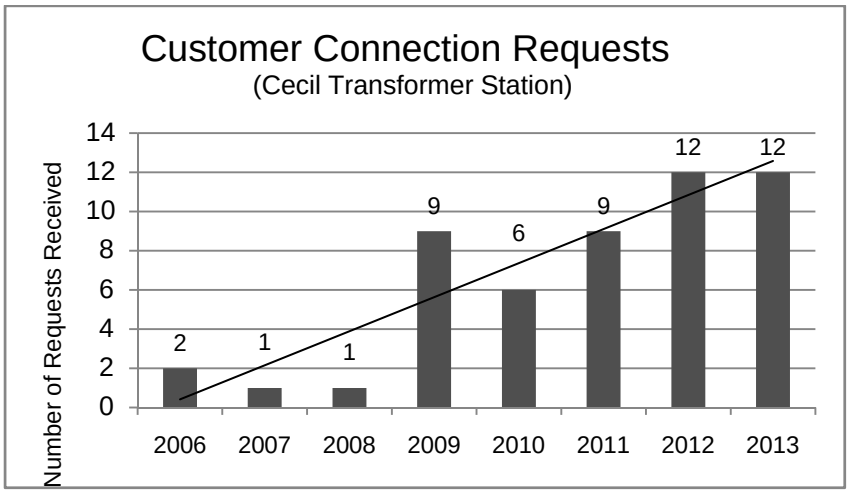

FIGURE 3: CECIL STATION CONNECTION REQUESTS

The data demonstrates an increasing trend in new customer connections, which directly contributes to the medium-term forecasted load constraint. For planning purposes, Toronto Hydro considers 95% of a bus capacity for the downtown stations to be overloaded. This figure takes into account the lead time required to offload a bus and implement a permanent solution, as well as the fact that the station must keep sufficient spare capacity on each bus to accommodate new customer connection requests. Customers typically request connection anywhere from one to three years in advance, whereas a load relief solution can take anywhere from one to four years to implement, depending on the nature of the existing configuration. This extended lead time

[3] Data represents gross number of feeder connection requests received for connection in each year. The source data was filtered to include only those requests which as of 2014 are in the "Approved", "Completed" or "Energized" state.

highlights the need for critical planning and approval as early as 2015 to accommodate for new load in 2020. Much of the Cecil TS service area is made up of large commercial and institutional buildings, multi-unit residential buildings and secondary networks. In these cases, individual loads from the primary distribution system's point of view are larger and indivisible, load that need to be wholly accommodated by a single feeder position. Assuming similar types of customers and corresponding new load make up future new connection requests, new applications may drastically impact the load forecast, and in the worst case, critically impact future capacity. It is imperative to develop a solution to create necessary spare capacity in place to mitigate 2020 load capacity risks.

Limited Opportunity for Station Expansion

As mentioned previously, capacity constraints are typically addressed by station expansion planning. However, these "wires solutions" require physical space for additional equipment, or space to install replacement equipment adjacent to assets in operation. Currently, Cecil TS has no remaining room for capacity additions. Moreover, installing new transformers at Cecil TS wouldn't increase the station's capacity since it is limited by the existing bus ratings. Accordingly, the only feasible solution would be to add new switchgear at a different Toronto Hydro-owned building that can be used for load relief from Cecil TS buses to new buses. However, this would require a site located sufficiently close to Cecil TS to offload the existing station. This option is usually the most costly and it requires considerable coordination with HONI, usually involving prolonged approval and lead times. Given these considerations, it is imperative that the work associated with the Local DR program at Cecil TS begin as soon as possible. Based on the fact that the conventional wires solution is very limited, and even if possible, it can only be relied upon within the medium to long term planning horizon, Local DR offers a valuable complimentary strategy to the task of ensuring that this service area is protected by effective short and medium-term demand management, which in turn will provide the necessary time to plan for long-term capacity solutions without negatively impacting the system's service and reliability.

E7.10.4 Timing & Pacing of the Program

The Local DR program is based on a system need at Cecil TS that is expected to produce a number of operational and reliability risks by 2020 if not addressed. The implementation of the Local DR solution in 2015 is justified by the amount of lead time required to minimize program risk and produce the intended outcome. Currently, the conventional station expansion solution is not considered an attractive option due to feasibility issues, and failure to address system

constraints at Cecil TS entirely could result in Toronto Hydro being forced to undertake costly, complex and impractical load transfer projects, or to operate the system in violation of its design parameters. As mentioned above, this could result in rotating blackouts, voltage reductions, inability to execute planned work (maintenance or capital), and reduced reliability. Irrespective of an ultimate solution (i.e. a conventional station expansion or Local DR project), the planning stages for future relief must begin now, as both options require long lead times for approvals, procurement, construction and/or customer uptake.

The following table represents the capital allowance which must be committed to effectively implement Local DR at Cecil TS:

TABLE 6: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	-	-	-	-	$0.17	$2.4	$0.60	$0.50	$0.35

The timing, pace, and magnitude of the annual program investments are appropriate considering the nature of the strategy. Capital spending is largely incremental to procured DR capacity, and therefore, the pace of the investment is directed by the level of anticipated program success. Historical CDM program analysis suggests that typical uptake will slowly increase from the first year to the next 2-3 years, where it is forecast to peak, and then market saturation will result in a certain level of decline. The projected program potential has been modeled with this uptake curve as the main guideline. The noteworthy spending exception is the considerable increase in 2016, relative to the other program years. The majority of the 2016 capital spend is allocated for the battery storage unit planned for installation at Cecil TS. The components of this unit are anticipated to cost nearly $2 million. This strategy is planned for year two of the program due to the length of time it may take to procure, design, install, and commission the system: it is unlikely to be in place and energized for 2015.

With respect to the program's overall operational window, Local DR is a strategic solution that is not commonly implemented to address distribution system constraint; as such it requires additional completion time for the following reasons:

- The Local DR program is comprised of a number of distinct design, implementation and evaluation efforts – all of which leverage effective customer outreach, acceptance, and participation as well as varying customer contributions that must be procured and

aggregated in order to address actual capacity constraint. In addition, the program may need to deviate from planned action if early lessons indicate a more effective alternative approach (e.g. adjusted/enhanced marketing and/or DR program offerings, etc.). This differs considerably from the conventional station expansion solution where the incremental capacity is pre-determined and definite, with limited uncertainty around timing and appropriate availability.

- While the ultimate goal is similar to the "wires solution", the necessary system relief will manifest incrementally over the course of at least the next five years.

Given these timing considerations, Cecil TS is an ideal candidate for this program, as the forecasted program achievement will require approximately five years to materialize, which aligns with the projected localized load constraint at Cecil TS. Furthermore, this program deserves strong consideration for immediate implementation when compared to other investment solutions due to the following factors:

- The financial model developed for this project produces a strong financial case for Local DR. The results, which are discussed below, indicate that immediate implementation of the Local DR program and the corresponding deferral of capital investment in station expansion of five to six years will produce both short-term and long-term financial benefit both to Toronto Hydro's ratepayers and the province as a whole. Overall, the financial model justifies the prioritization of Local DR over station expansion from a business planning perspective.

- The Cecil TS service area is strategically located in the densely populated downtown core and is surrounded by station service areas with more severe and more immediate relief needs. These adjacent areas have surpassed the lead time necessary for considering a Local DR solution. If Toronto Hydro does not begin this work immediately, Cecil TS is also expected to find itself in such a position, leaving no alternative but the most costly form of station expansion.

- If implemented immediately, this program is expected produce valuable insights with considerable planning implications on future system service decisions for both Toronto Hydro and the wider planning audiences. The program's financial model demonstrates convincing financial evidence for the implementation of Local DR in service areas which exhibit load relief requirements in the five to 10 year planning horizon. Toronto Hydro's submits that confirming this applicability would also be instructive to the OEB, as it may

undertake the evaluation of capital investment strategies in future rate applications. The importance of initiating this type of complimentary alternative positions Local DR as a higher-priority project when compared against traditional station upgrade.

E7.10.4.1 Ranking & Prioritization

When selecting the list of potential TS candidates for the Local DR program, Toronto Hydro's developed a list of stations with short- to medium-term projections of load constraints:

TABLE 7: CANDIDATE STATIONS WITH PROJECTED LOAD RELIEF REQUIREMENTS

Transformer Station	Year of Load Relief Requirement
Basin	2022
Carlaw	2019
Cecil	2020
Charles	2018
Dufferin	2014/2016
Esplanade	2018
Fairbank	2014
Horner	2019
Leslie	2018
Main	2016
Manby	2013
Strachan	2016
Terauley	2019
Windsor	2019

When determining best-suited service areas from this list, the following factors are considered:

- Load constraint forecast – when is load relief required? This is initially relied upon for station prioritization.
- Time to implement vs. need – what is the risk factor associated with overvaluing program potential? (unrealized projected demand reduction)
- Limitation on conventional station expansion – are there physical/logistical barriers with respect to station expansion that support DR alternatives?

- Asset life & condition – are there additional benefits of wires solution (possibly greater long-term reliability if current infrastructure is also nearing end of life), which Local DR does not address?
- Greater system need – what are the adjacent station capacities and are there future requirements for load balancing (incoming or outgoing) to satisfy overall system need?
- Cost of investment – is Local DR cost-effective compared to wires solutions and does it benefit the rate-payer?
- Demand response potential:
    - What is the DR potential based on customer and facility types?
    - What DR resources are already in place (the OPA's Peaksaver PLUS® and/or DR3 compared with the required additional capacity?

From these factors, four main guidelines were developed:

1) What are the consequences of unrealized projected demand reduction?

From the point of view of risk mitigation, TS service areas with near-term load relief requirements are sub-optimal candidates. If a locally targeted DR program falls short of the projected relief, a wires solution would then be then be prioritized. A program evaluation period of two to three years[4] is required to establish the success of local DR strategies and practices, while the approximate lead time necessary to coordinate a secondary station expansion solution is one to two years at minimum. Taking both into account, areas with near-term load relief requirements do not offer the flexibility to test this solution against real and imminent system capacity issues. Therefore, it was determined that this program should focus on a TS service area identified as requiring capital investment in the next five to 10 years. This would guarantee enough time for careful consideration and evaluation of DR implementation methods, while at the same time affording Toronto Hydro the opportunity to re-evaluate without system performance impact.

Taking the above into account, all stations demonstrating constraint issues before 2020 were considered too high-risk for Local DR investment. If a mid-term program evaluation identified a shortfall in program impact, it would be too late to begin the process of developing and installing a wires solution. This eliminated all stations with the exception of Cecil TS and Basin TS.

[4] The new provincial CDM framework ,'Conservation First' mandates mid-term reviews to be conducted three years after implementation, to assess program effectiveness, targets, budgets, and performance-incentive mechanisms.

2) Can DR potential meet future load constrain in a timely fashion?

The following Table 8 presents a comparison of DR potential for the two remaining candidate stations:

TABLE 8: DR POTENTIAL FOR REMAINING CANDIDATE STATIONS

Cumulative Curtailment Capacity (MVA)	2015	2016	2017	2018	2019
Cecil TS	0.9	2.5	4.4	7.2	9.5
Basin TS	0.7	1.7	3.1	5.2	6.9

Based on these projections, Local DR implementations would defer the need for capital upgrade or expansion for a minimum of five years in both service areas. However, the need is more urgent in the Cecil service area, which supports the decision for initial implementation there, but also suggests that early program success identified in the Cecil TS project may allow for secondary implementation in the Basin service area.

3) Does the financial case present a sensible business alternative to the wires solution and does it benefit the various stakeholders?

Both candidate stations present a series of positive benefits when compared against station expansion alternatives, and the Cecil TS results are presented in the Evaluation of Alternatives section of this narrative. However, due to the fact that there is greater potential for peak load reduction at Cecil TS, the fixed cost portion of the Local DR investment is allocated more favourably, and as a result, the magnitude of the net present values for the cost-effectiveness tests are higher in the Cecil TS case.

4) Do additional factors limit either the wires or DR solutions?

A key factor supporting the decision for Cecil TS is the physical space available for upgrade and/or expansion assets at each station:

- Basin TS is located in the “Portlands” area of Toronto south-east of the downtown core where physical space for additional capacity equipment is readily available.
- Cecil TS has no remaining room for capacity additions. Moreover, installing new transformers at Cecil TS with added capacity wouldn't increase the bus capacity since they are limited by the bus ratings. Hence, the only feasible solution is to add new switchgear at a different Toronto Hydro-owned building that could then be used for load

relief from Cecil TS buses to new buses. Additional costs would be incurred to acquire new real estate and to perform the necessary building changes for transformer station suitability.

The projected program potential for 2015 – 2019 is summarized in Table 9.

TABLE 9: SUMMARY OF PROJECTED PROGRAM POTENTIAL

Program Offering	Total Number of Participants	Total Demand Reduction (MVA)
peaksaver PLUS® – Legacy Residential Customers	270	0.19
peaksaver PLUS® – Legacy Small Commercial Customers	47	0.06
peaksaver PLUS® – New Residential Customers	1,617	1.11
peaksaver PLUS® – New Small Commercial Customers	65	0.09
SuiteSaver	19	2.68
GridSaver	32	0.86
DR3: 50kW – 1MW Customers	5	1.72
DR3: > 1MW Customers	2	2.40
Thermal Storage	10	0.13
Battery Storage	1	0.28
TOTAL	2,068	9.51

E7.10.5 Program Execution

To carry out the Local DR program, Toronto Hydro is required to fully develop, implement, and evaluate a targeted DR strategy for serving the Cecil TS service area and the diverse set of customers it supplies. In addition to the operational requirements, this project includes an annual capital program expenditure reflecting the costs associated with the DR assets being installed at end-user facilities as well as at Cecil TS.

E7.10.5.1 Proposed Work Plan

No major changes in design standards or planning methodologies are anticipated over the course of the five-year program; as such, there are no additional capital requirements expected beyond what is presented in the table above. There are unique scopes of work with respect to program operation that are scheduled in the long-term planning window, including mid-term evaluation exercises and enhancements, as well as the final program evaluation and reporting. Table 10 provides an overview of the annual operational requirements.

1 TABLE 10: PROJECT EXECUTION

Project Milestones	Milestone Tasks	Timing
Establish Local DR Enabling Policy	1. Seek approval to implement Local DR. 2. Work with external stakeholders to secure availability of Peaksaver assets (OPA) and DR3 participants (IESO) to reduce initial delivery costs. 3. Work with external stakeholders to confirm authorization to develop and activate new local DR programs.	Late 2014 – Early 2015
Develop DR Programs	1. Based on consultations and negotiations above, develop suite of DR programs: a. Develop program proposals for approvals, and b. Develop participant contracts.	Late 2014 – Early 2015
Market DR Strategies to Cecil Service Area	1. Assign dedicated Marketing and Sales staff to Local DR. 2. Conduct demographic analysis to identify key participant opportunities, barriers, and program drivers, and to efficiently manage promotional costs. 3. Create marketing and sales materials addressing findings from demographic analysis. 4. Promote appropriate DR program offerings to customer segments: a. Retain existing Peaksaver and DR3 customers to leverage installed assets and minimize cost of program delivery, and b. Attract new DR participants.	2015 – 2019 (Annual)
Develop DR Operations Experience	1. Procure Local DR operational systems and integrate with Toronto Hydro Grid Operations to reduce cost and task redundancies. 2. Develop and implement participant connection mapping protocol and evaluate load reduction potential by Cecil bus to maximize impact. 3. Examine Cecil load duration curve and station load profile to determine event timing and frequency. 4. Review DR operating strategy and assess unique local system needs to maximize value of event activation. 5. Develop activation protocol. 6. Develop and distribute program participation guide to better manage participant relations and deliver more efficient programming.	Early 2015 (Annual assessment of load profile for event activation schedule)
Enable Technologies	1. Identify existing DR inventory. 2. Install and commission new DR technologies. 3. Activate DR events during times of projected station peak load.	2015 – 2019 (Annual)

Project Milestones	Milestone Tasks	Timing
Monitor Program Implementation	1. Determine strategy for program development and impact monitoring. 2. Define key performance indicators. 3. Monitor local DR program impact.	2015 – 2019 (Annual)
Verify Program Impacts	1. Develop strategy for measurement and verification of load reduction and program cost-effectiveness. 2. Verify program impacts above.	2015 – 2019 (Annual)
Conduct Mid-term Program Review	1. Assess reported measurement and verification results. 2. Identify key lessons and refine processes to deliver more efficient and impactful programming. 3. Recommend course of action to Capacity Planning: a. Continued Local DR will relieve load relief requirement and defer capacity expansion project, or; b. A wires solution should be planned and implemented to address station need.	2017
Develop Future Guidelines	1. Compile lessons learned from Local DR pilot to minimize cost of future program testing and reduce costs. 2. Develop planning guide for potential future implementations of program to improve efficiency of wider application.	2019

E7.10.5.2 Program Risks

There are a number of risks to the implementation of the program:

TABLE 11: PROJECT RISKS AND MITIGATION STRATEGIES

Risk	Mitigation Strategy
Existing DR assets (Peaksaver PLUS® and DR3) may not be available to program	Alternatively develop Toronto Hydro-specific strategies mirroring existing DR programs and promote CEMLC more aggressively for GS >50kW customers; re-consider implementation of energy storage applications currently excluded.
Implementation of new DR programs not authorized/approved	Focus on localized energy efficiency alternatives similar to ConEd targeted DSM program; re-consider implementation of energy storage applications currently excluded.
Participant uptake lower than projected	Mid-term review will identify program inefficiency and to the necessary extent, recommend program enhancements or the planning of a wires solution.
Incremental DR contribution lower than expected	Mid-term review will identify program inefficiency and to the necessary extent, recommend program enhancements or the planning of a wires solution.
Targeted customers and	Further evaluation of participant mapping strategy with

Risk	Mitigation Strategy
corresponding participants do not address Cecil load constraint	recommendation for more effective identification methods.
Unexpected DR resource uptake/mix resulting in costlier provision of load reduction	Work within approved budget; mid-term review will identify unexpected program outcomes and to the necessary extent, recommend program accommodations or the planning of a wires solution.

E7.10.5.3 External Constraints

Successful delivery of the program must address two external constraints:

- Availability of existing DR resources – Uncertainty surrounding the future management of provincial DR resources presents issues with respect to confirming the types of DR programming available for Local DR and the potential load impact. As this program presents a valuable opportunity for all provincial stakeholders, it is recommended that responsible parties engage in the necessary consultations to obtain maximum value from DR assets for both provincial and regional benefit.

- New conservation mandate – the updated legislative framework promotes an "energy-first" approach to CDM planning as system capacity constraints shift from provincial to regional in the short- to medium-term. Given this underlying strategic direction, Toronto Hydro identifies a potential risk in that decision-makers may not currently prioritize peak constraint issues and corresponding investment solutions; however, to the same point, this may also offer an opportunity for positive strategic alignment with the implementation of a regional strategy.

E7.10.6 Evaluation of Alternatives

E7.10.6.1 Quantification/ Evaluation of Options

The forecasted capacity problem at Cecil TS may be seen as presenting three potential courses of action: (1) take no action and monitor the situation further; (2) plan conventional station capacity expansion; or (3) initiate the Local DR program being proposed by this application. However, planners are not required to choose between these options. Rather, this project will demonstrate that Local DR may serve as a cost-effective first step in addressing capacity constraint issues, and will ultimately serve to support the longer term plan; that is, to eventually acquire additional service area capacity when it's required on a more constant and therefore technologically and financially sensible basis. By first enabling Local DR, planners are provided with more time to determine the most suitable course of action; and furthermore, Toronto Hydro shareholders are offered an opportunity to optimize capital allocation strategy with more short and medium-term investment flexibility.

Nevertheless, for the purpose of evaluating the three directions as individual actions, the following outlines are provided:

(1) No Action – Cecil TS load constraint projections present relief needs in two of four buses by 2020, and total station relief in 2025. As with any forecast, the possibility exists that the forecast overestimates future loading, and thus, load relief is not necessary even in the medium term. However, failure to act may result in the following, should the load constraint materialize as expected:

- reduced reliability,
- costly short-term load transfer projects,
- suboptimal connection points for new customers,
- reduced flexibility to schedule outages for maintenance ,
- compromised ability to restore power under contingencies,
- inability to accommodate DG connections,
- forced voltage reduction and/or scheduled blackouts and
- increased risk of equipment failure and threat to worker safety.

(2) "Status Quo" Capacity Expansion – The more likely alternative is to address projected load relief requirements with traditional wired solutions. However, as mentioned in this narrative, there is little to no room for upgrading or installing new physical assets at Cecil TS, so this would present a costly alternative due to property and building purchase and design, and one constrained by the ability to obtain a suitable location. The specific forecast costs for this work are addressed below.

(3) Local DR Program - The Local DR program is positioned as the preferred option due to the strong financial case derived from the model, the difficulties anticipated with respect to station expansion at Cecil TS and a number of other societal benefits mentioned in this narrative. The choice of Cecil TS as candidate station was based on careful consideration of key factors and represents the best opportunity for Toronto Hydro and the wider planning audiences to obtain an alternative capacity planning guideline with minimal risk to real system operation, reliability, and employee and customer safety. Based on available information, implementation of this program will benefit the rate-payer and province in the long-term, and if the LDC lost revenues are sufficiently addressed, the LDC perspective will be more favourable due to stronger and more flexible investment opportunities.

As part of the financial analysis required for Local DR consideration, Toronto Hydro contracted an external consultant, ICF International, to develop a financial model capable of evaluating the business case for localized DR initiatives. The model was explicitly designed to support Ontario LDCs in their decisions as to whether Local DR should cause distribution and transmission asset upgrades to be deferred. It determines the value of such deferral (or full avoidance) and builds it in the business case, as well as other benefits, such as provincial avoided energy supply costs and provincial avoided generation capacity costs.

The model incorporates a series of cost-effectiveness tests which represent the business cases and financial impacts from the perspective of all stakeholders. Table 12 briefly summarizes these tests.

1 TABLE 12: INTRODUCTION TO THE COST-EFFECTIVENESS TESTS INCLUDED IN THE LOCAL DR MODEL

Test	Perspective	Question Answered
Total Resource Cost Test (TRC)	All ratepayers	Whether rate mitigation will be achieved in the long term as a consequence of DR being preferred to supply-side options; accounting for the deferral of local distribution and transmission asset upgrades.
Program Administrator Cost Test (PAC)	LDC & OPA, in their joint effort to administrate DR program(s)	Whether local DR is a cheaper alternative than supply-side options, including incoming local distribution and transmission asset upgrades.
Participant Cost Test (PCT)	Ratepayers participating in the local DR	Whether participating in the program will yield more benefits over time for the participating ratepayers than it will cost them; accounting for any cash incentive, bill credit or direct-install they will benefit from when they sign up in the program and/or as they stay in the program.
Rate-Impact Measure Test (RIM)	Non-participating ratepayers	Whether rates will go up in the short term as a consequence of DR being preferred to supply-side options; accounting for the deferral of local distribution and transmission asset upgrades.
Net benefit for distribution under the RIM test (RIM-d)	Non-participating ratepayers	Whether the distribution portion of the rates will go up in the short term as a consequence of DR, accounting for the deferral of local distribution asset upgrades, as well as incentive, direct-install cost and program administration cost incurred directly by the LDC and not refunded by the OPA.
Net benefit for transmission under the RIM test (RIM-t)	Non-participating ratepayers	Whether the transmission portion of the rates will go up in the short term as a consequence of DR, accounting for the deferral of local transmission asset upgrades.
Net benefit for generation under the RIM test (RIM-g)	Non-participating ratepayers	Whether the generation portion of the rates will go up in the short term as a consequence of DR, accounting for the provincial avoided cost of generation capacity.

Test	Perspective	Question Answered
Present value of provincial CDM costs (RIM-pc)	Non-participating ratepayers	Whether the regulatory fees and debt retirement portion of the rates will go up in the short term as a consequence of the provincial incentive handouts, direct-install costs as well as program administration costs of OPA-contracted DR programs, if any. The RIM-pc is needed to balance the following equation: NPV_RIM = RIM-d + RIM-t + RIM-g + RIM-pc The RIM-pc also factors in the lost revenues otherwise allocated to regulatory fees and debt retirement.
Local Distribution Company Test (LDCT)	LDC's shareholders	Whether rolling out the program and deferring the local asset upgrade optimizes the LDC shareholder's capital allocation strategy

Using the financial model described above, Toronto Hydro examined the business case for Local DR implementation in the Cecil TS service area. The model inputs and outputs are presented here:

Capacity Expansion

- Cecil TS contains four buses
  - Bus A1-2 is a dedicated bus for supplying load to University of Toronto.
  - Bus A3-4 and A7-8 will both reach their load capacity in 2020.
  - Bus A5-6 will be at 88% capacity in 2020, offering little room for load transfer from A3-4 and A7-8
- Even though entire station load will reach its 95% capacity in 2026, load relief will be required in 2020.
- Excluding Bus A1-2, total station loading will approach 93% in 2020.
- The projected station expansion solution would cost approximately $29.5M and provide a maximum of 72 MVA of additional capacity.
- For model comparison, the defending investment program was forecasted to begin in 2019 and energize in 2020.

Local DR

- A DR potential analysis was conducted for the Cecil TS service area, and the following projections were developed as inputs to the model:

TABLE 13: PROJECTED DR EXPENDITURE AND LOAD IMPACT

Cecil TS – DR Potential Analysis	2015	2016	2017	2018	2019
Cumulative Curtailment Capacity (MVA)	0.9	2.5	4.4	7.2	9.5
OPEX Expenditure ($'000)	$1,382	$1,079	$978	$1,052	$1,040
CAPEX Expenditure ($'000)	$167	$2,445	$596	$503	$346
Total Expenditure ($'000)	$1,549	$3,524	$1,574	$1,555	$1,386

- Based on the peak demand impact and financial analyses conducted by the model, the following results were produced for the work proposed at Cecil TS:

TABLE 14: COST-EFFECTIVENESS TEST RESULTS

Test Results	B/C Ratio	NPV ($'000)	LUC ($/kW-yr)
Total Resource Cost Test (TRC)	1.9	$7,557	$166
Program Administrator Cost Test (PAC)	1.7	$6,339	$191
Participant Cost Test (PCT)	1.8	$2,226	$58
Rate-Impact Measure Test (RIM)	1.5	$5,329	$211
Local Distribution Company Test (LDCT)	N/A	($418)	N/A
Station Expansion Project Deferral	5 – 6 years		

A review of the test results presents a convincing financial case for Local DR investment from the perspective of the ratepayer. Additionally, the TRC, PAC, PCT, and RIM tests demonstrate positive overall cost-benefit ratios for the majority of relevant stakeholders. Setting aside the LDCT result momentarily, the other four tests clearly advocate for Local DR project initiation at Cecil TS. More specifically, the total societal benefit, the project administration benefit, the Local DR participant benefit, and finally, the overall rate-payer benefit, all identify the deferral of station expansion by five years as a more financially attractive investment strategy than the conventional investment that would be carried out in 2019 and 2020. To interpret the model's output in the opposite way, if the model calculations identified the station expansion investment as the more

optimal strategy for any one of the four types of stakeholders, that specific NPV result would be negative. A more comprehensive outline of the model's design and functionality, as well as a discussion of the interpretation of its results can be found in Appendix A.

At this point, it is important to note that the negative LDCT net present value represents the amount that must be recovered to remain "whole" when compared to the planned capital investment. The model recognizes that by deferring investment, the creation of a new revenue stream and a new component of regulated rate of return are also deferred by Toronto Hydro. Therefore, one of the key assumptions accounted for during the design of the Local DR financial evaluation model was that, the model's output would highlight the need for a cost-recovery mechanism in order to encourage Local DR investments in place of immediate station upgrade and expansion projects, but this need would be justified by the anticipated total societal and overall ratepayer benefits also presented by the model.

It is also necessary to address the choice of evaluating this project investment with an external model, rather than the standard Business Case Evaluation (BCE) normally adopted for the purpose of Toronto Hydro rate application narratives. The justification for a new model includes the external factors not captured by the Toronto Hydro standard BCE. Primarily, the Local DR program produces avoided transmission and generation costs that are considerable variables when introduced to the ratepayer cost-benefit analysis. These financial impacts are incorporated into the benefit side of the equation, while the associated transmission and generation revenue losses are added to the cost side of the equation, and together these become significant factors in identifying the overall value of this solution.

While it is not a driver of this program, Toronto Hydro recognizes its commitment and ensuing responsibility toward the achievement of government mandated provincial CDM targets; especially considering Toronto Hydro's share of those provincial targets is currently greater than 20% and is expected to remain at this level. Recently, the Ministry of Energy released the new provincial CDM framework, "Conservation First – A Renewed Vision for Energy Conservation in Ontario", which suggests that LDCs should be able to consider and employ demand management alternatives to capacity expansion. Some of the key messages taken from this planning act in support of Local DR include the following:

- In the Conservation First stakeholder presentation, implementation plans noted that LDCs will be able to make rate applications to the OEB for local targeted demand response if cost-effective/deferring infrastructure investments.

- In discussing the current state of DR in the province, with a view toward greater impact, the Minister's Message states that, "Innovative demand response could enable faster, regionally targeted deployment, for periods that directly correspond with system needs."[5]

- In evaluating conservation's place in the supply mix: "it makes sense to invest as much to save a megawatt of power as it would cost to generate that same megawatt. When other benefits are factored in – conservation does not involve construction or the industrial processes that generation requires, it saves consumers money and relieves stress of the system – the arguments in favour become even stronger"

Finally, DR is a proven method for reducing peak demand that has produced a noticeable and positive impact on the provincial power system. During a heat wave in the summer of 2011, Ontario businesses and residential consumers provided 400 MW of DR to help manage the peak in demand for electricity[6]. In the Toronto Hydro service territory alone, there is a verified total of 63 MW of DR capacity available to address provincial system needs. While the Local DR program is positioned as a unique solution to local distribution system constraint, both the technology and customer acceptance have been comprehensively evaluated and proven to support peak demand reduction. A pilot project in New York City is one of the better known programs, and demonstrated considerable success in the targeting of DR.

CECONY's Targeted Demand Side Management (DSM) Program [7]

With limited potential for capacity expansion or generation imports in New York City, Consolidated Edison Company of New York, Inc.'s (CECONY) targeted DSM program was designed to alleviate peak demand in the most highly constrained networks, until permanent system relief could be established. The program employed energy efficiency measures to proactively reduce demand on specific circuits beginning in 2004. Third-party vendors were allowed to bid for load curtailment contracts and successful parties were then required to guarantee installation of equipment and future load reduction before summer peaking months. These vendors were only credited with projects in targeted networks, and paid only for measures that would directly impact peak loads. Through April 2013, CECONY had achieved approximately 107 MW of demand reductions and 278 GWh of annual energy savings. The program has

created $464M in net customer benefits, including $221M in avoided T&D capital, on $145M in total costs. Other benefits identified by the CECONY experience were reduced regulatory risk, reduced electricity costs for consumers, and a complementary alternative to load rejection.

1. Introduction

Through the Conservation Fund, the OPA has agreed to fund and support Toronto Hydro in evaluating a demand management protocol that specifically targets local areas of high constraint. Toronto Hydro has identified certain geographical segments within its overall service territory where peak load regularly approaches the local distribution infrastructure's capacity. Typically, this would result in the planning and implementation of a major capital investment in new and upgraded assets.

Toronto Hydro is exploring the idea of ramping up a portfolio of local demand side management programs, that will target areas of high constraint.

The purpose of this study is assessing the potential for demand response alternatives to offset capital investments, and to create a financial model which supports this approach. The study focuses on customers served by transmission and/or distribution systems identified as requiring significant capital investment in the next 5 to 10 years.

At term, the key outcomes of this study will include the following:

1. Phase 1
    a) To determine the most effective approach to reducing peak load in highly constrained areas, to the extent with which major capital investments can be significantly delayed or even offset entirely.
    b) To develop a financial model for such strategies which can be applied to similarly challenged areas, both in the THESL region and province-wide.
2. Phase 2:
    a) To develop a guideline for determining when activations are necessary, and the protocols for the implementation of future events.

Toronto Hydro has completed the first phase of the project, and this document outlines these preliminary outcomes.

As part of phase 1 of the study, Toronto Hydro developed an Excel based financial and business analysis model that was given the following a provisional name: the "CDM Challenger". The CDM Challenger builds the business case for localized DSM initiatives that specifically target areas of high system constraint in a local distribution company's (LDC) service territory; this includes, but may not be limited to demand response (DR) programs.

The CDM Challenger was designed to support Toronto Hydro in making a sound decision as to whether local DSM can and should cause distribution and transmission asset upgrades to be deferred or offset entirely. It determines the value of such deferral (or full avoidance) and builds it in the business case, as well as other benefits, such as provincial avoided energy supply costs, and provincial avoided generation capacity costs.

The model was initially built for targeted demand response programs. It was later found that regular conservation programming might also be of interest in areas of high constraints to curtail peak load. The model was therefore modified to encompass both types, demand response and regular conservation, hence the shift towards using the more inclusive acronym, DSM, rather than DR.

So far the development and testing of the CDM Challenger focused on Toronto Hydro customers served by Toronto Hydro distribution systems. However, at term, the CDM Challenger could be used to evaluate the need for investment in similarly challenged areas in other Ontario LDCs service territories.

The purpose of this report is to provide a high level description of the capabilities, purposes and uses of the CDM Challenger; to document and explain the model architecture and the algorithms; and to guide CDM staff on the use and interpretation of the model's inputs and outputs. OPA CDM Cost Effectiveness Guide and California Standard Practice Manual

The CDM Challenger builds the business case for local DSM based on the results of standard cost r effectiveness tests as defined by the 2010 OPA CDM Cost Effectiveness Guide[1], as applicable, and the 2001 California Standard Practice Manual[2] (SPM); the former being an Ontario specific offshoot of the latter. Both protocols were used as guidelines for the development of the financial and economical analysis algorithms of the CDM Challenger.

The California SPM is a sturdy economical analysis platform; however, the CDM Challenger had to be augmented with new tests to capture the nuanced market position of certain Ontarian stakeholders. For example, a key perspective is that of Toronto Hydro. Toronto Hydro is an investor owned LDC that earns a regulated return on equity from constructing or upgrading distribution assets that would be deferred by the local DSM programs. Similarly, introducing "Transmitters'" and "Generators" perspectives would facilitate identifying and allocating the system and network benefits from local DSM.

The method developed as part of this study and built in the CDM Challenger includes the most important benefits associated with CDM, which include avoided cost of generation, avoided or deferred cost of transmission and distribution capacity, and avoided cost of energy. As such, the model will carry out a set of tests, each of which represents the business case of local DSM alternative from a distinctive perspective as laid out in Exhibit 1.

Exhibit 1 Introduction to the Cost Effectiveness Tests Included in the CDM Challenger

Test	Perspective of	Applicable Guidelines, if Any	Question Answered

Rate Impact Measure Test (RIM)	Non participating ratepayers	2001 California SPM	Whether rates will go up in the short term as a consequence of CDM being preferred to supply side options to refund incentive being handed out, program administration cost, and lost revenues; accounting for the deferral of local distribution and transmission asset upgrades.
Net benefit for distribution under the RIM test (RIM d)	Non participating ratepayers	New test – Augmented SPM	Whether the [distribution portion of the rates] will go up in the short term as a consequence of CDM, accounting for the deferral of local distribution asset upgrades, as well as incentive, direct install cost and program administration cost incurred directly by the LDC and not refunded by the OPA, if any.
Net benefit for transmission under the RIM test (RIM t)	Non participating ratepayers	New test – Augmented SPM	Whether the [transmission portion of the rates] will go up in the short term as a consequence of CDM, accounting for the deferral of local transmission asset upgrades.
Net benefit for generation under the RIM test (RIM g)	Non participating ratepayers	New test – Augmented SPM	Whether the [generation portion of the rates] will go up in the short term as a consequence of CDM, accounting for the provincial avoided cost of generation capacity.

Test	Perspective of	Applicable Guidelines, if Any	Question Answered
Present value of provincial CDM costs (RIM pc)	Non participating ratepayers	New test – Augmented SPM	Whether the [regulatory fees and debt retirement portion of the rates] will go up in the short term as a consequence of the provincial incentive handouts, direct install costs as well as program administration costs of OPA contracted CDM programs, if any. The RIM pc is needed to balance the following equation: NPV_RIM = RIM d + RIM t + RIM g + RIM pc The RIM pc also factors in the lost revenues otherwise allocated to regulatory fees and debt retirement.
Local Distribution Company Test (LDCT)	LDC's shareholders	New test – Augmented SPM	Whether rolling out the program and deferring the local asset upgrade optimizes the LDC shareholder's capital allocation strategy
Transmission Company Test (TCT)	Transmission Company's shareholders	New test – Augmented SPM	Whether rolling out the program and deferring the local asset upgrade optimizes the transmission company shareholder's capital allocation strategy

The tests account for the provincial average avoided cost of energy, as well as generation capacity as provided by the OPA in its Cost Effectiveness Guide. Optionally, the users can use provincial averages for avoided distribution and transmission capacity instead of using the deferred localized asset upgrade projects.

The platform could be expanded in the medium term to include other benefits that are more challenging to quantify such as increased reliability, greenhouse gas abatements, etc. Furthermore, the model as it currently stands does not capture fuel savings and their associated avoided cost.

All the aforementioned cost effectiveness tests will be presented and defined in greater details in Section 2 and 3.

1.1. Users, Audiences and Contributors to the Model

The primary users of the CDM Challenger will be Toronto Hydro CDM staff, at first, and then the CDM staff of any other LDCs who choose to adopt. However, the current version of the model has not been tested by anyone other than Toronto Hydro CDM staff members.

All users are assumed to have a high level of proficiency with Excel. Users are provided with seamless access to both the front and back ends of the models. The workbook might be locked and some tabs, columns and rows are hidden to reduce the clutter and improve ergonomics, but the workbook can be unlocked without any password and any hidden tabs and ranges can be easily revealed.

All future users should be provided with a training session along with the model, to reach a level of understanding of the inputs and outputs, algorithms, and purpose. The scope of this project resulted in the development of a methodology to value Local DR case studies and pilot programs in THESL service territory that might be transferrable to other LDC territories. The resulting model exceeds expectations with respect to the initial project scope; however, THESL also recognizes that it is necessary to identify the inputs and portions of the model that are LDC specific before future dissemination.

Inside (and outside) Toronto Hydro, the following teams/groups had interest in the CDM Challenge for the reasons stated below:

- CDM Team:
  - The CDM team will be the main users of the models. They will share the results of the modeling with other teams.
  - They are designing the local DSM programs and therefore they will have a large portion of the information to feed in the models, and at the same time they will need immediate feedback from the model to allow them to tune their assumptions, establish the incentive levels and program administration costs.
  - The CDM Team wants to build the business case for each local DSM programs targeting various rate classes for areas of high constraints from the perspective of Toronto Hydro, of the society, of the participating rate payers (participants), and of the non participating ratepayers (non participants).

- Toronto Hydro Finance Department:
  - To start with, they need to compare the local DSM programs financial performance with that of other opportunities.
  - They also need specific streams of information, on an annual basis, to feed in their own modeling, forecasting and regulatory filing work. They agreed on an "incremental" approach; the model would output incremental cash flows caused by the DR initiatives against the business as usual approach to address capacity constrained areas (that is: upgrading the substation, or switching load to another substation).

- Toronto Hydro Capacity Planning, Investment Modeling & System Performance:
  - The capacity planning staff holds the information about what areas to focus on, what stations are to be upgraded, when are the upgrades planned, and how much capital investment is planned for each upgrade.
  - The capacity planning staff provide decision criteria whether a distribution asset upgrade can be deferred, and by how many years. It is expected that this decision criteria will take the shape of a level of impact that the CDM alternative(s) will need to achieve for a given location on a given year that would make the deferral of the asset upgrade acceptable.
  - The capacity planning staff will also be part of the final decision whether the projected impacts of the CDM alternative(s) for a given location are sufficient and robust, and whether the CDM alternative(s) as planned can trigger the deferral of upgrade project(s)

and by how many years. They will be responsible for effectively accounting for the decisions made in the distribution infrastructure investment plan.
    - The investment modeling & system performance staff is interested in the outputs of the model in a similar fashion than the finance department.

- Asset Management
    - The asset management team will support the CDM team with load control technology and how Toronto Hydro's advanced metering infrastructure will be leveraged to do direct load control, for instance.
    - Moreover, the asset management team is interested in the model themselves because of their involvement in distributed energy projects (for instance: PV, local energy storage). The CDM Challenger as it stands today cannot handle distributed energy projects before the meter. The asset management would be interested in this feature being added in the medium term.

- Transmission Company (the transmitter)
    - The transmitter will be interested in working with Toronto Hydro to roll out local DSM programs in areas where transmission asset upgrades are needed in the medium term as a result of high constraint.
    - The transmitter's finance department, as well as its capacity planning, investment modeling & system performance staff will have similar needs and roles than that of Toronto Hydro.

- Other external audiences like the OPA and the OEB
    - External audiences will want to see the business case of local DSM programs from the perspective of the society, the participating ratepayers, and the Ontarian ratepayers in general. They will also want to compare local DSM with supply side alternatives.

2. Incorporating Local DR into an LDC Rate Filing

(This section was added after the first draft of the Challenger model and corresponding report were completed. These first drafts did not incorporate the case for Local DR funding through distribution rate application, and therefore, the sections which follow this will not reference any of this information.)

The Challenger model is also capable of assessing the financial case for Local DR should it be incorporated into an LDC rate application and filed with the Ontario Energy Board (OEB). If the OEB was to approve this type of application and fund Local DR directly through the distribution rates, the benefits would include the following:

- The LDC would be refunded for all Local DR operational expenses (Opex) through distribution rates
- The depreciation of the of Toronto Hydro's Local DR capital assets (Capex) would be refunded through rates, as well as produce a regulated rate of return on investment for the LDC shareholder

The return on Local DR Capex would offset the negative impact of deferring infrastructure upgrade investment, and the model could determine whether the offset was beneficial enough to compensate for the delayed/foregone return on infrastructure investment.

To assess the financial case for Local DR funding through distribution rates, the following adaptations were made to the Challenger model:

- In the TP sheet, a distinction was added to differentiate Capex LDC direct install cost and Opex LDC direct install costs. It should be noted that the LDC's DR Capex is only for direct install, and can only be inputted in the TP sheet – which means it needs to be allocated to specific typical participants. Each Capex item needs to be provided with its specific book life (typically 1 to 20 years).
- In the TP sheet – and in a new, hidden, companion sheet for each TP sheet, ie. the TP Cashflows sheet – financial modeling was added that was needed to establish the incremental equity contribution, revenue requirement, ROE, depreciation, PILs, interest, and net income triggered by each typical participant. The same financial model was used for capital improvement projects that can be found in the DI and TI sheet, and their respective companion sheets, ie. the DI and TI Cashflows sheets.
- In the TP sheet, the TP level cost effectiveness tests were modified to reflect the new funding structure for DR (this is expanded upon below). Changes made to the TP level tests in the TP sheet are reflected in the Projections sheet, and thus in the Portfolio level test results, as well.
- In the Budget sheet, the LDC's Opex direct install cost was separated from Capex direct install cost, and from other LDC's incentive and program admin costs (which will be Opex by default).

The implications on the cost effectiveness test structure were as follows:

- The implications on the TRC were such that the Capex portion of the LDC's DR direct install cost (by definition, direct install is summed up as "incremental cost" in the TRC test) had to be replaced by the present worth of the full incremental revenue requirements to fund the DR Capex – which means the model now has to add PILs, interest and a return for the shareholders.
- Similarly, the implications on the PAC and the RIM were such that the Capex portion of the LDC's DR direct install cost (by definition, direct install is summed up as "incentive cost" in the PAC and the RIM tests) had to be replaced by the present worth of the full incremental revenue requirements to fund the DR Capex.
- The implications on the PCT were such that the Capex portion of the LDC's DR direct install cost (by definition, direct install is summed up as an "incremental cost" and an "incentive cost" in the

PCT test) had to be replaced by the present worth of the full incremental revenue requirements to fund the DR Capex.
- The implications on the LDCT test were such that the DR incremental equity contribution was added as a cost, and the DR incremental net income was added as a benefit.
- There were no implications on the TCT.

Overall, the impact of these adaptations on the test results for the TRC, PAC, and RIM should be minor. The impacts on the LDCT, however, can be significant – but likely still not enough to present DR as worthwhile for Toronto Hydro's shareholders without an additional cost recovery mechanism.

Another adaptation to the Challenger model was the inclusion of the LDC Report sheet. The LDC Report fundamentally aggregates data from all other sheets in the workbook. The LDC reports present annual figures for a 41 year time window – from the portfolio design year (Year00), through the five years of active program operation (Year01 to 05 inclusively), and all the way to 40 years after the start of the program portfolio (Year40). The LDC report can be used by the LDC Financial Department to extract outputs of the model to be added to their own financial models, which usually contemplate a 40 year window.

Most figures are in dollars; however, certain results are presented in units such as kW, MWh/yr, kVAR, kVA, and power factor percentages. All monetary figures are nominal; therefore, inflation is reflected in the table. All figures/values are broken down by rate class (Residential, Multi res, General Service, Large and so on). The upper table is a summary of all other rate class specific figures. The impacts and cash flows that are triggered by all "included" typical participants (where included/excluded is defined in the Projections Sheet) are reflected in the LDC Report, including an allocation of all indirect program administration costs that commensurate with the total curtailment at the end of the last year of active program operation.

Items that were retained in the LDC report include the following:
- Number of new sign ups in the DR programs, as well as cumulative participant numbers that account for persistence in the programs;
- Impact figures in kW, MWh/yr, kVAR and kVA;
- OPA's program administration budget, and OPA contracted incentives;
- Total DR incremental cost, total DR incentive, direct install costs, and program administration cost;
- All lost revenues at the distribution, transmission, generation levels, and as well as regulatory fees (GAM and others), based on actual LDC rates;
- The LDC's lost revenue adjustment mechanism expected cash flows (LRAM);
- LDC's deferred/avoided infrastructure upgrade Capex, equity contribution, incremental revenues, as well of the sub component of that incremental revenue (ROE, net income, PILs, interest, Opex, and depreciation); and

- LDC's incremental DR Opex and Capex, as well as the incremental funding triggered by the DR Capex (equity contribution, incremental revenues, ROE, net income, PILs, interest, Opex, and depreciation).

All monetary items above are not necessarily mutually exclusive; many are overlapping. Again, all figures are broken down by rate class, and projected through the 41 year window, as applicable.

The LDC Report contains certain sets of formulas which can be computationally demanding; therefore, a toggle button on top of the report was included to disable these when possible. Disabling the LDC Report significantly reduces the time Excel needs to refresh all calculations in the workbook. It is recommended to disable the report when not in use.

3. Research and Review of DR Alternatives

This study presents a financial and technical case for localized demand side management (DSM) in place of costly investment in new or upgraded infrastructure. Though many of the concepts of DSM are well documented and practiced, it is important to provide a general overview of the technologies and implementations being considered.

The term DSM was introduced by the Electric Power Research Institute in the 1980s. Typically, the purpose of DSM is to reduce electric demand during peak periods: while this doesn't necessarily reduce overall consumption, it can offset the need for investments in distribution and transmission infrastructure, and ultimately, avoid new and often expensive peaking generation sources.
There are three general strategies employed to reduce demand:

- Energy Efficiency (EE) – simply refers to using less power to perform the same tasks, and typically includes the permanent installation, replacement, or upgrade of customer electricity using equipment.

- Demand Response (DR) – includes all actions that reduce, flatten, or shift peak demand. DR refers to usage adjustments which can be carried out voluntarily or involuntarily, by the customer or the utility, in response to grid stress or high prices.

- Distributed Generation (DG) – refers to the utilization of smaller scale, non-centralized power generation sources as an alternative to, or as an enhancement to, the current grid supply. These sources are typically closer to the end use customer, and help improve transmission and distribution reliability by reducing losses and congestion on the power lines.

There are many different strategies encompassed by the groups listed above. These alternatives depend on the characteristics of the utility jurisdiction, including, end use equipment, utility

equipment, and energy storage and distributed generation potential. Table 1 provides a detailed list of these alternatives.[3]

Table 1 – Strategies for DSM

End Use Equipment Control	Utility Equipment Control
1. A/C—Residential and Commercial Package Units a. remote control cycling b. local controller c. thermostat control d. remote on or off control 2. AIC—Commercial and Industrial Chillers a. water column temperature control b. remote control cycling c. capacity reduction 3. Water Heater—Residential and Commercial a. remote on or off control b. timers 4. Pumps a. timers b. remote on or off 5. Heating a. alternate source heating b. remote on or off control c. remote cycling d. smart thermostat 6. Multiple Loads a. equipment interlock b. demand limiter c. energy management system d. demand controller e. peak alert f. timers 7. Processing Loads a. interlocks	1. Voltage Reduction 2. Feeder Control 3. Power Factor Control **Energy Storage** 1. Cool storage 2. Heat Storage 3. Storage Water Heater 4. Waste Heat Utilization **Incentive Rates** 1. Time Differentiated 2. Interruptible **Distributed Generation** 1. Wind 2. Solar Thermal 3. Solar Cells 4. Fuel Cells 5. Standby Generators 6. Cogeneration 7. Small Hydro **Performance Improvement or Equipment and Systems (Conservation)** 1. High Efficiency Equipment 2. Heat Pumps 3. Evaporative Boost Cooling for Air Conditioners 4. Improved Building Construction 5. Improved Process 6. Utility System Improvements

[3] R.M. Delgado, Demand Side Management Alternatives", Proc. IEEE, Oct. 1985.

b. alternate source c. pre arranged	

There are many inherent benefits associated with selecting a DSM alternative to increased grid capacity,:

- Energy savings – using less energy results in a direct cost savings to customers.
- Capacity savings – when load reduction is coincident with the system peak, new supply may be avoided.
- Transmission and distribution (T&D) savings – if the reduction is coincident with network peak, investments in distribution assets can often be deferred.
- Line loss savings – delivering less energy avoids losses in the wires. This tends to enhance the benefits of avoided generation and T&D mentioned above.
- Environmental benefit – avoided energy consumption minimizes the environmental and health impacts associated with many forms of generation, as well as the related life cycle costs of T&D infrastructure.
- Improved grid reliability

3.1. The LDC Perspective

Despite the obvious societal benefits, it is important that this study positions the concept of localized DSM as a financially viable alternative to all stakeholders, not the least of which, the local distribution companies (LDCs) who are largely responsible for the final decisions regarding capacity planning and meeting supply needs. This is a unique position because LDCs have an inherent motive to increase revenues from the generation, transmission and/or distribution of electricity. Furthermore, increased capital investment in capacity provides new potential revenue streams, and a positive rate of return on the investment; whereas, momentarily disregarding regulatory compensation mechanisms, decreasing an LDC's total load results simply in lost revenue. So even though the total societal benefits resulting from energy saving investments can be greater than traditional expenditures on new supply, these utilities often don't fully capture the benefits of conservation and efficiency in terms of revenues. Therefore, despite being the right decision for the public as a whole, it is not always optimal to do so from the view of the parties providing the commodity. So it is not uncommon for regulators to encounter resistance from LDCs with respect to conservation alternatives.

Thus, the LDC perspective is that which narrows the scope of this study. In the Toronto Hydro (TH) case, for the areas where local DSM may be considered in place of expanded distribution capacity, relief is often only required for a tiny fraction of the year. In one example, a transformer station being examined surpassed 95% loaded capacity for less than 20 hours in 2012. In a situation such as this, a program designed to offer effective relief for these smaller intervals of time, while minimizing the impact on an LDC's opportunity to earn maximum revenue during the rest of the year would be the strategy most widely accepted by LDC decision makers. Hence, the focus of this study and the likely strategies that would first be considered in a local DSM pilot include demand response programs before energy efficiency and conservation concepts. While distributed generation also fits the criteria presented here, early discussions with the TH Asset Management team suggest that it is not currently a viable option for pilot study implementation, due to equipment availability in the service region. For the purpose of this report, we presume this situation can be extended to other LDC jurisdictions.

3.2. The Landscape of Demand Response

In various forms, DR has been practiced in the electric utility sector for many years. With the increasing modernization of electricity grids, technologies, tools, and techniques are available that assist DSM in optimizing grid operations and resources to ensure service reliability. Smart grid infrastructure, distribution system modeling, consumer behaviour modeling, as well as high speed computational analysis are combining to further improve the results of DSM efforts. Today, there are demand response strategies and programs available to all sectors, and can generally be divided between two categories:

1) Price-based Programs – strategies which vary the price of electricity over time, to better align customer energy consumption and the costs they impose on the electric utility system.

2) Incentive/Event-based Programs – strategies which reward customers for reducing their electric loads upon request or for giving the program Administrator some level of control over their electricity using equipment.

Table 2 presents a summary of the types of programs that fall within these two categories:

Table 2 – Demand Response Program Types[4]

Price-Based Options	Incentive or Event-Based Options
Time of Use (TOU) Rates	Direct Load Control
Real-Time Pricing (RTP)	Demand Bidding/Buyback Programs
Critical Peak Pricing (CPP)	Interruptible/Curtailable
Peak Time Rebates (PTR)	Emergency Demand Response Programs
	Capacity Market Programs
	Ancillary Services Market Programs
	Critical Peak Pricing (CPP)
	Peak Time Rebates (PTR)

Table 3 summarizes the United States Federal Energy Regulation Commission's (FERC) brief explanations of the DR programs mentioned above.

Table 3 – FERC DR Program Classifications[5]

Type of Demand Response	FERC Definition
Direct Load Control or Direct Control Load Management	A demand response activity by which the program sponsor remotely shuts down or cycles a customer's electrical equipment on short notice. Direct load control programs are primarily offered to residential or small commercial customers.
Interruptible Load	Electric consumption subject to curtailment or interruption under tariffs or contracts that provide a rate discount or bill credit for agreeing to reduce load during system contingencies. In some instances, the demand reduction may be effected by action of the System Operator (remote tripping) after notice to the customer in accordance with contractual provisions.
Critical Peak Pricing with Load Control	Combines direct load control with a pre-specified high price for use during designated critical peak periods triggered by system contingencies or high wholesale market prices.
Load as Capacity Resource	Pre-specified load reductions when system contingencies arise.
Spinning/Responsive Reserves	Demand-side resource that is synchronized and ready to provide solutions for energy supply and demand imbalance within the first few minutes of an Emergency Event.
Non-Spinning	Demand-side resource that may not be immediately available, but may

[4] Table 1 is based on a table in a report for the National Action Plan for Energy Efficiency, NAPEE 2010, p 2.2, with a modification. The source document categorized CPP and peak time rebates as price-based options only. The modification identifies CPP and peak time rebates as incentive or event-based options because the structure of CPP or peak time rebates may reward customers for reducing their electric loads upon request or for giving the program administrator some level of control over their electricity-using equipment.

[5] Federal Energy Regulation Commission, "2010 Assessment of Demand Response and Advanced Metering, Staff Report," February 2011.

Reserves	provide solutions for energy supply and demand imbalance after a delay of ten minutes or more.
Regulation Service	A type of demand response service in which a demand resource increases and decreases load in response to real-time signals from the system operator. Demand resources providing Regulation Service are subject to dispatch continuously during a commitment period. This service is usually responsive to Automatic Generation Control to provide normal regulating margin.
Demand Bidding and Buyback	A program which allows a demand resource in retail and wholesale markets to offer load reductions at a price, or to identify how much load it is willing to curtail at a specific price.
Time of Use Pricing	A rate system where usage unit prices vary by time period. Time of use rates reflect the average cost of generating and delivering power during those time periods.
Critical Peak Pricing	Rate and/or price structure designed to encourage reduced consumption during periods of high wholesale market prices or system contingencies by imposing a pre-specified high rate or price for a limited number of days or hours. The total number of critical peak periods is typically capped for a calendar year.
Real-Time Pricing	Rate and price structure in which the retail price of electricity typically fluctuates hourly or more often to reflect changes in the wholesale price of electricity on either a day-ahead or hour-ahead basis.
Peak Time Rebate	Peak time rebates allow customers to earn a rebate by reducing energy use from a baseline during a specified number of hours on critical peak days. Like Critical Peak Pricing, the number of critical peak days is usually capped for a calendar year and is linked to conditions such as system reliability concerns or very high supply prices.
System Peak Response Transmission Tariff	The terms, conditions, and rates and/or prices for customers with interval meters who reduce load during peaks as a way of reducing transmission charges.
Other Demand Response Program/Tariff	A company or utility's service/product/compilation of all effective rate schedules general terms and conditions and standard forms related to demand response/AMI services for customers that are not residential, commercial and industrial, or other.

3.3. Demand Response by Sector

There are unique opportunities for demand response in the residential, commercial and institutional (C&I), and industrial sectors. Certain strategies have proven more effective for each, in terms of program participation and corresponding load curtailment and reliability. However, the landscape is constantly

evolving and adapting to make participation more inclusive.

Residential – demand response in the residential sector is primarily delivered through direct and automated load control. Devices such as central air conditioners, domestic hot water heaters, and pool pumps can be short cycled or turned off during summer peak times, with little to no impact on customer comfort. This also provides the participant reduced costs as a result of consumption savings or usage being shifted to mid r and off peak pricing intervals. In other examples of residential DR, automated thermostat setbacks may be used to induce load curtailment.

Commercial & Institutional – DR programs in the C&I sector can sometime be more challenging from an inclusive design perspective. End uses and facility operations vary more widely, and therefore, it is often difficult to fit this group of customers into the parameters of a direct load control or interruptible program. However, developments in technology and the increased need to address the large peak demand loads stemming from this sector, has created a new focus and marketplace for C&I demand response.

There is such a variety of electrical loads in C&I sectors that utilities and 3rd party firms are tasked with identifying specific curtailment strategies that achieve the maximum load reduction with the least amount of operational disturbance. Common strategies may include slowing down variable speed motors, reducing a portion of non-essential lighting, raising HVAC set points, and temporarily shifting load to on-site generation.

Industrial – Historically, the industrial sector has been considered as the lowest hanging fruit in the market for DR, because, on a per capita base, these facilities are usually able to provide higher load curtailment. Industrial customers typically secure lower energy rates through "interruptible tariffs" in exchange for load reductions during system peak. These programs are commonly implemented manually, with notification of an event taking place over the phone or by email, and traditionally, this has meant relatively low participation rates. However, automated DR strategies designed for the industrial sector are being reviewed and tested within the context of the opportunities and barriers presented by current and future market structures. Automated DR systems for industry could provide customers with online pricing signals, capabilities to program customized events, and provide the utilities with dispatchable supply alternatives similar to conventional resources. Of course, the barriers to automated event control include load scheduling that can be dictated by external factors such as customer demands or time sensitive production, the perceived lack of control presented by the term "automated", and aversion to risks such as unplanned downtime.

3.4. The Cost Effectiveness of Demand Response Programs

The main deliverable of this study is a modelling tool capable of producing the key financial outputs necessary to determine the cost-effectiveness of localized DSM. While there are a number of examples of cost-effectiveness test results available through both theoretical and practical investigation, the

advantage of this model is its ability to adapt and be tailored to a particular suite of DSM programs, and to the unique characteristics of the user's service region and potential participants. As such, cost benefit analyses are not included in the review of DR alternatives.

However, it should be noted that a number of widely accepted studies present DR as a viable alternative, both financially and technologically, to conventional supply resources. These studies extend the range of benefits to both the participant and non-participating rate payers, as well as to the T&D companies, the generators, and ultimately, society as a whole. For example, a report addressed to the United States Congress in 2006[6] included a literature review of ten demand response cost effectiveness studies. Examining various types and combinations of demand response programs, both illustratively and practically, all ten studies produced positive cost benefit ratios and a range between $0.88 – $2.07 of normalized gross benefit in $/kW-year. This metric represents net benefits ($) per unit of avoided capacity (kW); this is how the industry typically quantifies the value or cost of demand response. According to the OPA's CDM annual reports, the delivery cost of DR programs to date in Ontario has been approximately $10,000/MW-month, comparable to the cost of many conventional alternatives, but with more attractive societal benefits. Furthermore, a pilot offering in New York City has even demonstrated success in the targeting of DSM.

CECONY's Targeted Demand Side Management (DSM) Program[7]

With limited potential for capacity expansion or generation imports in New York City, CECONY's targeted DSM program was designed to defer the need for transmission and distribution upgrades in the most highly constrained networks. The program employed energy efficiency measures to proactively reduce demand on specific circuits beginning in 2004. Third-party vendors were allowed to bid for load curtailment contracts and successful parties were then required to guarantee installation of equipment and future load reduction before summer peaking months. These vendors were only credited with projects in targeted networks, and paid only for measures that would directly impact peak loads. Through April 2013, CECONY had achieved approximately 107 MW of demand reductions and 278 GWh of annual energy savings. The program has created $464M in net customer benefits, including $221M in avoided T&D capital, on $145M in total costs. Other benefits identified in CECONY's experience were reduced regulatory risk, reduced electricity costs for consumers, and a complementary alternative to load rejection.

These studies include reduced consumption and the avoided costs of capital investment as benefits, while from the LDC perspective, energy savings and avoided expenditure can represent lost revenue streams. So while these earlier analyses and experiences in other jurisdictions are valuable in portraying the societal benefits of demand response, this study is unique in that it may provide the final and more elusive piece in the argument in favour of load curtailment and capital deferral from the point of view of the distributor.

3.5. Demand Response in Ontario

It has been proposed[8,9] that successful CDM policies are those which leverage existing equipment, program experience and understanding, and current regulatory frameworks, while at the same time fostering innovation and new ways to provide more effective offerings. In a 2009 report, McKinsey & Co.[6] recommended CDM portfolios that utilize proven, piloted and reliable CDM strategies, while arguing that continued innovation is essential to generating advanced results. Applying the same principles to the planning of a new suite of DR programs for localized implementation, it would seem clear that the same path is the most prudent. Furthermore, given the current state of the electricity sector and governing framework in Ontario, certain DR strategies mentioned in the list above would require considerable changes and flexibility to today's rules and methods of doing business.

So rather than develop a local DR program – which may be tested as early as the summer of 2014 – based upon strategies which have not been fully developed, applied for, approved, or necessarily even feasible under the current framework, the proposed suite of measures includes a combination of tested OPA province-wide programs, and OPA-approved pilots which may further benefit from a localized introductory rollout. However, this selection is only a recommended suite of solutions which will be entered into the model as a functionality test: as each LDC contains a unique combination of customers, geographic characteristics, and potential supply uncertainties, the model contains complete flexibility in allowing any suite of programs to be tested individually, or in aggregate. The same flexibility applies should the provincial CDM framework or technological landscape evolve.

3.6. Proposed Demand Response Programs for Local DR

The intent of a local DR program is to reduce peak load in a highly constrained service area, in times of distribution system need. In the Toronto Hydro case, and likely in most others, these constrained service areas are made up of various combinations of residential, C&I, and Industrial customers, who require a suite of alternative demand response initiatives. As such, the following combination of programs has been chosen based on its collective ability to attract all customer sectors and sizes.

3.6.1. peaksaverPLUS®

- Target Market: Single-family Residential & Small C&I

The peaksaverPLUS® program is open to residential and small commercial consumers who participate by allowing a one-way paging network to control either a programmable communicating thermostat (PCT) or load control switch to curtail electricity demand for central air conditioners, electric water heaters or pool pumps during the peak period on high electricity demand days. peaksaverPLUS® also offers consumers an in-home display (IHD) which allows participants to monitor their electricity consumption and associated cost in real time. Ontario's local distribution companies (LDCs) are responsible for procuring the equipment offered and for marketing the program (jointly with OPA). As of December 2012, approximately 180,000 control devices were installed on central air conditioners in Ontario, nearly all of them at residential premises. Participants in the THESL service region accounted for over 70,000 of these devices. In addition, nearly 50,000 IHDs had been installed at participant premises[10].

The single family residential and small C&I sectors comprise over 700,000 individual accounts, and represent more than 20% of Toronto's peak demand and more than 30% of its annual consumption. In some of the highly constrained areas in the west end of Toronto, residential load is even higher than the Toronto average, and represents an important target market for effective demand management. Often the appliances contributing to afternoon summer peak demand are running in unoccupied homes and can be managed by direct load control without significant customer disturbance.

According to Freeman, Sullivan & Co., the OPA's peaksaverPLUS® evaluation contractors, achievable penetration rates for well-established residential DR programs can reach nearly 50%. Currently, typical penetration rates by transformer station service areas in Toronto are approximately 20-25%, suggesting plenty of remaining potential available for target in a geographically specific initiative.

3.6.2. Multi-Unit Residential Demand Response (MURB DR) – SuiteSaver

- Target Market: Multi-Unit Residential Buildings and Suite Owners

The MURB DR program is designed to offer multi-unit residential buildings (MURBs) the opportunity to participate in the provincial load control peaksaverPLUS® events. This sector presents a provincial peak demand of approximately 1 GW, and a considerable demand reduction potential of more than 20 MW in the THESL service region alone. The installation of load control devices on common area systems, and programmable communicating thermostats in the individual suites would facilitate these savings during activation periods, and in turn, building and suite owners would receive payment for their load control availability. Also included in the program offering is a comprehensive energy efficiency strategy, including system audits and retrofit incentives that will further increase the demand reduction and annual energy savings impact in the provincial MURB sector. With the increasing number of MURBs being constructed in Toronto and in the province as a whole, this program offers a complimentary load relief strategy to a form of development which, through increased load densification, could have one of the more profound impacts on local service constraints.

[10] Freeman, Sullivan, & Co. "peaksaverPLUS® Program Load Impact and Process Evaluation". September, 2013.

This program was piloted in the summer of 2013, and is currently in the final evaluation stage. The Total Resource Cost (TRC) analysis submitted with the proposal assumed a 4% penetration in the MURB sector and 40% suite penetration in participating buildings. These projections were derived from current peaksaver participation evaluations and incorporated the more attractive incentives being offered to both the building owner and participating suite owner. It was projected that the thermostat and occupancy setback controls could provide approximately 0.3 – 0.5 kW/suite and common area load controls could produce approximately 65 – 80 kW in curtailment, on average.

3.6.3. Commercial Energy Management & Load Control – GridSaver

- Target Market: C&I and Industrial Customers (50 – 400 kW)

The CEMLC pilot and program is designed to produce peak demand reductions in the 50 – 400 kW commercial, retail, institutional, and hospitality sectors. The strategy involves the installation of load control devices on rooftop cooling units, and programmable communicating thermostats that offer the opportunity for energy and demand reductions during peaksaver PLUS activation periods. The provincial peak cooling load in these sectors is nearly 2000 MW, offering a reduction potential of approximately 60 MW. The program design also recommends a facility energy management strategy, incorporating occupancy sensors to further improve the peak demand reduction and annual energy savings impacts.

Savings projections were developed with the use of the U.S. Department of Energy setback calculator, and resulted in an estimated 12% reduction in cooling load. It is proposed that facilities in this load class could produce an average of approximately 24 kW of summer peak reduction. Though anticipated penetration is low at 3 – 4%, this market is virtually untapped, with the previous DR program opportunity consisting solely of the OPA's Demand Response 3 program. Therefore, the potential DR resource that this customer represents is considerable, if marketed effectively. Furthermore, this program can essentially be expanded to include nearly any sized customer possessing rooftop cooling units. While it is assumed that customers larger than the somewhat arbitrary upper limit will more likely possess centralized cooling systems, should they not, this opportunity would be available and potentially even more effective.

3.6.4. Demand Response 3 (DR3)

- Target Market: C&I and Industrial Customers (>400 kW)

For those customers capable of meeting the minimum availability commitments of the OPA's DR3 program, the flexibility in choice of curtailment strategy and level of incentive payment may present this program most favourably. DR3 is a contractual demand response (DR) program that offers large commercial and industrial consumers reserve payments for being available to provide load reductions when called by the OPA. Participants are required to meet contractual demand reductions when called, or else payments are reduced or eliminated. In addition, DR3 participants notify OPA and the IESO of any short term fluctuations in load reduction capability due to facility maintenance or down time. Non r

performance days lead to reductions in the participant payments. Unscheduled non performance – failure to deliver scheduled load reductions during events – leads to even larger payment reductions[11]. Current DR3 penetration rates are virtually non existent in the Toronto Hydro service region, with less than 100 customers choosing to participate; however, individual load curtailment contributions can be quite considerable. With almost the entire segment of large C&I and industrial customers available for enrolment, and in a situation where a relatively small number of these participants can have a major impact during a curtailment event, this program should represent a key focus in any local DR strategy.

4. Project Finance of Distribution or Transmission Asset Upgrades

The CDM Challenger will be used to compare a DSM portfolio (i.e.: the challenger) that would target specific locations served by distribution and transmission infrastructures that are capacity constrained to infrastructure upgrade projects (i.e.: the defenders) that are currently planned to solve the problem under the baseline scenario.

To achieve this, the CDM Challenger models the finance of distribution or transmission infrastructure projects. Key outputs of the project finance modeling that are needed to value deferral or avoidance of such project include the following:

- Additional revenue requirements or capital recovery funding – these incremental revenues that would have to be generated through rates.
- Incremental earnings, net of any incremental O&M expenses (if any), net of debt services, and net of net of payments in lieu of taxes (PILs).

The intricacies of the utility infrastructure project finance that are captured by the CDM Challenger include the following:

- Financing Structure – e.g. debt & equity ratio, debt terms and interest rate.
- PILs and Capital Cost Allowance.
- Regulated Return on Equity Rate (ROE).
- Multi Year Capital Cost Schedule – Capital costs are incurred during multiple financial years, and for every given year investors are assigned a specific regulated ROE that might differ from the year before or the year after.

The model ultimately determines the level of capital recovery funding that will result in earnings that commensurate with the regulated ROE.

The capital recovery funding is the sum of the following components:

- Asset Depreciation
- PILs

[11] Freeman, Sullivan, & Co. "2012 Impact Evaluation of Ontario Power Authority's Commercial & Industrial Demand Response Programs" August, 2013.

- Incremental O&M expenses (if any)
- Interest payments
- Allowance for Funds Used During Construction (AFDUC)[12]
- ROE

The funding thereby follows a declining profile rather than equal installments; the profile of asset depreciation + interest payments.

The CDM Challenger as it stands, assumes that the finance of a transmission infrastructure upgrade project is modeled in an identical way than that of a distribution infrastructure upgrade project. This assumption will need to be validated with the transmitter.

4.1. Local DSM Benefit Valuation Options

Using the aforementioned output of the project finance model, the CDM Challenger can value the local DSM portfolio based on one of the following approaches for any given distribution or transmission project,[13] serving the areas where the portfolio will be rolled out, and based on the user's preferences or objectives.

Exhibit 2 Local DSM Benefit Valuation Options

Benefit Valuation Options	Discussion
Full Project Deferral – The present worth of the deferral of the full distribution or transmission project for a user defined number of years.	This method uses the difference between the present worth of the incremental revenues associated with the project(s) if they were to be accrued as planned, and that if they were to be accrued X years after (i.e. a user defined number of years). The model supports the decision of the user by computing the total curtailment capacity (in kW and kVA) for every given location/project, for every given year. The latter is indeed worth less than the former because of the time value of money. This should be the preferred option.
Full Project Avoidance – The present worth of the avoidance of the full distribution or transmission project.	This method uses the present worth of the incremental revenues associated with the project(s) if they were to be avoided all together because the local DSM portfolio made the upgrade project unnecessary. It is as accurate as the full project deferral option, but less likely.

[12] Reimbursement of interest paid during construction.

[13] The CDM Challenger can handle up to six distribution projects and six transmission projects in any given workbook.

Benefit Valuation Options	Discussion
Unitary Deferral – The unitary present worth of the deferral of distribution or transmission capacity for the specific area of constraint served by the infrastructure for a user defined number of years ($/kW for a 1 year deferral).	This method is based on the assumption that every kW curtailed as a result of the local DSM portfolio for a given area of high constrained, and for a given year will result in the unitary value of that kW to be accrued. This is the "usual" working assumption when valuing CDM on a provincial basis, because somehow the curtailment will cause projects to be deferred across multiple LDC territories, and the value will be averaged out. When narrowing down the scope to a few specific areas of high constraint, this option is indeed less accurate than full project deferral and full project avoidance. Under this option, however, the CDM Challenge attributes a value to any given kW curtailment capacity only starting when the distribution of transmission project is planned to be finalized. This option is suitable for a first pass, quick modeling, or when no decision can be made whether the CDM impact are sufficient to defer the project, by how many years or whether the CDM impact are sufficient to avoid the project altogether.
Provincial Average – The value of avoided generation, transmission and distribution capacity and avoided energy supply is established by using the OPA's provincial average avoided supply cost assumptions for demand and energy.	The users are provided with the option of using OPA provincial averages avoided supply cost assumptions for transmission and/or distribution capacity ($/kW yr). That being said, using exclusively provincial average avoided supply cost assumptions for both transmission and distribution would be missing the point of the model. It is expected that users will use one of the other. LDC's CDM staff would typically use this option to value avoided transmission capacity if they were on working a local DSM portfolio in areas where the constraints came from, for example, distribution stations exclusively, and/or if information on transmission project were not available. Likewise, transmitter' staff would use provincial avoided distribution capacity to value a local DSM portfolio delivered in areas served by a transmission transformer station in need of an upgrade, whereas distribution stations might or might not need to be invested in. This is option is the only one available for avoided generation capacity and avoided energy supply cost.

The provincial average avoided supply cost assumptions were determined by the OPA for 2007[14]. The OPA is currently working on updating these provincial averages. Users of the CDM Challenger should be able to input the new values in a seamless fashion.

5. Cost Effectiveness Tests Performed by the CDM Challenger

The cost effectiveness tests results are the main output of the CDM Challenger and the main indicators to make decisions. This section provide a thorough explanation of the tests, with a focus of the particularities of the tests as interpreted in the CDM Challenger, to accommodate particularities of local DSM, and the particularities of Toronto Hydro's regulatory and CDM framework. The purpose of this

[14] See Appendix A. Ontario Power Authority, OPA Conservation and Demand Management Cost Effectiveness Guide, October 15 2010, Canada

section is to provide to the readers the tools to understand the tests, interpret the results, and anticipate the effects of the inputs.

5.1. Potential Sources of Local DSM Funding

Toronto Hydro is exploring the following three funding options. The model accommodates all three options, and will therefore allow Toronto Hydro to assess the value of each, and thus, support sound decision making.

- Provincial OPA Contracted CDM Programs, Emphasized in the Areas of High Constraint: The local DSM program will be, in fact, a provincial OPA contracted program that will be vigorously emphasized by Toronto Hydro in a targeted area of high system constraint. All of the cost involved (incentive and non incentive) will therefore come from the OPA, and, ultimately, from all Ontarian ratepayers. Examples: the OPA's PeakSaver, and DR3. All administration cost (i.e. non incentive cost) would come from the OPA's Program Administration Budget (PAB).
- Stand Alone Local DSM Program: The local DSM program will stand completely alone. Toronto Hydro may seek additional revenues to fund the new incentives, as well as the program administration costs, through rate adjustment(s). No funding would come through the OPA; all of it would come directly from Toronto Hydro's ratepayers. The program would have its own set of eligibility criteria, incentive level, participation process, administrationistrative procedures, and measurement and verification rules.
- Enhanced or Extended Provincial OPA Contracted CDM Program (Hydrid): The local DSM program will build on a provincial OPA contracted program, but will consist of one or many additional offering(s) – like an incentive adder, or additional technical assistance – that would be available to ratepayers in the areas of high constraint. Alternatively, the local DSM program might be based on a provincial OPA contracted program, but extend the existing offerings to ratepayers that are not currently eligible in the OPA programs as long as they are located in the areas of high constraint. In both cases, Toronto Hydro would seek to increase the penetration of the OPA provincial programs in these areas. Toronto Hydro's might seek additional revenues to fund the additional offerings or extended eligibility criteria through a rate adjustment.

The CDM Challenger captures input and provides results that account for the three aforementioned funding options (Provincial, Stand Alone and Hybrid). Exhibit 3 shows the implications of two of the three funding options (Provincial, and Stand Alone) on the cost effectiveness tests. The Hybrid option, indeed, sits somewhere between.

Exhibit 3 Matrix Defining the Costs Included in the Definition of Each of the Proposed Tests

Column # →	1	2	3	4	5	6	7	8	9
Funding Options →	N/A	Provincial OPA Contracted CDM Programs				Stand Alone Local DSM Program			
		Incentive		Program Administration		Incentive			Prog. Ad.
Cost Items → / Cost Effectiveness Tests ↓	Install, Equipment, & O&M Cost Paid by Participants	Install, Equipment & O&M Cost Paid by the OPA	Cash Incentive Paid by the OPA	Program Administration Cost Paid by the OPA (PAB)	Direct OPA Administration Cost	Install, Equipment & O&M Cost Paid by the LDC	Cash Incentive Paid by the LDC	Credit on Energy Bills, Lost by the LDC	Program Administration Cost Paid by the LDC
TRC - Total Resource Cost test	Cost	Cost		Cost	Cost	Cost			Cost
PAC - Program Administrator Cost test		Cost	Cost	Cost	Cost	Cost	Cost	Cost	Cost
PCT - Participant Cost Test	Cost	Cost & Benefit	Benefit			Cost & Benefit	Benefit	Benefit	
RIM – Rate Impact Measure Test		Cost	Cost	Cost	Cost	Cost	Cost	Cost	Cost
RIM d – Net Benefit for the Distributor						Cost	Cost	Cost	Cost
RIM t – Net Benefit for the Transmitter									
RIM g – Net Benefit for the Generator									
RIM pc – Provincial Administration Cost		Cost	Cost	Cost	Cost				
LDCT - Local Distribution Company Test						Cost	Cost	Cost	Cost
TCT - Transmission Company Test									

Exhibit 3 is an excerpt from a much larger matrix shown in section 4.5, which also shows the avoided or deferred costs, the bill savings, and the lost revenues. Items shown in the column were selected because they all represent costs.

With respect to Exhibit 3, the following might seem counter intuitive and therefore deserve more explanation:

- Direct install cost such as installation and equipment, and "after sale" service offered free of charge to participating ratepayers through a CDM program (Column #2 & 6) should be considered an incentive and therefore accounted for as such in the PAC, the PCT and under the RIM.
- Cash incentives or credit on energy bill (Column #3, 7 and 8) do not constitute costs under the TRC because such costs are considered to be money changing hand yet staying in the province, thereby having no net economic impact. One of the key implications is that: CDM cost r

effectiveness modellers cannot improve the TRC by reducing the cash incentive levels. Their only levels include, finding ways to reduce the direct install cost, or to reduce the program administration costs.

- x Aforementioned direct install cost (Again, Column#2 & 6) should also be considered to be part of the "incremental CDM measure cost" (or DR program participation cost) along with similar cost paid by the participant (Column#1), and therefore must be accounted as such in the TRC and the PCT.
- x Under the PCT, the same direct install costs (#2 & 6) will be counted as a both an incremental cost and as a benefit. It is expected that in addition to the direct install cost, the participant might have to incur other costs that will not be provided through direct install (Column#1).
- x Direct OPA administration cost (Column#5) is the portion of OPA's operation cost that can be attributed to the local DSM portfolio. In the CDM Challenger, it needs to be inputted as a % of the total incentive.
- x Technical assistance and enabling activities such as customer education, marketing, energy audits, trainings offered to trade people or field visits for verification, auditing or measurement purposes usually all go under program administration costs (Column#4, 5, or 9).

5.1.1. Variable versus Fixed Program Administration Cost

It is useful to differentiate fixed administration costs from variable costs in order to (later) be able to test the sensitivity of the cost effectiveness test results to variations in the local DSM portfolio uptake.

Moreover, users of the CDM Challenger will be able to allocate a portion of the fixed program cost directly to certain programs or components of the local DSM portfolio. For another portion of the cost, the allocation will not be direct – i.e. the unallocated fixed program administration cost. As required, the model automatically allocates the unallocated fixed program administration cost to compute the cost effectiveness tests by using curtailment capacity (kW) as the driver.

The CDM Challenger had to capture all of the degrees of nuances with regard to incentive costs and program administration costs that were laid out in section 4.1.

5.2. Cash Incentive, Bill Credit or Direct Install Costs

The CDM Challenger supports the LDC CDM staff in establishing the incremental benefits being offered to the participating ratepayers. These benefits can be in the form of an initial cash incentive, a "gift" of some sort (a new in home display, for instance), direct install of some equipment, a stream of cash incentive payment, some adjustment on the rate, or some regular credits on the utility bill to compensate participants. Usually, all of the aforementioned benefits are rolled in under the term "incentive".

The CDM Challenger supports the LDC CDM staff in establishing the incentive levels by allowing the users to see the impact of the level of incentive that they input in the model on the cost effectiveness test results. A common approach to establishing the incentive levels relies on an iterative process in which the users test multiple incentive levels until test results are deemed satisfactory.

This iterative process takes the following form: [guessing an incentive level -> seeing the impacts on the tests -> repeat] until optimal win-win results are obtained from the perspective of most of stakeholders.

The CDM Challenger allows the users to effectively and quickly go through this process to establish the appropriate incentive levels.

Incentive levels will surely have impact on the PAC, the PCT and the RIM. They may have impact on the LDCT, the RIM-d, and the RIM-pc tests depending on where the funding for these incentives will come from, as shown in Exhibit 3. Similarly, if the funding comes from the OPA because the local DSM programs being modeled are OPA-contracted programs, then the incentive levels will have impact on RIM-pc only. If the funding comes from the LDC's ratepayers because it is a stand-alone local DSM program, then it will have impact on the LDCT and the RIM-pc.

5.3. Time Value of Money and Discount Rates

All benefits and costs under the cost-effectiveness test must be compared on the same basis because the promise of future benefits cannot be deemed as valuable as current cost. All future cash flows (cost or benefits) thereby get discounted.

The OPA CDM Cost-Effectiveness Test guide stipulates that a real discount rate of 4% and an inflation rate of 2% shall be used to discount future benefits and costs for the purpose of assessing cost effectiveness. These values are consistent with the discount rate and inflation rate used to develop the Integrated Power System Plan[15].

OPA-prescribed discount and inflation rates are directly applicable to the TRC and the PAC. Toronto Hydro has therefore decided to use the same discount rate for the PCT, RIM and all other tests attached to the RIM because it makes comparison between them easier.

Toronto Hydro made the decision of working with nominal cash flows as much as possible in its model because it is the common practice in its finance department. The prescribed real discount rate of 4% therefore becomes a nominal discount rate of 6.08%.

The CDM Challenger offers the option of using a differentiated discount rate for every given test, although Toronto Hydro is not currently using this option for the TRC, PCT, PAC and RIM. Differentiating the discount rate might be an attractive option in the future, because it would model how each set of stakeholders value future cash flows against current cash flows in a more realistic manner. For example, given that TRC looks at the cost-effectiveness of CDM from the perspective of the society, then arguably the discount rate used for the TRC could be closer to inflation. The matter is the subject of debates among CDM experts, and for the moment Toronto Hydro is following the lead of the OPA.

[15] Ontario Power Authority. Integrated Power System Plan. EB-2007-0707. Exhibit D Tab 4 Schedule 1 Attachment 3. Available at: http://www.powerauthority.on.ca/Storage/53/4868_D-4-1_Att_3_corrected_071019.pdf

5.3.1. Choice of the Discount Rate under the LDCT and the TCT

The discount rate being used in the LDCT and the TCT is a critical decision, and these discount rates should not be that of the TRC, the RIM or the PAC. The discount rates used in the LDCT and the TCT should notionally hover around the distributor's and the transmitter's regulated return on equity[16], respectively; because both tests compare the delayed or forgone future earnings, attached to the distribution or transmission infrastructure upgrade projects being deferred or avoided as a result of local DSM, with deferred or avoided equity capital contributions. This will become clearer to readers when they review the detailed definition of the tests in Section 4.5. When using the regulated ROE as a discount rate for the LDCT and/or the TCT, then the present worth of earnings should be equal to the present worth of equity capital contributions, regardless of how many years they will both be delayed or if they will be avoided altogether. This is a consequence of the very approach to establishing earnings, as laid out in Section 3, based on a specific project finance under the current regulatory framework,

The choice of the discount rate shall therefore be in line with the investment strategy of the distributor's or transmitter's shareholders:

- If the chosen discount rate is above the utility's regulated ROE, then the deferred/avoided equity capital contribution will be worth more than the delayed/foregone earnings. It would be the result of the utility's shareholders valuing their equity higher than the regulated ROE, perhaps because they have other investment opportunities that yield higher return than regulated infrastructure upgrade. It could also be because the shareholders deem the local DSM alternative to be riskier than the baseline scenario. It could also be the result of the shareholders' funding to be tight; therefore they do value the deferral/avoidance of the capital contribution.
- If the chosen discount rate is below the utility's regulated ROE, then the deferred/avoided equity capital contributions will be worth less than the delayed/foregone earnings. It would be the result of the utility's shareholders wanting to invest more or quicker in regulated distribution or transmission infrastructure; maybe because they have no other investment opportunities that yield as much and/or that are as safe.

5.4. Net Present Value, Benefit/Cost Ratio and Other Indicators

In Section 1.1, a set of cost-effectiveness tests was introduced that Toronto Hydro has used to depict the business case of its local DSM portfolio. The results of each test can be expressed using one or many

[16] It is recommended to use the regulated return on equity instead of WACC because the LDCT and the TCT look at the deferral of capital equity contribution as a benefit (i.e. the portion of the investment funded by THESL shareholders' money) and compare it with the delay of incremental net income as a cost (i.e.: after tax after debt r service cash flows going back to THESL shareholders).

indicators, each of which as a specific use. Toronto Hydro has built the most common indicators in the CDM Challenger. They are presented in the Exhibit 4 below.

Exhibit 4 Proposed Benefit Cost Analysis Indicators

Indicator	Acronym	Summary Approach	Key Question Answered
Benefit/Cost ratio	B/C ratio	Present worth of benefits divided by present worth of costs	Are benefits outweighing the costs?
Net Present Value	NPV	Present worth of benefits minus the present worth of costs	How worthwhile is it to undertake the program?
Levelized Unitary Cost of Demand	LUC ($/kW)	Present worth of cost divided by levelized impact. In the CDM Challenger, we have used the curtailed kW as the denominator.	How much is being paid for load curtailment?

What we seek to illustrate in Exhibit 5 is that all of the aforementioned "indicators" are cross cutting of the cost effectiveness tests.

Exhibit 5 Matrix Illustrating How Test Results Can be Presented through Multiple Indicators

Indicators W Cost Effectiveness Tests Y	B/C ratio	NPV	Levelized Cost
TRC – Total Resource Cost test	X	X	X
PAC – Program Administrator Cost test	X	X	X
PCT – Participant Cost Test	X	X	X
RIM – Rate Impact Measure Test	X	X	X
RIM d – Net Benefit for the Distributor		X	
RIM t – Net Benefit for the Transmitter		X	
RIM g – Net Benefit for the Generator		X	
RIM pc – Provincial Administration Cost		X	
LDCT – Local Distribution Company Test	X	X	X
TCT – Transmission Company Test	X	X	X

All tests can be computed at the measure or project level, for one typical participant, for a subset of participants, for a program and/or for a portfolio of program. The CDM Challenger can produce test results for multiple levels of aggregation, from the program participant level and up.

5.5. Detailed Definition of the Cost Effectiveness Tests and Cashflows

The complexity of the financial and economic analysis needed to build a comprehensive business case of local DSM lies in the number of stakeholders involved, the variety of cost categories (the reader had a taste of this in Section 4.1), the variety of sources of funding, the breakdown of the rates and of the

avoided cost between generation, transmission and distribution, and other considerations such as the Lost Revenue Adjustment Mechanism available to the distributors – but not for the transmitter or the generators.

The matrix shown in Exhibit 6 is an attempt to capture all of the complexity of the financial and economic model in one page. Benefits are shown as "Bs" and costs are shown as "Cs".

Exhibit 6 Definition of All Tests in the CDM Challenger

TC T - Transmission Company Test			C														B	C		

Regaring Exhibit 6, and looking at the cash flows from column #1 to #20:

- The incremental CDM measure cost as defined by the California SPM is the sum of the installation, equipment and additional O&M cost paid for by the participants, or directly by the LDC or the OPA, respectively Columns #5, 6, and 9.
- The incentives as defined by the California SPM are the sum of the installation, equipment and additional O&M cost if directly paid for by the LDC or the OPA (Columns #6 and 9), and all cash or bill credit incentive whether they are paid for by the LDC or paid by the OPA through existing OPA contracted programs (Columns #7 & 10).
- The program administration cost as defined by the California SPM is the sum of the program administration expenses that will have to be absorbed by the LDC as operation cost (perhaps funded through rates), the program administration expenses that will get reimbursed by the OPA with the LDC's Program Administration Budget (i.e. PAB money), and the actual OPA operation expenses once allocated to the local DSM initiative; respectively Columns #8, 11 and 12.
- The CDM Challenger uses the actual rates to compute bill savings or lost revenues. The users can pick any one of all of Toronto Hydro's rate classes. The modeling team has singled out all volumetric items of the rate structures (i.e. ¢/kWh or $/kW) for all rate classes, and aggregated all the items sorted in the four following categories: distribution, transmission, generation, and regulatory fees & debt retirement – respectively Columns #1, 3, 4 and 2. The last category includes the Global Adjustment Mechanism. The Generation category (Columns #4) requires the annual kWh savings (or increases) to be disaggregated using the time of use brackets: Summer On Peak, Mid Peak and Off Peak; and Winter On Peak, Mid Peak and Off Peak
- Deferred or avoided additional revenue requirements as a result of local DSM pushing back or entirely offsetting distribution or transmission capital project(s) – respectively Column #13 and 14 – are CDM benefits that can be established using the project finance model built in the CDM Challenger or using OPA's provincial averages. If using the built in project finance model, then the users can pick between unitary deferral ($/kW for one year of deferral), full project deferral (for 1, 2, 3 up to 10 years), or full project avoidance. The LDC's CDM staff will have to decide on an approach and scenarios with the capacity planning staff.
- Delayed or foregone earnings due to local DSM pushing back or entirely offsetting distribution or transmission capital project(s) – respectively Column #15 and #17 – are established using the project finance model built in the CDM Challenger. The same applies to deferred or avoided equity capital contributions for distribution or transmission capital project(s) – respectively Column #16 and #18. Consequently, wherever the modellers were to decide to use the provincial averages for distribution avoided cost, the LDCT would then become void. Likewise, if the modellers decided to use the provincial averages for transmission avoided cost, the TCT would then become void.
- The avoided cost of generation capacity and energy – respectively Column #19 and 20 – can only be established using OPA's provincial averages. Computing the avoided cost of energy supplies requires the annual kWh savings (or increases) to be disaggregated using the time of use brackets.

5.5.1. Interpretation of the Cost Effectiveness Tests

Cost effectiveness tests were introduced in Section 1.1. Each test represents a specific definition of the cost and benefit cash flows being considered, as laid out in detail in Section 4.5. The purpose of this section is to help reader deepen their understanding of the tests and how to interpret them Exhibit 7.

Exhibit 7 Interpretation of the Proposed Cost Effectiveness Tests

Test	Summary Approach
TRC – Total Resource Cost test	Comparison of program administration and customer costs to resource savings. This test tells you if local DSM is the right thing to do for the "greater good". Cash incentive or bill credits are invisible in this test, because they are simply a change in who pays, not how much is paid. Key Question Answered: Will the total costs of electricity in Ontario decrease in the long term?
PAC – Program Administrator Cost test	Comparison of local DSM program Administrator costs to supply side resource costs. This includes any incentives or costs that the program Administrator pays, and that goes behind the meter. A CDM program Administrator should seek to design and deliver a portfolio that maximizes impact in the short, medium and long term while minimizing cost (i.e. incentive + program administration costs), while still achieving other policy goals (e.g. low income programs, etc.). The PAC measures how effective the program Administrator was at optimizing its portfolio. The program Administrator cost test used to be known as the Utility Cost Test or UCT. Key Question Answered: How much will the Ontario Power System pay for load curtailment?
PCT – Participant Cost Test	Comparison of costs and benefits to the ratepayers that decide to partake in the local DSM program – i.e. the participant. This test tells you if participating in the program is genuinely a good thing to do for the participants, and by how much. The modellers should use the PCT to appreciate how much the incentive is improving the business case of CDM from the perspective of participants; an ideal (yet rare) situation being when the CDM incentive makes projects economically feasible which otherwise would not. In DR, often projects do not yield any bill savings from energy conservation or from shaving the facility's monthly peak demand, and thereby a constant stream of incentive might be needed to get ratepayers to sign in, and then participants to stay in the program. Key Question Answered: Will the local DR participating ratepayers benefit over the duration of their participation in the DR program?

Test	Summary Approach
RIM – Rate Impact Measure Test	Comparison of administration costs and lost revenue to supply side resource costs. If the RIM test is "passed" then the rates will decrease as a result of the program/measure in the short term. This is a critical test for anyone interested in minimizing rate increases in the near term. The ratepayer impact measure test is often referred to as the non participant test, because the ratepayer is on average not participating in any given program. The RIM results are often negative; which does not necessarily preclude a CDM program from being taken to market as long as the TRC and the PAC are positive. Computing the RIM regardless only show that the short term rate increases are not undue. However, in local DSM, in areas of high constraint, we expect the RIM to be positive. Key Question Answered: How will utility rates be affected in the short term as a result of the local DR program, in comparison to other infrastructure upgrades?
The RIM test is more comprehensive than the PAC because it includes lost revenues. It has been decided to disaggregate the RIM in four different tests: one for the distributor, one for the transmitter, one for the generators, and one last test to capture all costs that are incurred neither by the distributor, transmitter nor the generators. These tests are respectively the RIMd, RIMt, RIMg, and RIMpc. Arithmetically, the disaggregated RIM test offshoots were constructed so that the sum of their net present value would result in the net present value under the RIM test.	
RIMd – Net Benefit for the Distributor	The RIMd shows the present worth of deferral of avoidance of distribution capacity cost against all costs (incentive and program administration) that will be incurred by the LDC, and not reimbursed by the OPA. The RIMd also factor in the distribution component of the lost revenues as a cost. If the regulator was to authorize the program cost to be funded by LDC's customers through local rates, then the RIMd would actually represent the impact on non participant's rate. If not, then the RIMd just shows how bad of a financial idea delivering the local DSM portfolio would be.
RIMt – Net Benefit for the Transmitter	The RIMt is the present worth of deferral of avoidance of transmission capacity cost avoided cost of transmission capacity due to local DSM, minus the lost revenues that would otherwise be paid to the transmitter. The transmitter incurs no direct incentive or program administration costs (as part of its transmission business).
RIMg – Net Benefit for the Generator	The RIMg is the present worth of avoided cost of generation capacity and avoided cost of energy supply due to Local DSM, minus the lost revenues that would otherwise be paid to the generators. The generators incur no direct incentive or program administration costs.

Test	Summary Approach
RIM pc – Provincial Administration Cost	The RIM pc is the present worth of OPA's and OPA contracted program costs, as well as the lost revenues otherwise allocated to fund regulatory mechanisms, debt retirement and GAM. These are required to balance the following equation: NPV_RIM = RIM d + RIM t + RIM g + RIM pc
LDCT – Local Distribution Company Test	The LDCT is a comparison between the present worth of shareholders' equity capital contributions being deferred/avoided and earnings being delayed/foregone as a result of local DSM and that would otherwise be triggered by capital distribution projects to serve areas of high constraint. The LDCT also factors in cash incentive, bill credits, direct incentive and/or program administration cost directly incurred by the LDC, if any. The LDCT does not include lost distribution revenues because it assumes that these will be repaid through the Lost Revenue Adjustment Mechanism (LRAM). The LDCT does not include OPA contracted program incentive, direct r install or program administration costs because they will be repaid by the OPA. The choice of the discount rate is critical for the LDCT as discussed in 4.3.1. Key Question Answered: Is local DSM optimising the shareholders' investment plan considering the availability of equity and what they want to do with it to maximize return?
TCT – Transmission Company Test	The TCT is a comparison between the present worth of shareholders' equity capital contributions being deferred/avoided and earnings being delayed/foregone as a result of local DSM and that would otherwise be triggered by capital transmission projects to serve areas of high constraint. The TCT does not factor any program cost because none would actually be directly incurred by the transmitter. The TCT includes lost transmission revenues because there is not a LRAM for transmission. The choice of the discount rate is critical for the TCT as discussed in 4.3.1. Key Question Answered: Similar to that of the LDCT, but from the perspective of the transmitter's shareholders.

6. Main Characteristics and Architecture of the CDM Challenger

The purpose of this section is to guide users through the CDM Challenger model.

6.1. High level Description of the Model

The CDM Challenger is built around a set of worksheets that appear in the workbook as TP01, TP02, to TP40; each one of which represents a typical participant in the local DR portfolio. A TP sheet computes all cost effectiveness tests for one typical participant; the lowest level of aggregation of the results.

Each typical participant is defined as, pertaining to one program/offering, pertaining to one rate class, pertaining to one distribution location, and pertaining to one transmission location, inclusively. "Location" refers to an area of constraint which is in need of capital improvement upstream on the distribution and/or on the transmission system. There can be more than one TP sheet per program, more than one TP sheet per rate class, and more than one TP sheet per location. There are 40 TP sheets; each one is a placeholder for one typical participant.

One single CDM challenger workbook can therefore handle multiple permutations of programs, rate classes, and locations as defined by users, and then aggregate and breakdown results accordingly. The model can handle both prescriptive and custom CDM measures, although the model is exclusively forward looking.

The TP sheets draw key data about the benefits and value of local DSM from the following sheets:

- The Provincial sheet: The Provincial sheet contains the OPA's provincial average avoided cost assumption for energy supply, generation capacity, transmission capacity and distribution capacity. It currently stores 2007 information from Appendix A of the OPA CDM Cost Effectiveness Guide[17]. This data is expected to be updated by the OPA in the short term.
- The rate class sheets, namely RES, MULTIRES, GS<50, GS<1000, GS<5000, LARGE, UNMETERED and STLIGHT[18]: Rate class sheets contain data about the volumetric portion of the rate ($/MWh & $/kW month), broken down by energy supply, transmission, distribution, and regulatory fees & debt retirement.
- The DI and TI sheets: Respectively the distribution investment sheets and the transmission investment sheets.
- The Deferral sheet: The Deferral sheet contains the present worth of the deferral or the

[17] Ontario Power Authority, OPA Conservation and Demand Management Cost Effectiveness Guide, October 15 2010, Canada [ONLINE] Asseen on November 4, 2013, URL: http://www.powerauthority.on.ca/sites/default/files/OPA%20CDM%20Cost%20Effectiveness%20Test%20Guide%20-%20101015%20F.pdf

[18] Corresponding to the following rate classes, respectively: Residential, Multi Unit Residential, General Service < 50 kW, General Service 50 - 999 kW, General Service 1,000 - 4,999 kW, Large Use, Unmetered Scattered Loads, and Street Lighting.

DI and TI sheets represent a critical component of the CDM Challenger. Each one DI or TI sheet models the finance of one capital distribution or one transmission improvement project that supplies a location of high constraint. The approach to capital improvement project modelling was laid out in section 3. There are six DI sheets and six TI sheet; each one is a placeholder for one capital improvement project.

The Projection sheet is where the aggregation of the data and results contained in the TP sheets happens; and this is also where the main output of the CDM Challenger, the program level cost r effectiveness test results, is displayed. This is the worksheet where users have to input forecast uptake in the program portfolio – that is: number of new ratepayers signing in the DR or conservation program.

The modeling period is bound by a 5 years program operation window, and participants can persist in the program up to 20 years, which makes the modeling window span inclusively from Year 00 (now), through Year 01 to Year 05 (the program operation window), all the way to Year 24 (Year 05 + 20 1).

From the Projections sheet, users can obtain rest results for different slices of the local DSM portfolio by excluding and including typical participant. For example, users could single out the following:

- One program across all rate classes and locations,
- One rate class across all programs and locations,
- One transmission location or one distribution location across all programs and rate classes, or even
- One typical participant.

The Projection sheet also draws information from the Budget sheet. The Budget sheet is where users can input information about fixed program administration costs. Users can input both fixed program administration expenses that will paid for by the OPA (PAB money), and fixed program administration expenses that will not. Users can directly allocate the fixed cost to specific typical participant, or not. The Budget sheet gathers incentive and program administration cost information from all TP sheets to compute the Grand Total for the local DSM program portfolio contained in one CDM Challenger workbook.

The Deferral sheet is the worksheet were users get to decide whether the local DSM portfolio will achieve the deferral (or even avoidance) of distribution or transmission capital improvement upstream of locations of high constraint, and by how much. In order to support decisions, the Deferral sheet draws information from the Projections sheet and the TP sheets to aggregate the kW and kVA curtailment capacity for every year from Year 01 to Year 24, and broken down by location (up to six distribution locations and up to six transmission locations). Users can then choose the preferred valuation option. There are three valuation options offered in the Deferral Sheet.

- Full Project Deferral
- Full Project Avoidance
- Unitary Deferral

The valuation options above were explained in Section 3.1.

The Deferral Sheet also presents the total program impact outputs from Year 01 to Year 24 such as total participant, total kW and kVA curtailment, and total kWh savings broken down per Time of Use bracket. The Deferral Sheet shows aggregated results behind the meter, and then results that include distribution losses, and then that include distribution & transmission losses.

6.2. Before You Get Started

Before they get started, new users will need to gather the following information.

- For each individual incoming distribution and transmission capital improvement projects due to capacity constraint:
  - Investment start year – when investment starts
  - Investment end year – when overhauled/modified station is planned to come online
  - Investment for each year – the data will need to be inputted in real $.
  - First guess power factor of the curtailment
  - Capacity used for levelizing (MVA). Either:
    - Incremental capacity sought by the LDC (if available)
    - Current spare capacity (if the incremental capacity is not available)
  - Load forecasting or trend at the substation to inform the decision whether it is possible to defer the project, and by how much.
  - Financial Information for the capital improvement project such as:
    - Debt/equity ratio, for each investment year
    - Debt rate, debt term
    - Interest rate for the bridge financing (before project completion)
    - Book life
    - Regulated after tax nominal return on equity (ROE) – for every investment year
    - Rate for the payment in lieu of tax (PILs)
    - Incremental O&M cost, if any.
    - Capital Cost Allowance rate (CCA rate) – for every investment year
    - Weighted percentage applicable on year 1, to model the 50% rule – for every investment year
    - Depreciation rate
  - Decision criteria, agreed with capacity planning staff, on how much on peak curtailment is needed for every given year to defer the incoming investment – perhaps including a safety factor.

- Discount rates
  - From the perspective of the LDC's shareholders, to be used in the LDCT. We suggest for the rate to be close to the regulated ROE.
  - From the perspective of the transmitter's shareholders, to be used in the TCT. Similarly, we suggest for the rate to be close to the regulated ROE.

- For the TRC, the PAC, the PCT, and the RIM, we suggest using the OPA prescribed nominal discount rate of 6.08%. (Real discount rate: 4%. Inflation: 2%.)

x For each typical participant in a local DSM program (conservation or DR)
  - Rate class
  - Distribution location (or local distribution capital improvement project)
  - Transmission location (or local transmission capital improvement project)
  - Average coincident peak curtailment in kW
  - Power factor for the above
  - On peak demand savings seen on participants' bill (in kW/month)
  - Incremental redistribution of energy use for each TOU bracket, that is: winter on peak/mid peak/off peak, summer on peak/mid peak/off peak, and then shoulder mid peak/off peak.
  - Persistence in the CDM program in years – average duration of the participation in the DR program or, alternatively, the effective conservation measure life.
  - Installation, equipment and incremental O&M cost
    - Portion paid for by the participant
    - Portion paid for by the OPA as part of an OPA contracted province wide program
    - Portion paid by the LDC in a stand alone local DSM program or portion paid by the LDC over and above what was already made available by the OPA.
  - Variable administration cost ($ per typical participant, initial, and then on going)
    - Portion paid for by the OPA as part of an OPA contracted province wide program.
    - Portion paid by the LDC in a stand alone local DSM program or portion paid by the LDC over and above what was already made available by the OPA.
  - As applicable, fixed administration cost, directly allocated to one or a subset of typical participants.
  - Level of OPA contracted initial cash incentive, and on going cash incentive, if any.
  - Transmission system losses for this typical participant
  - Distribution system losses for this typical participant

x For each local DSM program in the portfolio:
  - Annual uptake (# of ratepayers signing in, for each typical participant)
  - Fixed program administration cost that cannot directly be allocated to any TP or subset of TPs – the model will thereby allocate it using curtailment (kW) as the driver.

x Information related with the cost of energy:
  - Future rate updates – the models are pre loaded with rates as per December 2013 and assumptions about their evolution in nominal $ (i.e. an escalation rate). If there were any updates later on to the rates and prediction, that will need to be uploaded.

- Future province-wide assumptions related with avoided cost of transmission and generation capacity and energy – the models will be pre-loaded with the 2007 OPA assumptions. We know the 2013 assumptions are coming soon.

6.3. Getting Started

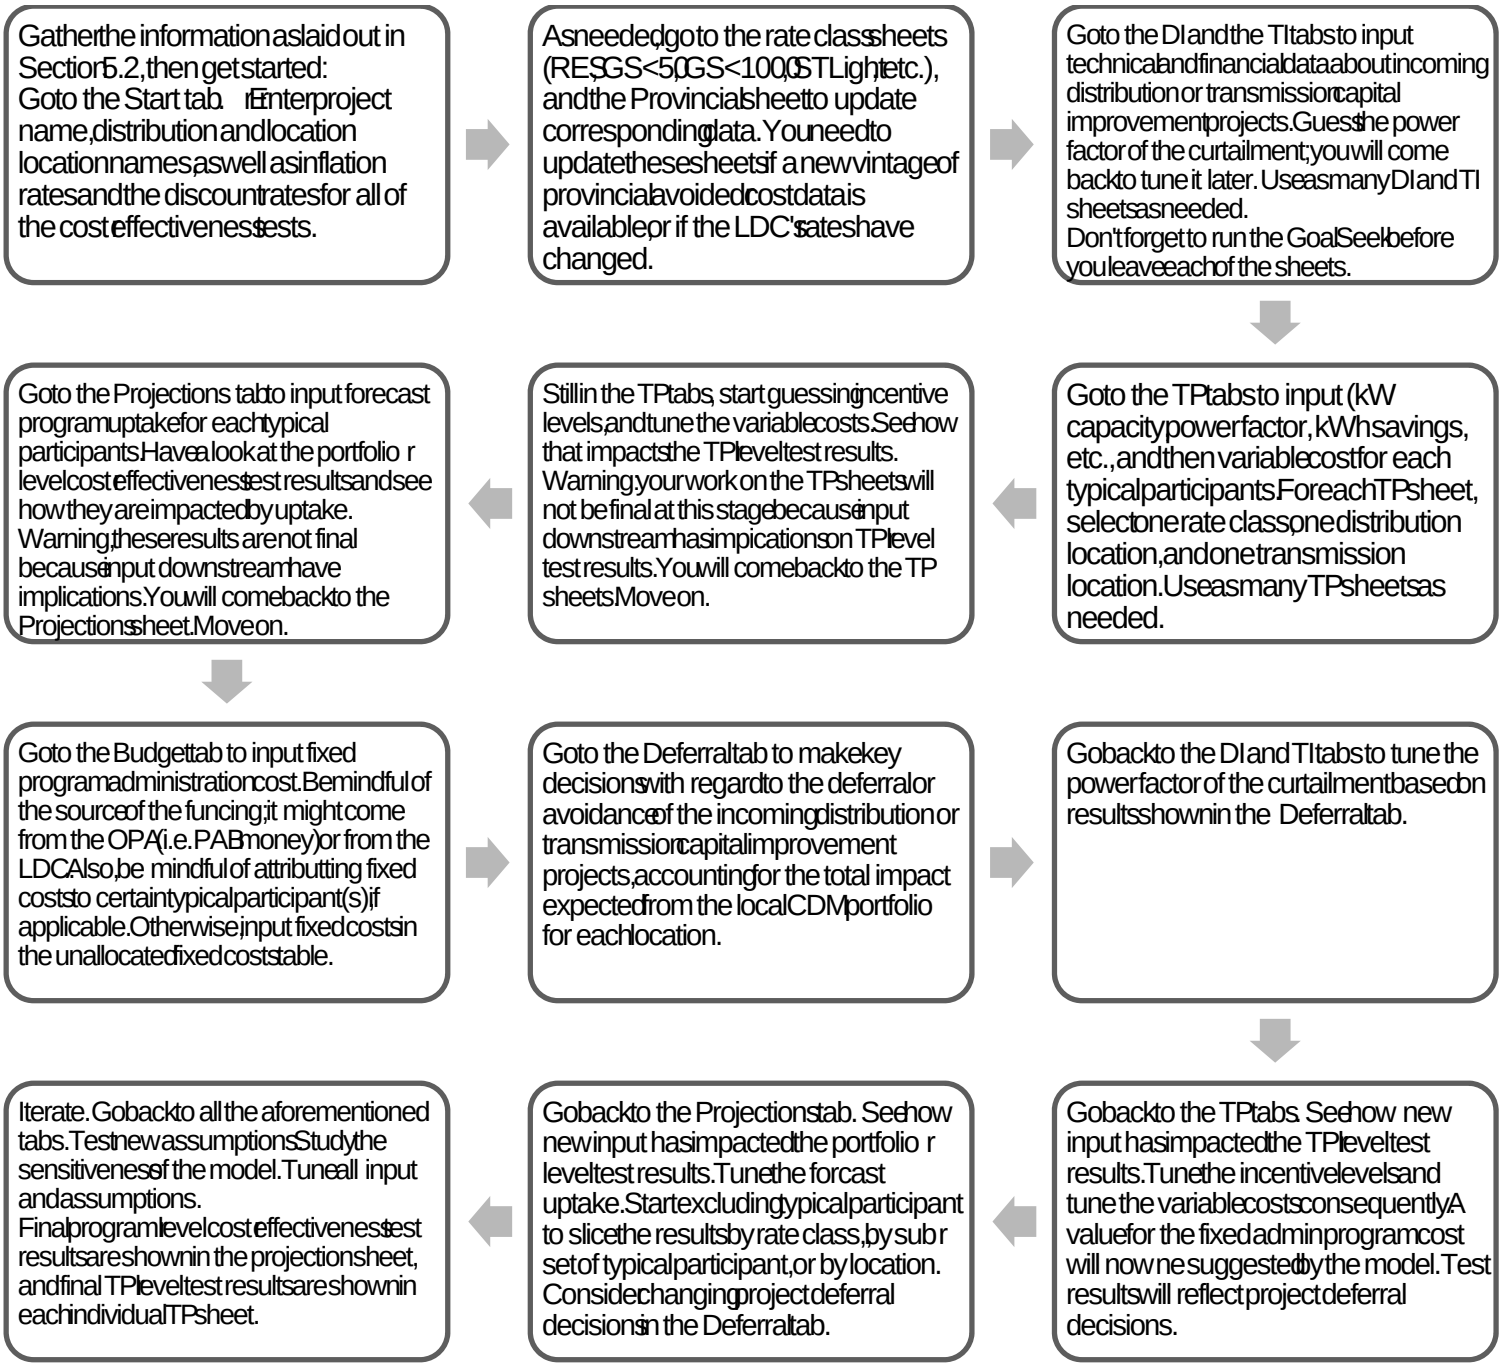
The purpose of this section is to help Toronto Hydro first time users to use the CDM Challenger.

To start with, all cells in the CDM Challenger workbook are color coded as shown in Exhibit 8. This should make the cells where an input is needed very obvious.

Exhibit 8 Cell Color Code in the CDM Challenger

Exhibit 9 walks a new user from the beginning to the end of a modeling exercise with the CDM Challenger.

Exhibit 9 Getting Started with the CDM Challenger – Chronological Sequence



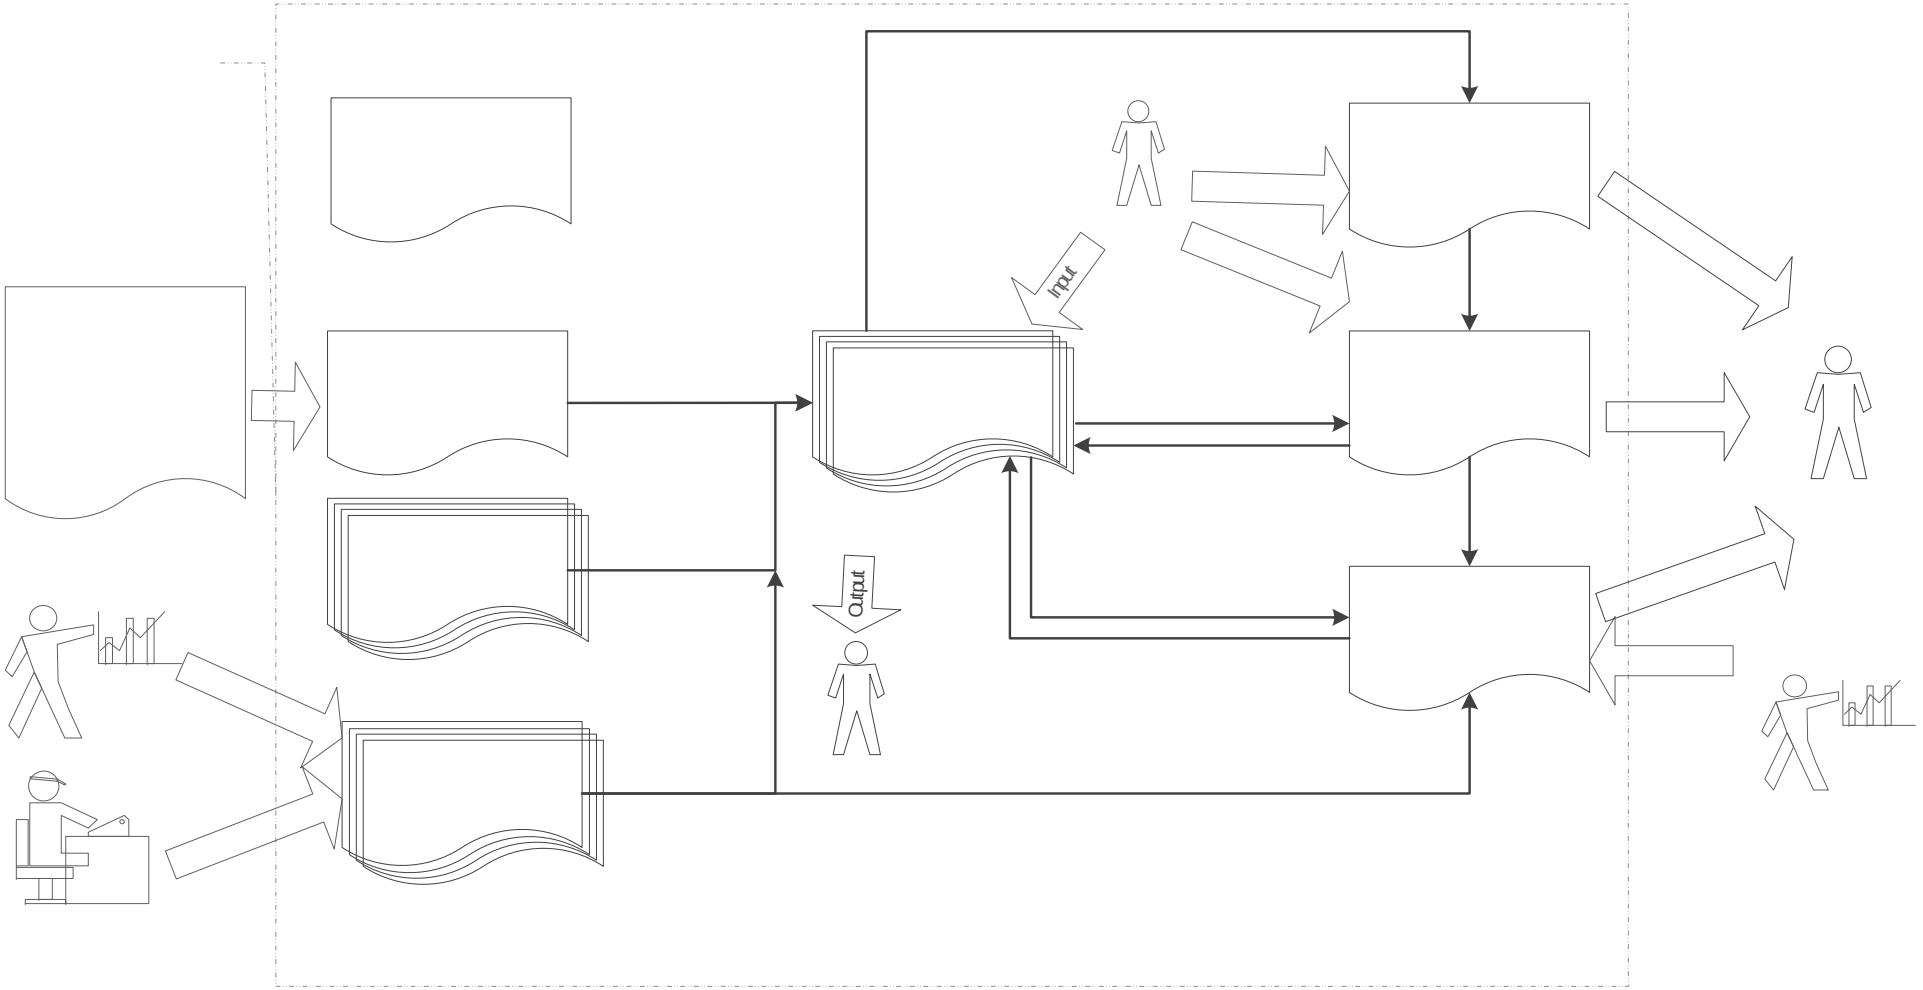


Exhibit 9 shows one possible path. There are many other paths, and the users, as they get familiar and comfortable in the model, will likely jump around freely from one tab to another.

6.4. Model Architecture Block Diagram

Exhibit 10 lays out most critical sheets in the Challenger workbook, and how they are linked together. It also gives an idea of where key data is inputted and where key output can be retrieved.

Exhibit 10 Detailed Architecture of the Model

6.5. Detailed Description of Each Worksheet

All sheets referred to in section 5.1 to 5.4 find their description in the next paragraphs. This section was drafted for the advanced users who want complete visibility.

6.5.1. Start Sheet

The Start sheet is a repository of most of reference information regarding the local DSM portfolio being modeled. It is the front page of the model.

Key inputs in the Start Sheet include:

- Project Title / Local DSM portfolio title
- Full names of the distribution and transmission locations where capital improvement projects are planned
- Current year
- Inflation rate
- Discount rate for all of the cost effectiveness test

Section 4.3 provides guidance about the choice of the discount rates and the inflation rate.

6.5.2. DI and TI Sheets

The purpose of the Distribution Investment (DI) and Transmission Investment (TI) sheets is to model the project finance of incoming distribution or transmission capital improvement projects to relief areas of high constraints. One DI or TI sheet is needed for each project. The full names of these projects were entered in the Start sheet.

The DI and TI sheets convert technical and financial information about the projects into additional revenue requirement as result of the projects, as well as incremental shareholders' equity capital contributions, and incremental earnings. Section 3 presents a more thorough description of the finance modeling of capital projects.

Table (A) is where all parameters need to be inputted. Table (B) contains primary outputs. Table (C) and (D) contain unitary present worth of local project deferral depending on, alternatively, when the participant will sign off the DR program, or at the end of the useful conservation measure life. Table (E) contain the actual annual cash flows of interest (revenue requirement, equity capital contributions and earnings) from the investment start year all the way until the end of the project book life (up to 80 years).

Key inputs in the DI and TI Sheets include:

- Investment start year – when investment starts

- Investment end year – when overhauled/modified station is planned to come online
- Investment for each year – the data will need to be inputted in real $.
- Power factor of the curtailment
  - At first, users will enter an initial most likely guess.
  - The actual power factor of the curtailment capacity can actually be retrieved from the Deferral sheet once most of the workbook will be populated. The users should probably come back at the end of their modeling work and replace the initial guess, as suggested in Section 5.3.
- Capacity used for levelizing (MVA). Either:
  - Incremental capacity sought by the LDC (if available)
  - Current spare capacity (if the incremental capacity is not available)
- Financial Information for the capital improvement projects such as:
  - Debt/equity ratio, for each investment year
  - Debt rate, debt term
  - Interest rate for the bridge financing (before project completion)
  - Book life
  - Regulated after tax nominal return on equity (ROE) – for every investment year
  - Rate for the payment in lieu of tax (PILs)
  - Incremental O&M cost, if any.
  - Capital Cost Allowance rate (CCA rate) – for every investment year
  - Weighted percentage applicable on year 1 CCA, to model the 50% rule – for every investment year
  - Depreciation rate

DI and TI sheets have direct downstream implications on the following sheets:

- TP Sheets – Unitary value of project deferral ($/kW for 1 year of project deferral)
- Deferral sheet – The full schedule of the additional revenue requirements to fund the capital project, that of the shareholders' equity capital contributions and that of the earnings.

Tip: All DI and TI sheets can be renamed to something more meaningful to ease navigation in the workbook. We recommend keeping the new tab name under 12 digits or letters.

Developers: Each DI and TI sheet is linked with a corresponding Cashflows sheet. Usually, the Cashflows sheet will be hidden to reduce clutter in the workbook.

6.5.3. TP Sheets

The purpose of the Typical Participant (TP) sheets is to store all information on the TP, and output the participant level cost effectiveness test results, namely: TRC, PAC, PCT, RIM, RIM nd, RIM nt, RIM ng, RIM npc, LDCT and TCT. They were extensively discussed in Section 1.1, and 4.5. Each of the test results are presented in term of Benefit/Cost ratio (B/C ratios), Net Present Value (NPV), and levelized unitary cost (LUC) – $/kW. These indicators were introduced in Section 4.4.

Table (A) and (C) is where all parameters need to be inputted. Table (B) presents the participant level cost effectiveness test results. Table (D), below, shows the details of the present worth of all costs and benefits for all of the tests. These present worth of costs and benefits are pushed into the Projections sheet, were they will be aggregated to compute the portfolio level results.

Key inputs in the TP Sheets include:

- Rate class
- Distribution location (or local distribution capital improvement project)
- Transmission location (or local transmission capital improvement project)
- Average coincident peak curtailment in kW
- Power factor for the above
- On peak demand savings seen on participants' bill (in kW month) – The users should beware that:
  - The on peak demand savings is measured in kW month, not in kW year like the curtailment. For example, if on peak demand savings were to occur during three months, then the kW value would need to be multiplied accordingly.
  - The on peak demand savings might not correspond to the average coincident peak curtailment because the demand might snap back after the curtailment during the on peak period, and/or the curtailment might not be triggered every day of the month. The peak demand charge might be incurred on the day after a DR event.
- Incremental redistribution of energy use for each TOU bracket, that is: winter on peak/mid peak/off peak, summer on peak/mid peak/off peak, and then shoulder mid peak/off peak.
- Persistence in the CDM program in years – average duration of the participation in the DR program or, alternatively, the effective conservation measure life.
- Transmission system losses for this typical participant
  - The suggested average value is 2.5% as per the 2007 IPSP.
  - However, the users might decide to decide to use a higher or lower percentage depending on who the rate payer is. For example, industrial ratepayer might have a lower percentage of transmission losses.
- Distribution system losses for this typical participant (Suggested average value: 4.2% per the IPSP)
  - The suggested average value is 4.2% as per the 2007 IPSP.
  - However, the users might decide to decide to use a higher or lower percentage depending on who the rate payer is. For example, a residential ratepayer might have a higher percentage of distribution losses.
- Installation, equipment and incremental O&M cost
  - Portion paid for by the participant
  - Portion paid for by the OPA as part of an OPA contracted province wide program
  - Portion paid by the LDC in a stand alone local DSM program or portion paid by the LDC over and above what was already made available by the OPA.

- Variable administration cost[19] ($ per typical participant, initial, and then on going)
  - Portion paid for by the OPA as part of an OPA contracted province wide program.
  - Portion paid by the LDC in a stand alone local DSM program or portion paid by the LDC over and above what was already made available by the OPA.
- As applicable, fixed administration cost, directly allocated to one or a subset of typical participants.
- Level of OPA contracted initial cash incentive, and on going cash incentive, if any.

Users should read Section 4.1 to get a better understanding of the funding options, as well as the concept of variable versus fixed costs.

Users will use the TP sheet, and the preliminary participant level cost effectiveness test results to establish incentive levels. The process is described in Section 4.2.

OPA's or the LDC's fixed administration costs are to be inputted in the Budget sheet, not the TP sheet. Once the Budget sheet will be completed, users will be suggested a value for fixed administration cost in term of percentage of incentive in the TP sheet. Before then, users must guess their own percentage. The fixed administration costs percentages inputted in the TP sheet are used exclusively to compute the participant level cost effectiveness tests shown in Table (B); they are not carried into the Projections sheet and they do not influence portfolio level test results. Only fixed cost data inputted in the Budget sheet do.

Given the above, the users will probably have to populate the TP sheets in at least two passes as described in Section 5.3.

- During the first pass, they will have to guess the fixed administration cost as percentage of the incentive level. Also, at that stage, they will probably have to use unitary deferral or provincial average as the method to valuate the avoided distribution and/or transmission capacity.
- During the second pass, they will have had populated the Projections sheet, the Budget sheet and the Deferral sheet, and thereby they will have test results that are more accurate. They might have had selected the full project deferral or avoidance in the Deferral sheet. They will also use fixed administration costs as suggested by the model, based on data entered in the Budget sheet. Users will be able to tune the incentive level and variable administration cost accordingly.

In order to compute all costs and benefits, the TP sheets draw data from the following sheets:

- The Provincial sheet – Provincial average cost of energy and capacity, as applicable.
- The Rate Class sheets – Actual rates used to compute bill savings and lost revenues.

[19] Technical assistance and enabling activities such as customer education, marketing, energy audits, trainings offered to trade people or field visits for verification, auditing or measurement purposes usually all go under program administration costs; not under install, equipment & O&M costs.

- The DI and TI sheets – Unitary present worth of local distribution or transmission project deferral, as applicable
- The Deferral sheet – Present worth of local distribution or transmission project deferral or avoidance.
- The Projections sheet – Suggested fixed administration cost percentages, used exclusively in participant level cost effectiveness tests as desired by the users.

TP sheets have downstream implications on the following sheets:

- Projections sheet – Curtailment and the present worth of benefits and costs for every typical participant. The present worth of costs does not include fixed administration cost.
- Budget sheet – Incentive cost and Variable Administration cost.
- Deferral sheet – kW curtailment, non productive kVAR curtailment (to re build the kVA, and the power factor), kWh savings broken down per TOU bracket, distribution losses, and T&D losses.

Tips:

- All TP sheets can be renamed to something more meaningful. We recommend keeping the new tab name under 12 digits or letters.
- Use a TP sheet to model cash incentive or bill credit offerings that do not result in a direct impact – example: incentive to offset the cost of an energy audit.
  - Analysts will want to use this tip because it will allow them to disassemble pre investment incentive from investment incentive so that they can model pre investment that will be disbursed but that will not result in actual implementation. This tends to happen when participants abandon the program before they reach implementation, thus they never get to receive the implementation incentive and their participation never result in program impact claim.
  - If you wanted to do this, then you would have to set the average curtailment and all other participant level impact estimates to zero, and ignore the participant level test results in Table (B). These results will not have implications downstream, like in the Projections sheet; only the incentive data will. The “investment incentive(s)” would have to be inputted in another TP sheet.

6.5.4. Projections Sheet

The Projections sheet draws present worth data for benefits and costs from all TP sheets, then multiply by the number of new participants who sign in (uptake) on every given year of the program operation window (Year01 to Year05), and sum them up to build the program level cost effectiveness test results. The Projections sheet is where the program portfolio forecast uptake is inputted.

Table (A) is where portfolio uptake needs to be inputted. There are no other input cells in this sheet beyond Table (A).

Table (B) presents the portfolio level cost effectiveness test results, which are the most critical outputs of the CDM Challenger. They were extensively discussed in Section 1.1, and 4.5. Each of the test results are presented in term of Benefit/Cost ratio (B/C ratios), Net Present Value (NPV), and levelized unitary cost (LUC) – $/kW. These indicators were introduced in Section 4.4.

Table (C) shows key incremental program level impact during the program operation window such as total new participants signing in, incremental curtailment, total present worth of benefits and costs under the TRC, etc. All results presented in Table (C) are incremental values for every given year of the program operation window. For example, incremental kW curtailment projected on Year 01 has no implication on the cumulative kW curtailment for year 02 and onward. Users interested in the cumulative curtailment achieved by the local DSM portfolio at the end of the program operation window shall either look at the total column of Table (B), or, for more details, go see cumulative results in the Deferral sheet.

Table (D) draws data from the Budget sheet. The purpose of table (D) is to proceed with a few arithmetic manipulations to allocate the unallocated fixed administration cost to the subset of included participants, using behind the meter kW curtailment as a driver.

Table (A) is where the users can include or exclude each typical participant individually to single out subset of key participants. For example, users could use this feature to single out typical participants from a single rate class, or single out all typical participants for a single location. Unless specified, all results shown in Table (B) and (C) are for the "included" typical participant exclusively. This is the reason why fixed administration costs that are not directly allocated to specific typical participants must be re allocated to the subset of included participant. This explains the purpose of the arithmetic manipulations shown in table (D).

Table (F) is where the data drawn from all TP first lands in the Projections sheet Sheets (e.g. kW curtailment, present worth of costs and benefits for every test, etc.). This is also where the values for every individual typical participant are multiplied by the forecast uptake.

One key principle of the CDM Challenger engine is visible in Table (F). Only present worth values of benefits or cost are transferred to the Projections sheet to be aggregated, instead of transferring the full 20 year nominal cash flow schedule, for every given stream, and for participants signing in on Year 01 to 05. It makes the calculation clearer, and more condensed. For instance, uptake, benefits and costs shown non Year 01 have no implications on that for Year 02 and onward.

Key input in the Projections sheet includes the annual uptake (# of ratepayers signing in, for each typical participant) for the 5 year program operation window. This is also where the users can choose for what subset of typical participants they want to see results in Table (B) – That is: for which "aggregation scenario".

In order to compute all costs and benefits at the portfolio level, the Projections sheet draws data from the following sheets:

- TP Sheets – Curtailment and the present worth of benefits and costs for every typical participant. The present worth of costs does not include fixed administration cost.

- Budget sheet – Fixed administration cost; directly allocated or not.

Projections sheet has direct downstream implications on the following sheets:

- Deferral sheet – # of new participants signing in for every given year, and aggregation scenarios.
- TP Sheets – Fixed administration cost. The Projections sheet sends the fixed CDM administration cost resulting from Table (D) into the TP Sheets. It gets allocated using kW curtailment as the driver, and then it gets converted in % of incentive. It is shown in the TP sheet as a "Suggested" Fixed Administration Cost. This data does not loop back in the Projections sheet.

Tip:

- In Table (A), the users can list the typical participants in whatever sequence that suits their need.
  - By default, it is going to be sorted out using the original placeholder sequence (TP01, 02, 03, etc).
  - Users can later change the sequence shown in Table (A) by selecting the name of the typical participant in the drop down lists for every given row of the table.
  - Users should however beware: typical participants that will not be listed in Table (A) will be completely ignored by the model. This makes sense: if the uptake figures were not listed in Table (A), then they are deemed to be zero, and a typical participant with no uptake should logically have no implication on the total impact.

6.5.5. Budget sheet

The Budget sheet is where the users must enter the fixed administration costs for the program portfolio. Besides, the Budget sheet draws incentive and variable administration cost information from all TP sheets, sum all of these up to build Grand Totals and other useful tables.

Input cells in the Budget sheet can be found in Table (B) and Table (C). Beware that certain input cells, those in Table (C), are not shown at first glance on a 17 inch screen. Users will have to scroll down.

Table (A) is a useful output of the Budget sheet. It shows the Grand Total for the Local DSM portfolio, for every year from Year00 (i.e. current, planning year) to Year24 (for a participant signing in the program on Year05, and staying in the program for 20 years inclusively).

Table (A) presents the budget using the following breakdown structure:

- Fixed administration, variable administration and incentive cost. – This is a standard breakdown structure in the CDM field.
- LDC cost vs OPA cost – Illustrative of the funding structure. The former would show costs of stand alone local DSM programs and a portion of the cost pertaining to the hybrid funding programs, if applicable. The latter would show costs attributed to the OPA contracted province wide local DSM program and a portion of the cost pertaining to hybrid funding programs. See Section 4.1.

Aggregation scenarios as defined in the Projections sheet do not have implications on Table (A). Table (A) will always show the grand total for all typical participants with some uptake.

Table (B) is where users must input all fixed costs that are not directly allocated to specific typical participants. Inputs must be sorted whether they are cost that are incurred by the LDC without expected reimbursement by the OPA (LDC cost), or if they are cost incurred as part of the OPA contracted province-wide programs (i.e. the fixed cost portion of the PAB). Further breakdown suggested under the LDC Cost and the OPA Cost categories is not mandatory. That suggested breakdown came from the OPA Conservation Program Resource Planning Tool. Other breakdown might make more sense; such as that for the Board-Approved Programs.

Table (C) is where most of the incentive and variable administration cost land from the TP sheets. Table (C) is where these numbers are multiplied by participation figures and then summed up for each typical participant.

Costs shown in Table (C) can be variable or fixed. They all share the following: they are directly allocated to each individual typical participant. For variable administration cost and the incentive cost, this concept is relatively straightforward.

Table (C) is where to input the fixed administration costs that are directly allocated to each typical participant, as applicable or as desired by the users. Users will want to do that to achieve a greater degree of accuracy of the test results when singling out sub-sets of typical participants, or to achieve a greater accuracy of rate-class cost allocation. They will want to input directly allocated fixed administration costs if and for portions of the fixed administration cost that they know would have significant impact on the results for the corresponding TP or subset of TPs, and thereby that they believe should not be split between the typical participants using the kW curtailment as the only driver. Whether direct fixed cost allocation is used or not will not have influence on the test results for the total portfolio.

Key inputs in the Budget sheet include:

- Fixed program administration costs that cannot directly be allocated to any TP or sub-set of TPs – the model will thereby allocate it using curtailment (kW) as the driver.
- Fixed program administration costs must be directly be allocated to any TP or sub-set of TPs, as applicable

The Budget sheet draws data from the following sheets:

- TP sheets – Incentive cost, variable administration cost

The Budget sheet has direct downstream implications on the following sheets:

- Projections sheet – Unallocated and directly allocated fixed administration cost. Ultimately, that same information gets passed to the TP sheets.

6.5.6. Deferral Sheet

The Deferral sheet is where users must input decision with regard to the deferral or avoidance of the local distribution or transmission capital improvement projects of interest as a result of the local DSM. The Deferral sheet shows the total cumulative curtailment forecast for every location in kW and kVA to support the decision. The Deferral sheet also presents the cumulative impact of the program for every given year from Year 01 (First year of the program operation window), all the way to Year 24 (for one participant signing in on Year 05 and persisting in the program for 20 years.). The impacts are shown in term of kW, kVAR, kVA, power factor, and kWh for each TOU bracket. Impacts are also shown straight from behind the meter, then with distribution losses, and with transmission and distribution losses.

The Deferral sheet (Table (A) and (B)) obey the inclusion/exclusion rules set in the Projections sheet, or aggregation scenario.

Table (A) is where full project deferral decisions are made, as applicable. By default, the sheet will show the "Unitary Deferral" option for all the locations. Users will be able to switch it to full project deferral of full project avoidance A discussion about these three options was provided in Section 3.1.

Once the decision is made, and if that decision is either full project deferral or full project avoidance, then Table (A) will unveil the present worth of such deferral/avoidance at the right hand side of the table. For the TRC, PAC and RIM, the present worth is that of the deferred/avoided expected revenue requirements associated with the project. For the LDCT and the TCT, the model computes the present worth of the delayed/foregone earnings, and the deferred/avoided equity capital contribution.[20]

In addition, in both cases (full project avoidance of deferral), table (A) will also unveil the following item: Allocation denominator which corresponds to kW curtailment with distribution losses (or T&D losses for the transmission projects) one year before the deferred investment schedule end year (for deferral) or one year before the end year of the planned investment schedule (for avoidance). kW curtailment is used as the driver to allocate the present worth to each typical participant, hence the need for a denominator.

At the very right hand side of the table, users will find curtailment power factor for the end year of the planned investment for each specific location. If the users were to use the "unitary deferral" option, then those users would be encouraged to feed back this power factor into the corresponding DI or TI sheet to increase the accuracy of the results.

Table (B) shows the full schedule of the total annual impacts from Year 01 to Year 24. These are cumulative impact – that is Year 02 impact cumulates impacts achieved on Year 01. The impact shall ramp up during the program operation window, Year 01 to 05, and then ramp down as participants abandon the programs or as the conservation measures go over their effective useful life.

[20] If the discount rate used is identical to the regulated ROE, then the present worth of delayed/foregone earnings will be nearly equal to the present worth of the delayed/foregone capital contributions.

Key inputs in the Deferral sheet include:

- Decisions whether distribution or transmission capital improvement project can be avoided or deferred, and if it is deferred, then by how many years.

The Deferral sheet draws data from the following sheets:

- TP sheets – Curtailment in kW, kVAR, kWh for all TOU brackets, distribution losses and T&D losses.
- Projections sheet – Uptake, and aggregation scenarios

The Deferral sheet has direct downstream implications on the following sheets:

- TP sheets – Present worth of full project deferral/avoidance, as applicable. Three items get passed: deferral/avoidance revenue requirements, delayed/foregone earnings, and deferral/avoidance equity capital investment. The present worth gets allocated using curtailment as the driver.[21] Ultimately, these values get their way back in the Projections sheet through the test benefits and costs.

6.5.7. Provincial Sheet

The provincial sheet stores the 2007 provincial avoided supply cost assumptions for demand and energy from the Appendix A of the OPA CDM Cost Effectiveness Guide. The OPA is working on updating this information.

The OPA data is stored in Table (A). Table (B) and (C) turn the cost assumptions into coefficients that represent the unitary present worth of avoided cost of energy or capacity depending on, alternatively, when the participant will sign off the DR program, or at the end of the useful conservation measure life.

The Provincial sheet has direct downstream implications on the following sheets:

- TP sheets – Present worth coefficients used to value avoidance of energy supply, generation capacity, and transmission or distribution capacity as applicable.

6.5.8. Rate Class Sheets

The Rate Class sheets – namely RES, MULTIRES, GS<50, GS<1000, GS<5000, LARGE, UNMETERED and STLIGHT[22] – store the volumetric portion of the rates ($/MWh and $/kW month). All rate components

[21] [Present worth / Curtailment denominator as per Table (A) x Average curtailment for that participant] IF that participant is online the year before the end year of the deferred investment schedule. Otherwise, that typical participant gets allocated $0.

[22] Corresponding to the following rate classes, respectively: Residential, Multi Unit Residential, General Service < 50 kW, General Service 50 – 999 kW, General Service 1,000 – 4,999 kW, Large Use, Unmetered Scattered Loads, and Street Lighting.

were consolidated to fit into Table (A) by aggregating all volumetric components together, then broking them down by segment of the supply chain: generation, transmission and distribution, as well as regulatory fees and debt retirement. The Rate Class sheets were pre loaded with Toronto Hydro rate data from December 2013. We made assumptions regarding the escalation of the rates and used these to forecast the nominal value of these rates all the way until the end of the modeling window – Year 00 to Year 24.

The rate data and escalation scenarios are stored in Table (A). Table (B) turns the rates into coefficients that represent the unitary present worth of lost revenues depending on, alternatively, when the participant will signoff the DR program, or at the end of the useful conservation measure life.

The Rate Class sheets have direct downstream implications on the following sheets:

- TP sheets – Present worth coefficients used to value bill savings and lost revenues.

7. Main Findings and Conclusions

Toronto Hydro is studying the potential and the business case for local demand response and conservation alternatives to offset capital investments. These local DSM alternatives would target customers served by transmission and/or distribution systems identified as requiring significant capital investment in the next 5 to 10 years.

There are two phases to this project and this report laid out the achievement made during Phase 1. In short, these achievements are:

- Toronto Hydro created a financial model to support this approach – the CDM Challenger.
- Toronto Hydro provided a review of DSM alternatives, as laid out in Section 2.
- Toronto Hydro documented both its methodology and the architecture model, as laid out in Section 3, 4 and 5 of this report.
- Toronto Hydro started testing options in multiple sites, and using a variety of program options – although Toronto Hydro is not ready to present its result yet.

During Phase 2, Toronto Hydro will achieve the following:

- Carry on the testing and fine tuning of the portfolio of programs it intends to roll out. It will show the result of that work in the final report, in the form of a Toronto Hydro case study.
- Design activation protocols
- Facilitate the necessary knowledge transfer – including a final report, summary of results, lessons learned, and formal presentation.

Future extensions and add ins to the CDM Challenger that might be worked on in the future, beyond the scope of the current project include:

- Adding other resource savings (such as natural gas, heating oil, water), and their respective consumer cost and avoided cost.

- Valuation of other utilities' benefit:
  - Improved economic efficiency in the provision of operating reserves
  - Improved reliability – perhaps through evaluating lost loads in case of blackouts
  - Environmental benefits – perhaps per unit CO_2
- Before meter distributed energy options such as energy storage – or utility capital investment in distributed energy (that would earn a return in exchange) that would defer other, larger capital improvement projects.
- Development of a Wizard – Some buttons and macros that would help first time users to skip from one sheet to another in chronological order, along with a commentary.
  - Perhaps including: building in extensive documentation and directions directly into the workbook. Similar to that of RETScreen.

E7.11 Energy Storage Systems

LITHIUM ION BATTERY ES INSTALLATION

E7.11.1 Summary

Program Description

The Energy Storage Systems (ESS) program was developed to provide Toronto Hydro with strategic ancillary capabilities to address system efficiency, reliability and power quality, as well as Distributed Generation (DG) and Electric Vehicle (EV) enablement in targeted areas of the Toronto Hydro distribution system. Energy storage refers to the process of storing electrical energy for future use. An ESS can be constructed using various technologies and can be classified as either a centralized or decentralized system. By placing ancillary ESS strategically throughout the distribution system, localized issues can be addressed. This approach allows for a minor augmentation of the distribution system, rather than an expensive rebuild or major asset replacement. In this way, ESS deployments can be a creative and prudent approach to system risk mitigation.

Toronto Hydro plans to install 24 energy storage systems during the 2015-2019 forecast period. This represents a total installed aggregate capacity of approximately 4.4 MW with a total energy output of 10,000 kWh

Table A summarizes the anticipated benefits associated with the ESS program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Provides backup power during emergency situations for critical customers (e.g. emergency services, hospitals, government buildings etc.).
Reliability	ƒ Facilitates increased reliability and power quality. ƒ Provides the system with dynamic voltage support, low harmonics and uninterrupted service. ƒ Reduces demand fluctuations with peak shaving during peak demand periods and load leveling during off peak periods.
Safety	ƒ Improves asset utilization, which extends the service life of distribution assets (e.g. transformers, conductors etc.), ensuring that equipment operates within nominal system parameters and helps to prevent catastrophic equipment failures.
Efficiency	ƒ Station based ESS provide backup power for ancillary station services in case of an interruption or an emergency situation, enabling remote monitoring and control is maintained (e.g. station service for protection systems, communication system, station lighting etc.)

Program Drivers

The trigger and secondary drivers for this program are summarized in Table B.

TABLE B: PROGRAM DRIVER

Trigger Driver	Reasoning
System Efficiency	ƒ Enhances system performance by storing electricity at off-peak times, and releasing it into the distribution system during peak times. These capabilities are expected to help Toronto Hydro manage the increasing variability of distribution system load. ƒ Capacity in certain areas of the system is strained due to load growth. ESS can help defer the need for large scale asset replacements that would otherwise be required to maintain sufficient capacity to meet demand through peak load reduction. ƒ ESS can increase the utilization and lifespan of existing distribution assets through peak load reduction. ƒ Assists in reducing the overall impact of routine maintenance programs carried out at MS. ƒ Helps dynamically correct phase imbalances. ƒ Enablement of DG & EVs.
Secondary Drivers	**Reasoning**
Reliability	ƒ Increases the resiliency of the distribution system by providing reliable power for essential services over an extended period of time during emergency situations.
Power Quality	ƒ Delivers consistent service voltage, low harmonics and uninterrupted service.

	ƒ Provides dynamic voltage regulation/reactive power support.

Preferred Alternative

Toronto Hydro evaluated this program against the alternative of excluding ESS from the suite of possible technological distribution system solutions for the 2015-2019 period. Executing the ESS program as described is the preferred alternative as it would provide Toronto Hydro with strategic capabilities to address specific issues relating to system efficiency, reliability and power quality, and DG and EV enablement in targeted areas of the Toronto Hydro distribution system in a cost-effective manner.

The difference in the cost of ownership between existing and renewed assets ("COO) for the first year of the program is $1.1 million, representing a reduction in negative impacts to customers (in this case represented by a $/kW benefit cost) over the life of the assets (see Section E7.11.7). Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.58 million, confirming the economic prudence of the investments (see Section E7.11.7).

Timing and Pacing

Based on experience gained through current and past ES implementations, the ESS program will proceed at a gradual and methodical pace. In 2015, technology selection, detailed engineering and design work and site selection are planned for all ESS, followed by the installation and commissioning of one Local Support Energy Storage (LSES) and one Grid Support Energy Storage (GSES) unit. For 2016, Toronto Hydro plans to install and commission two LES and GSES units and one Municipal Substation Energy Storage (MSES) unit. From 2017 to 2019, Toronto Hydro plans to install and commission three LSES units per year, two GSES units per year, and one MSES unit per year.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	-	-	-	1.02	0.54	1.10	2.20	3.20	3.80

E7.11.2 Program Description

The Energy Storage Systems (ESS) program provides Toronto Hydro with the capabilities needed to address specific issues relating to system efficiency, reliability and power quality, and distributed generation (DG) and electric vehicle (EV) enablement in targeted areas of the distribution system. The program is expected to achieve the benefits listed Table 1 by installing 24 ES systems from 2015 through to 2019. This represents a total installed aggregate capacity of 4.4 MW with a total energy output of 10,000 kWh. The objective of the program is to enable Toronto Hydro to address specific issues and limitations within the distribution system with a prudent alternative to existing solutions and methods.

TABLE 1: APPLICATIONS AND BENEFITS OF ESS

Application	Benefit
Peak shaving/Load Levelling	ESS supply energy during peak hours ('peak shaving') and store excess energy during low demand hours ('load levelling') improving asset utilization and efficiency, deferring the need for large scale asset upgrades (e.g. power transformers, stations switch gear, etc.).
Reliability & Power Quality Improvements	ESS can improve the overall power quality for customers by counteracting variations in voltage and harmonics, and the effects of switching.
DG & EV Enablement	ESS can enable the connection DG & EV to the Toronto Hydro distribution system by addressing local system constraints.
Phase Balancing	ESS can help rebalance feeders that exceed the threshold for single phase imbalances, decreasing the return current on the neutral conductor.
Critical Load Emergency Service	As a last resort during an emergency, ESS can provide backup power for critical loads (e.g. emergency services, hospitals, government buildings etc.).
Temporary Station Maintenance Load Displacement	ESS can help with maintenance that is carried out at the station level by acting as a temporary supply for downstream customers during work execution, negating the need for a scheduled outage.
Station Ancillary Services	ESS can provide power for ancillary services (protection system, communication system, station lighting, etc.) ensuring remote monitoring and control capabilities are maintained during emergency situations.

ESS can be constructed from various technologies, which can be deployed at strategic locations in Toronto Hydro's distribution system. These technologies include:

- lithium-ion,

- sodium-sulphur, and
- compressed air (under water).

Lithium-ion and sodium-sulphur are types of electrochemical battery cell technology that consist of an electrolyte chemical separating two electrodes. Lithium-ion batteries are useful for large centralized and small de-centralized applications mainly because of their high energy density and efficiency, lower self-discharge rate (i.e. the rate at which the batteries lose their charge capacity) and low maintenance requirements.[1] Comparatively, while sodium-sulphur batteries are highly energy efficient and are made from inexpensive/non-toxic materials, their high operating temperatures and highly corrosive nature limits their use to centralized settings[2]. Underwater Compressed Air Energy Storage systems (UCAES) use off-peak power to compress air underwater and during peak hours the compressed air is released to power a turbine/generator system for power production. UCAES systems are only feasible if deployed in Municipal Substations (MS) located near Lake Ontario.

ESS can be divided into two categories, which make up the proposed investments as part of this program:

- Centralized ESS, and
- De-centralized ESS.

Sections E7.11.2.1 and E7.11.2.2 provide further information with respect to the different ESS categories. Toronto Hydro forecasts that the ESS categories described in detail below will cost an estimated $10.8 million over the 2015 to 2019 period.

E7.11.2.1 Centralized ESS

Centralized ESS can utilize lithium ion or sodium sulphur battery cell technology or UWCAES (when located near Lake Ontario). Toronto Hydro intends to use centralized ESS by deploying them within municipal stations. As described in Section E7.11.4.1, the locations will be determined by the severity of the specific issue(s) present, and by assessing whether these issues can be prudently addressed with an ESS (e.g. peak demand shaving, reliability and power quality issues, DG & EV connections, etc.). Table 2 provides an overview of centralized ESS.

[1] L. Hadjipaschalis, A. Poullikkas, and V. Efthimiou, Overview of current and future energy storage technologies for electric power applications, (2009) 13 ScienceDirect at page 10. ["ScienceDirect"]
[2] ScienceDirect.

TABLE 2: CENTRALIZED ESS

Energy Storage System Type (Typical Size & Duration)	Energy Storage Technology
Municipal Substation Energy Storage (MSES) (400 kW & 3 hrs)	ƒ Lithium Ion ƒ Sodium Sulphur ƒ Under Water Compressed Air

Figures 1 to 2 provide examples of centralized ESS installations. Figure 1 shows the typical configuration of a Lithium Ion Battery ESS Installation. The entire solution is contained within large truck trailers. Similarly, Figure 2 shows the typical configuration of a Sodium Sulphur Battery ESS installation. Rather than truck trailers, the solution is contained within cabinets. A potential location for an MSES system within Toronto Hydro's distribution system is shown in Table 3 and Figure 3.

FIGURE 3: MSES EXAMPLE LOCATION

Table 4 below outlines the total units of equipment to be installed as part of this portion of the ESS program.

TABLE 4: TOTAL MSES INSTALLATIONS (2015 – 2019)

Assets	2015	2016	2017	2018	2019	Total (Units)
Municipal Substation Energy Storage (MSES)	0	1	1	1	1	4

E7.11.2.2 De-centralized ESS

Unlike centralized ESS, de-centralized ESS only utilizes lithium ion battery cell technology. De-centralized ES systems are deployed at various strategic locations within the distribution system. As described in Section E7.11.4.1. – Ranking and Prioritization, the locations are determined by the severity of the specific issue(s) present, which can be addressed with an ESS (e.g. reliability & power quality issues, phase imbalance, DG & EV connections etc.). As a result of different needs, de-centralized systems can be further subdivided into two categories:

- Grid Support ES (GSES) systems, and
- Local Support ES (LSES) systems.

GSES systems are placed at strategically determined points along the primary portion of a feeder (e.g. the beginning, mid-point or end of a feeder) and LSES systems are positioned on single phase laterals. Table 5 provides an overview of de-centralized ESS.

TABLE 5: DE-CENTRALIZED ESS OVERVIEW

Energy Storage System Type (Typical Size & Duration)	Energy Storage Technology
Grid Support Energy Storage (GSES) (200 kW & 2.5 hrs)	Lithium Ion
Local Support Energy Storage (LSES) (100 kW & 1 hr)	Lithium Ion

Figures 4 and 5 provide examples of de-centralized ESS installations. The ESS in both figures have a smaller size and foot print than centralized systems and are housed in pad-mount enclosures (similar to pad-mount transformers and switches). In Section E7.11.7 – 2015 Projects, two proposed project locations have been determined for an LSES and GSES installation within the Toronto Hydro distribution system.

FIGURE 4: EXAMPLE OF GRID SUPPORT ENERGY STORAGE INSTALLATION [6]

[6] eCamion, Community Energy Storage (CES) Overview, online: eCamion <http://www.ecamion.com/portfolio/ces/>.

FIGURE 5: EXAMPLE OF LOCAL ENERGY STORAGE INSTALLATION [7]

Table 6 below outlines the total units of equipment to be installed as part of this portion of the ESS program.

TABLE 6: TOTAL GSES & LSES INSTALLATIONS (2015 – 2019)

Assets	2015	2016	2017	2018	2019	Total (Units)
Grid Support Energy Storage (GSES)	1	1	2	2	2	8
Local Support Energy Storage (LSES)	1	2	3	3	3	12

The assets that make up an entire ESS are expected to last approximately 10-20 years. While each type of system requires maintenance, including inspections of the ESS itself and associated ancillary equipment (such as backup power supply for remote communication equipment etc.), maintenance programs would be tailored to each particular ESS.

It is anticipated that the ESS program will provide Toronto Hydro with additional capabilities to address system efficiency, reliability and power quality, and DG and EV enablement challenges. The program is inherently customer-driven as the proposed work would assist Toronto Hydro to improve the operating conditions of the distribution system in a targeted, strategic and prudent

[7] S&C Electric Ltd., Energy Storage Systems, online: S&C Electric Ltd. <http://www.sandc.com/products/energy-storage/ces.asp>.

manner, which would benefit the utility's customers now and in the future by helping deliver greater value for money from the existing system in light of evolving grid utilization and general economic growth and development.

The planned investments are expected to provide load relief for particularly constrained areas in the distribution system. Consistently operating close to the peak can lead to the accelerated deterioration of distribution system infrastructure. By having the ability to offset demand closer to the load, ES systems can help shave peak during high demand times, and level load during off peak hours. This can result in less strain on existing distribution system infrastructure, such as large power transformers, primary conductors, and distribution transformers. Figure 6 illustrates the concepts of peak shaving and load levelling.

FIGURE 6 PEAK SHAVING AND LOAD LEVELLING [8]

Toronto Hydro also plans to use ESS to improve the utilization of existing assets. For example, a large power transformer is selected to accommodate future load growth over a 15-20 year planning horizon. A large portion of the investment made into this asset is underutilized for most of the new equipment's life. The upgrade of this asset can be deferred by using an ES system to offload it during peak periods, extending its service life.

Reliability is expected to be positively affected by the addition of ESS. Recent adverse weather events have demonstrated the distribution system's vulnerability to large scale disruptions, which

[8] NGK Insulators Inc., NAS Batteries, online: NGK Insulators Inc. <http://www.ngk.co.jp/english/products/power/nas/index.html>.

can result in outages to critical infrastructure that may need to be relied on during emergency situations. These include interruptions to supply, and damage to the primary and lateral sections of a feeder. At this time, Toronto Hydro does not have the ability to quickly restore service to critical loads when there is a major outage event (e.g. major failure, loss of supply etc.). With appropriate switching and isolation, ESS can provide temporary backup power to critical infrastructure, ensuring continual service for critical loads while repairs take place. Some examples of critical loads include emergency services, hospitals, government buildings and financial institutions. ESS located at MS would facilitate routine maintenance activities. The ESS would be able to temporarily support the load from equipment taken out of service for maintenance purposes. More specifically, it would prevent a temporary outage and support the load with other feeders decreasing the temporary burden experienced by alternate feeds.

The projected levels of DG connections from 2015 through to 2019 are expected to increase by 450 MW, to 626 MW of connected DG. In addition, the Government of Ontario's aspiration is for one in 20 vehicles in the province to be an electric vehicle by 2020.[9] These developments would impact Toronto Hydro's distribution system by introducing additional dynamic two-way generation and mobile loads and this impact is expected to increase as the penetration of DG and EV increases. Toronto Hydro is already attempting to address system-wide issues to enable the connection of DG, as outlined in the Generation Planning Monitoring & Control program; however specific locations in the distribution system are expected to have additional technical issues that may prevent the connection of DG and EVs. ESS can help to alleviate these localised issues and enable the connection of DG and EVs. This is illustrated by the proposed projects in Section E7.11.7 – 2015 Projects. Table 7 provides an overview of the anticipated benefits associated with the ESS program.

TABLE 7: PROGRAM BENEFITS

Customer Value	ƒ Enables the integration of customer-owned DG and EVs ƒ Provides backup power during emergency situations for critical customers (e.g. emergency services, hospitals, government buildings etc.). x The difference in the cost of ownership between existing and renewed assets (ûCOO) for the first year of the program is $1.1 million, representing a reduction in negative impacts to customers (e.g., customer interruption costs, emergency repair costs) over the life of the assets (see Section E7.11.7). x Accounting for capital program costs, the first year's activities deliver a positive NPV of $0.58 million, confirming the economic prudence of the investments (see Section E7.11.7).

[9] Pollution Probe, Unlocking the Electric Mobility Potential of Toronto: Moving Toward an Electric Mobility Master Plan for the City (Toronto: Pollution Probe, 2010), at page 67, online: Pollution Probe < http://www.pollutionprobe.org/pdfs/EMMP.pdf>.

Reliability	ƒ Provides increased reliability and power quality. ƒ Provides the system with dynamic voltage support, low harmonics and uninterrupted service. ƒ Reduces demand fluctuations with peak shaving during peak demand periods and load levelling during off peak periods.
Safety	ƒ Improves asset utilization, which extends the service life of distribution assets (e.g. transformers, conductors etc.), ensuring that equipment operates within nominal system parameters and helps to prevent catastrophic equipment failures.
Efficiency	ƒ Station based ESS provide backup power for ancillary station services in case of an interruption or an emergency situation, enabling remote monitoring and control is maintained (e.g. station service for protection systems, communication system, station lighting etc.). ƒ Enables station maintenance for station assets (e.g. power transformer, switch gear, etc.) by providing temporary service for customer loads while the asset is isolated, negating the need for an extended planned service interruption. ƒ Defers the need for conventional infrastructure upgrades

E7.11.3 Why the Program is Needed

The ESS program is expected to provide Toronto Hydro with alternative methods to address specific issues relating to system efficiency, reliability and power quality, and DG and EV enablement. ESS deployments are planned to occur in targeted areas where ES can be a more prudent investment versus traditional solutions. The ESS program is expected to address the aforementioned issues by placing ESS strategically throughout the distribution system. This distributed approach would enable a minor augmentation of the performance of the existing distribution system to address localized technical limitations and issues, helping Toronto Hydro to mitigate the need for potentially expensive rebuilds or major asset replacements.

E7.11.3.1 Program Drivers

Table 8 presents the trigger and secondary drivers for the program.

TABLE 8: TRIGGER AND SECONDARY DRIVERS FOR ESS PROGRAM

Trigger Driver	Reasoning
System Efficiency	ƒ Enhances system performance by storing electricity at off-peak times, and releasing it into the distribution system during peak times. These capabilities would help Toronto Hydro manage the increasing variability of distribution system load. ƒ Capacity in certain areas of the system is strained due to load growth. ESS can help defer the need for large scale asset replacements that would otherwise be required to maintain sufficient capacity to meet

	demand through peak load reduction. ƒ ESS can increase the utilization and lifespan of existing distribution assets through peak load reduction. ƒ Minimizes overall impact of routine maintenance programs carried out at MS. ƒ Dynamically correct phase imbalances. ƒ Enablement of DG & EVs.
Secondary Drivers	Reasoning
Reliability	ƒ Increases the resiliency of the distribution system by providing reliable power for essential services over an extended period of time during emergency situations.
Power Quality	ƒ Delivers consistent service voltage, low harmonics and uninterrupted service. ƒ Provides dynamic voltage regulation/reactive power support.

Toronto Hydro creates capital projects to address issues within the distribution system. In specific cases, existing methods and solutions (e.g. capital replacement, major asset upgrades, etc.) may not be feasible for all issues related to system efficiency, reliability and power quality, and DG and EV enablement. This is when a targeted ESS installation can provide a more useful and prudent solution. Specific issues include peak load reduction, addressing customer power quality, and DG enablement. High peak loads on main and alternate feeders limit the ability of planned or emergency load transfers, resulting in stranded customers. Fluctuations in system voltage can cause issues for customers who have sensitive processes or equipment. This can lead to an interruption in customer operations by disrupting processes and may damage equipment. While Toronto Hydro has the Generation Protection Monitoring & Control program to address system-wide issues to enable DG, some localised areas would still have feeder phase imbalances, which can inhibit the connection of a DG project. The specific issues mentioned above can be addressed with a targeted deployment of ESS.

Peak Load Reduction

Currently there are areas in Toronto Hydro's distribution system that contain feeders that have large peak loads. Feeder 88M15, fed from Richview TS, is an example of this case. The issue with 88M15 is that the feeder is heavily loaded during summer months and the last section of the feeder contains a high concentration of that load. During a contingency situation, where a fault occurs upstream of the last section, customers may not be reconnected until after the fault has

been addressed. Capacity issues with potential tie feeders 88M18, 11M3, and 38M7 prevent supplying the last section of 88M15. An option to address this would be to run a new feeder into the area from nearby stations. This solution would be viable; however both Runnymede TS and Manby TS are close to capacity. Additionally, the Humber River is a natural barrier that makes it difficult to bring in feeders. Figure 7 provides a feeder print and map of the area described by the example above. ESS can be strategically placed along 88M15, or any of the tie-feeders, to provide peak load reduction and ensure that customers are not stranded during contingency situations.

FIGURE 7: FEEDER PRINT AND MAP OF 88M15 AREA

Addressing Customer Power Quality Concerns

Customer engagements by Toronto Hydro have identified over 100 customers who have expressed specific needs regarding power quality. These needs can include dynamic voltage regulation/reactive power support, harmonic mitigation, and uninterrupted service. These customers include health care and industrial manufactures, information technology service providers, and public service loads such as hospitals and water pumping stations. For example, a customer may have issues with their equipment and process, because they are sensitive to voltage fluctuations. One method to address voltage fluctuations is to change the tap position of

the service transformer, which would allow for voltage regulation. While this is a possible solution, the dynamic nature of the load along a feeder makes it virtually impossible to change a transformer's tap position dynamically in reaction to the load. Figure 8 illustrates and example of a voltage spike experienced by a customer. ESS can address this issue by dynamically counteracting voltage fluctuations through voltage regulation. This can minimize the voltage fluctuations that affect customer equipment and processes. Additionally, any negative power quality effects caused by any customers to the distribution system can also be mitigated by ESS.

FIGURE 8: VOLTAGE SPIKE EXPERIENCED BY CUSTOMER

DG Enablement

When assessing the potential to connect a DG project within Toronto Hydro's distribution system, planning engineers determine if a feeder's phase current imbalance exceeds 10% of the total load on the feeder (at the station) when DG is added to the feeder. If the DG causes the current imbalance to exceed the 10% threshold it must be corrected. Phase imbalances in general result in a return current on the neutral conductor. A return current typically causes line losses and in some cases, where the imbalance is exacerbated, cable splice failures due to overheating. A method of correcting phase imbalances is to redistribute load among the other phases of the feeder, which is technically and operationally complex. Additionally, 450 MW of generation is

forecasted to be connected to the distribution system over the 2015-2019 period. As a result, it is anticipated that situations will arise where local phase imbalances in sections of system will increase. ESS can address this issue by dynamically balancing phases to maintain the 10% threshold, without redistributing the load to different phases. Immediately and over time, this approach would address connection issues for many projects seeking connection in that local area. Additionally, if the EVs is significant in the future, ESS would help ensure they can be connected as well, as ESS can help charge EVs off peak. As is demonstrated with the proposed 2015 projects, detailed in section E7.11.7 – 2015 Projects, ESS is expected to help to enable the connection of DG to the distribution system.

Table 9 provides a summary of the proposed technologies of the ESS program and their targeted applications. Toronto Hydro anticipates that the successful implementation of the ESS program will allow Toronto Hydro to address specific issues in the distribution system with targeted applications of ESS. Figure 9 below provides a general schematic of the locations of centralized and de-centralized energy storage systems in a distribution system. (1) is an example of a centralized ESS, while (2) and (3) represent de-centralized ESS.

TABLE 9: SUMMARY ESS APPLICATIONS

Energy Storage System Type	Targeted Applications
Municipal Substation Energy Storage (MSES)	ƒ Peak Shaving/Load Levelling ƒ Reliability/Power Quality improvements ƒ DG & EV enablement ƒ Critical Load Emergency Service ƒ Temporary Station Maintenance Load Displacement ƒ Station Ancillary Services
Grid Support Energy Storage (GSES)	ƒ Peak Shaving/Load Levelling ƒ Reliability/Power Quality improvements ƒ DG & EV enablement ƒ Phase Balancing ƒ Single Load Emergency Service
Local Support Energy Storage (LSES)	ƒ Local Peak Shaving/Load Levelling ƒ Local Reliability/Power Quality improvements ƒ Local DG & EV enablement ƒ Phase Balancing

FIGURE 9: GENERAL SCHEMATIC OF ESS

E7.11.4 Timing and Pacing of the Program

The total cost of the ESS program over the 2015 – 2019 period is an estimated $10.8 million. During the five-year timeframe, Toronto Hydro plans to install a total of 24 ESS with a total aggregated capacity of 4.4 MW and a total energy output of 10,000 kWh. Table 10 summarizes historical and future program spending.

TABLE 10: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	-	-	-	-	$1.02	$0.54	$1.10	$2.20	$3.20	$3.80

The historical cost for the ESS program consists of the pilot projects. The projects are forecasted to incur a cost of $1.02 million in 2014. The costs are associated with the commissioning of two

ES pilot projects and the retrofit and commissioning of another ES pilot project. The pilot projects consist of:

- HydroStor Underwater Compressed Air Energy Storage (UWCAES) – Commissioning of a 700 kW Energy Storage System that utilizes underwater compressed air to charge and release energy back into the distribution system
- Ryerson Energy Storage System – Commissioning of a 300 kW Energy Storage System comprised of Lithium Ion batteries
- Community Energy Storage (CES) – Retrofit and commissioning of a 250 kW Energy Storage System comprised of Lithium Ion batteries

These pilot projects helped to define the technology, sizing and use of the proposed projects from 2015 through to 2019. Based on experience gained through the pilot projects, the ESS program will proceed at a gradual and methodical pace, targeting areas where an ES can be the most prudent solution to a significant localized technical issue or limitation. In 2015, technology selection, detailed engineering and design work, and site selection will take place for all ESS types. Work scheduling will ensure that the necessary personnel and resources are available. This will enable the installation and commissioning of one LSES and GSES unit each. For 2016, Toronto Hydro plans to install and commission two LSES and GSES units each and one MSES unit. From 2017 to 2019, Toronto Hydro plans to install and commission:

- three LSES units per year,
- two GSES units per year, and
- one MSES unit per year.

Table 11 summarizes the pace at which LSES, GSES and MSES units will be deployed.

TABLE 11: ASSETS TO BE INSTALLED AS PART OF THE ESS PROGRAM

Assets (Units)	2015	2016	2017	2018	2019	Total (Units)
Local Support Energy Storage (LSES) System	1	2	3	3	3	12
Grid Support Energy Storage (GSES) System	1	1	2	2	2	8
Municipal Station Energy Storage (MSES) System	0	1	1	1	1	4

E.7.11.4.1 Ranking & Prioritization

Sequencing of work within the ESS program is determined by several factors, which are used independently of one another and are based on the desired application for the ESS. These factors include:

- Station Capacity: Stations that are currently overloaded would be given higher priority of selection for an MSES in order to extend the life of these assets in a timely manner.
- Reliability Issues: Feeders that are experiencing reliability issues would be prioritized. Toronto Hydro will study whether reliability issues can be addressed by a LSES or GSES system (e.g. phase imbalance, voltage stability issues, etc.) Where applicable, feeders in the FESI program will be examined to see if LSES or GSES have any potential applications to improve reliability.
- Power Quality Issues: Areas of the distribution system that are experiencing power quality issues will be prioritized for an ESS (depending on the required size).
- DG & EV Enablement: Areas of the distribution system that are experiencing issues connecting DG & EVs to the grid will be prioritized for an ESS (depending on the required size).

E7.11.5 Program Execution

In general, the ESS program will be executed in accordance with following process:

(1) System Requirements: Identify the technical and operation requirements of the various ESS (this includes a high level site selection analysis).

(2) Technology Selection: Identify suitable technology that can meet Toronto Hydro requirements and specifications.

(3) Detailed Site Selection: Based on the criteria mentioned in Section E7.11.4.1, select candidate sites for ESS deployment.

(4) In-depth Engineering and Design: Conduct detailed engineering analysis and system design work required for ESS deployment.

(5) Material Sourcing and Construction: Taking lead times into account, source the required materials for ES system and create construction schedule.

(6) Project Commissioning: Once construction is completed, commission the ESS and bring it into service.

E7.11.5.1 Proposed Work Plan

TABLE 12: 2015-2019 LONG TERM PLAN

Year	Feeder	Station
2015	LSES Unit 1 – H9M24	LSES Unit 1 – Elesemere TS
2015	GSES Unit 1 – SS68F1	GSES Unit 1 – Leslie MS
2016	LSES Unit 2 – Feeder TBD	LSES Unit 2 – Station TBD
2016	LSES Unit 3 – Feeder TBD	LSES Unit 3 – Station TBD
2016	GSES Unit 2 – Feeder TBD	GSES Unit 2 – Station TBD
2016	MSES Unit 1 – Feeder TBD	MSES Unit 1 – Station TBD
2017	LSES Unit 4 – Feeder TBD	LSES Unit 4 – Station TBD
2017	LSES Unit 5 – Feeder TBD	LSES Unit 5 – Station TBD
2017	LSES Unit 6 – Feeder TBD	LSES Unit 6 – Station TBD
2017	GSES Unit 3 – Feeder TBD	GSES Unit 3 – Station TBD
2017	GSES Unit 4 – Feeder TBD	GSES Unit 4 – Station TBD
2017	MSES Unit 2 – Feeder TBD	MSES Unit 2 – Station TBD
2018	LSES Unit 7 – Feeder TBD	LSES Unit 7 – Station TBD
2018	LSES Unit 8 – Feeder TBD	LSES Unit 8 – Station TBD
2018	LSES Unit 9 – Feeder TBD	LSES Unit 9 – Station TBD
2018	GSES Unit 5 – Feeder TBD	GSES Unit 5 – Station TBD
2018	GSES Unit 6 – Feeder TBD	GSES Unit 6 – Station TBD
2018	MSES Unit 3 – Feeder TBD	MSES Unit 3 – Station TBD
2019	LSES Unit 10 – Feeder TBD	LSES Unit 10 – Station TBD
2019	LSES Unit 11 – Feeder TBD	LSES Unit 11 – Station TBD
2019	LSES Unit 12 – Feeder TBD	LSES Unit 12 – Station TBD
2019	GSES Unit 7 – Feeder TBD	GSES Unit 7 – Station TBD
2019	GSES Unit 8 – Feeder TBD	GSES Unit 8 – Station TBD
2019	MSES Unit 4 – Feeder TBD	MSES Unit 4 – Station TBD

E7.11.5.2 Program Risks

The risks associated with the installation and commissioning of ESS include:

- Limited technical resources with knowledge on ESS are available to design, install and commission the systems, which can lead to a delay in program implementation and increase costs.

- Transferring existing customer loads to standby feeders during system installation may be challenging due to system constraints and other capital project and planned maintenance work, which can lead to a delay in program implementation.
- Labour availability and project prioritization with other capital project and planned maintenance work could lead to delays in program implementation.

To mitigate the above risks, Toronto Hydro will:

- Provide in-depth training to crew members who will take part in the installation and commissioning of ESS in advance of the actual field work.
- Schedule work to be completed during off-peak periods in order to manage the impact to standby feeders.
- Undertake advanced planning and co-ordination between applicable Toronto Hydro departments to address resource availability issues and constraints.

E7.11.5.3 External Constraints

For LSES and GSES systems Toronto Hydro will need to co-ordinate its activities with the City of Toronto and/or private land owners in order to obtain site permits and to arrange lease agreements (if required; site specific). In order to manage these external constraints and plan the program in general, Toronto Hydro will dedicate its efforts in 2015 to selecting suitable locations and obtaining permits and/or lease agreements. Successful completion of these initiatives will help to ensure that the construction and commissioning of the program will be carried out in accordance with the five-year planning period.

E7.11.5.4 Standards & Regulation Adherence

The proposed ESS conforms to best utility practices and adhere to industry standards such as IEEE 1547 Standard for Interconnecting Distributed Resources with Electric Power Systems, CSA C22.3 No. 9 Interconnection of distributed resources and electricity supply systems and CSA C22.2 No. 257 Interconnecting inverter-based micro-distributed resources to distribution systems. There are no applicable construction standards for LSES, GSES and MSES. Toronto Hydro will co-ordinate among its various departments in order to develop these standards.

E7.11.6 Evaluation of Alternatives

E7.11.6.1 Quantification/ Evaluation of Options

Toronto Hydro evaluated two options in order to determine the optimal choice to help realize the potential benefits of the ESS program. These options are explained in detail below.

(i) Status Quo

If Toronto Hydro maintained the status quo, it would not have the ability to utilize ESS as a viable alternative to existing methods and solutions (e.g. capital replacement, major asset upgrades, etc.) to existing and emerging technical issues and limitations on the distribution system. Problems may continue to exist within the distribution system or may require more expensive solutions in the short-term. Additionally, by not implementing the ESS program, Toronto Hydro will not realize the benefits of the applications noted in Table 1.

(ii) Energy Storage Systems (ESS)

The planned ESS program will provide Toronto Hydro with strategic capabilities to address specific issues relating to system efficiency, reliability and power quality, and DG and EV enablement in targeted and areas of the Toronto Hydro distribution system. It will allow Toronto Hydro to mitigate the problems described in Section E 7.11.3 and realize the additional benefits listed in Table 1. The overall cost of this option is an estimated $10.8 million over the 2015 to 2019 period.

The cost of ownership (COO) and program net benefit (NPV) associated with the ESS program is further detailed in Table 15. The cost of ownership for the existing state (COO_E) is zero since there are no ES units with the status quo and no quantifiable benefits or risks associated with the existing state. The cost of ownership for the new state (COO_N) is comprised of additional quantifiable benefit (AQB). Any quantifiable benefit that is associated with the program that is external to asset and non-asset related risk evaluation is quantified for the new state (AQB_N). The benefits used in determining the AQB_N for the first year of activities include deferred distribution upgrades, area regulation, voltage support, congestion relief, supply reserve capacity, power quality, and renewable energy integration. Table 14 provides a summary of the benefits. For further details on the COO approach, please refer to Section D3.3. When the difference in cost of ownership (ûCOO) is compared to the associated program costs (PC) for the first year of activities, the ESS program produces a net benefit (NPV) value of $0.58 million, as shown in Table 14.

TABLE 14: BENEFITS [11] USED FOR AQB_N

Benefit Type	Benefit ($/KW)
Defer Distribution Upgrade	$919
Area Regulation	$1,398
Voltage Support	$400
Congestion Relief	$86
Supply Reserve Capacity	$535
Power Quality	$669
Renewables Integration	$750
Total Benefits	$4,757

This cost of ownership for the new state (COO_N) was calculated using information from Sandia National Laboratories Study on Energy Storage.[12] The report was commissioned by the United States Department of Energy and was meant to provide a high-level framework for assessing the potential benefits of energy storage from an economic perspective. Toronto Hydro mapped the benefits in the Sandia report to the ESS types mentioned in Section E7.11.2 and utilized the average $/kW benefit cost to determine the total $/kW value of each installation during the first year of activities. The values in the report were obtained using standard assumptions for storage power and discharge duration, a 10% discount rate, a 2.5% escalation factor and calculated based on a 10 year life cycle.

TABLE 15: ENERGY STORAGE SYSTEMS PROGRAM BUSINESS CASE EVALUATION (BCE)

Business Case Element	Cost (in Millions)
Option 1: Energy Storage Systems	
Asset Risk [AR_N]	$0
Non Asset Risk [NAR_N]	$0
Maintenance Cost [MC_N]	$0
Additional Quantifiable Benefits [AQB_N]	-$1.1*
Cost of Ownership of New Assets [COO_N]	-$1.1*
Option 1: Project Net Benefit (NPV_1)	
Difference in Cost of Ownership [$\hat{u}COO_1 = (COO_E - COO_N)$]	$1.1
Program Cost [PC_1]	$0.54
Program Net Benefit [$NPV_1 = (\hat{u}COO_1 - PC_1)$]	$0.58

*negative value only for calculation purposes, AQB_N benefit is positive

E7.11.7 2015 Projects

Table 16 lists all projects expected to be partially or completely executed as part of the 2015 work program. Note that the table shows total costs for each project. Depending on the precise start date of each project, portions of the total project cost may be incurred after 2015.

TABLE 16: 2015 PROJECTS

Project Number	Project Name	Cost	Start Date
E31557	LSES Unit 1 – H9M24	$0.10	2015
E31558	GSES Unit 1 – SS68F1	$0.44	2015

E7.11.7.1 E31557 Project Description

Portfolio: System Service

Program: Energy Storage Systems

Project Title: LSES Unit 1 – H9M24

Project Number: E31557

Project Year: 2015

Estimated Cost: $100,000

(i) Objective

To install a LSES system on feeder H9M24 in order to dynamically mitigate an existing phase imbalance and enable the connection of DG.

(ii) Scope of Work

The scope of work involves the installation and commissioning of an LSES system on feeder H9M24. The LSES system will be deployed in to distribution grid and will be interconnected through a radio communication network system that will interface with Toronto Hydro's Control Room. It will serve the purpose of providing dynamic phase balancing. Figure 10 illustrates a map of the project area.

TABLE 17: E31557 SCOPE OF WORK DETAILS

District Neighbourhood	East Toronto
Station(s)	ELLESMERE TS
Feeder(s)	H9M24

TABLE 18: E31557 ASSETS INSTALLED

Assets (Units)	2015
LSES System	1

FIGURE 10: E31557 MAP OF PROPOSED PROJECT AREA

(iii) Justification & Benefits

There are significant numbers of single phase laterals across Toronto Hydro's distribution system. It is difficult to balance load across three phases because it is impossible to accurately predict the usage pattern for every customer and as a result, a phase imbalance of 10% (at the station level) is allowed. A phase imbalance in a three-phase system would result in a return current on the neutral conductor. A return current typically causes line losses and in some cases splices failures (due to overheating). In this specific project, a feeder has a DG unit that will be commissioned on a single phase. A study was conducted after Toronto Hydro was notified of a connection request for a Feed-in-Tariff (FIT) DG contract. The study identified an existing phase imbalance of 13% at the station which does not conform to the 10% threshold. Adding DG at the customer site could potentially exacerbate a phase imbalance, leading to increase in the imbalance along the three phases and larger line losses (increase in the return current). When the DG site was added to the study, the resulting phase imbalance went above the threshold to 17.8%. To mitigate the effects of this DG connection and facilitate the connection itself, Toronto Hydro plans to install LSES system. It is expected that the LSES system will reduce the phase imbalance by 88%, allowing the connection of the DG and reducing the phase imbalance.

E7.11.7.2 E31558 Project Description

Portfolio: System Service

Program: Energy Storage Systems

Project Title: GSES Unit 1 – SS68F1

Project Number: E31558

Project Year: 2015

Estimated Cost: $440,000

(i) Objective

To install a GSES system on feeder SS68F1 in order to dynamically mitigate an existing phase imbalance and enable the connection of DG.

(ii) Scope of Work

The scope of work involves the installation and commissioning of a GSES system on feeder SS68F1. The GSES system will be deployed in to distribution grid and will be interconnected through a radio communication network system that will interface with Toronto Hydro's Control Room. It will serve the purpose of providing dynamic phase balancing. Figure 11 illustrates a map of the project area.

TABLE 19: E31558 SCOPE OF WORK DETAILS

District/Neighbourhood	UPTOWN/Toronto
Station(s)	LESLIE MS
Feeder(s)	SS68F1

TABLE 20: E31558 ASSETS INSTALLED

Assets (Units)	2015
GSES System	1

FIGURE 31: E31558 MAP OF PROPOSED PROJECT AREA

(iii) Justification & Benefits

There are significant numbers of single phase laterals across Toronto Hydro's distribution system. It is difficult to balance load across three phases because it is impossible to accurately predict the usage pattern for every customer and as a result, a phase imbalance of 10% (at the station level) is allowed. A phase imbalance in a three-phase system would result in a return current on the neutral conductor. A return current typically causes line losses and in some cases splice failures (due to overheating). In this specific project, a feeder has a DG unit that will be commissioned on a single phase. A study was conducted after Toronto Hydro was notified of a connection request for a Feed-in-Tariff (FIT) DG contract. The study identified an existing phase imbalance of 8.3% at the station which does not conform the 10% threshold. Adding DG at the customer site could potentially exacerbate a phase imbalance, leading to increase in the imbalance along the three phases and larger line losses (increase in the return current). When the DG site was added to the study, the resulting phase imbalance went above the threshold to 10.4%. To mitigate the effects of this DG connection while facilitating the connection itself, Toronto Hydro plans to install GSES

system. It is expected that the GSES system will reduce the phase imbalance by 73%, allowing the connection of the DG and reducing the phase imbalance.

sustaining Toronto Hydro's operations by providing its employees with a safer environment to operate in an efficient and reliable manner and to provide quality service for customers. Table 1 provides the trigger drivers for capital investments in this category.

TABLE 1: TRIGGER DRIVERS FOR GENERAL PLANT CATEGORY

Driver	Description
Functional Obsolescence	*f* The asset is no longer aligned to Toronto Hydro processes and practices such that it can no longer be maintained (e.g., lack of vendor support) or utilized as intended in support of the utility's business processes.
Safety	*f* Assets are an integral part of maintaining safe work practices, and the failure or lack of support of those assets would likely result in safety-related hazards or risk exposure.
System Maintenance and Capital Investment Support	*f* Required investments to support day to day business operations activities; sustaining operations by providing its employees with a safer environment to operate in an efficient and reliable manner.

Table 2 provides a brief description for each investment program within the General Plant narrative along with total expenditures for each program from 2015 onwards to 2019. Individual section numbers for each investment program can also be accessed from this table.

TABLE 2: DESCRIPTION OF INVESTMENT PROGRAM

Program Index and Name		Brief Description	Total (5 years)	
E8.1	**Fleet and Equipment Services**	As Toronto Hydro's fleet ages, regular vehicle replacement and repair is necessary. This program replaces 24-95 vehicles a year as well as installing new equipment on existing vehicles requiring refresh or replacement, all to ensure the fleet is safe, reliable, and cost-efficient.	**$17.9 M**	
E8.2	**Facilities Management & Security**	Security enhancements are necessary to ensure assets, employees, and the general public are protected by up-to-date security equipment and technologies. Additionally, facilities program is needed to improve the safe, reliable and efficient operation of the work centers and stations as well as increase the overall asset value for all of Toronto Hydro.	**$31.8 M**	/C
E8.3	**Operating Centers Consolidation**	Consolidation of Toronto Hydro's operating centers is required to secure tenure for Toronto Hydro in the northwest and northeast areas of the City while delivering benefits to ratepayers. Toronto Hydro plans to vacate four facilities, two of which it currently owns, and relocate staff, equipment and operations to three facilities already owned by Toronto Hydro to achieve efficiencies and improve space utilization. The utility plans to sell the two surplus Toronto Hydro-owned facilities, crediting the net after-tax gains on sale and related	**$52.2 M**	/C

Program Index and Name		Brief Description	Total (5 years)
		tax savings to ratepayers through rate riders.	
E8.4	IT Hardware Refresh	The program addresses the renewal and maintenance of core backend infrastructure (e.g. servers, storage disks) and endpoint assets (i.e. laptops, desktops) that enable Toronto Hydro to plan and execute capital and operational programs and to fulfill its obligations to customers and applicable regulatory bodies.	$36.7 M
E8.5	IT Software	The Software program covers planned IT upgrades to more than 70 software applications that support Toronto Hydro's core functions and processes. Toronto Hydro must upgrade these applications to ensure their availability to meet operational needs, and to protect itself against cyber threats that could jeopardize the security of the distribution system and the privacy of sensitive operational, customer and employee information. The program also includes initiatives to enhance, modify or implement new software applications that are necessary to optimize business operations, or to comply with external requirements imposed by entities such as Measurement Canada, the OEB and the IESO.	$81 M
E8.6	ERP Implementation	The current end-of-life ERP, Ellipse, will soon no longer be supported by its vendor, introducing a number of technical risks. The program will replace Ellipse and 30 other legacy applications with a new ERP that meets functional requirements.	$51 M
E8.7	Voice Radio System Upgrade	The voice radio system is critical to Toronto Hydro's ability to safely and effectively deliver its planned capital and maintenance programs and to respond to trouble calls in a safe, timely and efficient manner. The current voice radio system cannot be supported by the vendor beyond 2016 and must be upgraded to mitigate safety and operational risks.	$20 M
E8.8	Program Support	This program will perform two studies to enhance the asset management process and improve the long-term and short-term strategy. The first will be a climate adaption study, focusing on at risk areas to extreme weather and climate change. The second will be a customer interruption study to estimate outage costs.	$1.7 M

1 The following Sections E8.1 though to E8.8 contain the details and justification for each capital
2 investment program contained within the General Plant investment category.

E8.1 Fleet and Equipment Services

TORONTO HYDRO BUCKET TRUCKS

E8.1.1 Summary

Program Description

The Fleet and Equipment Services program proposed for 2015 to 2019 funds the acquisition of new vehicles and equipment to replace existing units in accordance with Toronto Hydro's fleet replacement criteria (see Table 4 in Section E8.1.3.2). This program also includes required on-vehicle equipment.

Toronto Hydro plans to maintain a steady vehicle replacement plan focused on minimizing total vehicle life cycle costs. Routine vehicle retirement and replacement is necessary so that Toronto Hydro's fleet remains safe, reliable and cost-efficient. A proactive and timely replacement program ensures that Toronto Hydro will continue to have access to the number and types of vehicles needed to accomplish its distribution function.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Optimal replacement to minimize overall costs to the utility and ultimately, for the rate payer. ƒ Decrease maintenance time and repair costs, and reduced cost to the rate payer.
Safety	ƒ New vehicles resolve potential safety risks that increase as vehicles age ƒ New safety features and devices that improve overall vehicle safety

	ƒ Modern GPS/Telemetry systems include risk management features to monitor vehicle speed, and log safety system performance. ƒ Continuous replacement of rubber line covers ensures product availability
Efficiency	ƒ Vehicles more fuel efficient than older units ƒ Newer vehicles require less maintenance, lowering overall maintenance costs, and increasing overall fleet reliability. ƒ GPS/Telemetry systems enable more rapid outage response.

Program Drivers

The trigger driver and secondary drivers for the Fleet and Equipment Services program are described in the following table.

TABLE B: PROGRAM DRIVER

	Drivers	Reasoning
Trigger Driver	System Maintenance and Capital Investment Support	ƒ Toronto Hydro vehicles transport equipment and personnel to the field, and are used to perform maintenance and investment activities. ƒ Over time, units are subject to wear and tear that will directly impact vehicle safety, reliability, and operational efficiency. ƒ Toronto Hydro requires access to vehicles and equipment that meet current and/or future functional requirements. Over time, operational needs and requirements may change in a manner that necessitates certain vehicle and equipment types, technologies and configurations that are not found in the current fleet.
Secondary Drivers	Safety	ƒ As a vehicle ages, there is an increased potential risk of safety issues such as rust on vehicle structural members, component failure, and electrical faults. These issues can pose a risk to both operators and the public. ƒ Over time and with continued use, rubber cover up units can fail inspection/testing. Failed units must be immediately removed from service and replaced.
	Reliability	ƒ Field failures and unreliable and/or unavailable vehicles can adversely impact Toronto Hydro's ability to provide acceptable levels of reliable customer service. ƒ Rubber that fails visual or electrical testing must be disposed of. Toronto Hydro must have access to cover-up material at all times to ensure that it can perform system maintenance and complete capital investment work in a timely manner.

	Drivers	Reasoning
	Business Operations Efficiency	ƒ Toronto Hydro's policy is to replace vehicles in line with a life cycle assessment, which is intended to minimize the total cost of ownership of Toronto Hydro's fleet, and thus, minimize the costs of the fleet for the rate payer. ƒ As vehicles age, performance – including, but not limited to fuel economy, emissions, acceleration, lifting speed – tends to decline.

Preferred Alternative

Toronto Hydro considered the following options for investing in critical fleet and equipment assets.

(i) Run to failure (i.e. reduce capital spending to zero during the 2015-2019 period)

(ii) Status quo (i.e. spending in line with IRM/ICM years, which would be lower than the planned program for 2015-2019)

(iii) Managed fleet replacement (i.e. the proposed Fleet and Equipment Services program)

Under the "run-to-failure" option, vehicle performance would decline significantly, failures would increase, and crew ability to execute programs and emergency event responses would decrease. Using the status-quo approach is also not preferred due to units being replaced at intervention times which are suboptimal, resulting in higher total lifecycle costs. The preferred managed fleet replacement incorporates modeling which considers multiple lifecycle and resource constraints to maximize utilization and minimize costs.

Timing and Pacing

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Forecasted Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	10.6	11.8	0.79	2.9	2.6	3.6	3.3	3.8	3.6	3.7

Toronto Hydro plans to maintain a consistent vehicle replacement plan that is focused on minimizing total lifecycle costs.

Spending pre-2012 was significant due to increasing support required for work programs. Spending from 2012-2014 was significantly lowered, due to realignment with the IRM/ICM regulatory criteria in that period.

Toronto Hydro is electing to replace the on-vehicle GPS/Telemetry system in 2015 as it is the final year of the support contract for the current system due to maturity and limited support of the existing system.

E8.1.2 Program Description

As of April 30th, 2014, Toronto Hydro's fleet is composed of 660 units, including cars, pickups, bucket trucks and other vehicles, such as sweepers, backhoes and forklifts. The Fleet and Equipment Services program proposed for 2015 to 2019 funds the acquisition of new vehicles and equipment to replace existing units in accordance with Toronto Hydro's fleet replacement criteria (see Table 4 in Section E8.1.3.2). Program expenditures will also include the purchase of required on-vehicle equipment.

FIGURE 1: BUCKET TRUCKS IN THE FIELD

Toronto Hydro plans to maintain a steady vehicle replacement plan focused on minimizing total vehicle life cycle costs. Routine vehicle retirement and replacement is necessary so that Toronto Hydro's fleet remains safe, reliable and cost-efficient. A proactive and timely replacement program facilitates Toronto Hydro having access to the number and types of vehicles needed to accomplish its distribution function. In building the program, Toronto Hydro must primarily consider the inventory of vehicles and equipment that will be needed to support functional needs and performance requirements associated with dynamic capital and maintenance programs. For example, a change in long-term capital plan work mix may require an increase in the number of

transformer installations, which in-turn, requires the vehicle capacity, reach, and cargo-carrying capability of a material handling bucket truck as opposed to that of an auto crane-equipped truck.

FIGURE 2: CUBE VANS PARKED AT 500 COMMISSIONERS STREET

Execution of a proactive and timely replacement plan based on the fleet replacement criteria can also result in the following benefits:

- minimization of total vehicle costs;
- minimization of fleet downtime due to repairs, and a corresponding increase in fleet reliability;
- increases in vehicle efficiency – i.e. lower fuel consumption, and idle reduction via available on-board technology;
- improvements in shop efficiency – as less labour is required to maintain new vehicles, more labour can be allocated to maintain older, less reliable vehicles;

- reduction in environmental impacts – improvements in emissions standards and engine design on newer vehicles will result in a reduction in green house gases emitted by Toronto Hydro vehicles, as well as a reduction in maintenance fluids used – such as engine oil – to maintain them; and,

- safer vehicles – both due to new safety technology offered on newer vehicles, and to a reduced likelihood of field failures that could result in injury to an employee, the public, and/or damage to property.

Toronto Hydro also plans to invest in necessary on-vehicle equipment, including rubber power line covers and a replacement telemetry system. An example of a rubber power line cover is seen below in Figure 3.

FIGURE 3: RUBBER POWER LINE COVER

In accordance with Electrical Utilities Safety Rule 129,[1] workers must comply with safe limits of approach and use equipment - such as rubber power line covers – as protection against electrical shock or burns. These covers require visual inspection prior to each use as well as annual

[1] Infrastructure Health and Safety Association, Electricity Utilities Safety Rules, (Mississauga: Infrastructure Health and Safety Association, 2014) Rule 129. ["EUSR"]

electrical and visual testing by a certified laboratory. Over time and continued use, units will fail inspection/testing, which necessitates immediate removal from service and replacement.

Toronto Hydro vehicles are equipped with a telemetry system (i.e. remote monitoring and measurement system) that provides real-time visibility of vehicle locations and facilitates multiple utility functions such as vehicle dispatching, productivity analysis, vehicle maintenance, public trust reviews (e.g. customer reports) and vehicle risk-management (e.g. accident reconstruction, and tracking of stolen assets for recovery purposes). In the four years since installation, telemetry technology has continued to advance, incorporating new features such as the tracking of trailers (typically a platform or piece of equipment on wheels pulled by a powered vehicle) that do not have onboard power sources, advanced routing, real-time speed vs. speed limit analysis, and enhanced acceleration monitoring capabilities that are not available on the currently installed system. Advanced routing will enable dispatch to direct Toronto Hydro vehicles along specific routes to field assets, helping them to find asset locations faster, and thus maximizing crew efficiency. Identification of more direct routes to assets will also likely result in a reduction in fuel use and green house gas emissions. Real-time speed vs. speed limit analysis and enhanced acceleration monitoring capability will enable improved risk management for licensing purposes, and more focused driver training programs to address driver performance.

Toronto Hydro plans to replace the current telemetry system in 2015, which will require purchase and installation of new hardware in/on vehicles and equipment, integrate new server or front-end software, and implement a new telemetry service licensing agreement. With replacement of the units, it is possible that monthly licensing fees could be reduced – perhaps significantly – from current levels.

The planned total capital expenditures for the Fleet and Equipment Services program are estimated at $17.9 million over the period of 2015 to 2019. Table 1 summarizes projected capital investment by vehicle type between 2015 and 2019. All vehicles selected for replacement meet Toronto Hydro replacement criteria. The ‘Number’ column indicates the number of vehicles to be purchased within each particular vehicle description class. The ‘Cost’ represents the estimated total cost to purchase the ‘number’ of vehicles indicated for that class. Per plan, spend related to vehicle purchases has been limited to approximately $3.6 million year-over-year to avoid spending variation and to limit planning challenges associated with commissioning and decommissioning a high number of vehicles.

TABLE 1: ASSETS TO BE REPLACED BY ASSET CLASS ($ MILLIONS)

	2015		2016		2017		2018		2019

The following table provides a summary of anticipated Fleet and Equipment Services program benefits:

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Replacement of Toronto Hydro fleet assets per the replacement criteria is expected to minimize overall costs to the utility and ultimately, for the ratepayer. ƒ The purchase of new vehicles is expected to decrease maintenance time and repair costs, as well as improve reliability, efficiency and safety providing the opportunity for improved service, and reduced cost to the rate payer.
Safety	ƒ New vehicles resolve potential safety risks that increase as vehicles age (e.g. frame corrosion, critical component failure, and electrical failure). ƒ New vehicles include new safety features and devices that improve overall vehicle safety (e.g. additional airbags, advanced stability and traction control). ƒ Modern GPS/Telemetry systems include risk management features to monitor vehicle speed, and log

	safety system performance. These features can be used to create and enhance driver safety programs. ƒ Continuous replacement of rubber line covers ensures product availability for ongoing maintenance and capital investment
Efficiency	ƒ New vehicles are notably more fuel efficient than older units, and include technology that further enhance manufacturer legislated reductions in fuel use. ƒ Newer vehicles require less planned and unplanned maintenance than older vehicles, lowering overall maintenance costs, and increasing overall fleet reliability. The result is that mechanic labour can be redirected to better maintain older vehicles. ƒ GPS/Telemetry systems incorporate advanced routing and dispatching functions that may enable more rapid outage response.
Other Benefits	ƒ Newer vehicles generally include new technologies that can improve field efficiency such as stability protection and idle reduction devices. ƒ Data provided by modern telemetry systems enable improved asset monitoring – such as unpowered trailer tracking – as well as enhance risk management and asset maintenance. ƒ New telemetry systems may entail new licensing, which could result in lower fees.

E8.1.3 Why the Program is Needed

Toronto Hydro requires vehicles and equipment to transport employees and materials to and from job sites, to perform work onsite, provide an onsite working area and to provide shelter. The principal driver for this program is the need to ensure that Toronto Hydro continues to have access to vehicles that support system maintenance and capital investment during the 2015-2019 period and beyond. Secondary drivers include safety, reliability, and operational efficiency.

E8.1.3.1 Purpose

TABLE 3: VEHICLE REPLACEMENT PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	System Maintenance and Capital Investment Support	ƒ Toronto Hydro vehicles transport equipment and personnel to the field, and are used to perform maintenance and investment activities. ƒ Over time, units are subject to wear and tear that will directly impact vehicle safety, reliability, and operational efficiency. ƒ Toronto Hydro requires access to vehicles and equipment that meet current and/or future functional requirements. Over time, operational needs and requirements may change in a manner that necessitates certain vehicle and equipment types, technologies and configurations that are not found in the current fleet.
Secondary Drivers	Safety	ƒ As a vehicle ages, there is an increased potential risk of safety issues such as rust on vehicle structural members, component failure, and electrical faults. These issues can pose a potential risk to both operators and the public. ƒ Over time and with continued use, rubber cover up units can fail inspection/testing. Failed units must be immediately removed from service and replaced.
	Reliability	ƒ Field failures and unreliable and/or unavailable vehicles can adversely impact Toronto Hydro's ability to provide acceptable levels of reliable customer service. ƒ Rubber that fails visual or electrical testing must be disposed of. Toronto Hydro must have access to cover-up material at all times to ensure that it can perform system maintenance and complete capital investment work in a timely manner.
	Business Operations Efficiency	ƒ Toronto Hydro's policy is to replace vehicles in line with a life cycle assessment, which is intended to minimize the total cost of ownership of Toronto Hydro's fleet, and thus, minimize the costs of the fleet for the rate payer. ƒ As vehicles age, performance – including, but not limited to fuel economy, emissions, acceleration, lifting speed – tends to decline.

System Maintenance and Capital Investment Support

Toronto Hydro's fleet consists of many types of vehicles that are designed for multiple purposes. Fleet vehicles are used to transport both materials and personnel to and from the field. On the job-site, unit uses include, but are not limited to, lifting and positioning material, storing material, preparing material for installation, acting as a planning station and serving as shelter. Fleet vehicles must be available to support these functions in a safe, reliable, and operationally efficient manner.

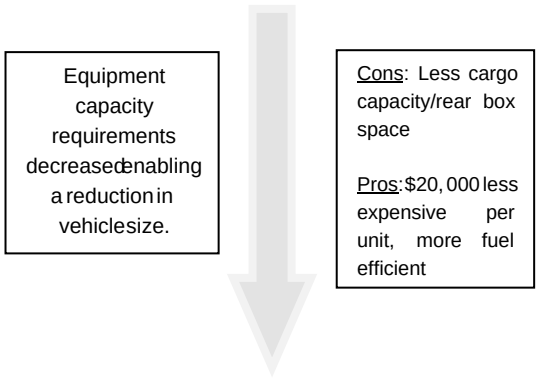

FIGURE 4: EXAMPLE OF A VEHICLE TYPE CHANGE DUE TO A CHANGE IN FUNCTIONAL REQUIREMENTS AT THE TIME OF REPLACEMENT

A consistent replacement cycle enables Toronto Hydro to commission new vehicles that may better meet current and/or future functional requirements, as demonstrated in Figure 8. Toronto Hydro vehicle replacement cycles currently span six to 16 years depending on vehicle type/class. During this period, there is potential that operational needs and requirements change, which necessitates the introduction of vehicles and equipment with new and/or different capabilities and configurations. A fluid vehicle replacement schedule ensures continuous review and commissioning of vehicles that both support, and improve Toronto Hydro's operational efficiency in the performance of its distribution function.

Safety

The following factors can directly impact the safety of a vehicle as it ages.

Corrosion

Toronto Hydro vehicles are used continuously throughout all four seasons and spend much of their operating lives in the outdoors, exposed to the elements. Road salt is commonly used to control snow and ice on City of Toronto roads. Exposure to road salt and moisture eventually leads to vehicle corrosion, which can damage and weaken the frame of the unit over time. The frame is the main structure of a unit, and all vehicle running gear are fastened to it. Thus, the frame supports the entire weight of the vehicle except for the wheels, suspension, and some steering components. Severe rust can lead to frame breaks while under load, e.g., while a unit performs a lift, while performing a cable pull, or while loading material. Frame weakness can also decrease the ability of the vehicle to withstand crashes.

FIGURE 5: UNDERBODY RUST ON A UNIT THAT HAS CHANGED THE SHAPE OF THE FRAME, AND WILL COMPLICATE COMPONENT REMOVAL

Corrosion can also appear on vehicle body panels, weakening them and making them brittle. Brittle panels are then subject to breaking, leaving sharp edges, or presenting a potential fall hazard if the rusting occurs on a step, handle, or vehicle floor.

Corrosion may also occur on components that are critical to the operation of the vehicle, such as transmission and brake lines, that are often not observable between vehicle services. Rust on these components results in weak spots that have the potential to rupture and leak, and/or catastrophically fail while in use. For example, a transmission line rupture could result in a seized transmission. If this occurs while in motion, the operator is at risk of losing

FIGURE 6: CORROSION HAS INFILTRATED INTERFACE BETWEEN AERIAL ELECTRICAL INSULATION AND AERIAL. THE BOOM CANNOT BE USED SAFELY IN THIS CONDITION AND IS VERY COSTLY TO REPAIR

control of the vehicle. Brake line leaks can result in brake failure, possibly leading to a loss of control.

Critical Component Failure

Regular use of the fleet over time can lead to the failure of critical components that are not readily serviceable or observable by maintenance staff. Components such as the hydraulic hoses running through an aerial cannot be directly inspected at service intervals. As the hoses age, they become less flexible and more brittle. Hose failure results in hydraulic fluid leaks to the environment, and could also result in an inability to lower an employee operating a bucket to the ground. Rescuing an employee from an aerial bucket presents a potential risk to both the employee in the bucket, and other field employees who are assisting with the matter.

FIGURE 7: EMPLOYEES PERFORMING FORESTRY WORK IN A TRUCK EQUIPPED WITH AN AERIAL

Electrical Failures/Faults

Manufacturing measures designed to protect electrical circuitry can become compromised as a vehicle ages and wears with regular use, leading to electrical failures. The longer a vehicle is in service, the more likely it is that this will occur. Electrical failures could lead to the disabling of auxiliary safety lighting systems and onboard equipment required as field staff perform their distribution functions.

As noted earlier, in accordance with EUSR 129 workers must comply with safe limits of approach and use equipment - such as rubber power line covers – as protection against electrical shock or burns. It is essential that this material be available for Toronto Hydro to continue to perform all of its intended functions and conform to the law. Further, their use significantly decreases potential exposure risk for Toronto Hydro employees and the public when near exposed conductors.

Reliability

Field crews require vehicles to perform Toronto Hydro's distribution function. Field failures and unreliable and/or unavailable vehicles adversely impact Toronto Hydro's ability to provide acceptable levels of reliable customer service, and could also result in lost productivity or a

disruption to the construction and/or maintenance plans. As is discussed later in this evidence, Toronto Hydro vehicles generally require increasing maintenance as they age; yet, even with these activities, vehicles are more likely to fail while in use or will need to be held out of service for repairs following an inspection as time goes on. Furthermore, parts availability decreases over time. As a result, as a vehicle ages, there is an increased probability that it will taken out of service, and for longer periods of time, while Toronto Hydro procures necessary parts.

Operational Efficiency

A well timed vehicle replacement strategy is required in order to minimizing total fleet costs over time and to ensure the correct vehicles are available to support system maintenance and capital investment plans. As a fleet unit ages, ownership costs (such as purchase cost and cost of capital) decrease as operating costs (such as fuel, maintenance costs, downtime) increase. At a point in the asset's life cycle, the operating costs begin to outweigh ownership costs; total life cycle vehicle costs are at a minimum at a point in time just before operating costs overtake ownership costs. Vehicle replacement at that point in time minimizes total vehicle costs. The optimal time for replacement can be determined by performing a LCA, which has been completed for Toronto Hydro's fleet and is later detailed in sections E8.1.3.2 (ii) and E8.1.4.1.

New vehicles tend to be associated with low maintenance costs in early years, as they tend to experience fewer failures that require repair. As a result, repair staff can be re-allocated to focus older units. In all, this focus can improve unit reliability, which reduces the likelihood of field failures and/or the number of units that need to be taken out of service and repaired.

Field operational efficiency can also be improved with the use of new equipment. Over time and with regular usage, the performance of equipment can decline. Examples of reduced performance include slower equipment acceleration, lower lifting power/speed, braking responsiveness, and operability under load. These issues are largely non-existent in newer units.

E8.1.3.2 Asset Details

(i) Asset Lifecycle

Vehicles

Toronto Hydro vehicles are replaced in accordance with the vehicle replacement criteria outlined in Table 4 below. Prior to 2013, vehicle replacement criteria were two-tiered, with vehicles being categorized as light or heavy. The two categories had unique replacement periods that were determined based on past Toronto Hydro maintenance and replacement experience. Effective 2013, the ages and kilometers of the vehicles drive the replacement timelines for Toronto Hydro's vehicles; these timelines were derived from a third-party life cycle analysis (LCA).[2]

TABLE 4: 2013 VEHICLE REPLACEMENT CRITERIA

Vehicle	KM	Age	Special Considerations
Light Vehicle (Car, SUV, Minivan-Passenger)	>120,000	6-7 years	Exceptions: above average maintenance costs, obsolescence, and unsuitability for the task, poor reliability, excessive downtime and non-availability of parts
Light Vehicle (Minivan - Cargo)	>140000	7-10 years	Exceptions: above average maintenance costs, obsolescence, and unsuitability for the task, poor reliability, excessive downtime and non-availability of parts
Light Vehicle (Pickup, Full Size Van – Passenger/Cargo)	>180000	9-10 years	Exceptions: above average maintenance costs, obsolescence, and unsuitability for the task, poor reliability, excessive downtime and non-availability of parts
Heavy Duty (Single Bucket - Van Mounted)	>160,000	8-9 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Heavy Duty (Cube Van)	>240,000	12-14 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Heavy Duty (Line Truck)	>260,000	13-16 years	Heavy vehicle replacements are routinely evaluated on an individual basis

[2] Richmond Sustainability Initiatives, Toronto Hydro Life Cycle Cost Analysis & Peer Fleet Comparison (Element 2) – Final Report (Report prepared for Toronto Hydro-Electric Limited, 23 May 2013). ["Life Cycle Cost Analysis & Peer Fleet Comparison Report"]

Vehicle	KM	Age	Special Considerations
Heavy Duty (Single Bucket)	>210,000	14-16 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Heavy Duty (Small Digger Truck)	>260,000	13-14 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Heavy Duty (Double Bucket, Large Digger Truck, Small Crane Truck, Small Dump Truck)	>280,000	14-16 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Heavy Duty (Cable Truck)	>320,000	16-18 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Heavy Duty (Large Crane Truck)	>320,000	16-19 years	Heavy vehicle replacements are routinely evaluated on an individual basis
Non-Transportation Equipment			Major overhauling and remounting of hydraulic units including aerial devices, cranes and radial booms derricks is an alternative to replacement. This decision is based on the cost and technical considerations

The LCA identifies the approximate age at which a vehicle's total costs – e.g. ownership, maintenance, driver productivity loss due to reduced vehicle reliability – are minimized. Figure 8 illustrates the lifecycle analysis concept.

FIGURE 8: LIFE CYCLE ANALYSIS CONCEPT

As vehicle age increases, ownership costs decrease, and the cost of vehicle operation (operating costs) increases. LCC (Life Cycle Cost) represents the sum of all ownership and operating costs over the life of a vehicle. LCC is determined by modeling actual and anticipated ownership and operating cash flows for a particular vehicle over multiple years. The projected costs are then used to determine the replacement cycle that results in the lowest overall total cost of ownership (i.e. operating costs plus ownership costs). The period in the cycle in which this occurs is the optimal point at which to replace a vehicle.

Total LCCs and the optimal period of replacement will differ from vehicle to vehicle due to variability in factors such as the vehicle's make, model year, equipment design, initial cost, maintenance costs, and operator usage. Due to this variability, the optimal period is an estimation of the optimal replacement time for most units within the class. Specific vehicles identified by the analysis also require qualitative analysis in the year of tender to ensure that vehicles that are unsafe or are in poor condition are prioritized for replacement, while those that are in excellent condition are not prematurely replaced.

On-vehicle Equipment

Rubber line covers require visual inspection on each use, and at minimum, annual electrical and visual testing by a certified laboratory. Over time and continued use, units can fail inspection/testing, which necessitates immediate removal from service and replacement. Rubber cover-up life is variable, and highly dependent on handling, and use.

Toronto Hydro plans to replace the GPS/Telemetry system in 2015 as it is the final year of the support contract for the current system. Further details on the timing and purpose of GPS/Telemetry system replacement can be found in section E8.1.4.

(ii) Asset Failure Impacts

Toronto Hydro requires an adequate number of vehicles that are safe, reliable, and can be operated and maintained at reasonable cost to accomplish its distribution function. Among other things, vehicle failures could potentially result in the following:

- increasing maintenance costs that, over time, are consistently greater than, or escalate at a faster rate than, a comparable peer vehicle within the fleet;
- potential safety risks to both employees and the public; and,
- failure to meet Toronto Hydro's functional needs or performance requirements, with potential impacts on system reliability and operational efficiency.

As previously stated, EUSR 129 requires that workers comply with safe limits of approach and use equipment - such as rubber power line covers – as protection against potential electrical shock and burns. It is essential that this material be available for Toronto Hydro to continue to perform all of its intended functions and conform to law. When rubber cover-up fails in the field or fails when certified, it is removed from service. If rubber cover-up inventory is not maintained and thus not available when required by field workers, Toronto Hydro may be unable to perform necessary overhead line work.

E8.1.4 Timing & Pacing of the Program

Toronto Hydro plans to maintain a consistent vehicle replacement plan that is focused on minimizing total LCC. Table 5 outlines Toronto Hydro's forecasted cost of unit replacement over the 2015-2019 period, as well as projected on vehicle equipment costs in the same period.

As explained in section E8.1.3.2 (i), the optimal age of replacement is essentially an estimate for a particular vehicle class, and can be interpreted as an optimal age range within which replacement should occur to minimize LCCs. All vehicles were identified as having one- to three-year optimal replacement windows. Total annual projected operating and capital replacement costs were modeled across the age range of replacement for all eligible vehicles with a view to leveling annual capital spend, while also ensuring that the number of vehicles planned for in-service/decommissioning over the year were planned at a rate that can be efficiently managed.

TABLE 4: HISTORICAL AND FORECASTED SPENDING

	Historical Spending					Future Spending				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M) Vehicle Sub-Total	10.1	11.4	0.67	2.00	2.00	3.2	3.2	3.7	3.5	3.6
CAPEX ($M) On-Vehicle Equipment	0.25	0.15	0.06	0.10	0.0	0.4	0.1	0.1	0.1	0.1
CAPEX ($M) Total	10.6	11.8	0.79	2.9	2.6	3.6	3.3	3.8	3.6	3.7

In 2011, Toronto Hydro expanded its plans to renew the fleet per the vehicle replacement criteria in order to reduce the average age of the fleet, while further increasing fleet count. This expansion was driven by concerns about deteriorating unit condition across the fleet, and projected increased operating costs to support maintenance/repairs and expected growth in capital program execution.

Spending from 2012-2014 was significantly lowered, due to realignment with the IRM/ICM regulatory criteria in that period. Toronto Hydro reduced its staff in early 2012, and with this reduction came a corresponding drop in need for vehicles. Over the course of 2012, Toronto Hydro decommissioned and did not replace 66 units that had reached the end of their service lives. As a result of the fleet renewal investments made in 2011, Toronto Hydro had also significantly reduced the average age of the fleet. This age reduction increased overall reliability, which reduced the need for capital investments between 2012 and 2014.

Toronto Hydro plans to replace the GPS/Telemetry system in 2015 as it is the final year of the support contract for the current system. Telemetry technology has developed significantly since the current system was installed, and there is an increase in the number of vendors that now offer this service. For this reason, it is prudent to review hardware options at this time, since a new

system may result in hardware costs and ongoing subscription fees that are significantly less expensive than the services available for the current hardware. Toronto Hydro will issue a Request for Proposal (RFP) to ensure that the vendor(s) with the best value proposition is/are selected for network access and system support. The complexity of performing this upfit, the variability in the features of the telemetry systems available, and the variety of subscription services available to support the system make an RFP process the best method of selecting a vendor.

E8.1.4.1 Ranking & Prioritization

As mentioned in section E8.1.3.2 (i), the replacement criteria were derived from the results of a third-party LCA. The LCA was based on actual Toronto Hydro vehicle ownership data from 2008-2012. As shown in Figures 9 and 10, the analysis indicated that both age and distance traveled (odometer) were strongly correlated with increasing maintenance cost for Toronto Hydro's fleet. Both were ultimately used as principal inputs and outputs for determining the optimal time at which to replace a Toronto Hydro vehicle.

Due to the geographic footprint of the operating territory, Toronto Hydro vehicles travel, on average, 12,000 km per year. 88% of vehicles travel less than 20,000 km per year and 12% of vehicles travel more than 20,000 km per year. If kilometers were to be used as the primary parameter for selection of vehicles for replacement, the variation in annual vehicle travel from year to year would make the task both complex and exceptionally time consuming. At minimum LCC, there could be a number of vehicles that are all the same age but with widely varying odometer readings. Within the kilometer ranges considered, vehicle condition (which must be assessed to validate vehicle replacement) would also likely be highly variable, and a review of a large number of vehicles within a given odometer range would be required before a replacement list could be finalized. Analysis by age provides a common parameter of analysis that progresses in the same manner for all vehicles in the fleet. Therefore, LCC analysis is focused on asset age as the primary replacement criterion. Kilometers travelled are used as a secondary criterion to prompt condition review if a vehicle has exceeded 20,000 km of travel per year.

FIGURE 9: TORONTO HYDRO FLEET MAINTENANCE COST AND RELIABILITY VS. AGE

FIGURE 10: TORONTO HYDRO FLEET MAINT. COST VS. ODOMETER

Toronto Hydro generally conducts quantitative and qualitative analysis of vehicle condition for units identified for replacement in the year prior to the year of replacement. Criteria include:

- Unit safety – an assessment of the safety equipment installed on the unit and how well it continues to accomplish its intended function. Safety equipment includes, but is not limited to, seatbelts, anti-lock brakes, and stability control.

- Body and chassis integrity – an assessment of the unit's appearance and how well the body and chassis have, and will continue to, resist corrosion/wear and tear. Note that significant corrosion/wear can affect body and chassis integrity to the degree that user and public safety is compromised.

- Vehicle Reliability – an assessment of the relative propensity for a part failure and/or total unit failure against units of similar class in the fleet, as well as an assessment of the availability of parts and equipment to service the unit.

- Maintenance – an assessment of the relative cost of maintaining a unit, and/or a determination of the cost required to return a vehicle to a condition that will ensure ongoing productive use.

- Fitness for current function – an assessment of whether the unit is still capable of, or required to, performing the functions for which it was purchased.

The results of the qualitative assessment are used to adjust and determine vehicle replacement priority. Following qualitative assessment, one vehicle may be assessed as poor in multiple categories above (e.g. heavy corrosion on the body and frame, repair costs are above the class average) whereas another may be assessed as excellent in multiple categories. In such a case, the first vehicle will be prioritized for replacement, and replacement of the second vehicle can be deferred and re-assessed in the following year.

E8.1.5 Program Execution

Toronto Hydro usually procures vehicle by drafting a specification and circulating an RFP is to prospective vendors. Vendor submissions are then evaluated across multiple criteria, including cost, compliance with specification, and unit availability. One or multiple vendors may be awarded a bid to supply the requested vehicles. Pre-production meetings are then held as necessary through to delivery of the units. The complete process, from specification through to vehicle delivery – including internal collaboration and approvals – can range from approximately four months to more than one year.

(i) Program Risks

The most significant risk to the successful completion of the program within the planning period is product lead time. Once a vehicle has been technically specified, and the procurement process has been completed, vendors must be awarded the bid and a purchase order must be issued with

sufficient time for the vehicle to be delivered in the current plan year. While unit order size and vendor relationship can at times reduce product lead time, many variables such as the manufacturer's inventory of the requested vehicle, vendor time availability to perform upfits/customizations, and specification complexity, are not controlled by the successful RFP bidder. For example, the successful bidder may only perform the upfit portion of the delivery in-house, and may order all other parts of the unit specified in the tender from another party.

Typical vendor lead times are shown below:

TABLE 5: DELIVERY LEAD TIMES

Vehicle Description	Delivery Lead Time (Months)
Car/SUV/Pick Up/Van	3-6
Cube Van/Line Truck	6-9
Bucket Truck/Cable Truck	9-12
PPE Description	
Rubber Power Line Covers	0-4

The lead-time risk can be mitigated by awarding plan submissions well in advance of the calendar year of purchase. Doing so requires that vehicle review, specification, and RFP distribution are largely complete in the first half of the prior calendar year.

E8.1.5.1 Quantification/Evaluation of Options

Toronto Hydro considered three options for renewing its fleet: run to failure, maintaining previous IRM-level spending, and managed fleet replacement. Each of these options is discussed below.

(i) Run to Failure (Reduce Capital Spending to Zero)

Running the fleet to failure would involve replacing a vehicle only when it could no longer perform its intended functions. Depending on the vehicle type, design, and use, the point of total failure could be several years later than the time prescribed by Toronto Hydro's replacement criteria. While capital costs would be at a minimum (see Table 8 below) during the 2015-2019 period, this is not a viable alternative for the following reasons:

- Vehicle performance is likely to decline significantly over time – though the vehicle may be periodically maintained and capable of performing the intended function, it may do so more slowly, or with compromised precision that will affect Toronto Hydro's productivity and operational effectiveness.

- Unit field failures will likely increase as vehicles age – these field failures will adversely affect field crew productivity, and in some cases result in Toronto Hydro's inability to conduct system maintenance and capital investment as planned. This in turn will lead to higher labour and support costs (such as permits, penalties for late work completion, additional fuel on account of more frequent trips to and from a work location, etc.).

- The severity of failures is likely to increase, and these failures could potentially become more catastrophic, leading to safety risks, injuries, damage to property and/or equipment and environmental spills. For example, hydraulic hoses are more prone to failure over time. A catastrophic hydraulic line failure could, at minimum, result in an employee becoming trapped in a bucket, as well as result in a significant hydraulic fluid spill on to a roadway.

- Toronto Hydro operating costs for repairs are likely to significantly increase as parts fail and are replaced. As the vehicle ages, parts will likely become less available, resulting in increasing costs with respect to their purchase. Furthermore, to keep pace with increasing failures, it may be necessary for Toronto Hydro to increase the frequency of preventative maintenance tasks, as well as the number of mechanics it employs and/or the additional external resources it commissions.

- Perception of Toronto Hydro's level of service, to the extent it is affected by the appearance of Toronto Hydro vehicles and as perceived by Toronto Hydro's customers, may decline as vehicle appearances deteriorate (e.g. rust and fading paint) over time.

- Toronto Hydro may have to significantly increase vehicle/unit count to maintain similar vehicle availability levels to deliver equivalent service levels to customers – as vehicles age, out of service time will likely also increase due to repair challenges that increase as a vehicle ages (such as rusted bolts). This will increase repair complexity as failure modes increase and as needed parts become scarcer over time. To ensure that vehicles are available for use, Toronto Hydro would likely require the use of 'spare' vehicles should the main service vehicles become unavailable on account of maintenance and/or repairs. Toronto Hydro may have to rent or lease new equipment at significant cost.

- Replacement for units that have reached total failure require a lead time of between 3-12 months for purchase and delivery. In that time, Toronto Hydro's ability to perform system maintenance and capital investment may be impaired and/or delayed if alternate units cannot be sourced internally, or via a temporary path such as renting or leasing.

Though total spend for this option is significantly lower than the preferred Managed Fleet Replacement scenario described below, deferring the purchase of all vehicles from 2015-2019 and then implementing a vehicle replacement plan in accordance with the replacement criteria outlined above in section E8.1.3.2(i) will require a minimum investment of $17 million, and the purchase of over 302 units following the forecast period. Generally, due to limited labour availability, limited on-site storage and service space and limited administrative capacity, Toronto Hydro can only reliably in-service and decommission approximately 100 units per year. Under this scenario, it would take over three years before Toronto Hydro's fleet would fully comply with the replacement criteria.

Total cost of the Run Total Failure option (TCTF) is shown below in Table 7.

TABLE 6: TOTAL COST – SCENARIO (I) – RUN TO TOTAL FAILURE

Business Case Element	Cost (in Millions)
Run To Total Failure (Reduce Vehicle Capital Spending to Zero)	
Capital Cost of vehicle and equipment purchases [TC_{TF}]	$0.8

(ii) Status Quo (maintain previous IRM-level spending)

For 2013 and 2014, Toronto Hydro forecasted Fleet and Equipment Services capital program spending of $2.0 million each year. By maintaining this status quo, Toronto would continue to replace vehicles as per the new fleet replacement criteria, but capping replacement purchases at approximately $2.0 million per year.

In executing the status quo, the rate at which vehicles will be replaced will result in an increase in the average age of the fleet by 2.5 years. Operating costs are anticipated to steadily increase over the five-year planning period. Reliability will likely be impacted as the vehicles age, potentially leading to an increase in the number of vehicles that need to be removed from service for repairs, and/or an increase in the number of vehicle failures in the field. As discussed in section E8.1.3.1, this vehicle unavailability and a decrease in reliability will likely have an impact on Toronto Hydro's ability to perform system maintenance and execute capital investment. Like Option 1, the total spend for this option is lower than that of the preferred Option 3. However, to bring the fleet in line with the replacement criteria outlined above in section E8.1.3.2(i), a $12.0 million investment will be required by 2020. The needed pace of investment would be subject to the same resource, storage, and other constraints detailed in Option 1.

Total cost of the Status Quo option (TCQ) is shown below in Table 8.

TABLE 7: TOTAL COST – SCENARIO (II) – STATUS QUO/EXISTING STATE OF INFRASTRUCTURE

Business Case Element	Cost (in Millions)
Status Quo/Existing State of Infrastructure	
Capital Cost of vehicle and equipment purchases [TC_Q]	$10.4

(iii) Managed Fleet Replacement

Toronto Hydro recommends the Managed Fleet Replacement alternative. Under this alternative, Toronto Hydro would undertake a like-for-like replacement of vehicles in line with the fleet replacement criteria outlined in section E8.1.3.2(i), capping vehicle replacement expenditures at an average of $3.4 million per year.

Replacing vehicles precisely to the minimum or maximum recommended replacement ages in the plan will result in capital spending that could swing by up to $4 million from year to year. The number of vehicles to be replaced would also vary greatly year to year, creating logistical challenges with in-servicing and disposing of decommissioned vehicles. Toronto Hydro therefore prefers to adopt a consistent investment spending level of $3.4 million per year to ensure that:

- operating expenses remain relatively stable over the plan years;
- the number of vehicles processed in any given year are manageable by the operation; and,
- the investment required to comply with the fleet replacement criteria post-2019 does not increase suddenly or rapidly.

With the selection of this option, Toronto Hydro ensures that replacement of vehicles identified per the criteria will optimize the total cost of vehicle ownership on average over time, which translates into maximum value for money for customers. Replacement at recommended intervals will likely also generate several benefits, including:

- greater overall vehicle reliability, translating to less downtime, fewer failures in the field, and resulting improved field personnel productivity,
- reduced shop load leading to improved shop productivity,

- likely increases in fleet vehicle and equipment performance,
- improved overall safety of fleet due to new/improved safety systems, and
- improved fuel efficiency leading to reduced green house gas emissions and fuel spend.

This option will result in a $7.5 million increase in total costs – made up of capital costs for asset purchases and maintenance costs – when compared to a Status Quo investment over the 2015-2019 period. However, following this initial level of investment, Toronto Hydro's vehicle replacement cost in accordance with the fleet replacement criteria is projected to remain consistent at approximately $3 million per year following the forecast period.

TABLE 8: TOTAL COST – SCENARIO (III) – MANAGED FLEET REPLACEMENT

Business Case Element	Cost (in Millions)
Managed Fleet Replacement	
Capital Cost of vehicle and equipment purchases [TC_{MF}]	$17.9

E8.2 Facilities Management and Security

E8.2.1 Summary

Program Description

Through the Facilities Management and Security program, Toronto Hydro plans to invest in building improvements that are integral to the proper functioning of Toronto Hydro's electricity system. The operation centers addressed by this program are specialized buildings, each with unique footprints and functions. Investments in this program are classified into five categories according to the relevant building system: security, mechanical, electrical, civil and architectural. Examples of material investments that are planned for the 2015-2019 period in each of these categories include the following.

- Security: Security enhancements are necessary to protect Toronto Hydro's assets as well as its employees and the general public with up-to-date security equipment and technologies. For example, Toronto Hydro plans to continue installing pan-tilt-zoom (PTZ) cameras and access control equipment to improve security infrastructure within stations. Toronto Hydro also plans to replace cameras that have reached or exceeded their life expectancy and are functionally obsolete at 500 Commissioners, 60 Eglinton, and 14 Carlton. Toronto Hydro also plans to install new cameras and security devices to reinforce protection and the safety of critical functions at 500 Commissioners.

- Mechanical: The Building B HVAC system at Toronto Hydro's 500 Commissioners location has reached its end-of-life and requires replacement. Mechanical renewal and modernization projects are also required at 14 Carlton and 60 Eglinton.

- Electrical: The 50-year old panel boards, disconnects and transformers installed at 14 Carlton and 60 Eglinton are obsolete, as many of the breakers, relays and switches are very difficult to source and maintain. These panel boards, as well as the Building Automation Systems at 14 Carlton and 500 Commissioners, must be upgraded during the planning horizon.

- Civil: Toronto Hydro must improve storm water management at 14 Carlton by grading and paving the parking lot to stop water infiltration. Currently, the lobby at this location floods during major storms.

- Architectural: Toronto Hydro plans to address issues regarding the foundation and building envelope – in particular, the brick masonry walls, windows and roofs at various locations. For example, roof replacements at 500 Commissioners, 60 Eglinton and 14 Carlton are required, as Toronto Hydro expects these assets to exceed their respective useful lives within the 2015-2019 period.

The anticipated benefits from these investments are summarized in the following table.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	• Addressing security issues and facility issues can mitigate safety risks to the public and ensures that Toronto Hydro employees are well equipped to provide timely and effective customer service.
Reliability	• Addressing of obsolescent systems which are not functional and unreliable such as BAS upgrades and HVAC/Boiler repair. • Managing risk at facilities reduces risk to system operations and system reliability during event response
Safety	• Security enhancement is a visual deterrent and also increases employee and public safety. • Addressing operational centre issues which pose safety risks (e.g. increased lighting)
Efficiency	• Renovations, heating/cooling to enable greater productivity of employees.

Program Drivers

The following table summarizes the trigger and secondary drivers of the investments in this program.

TABLE B: PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	System Maintenance and Capital Investment Support	ƒ Toronto Hydro's various facilities house support functions that are critical to the effective and efficient operation of all facets of the utility's business, including the planning and execution of maintenance and capital investment programs. ƒ A number of critical building assets have reached the end of their expected useful lives and/or are obsolete (i.e. no longer vendor supported). ƒ Failure of old and/or obsolete building assets can hinder the productive operation of Toronto Hydro's business functions. The failure of certain critical facilities assets could directly impact Toronto Hydro's ability to respond effectively to power interruptions or emergency situations. ƒ Toronto Hydro's facilities continue to require investments in security infrastructure in order to align with NERC standards and to help eliminate potential threats to the visiting public and to utility personnel and property.
Secondary Drivers	Safety	ƒ Employees must be safe in the workplace. ƒ Floors at 500 Commissioners are not smooth or free of potential hazards, which can result in injury. ƒ Unauthorized personnel may be able to enter certain buildings. ƒ Carbon monoxide warning levels are not linked into the BAS system at 500 Commissioners, so a cracked heat exchanger could potentially expel carbon monoxide into the workplace. ƒ The general public should be protected from power outages due to accidental exposure to equipment or deliberate attempts to destroy equipment. ƒ There are 50 stations that are not monitored by CCTV. ƒ Toronto Hydro is at risk of an accidental or deliberate breach that can result in equipment failure. ƒ Occupational Health and Safety compliance. ƒ The temperature of office space at 500 Commissioners and 14 Carlton was not consistently above 18 degrees Celsius during the 2013/14 winter due to several heat exchangers cracking and malfunctioning. ƒ asbestos and other designated substances need to be treated and handled via strict procedures when work commences on these project.

	Drivers	Reasoning
	Failure Risk	ƒ Toronto Hydro buildings feature components that have reached or exceeded their expected useful lives and/or are functionally obsolete. ƒ Maintenance costs for old and obsolete assets are expected to continue to increase over time. ƒ The potential impact on safety and system reliability of certain assets failing is notable. For example, a cracked heat exchanger may allow carbon monoxide (CO) to enter the workplace.
	Reliability	ƒ The capital investment program is required to help ensure that all work centers, stations and the power systems operate as required. ƒ Gates and dock levelers are breaking down due to age, which can delay trucks from getting equipment and leaving the work centers. ƒ Roof top heating units are failing due to age and design and can create unsatisfactory conditions for employees. ƒ Security cameras and equipment are continually breaking down and are not always functioning as required. As of May 23, 2014, there have been 38 camera failures that have been documented for the year.

Preferred Alternative

Maintaining the current state (the "do-nothing" option) is expected to result in a number of consequences requiring emergency attention. These include major facility failures causing flooding and compromised civil structures. The results of the failures could result in injury and interruptions to customer service and business operations. Toronto Hydro's preferred alternative is to proceed with the proactive investments as planned in order to ensure continuity of business operations and efficient delivery of customer service and capital and maintenance programs.

Timing and Pacing

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Forecasted Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	12.1	8.1	6.6	6.8	7.5	16.5	9.4	2.0	2.0	1.9

/C

Facilities Management and Security investments are forecasted to increase in 2015 and 2016 compared to the spending in previous years. Investment is then expected to drop considerably. The initial increase is due to the infrequent replacement of several large building components. These components (such as HVAC systems) are prone to malfunction and/or they put Toronto Hydro at risk of experiencing significant water damage (e.g. roofing systems). These projects are considered urgent and highly non-discretionary for the years scheduled. Routine facilities capital investment is expected to taper off in the later years, in part due to the execution of the Operating Centers Consolidation Program (E7.3).

The total cost of the program over the 2015 to 2019 period is projected to be approximately $32 million. /C

E8.2.2 Program Description

Through the Facilities Management and Security program, Toronto Hydro plans to invest in building improvements that are integral to the proper functioning of Toronto Hydro's electricity system. The operation centers addressed by this program are specialized buildings, each with unique footprints and functions. The buildings are mixed-use facilities, containing warehousing, fleet garage, office space and training centers. Each operations center is described below.

500 Commissioners

FIGURE 1: 500 COMMISSIONERS STREET

500 Commissioners complex is Toronto Hydro's primary service center located on the northeast corner of Carlaw Avenue and Commissioners Street. It is comprised of four buildings (A, B, C and D) and was built in November 1996. 500 Commissioners is Toronto Hydro's Central Service Centre. The buildings are located on 16.8 acres of land and include 94,717 square feet of warehouse space, 213,854 square feet of office space, 51,497 square feet of garage space, 384,299 square feet of parking space and 192,898 square feet of yard space. The structure is a multi-use facility for many divisions, including warehouse, fleet, facilities, call center, engineering and field operations. The complex houses over 700 employees and over 280 system vehicles. 500 Commissioners must be accessible throughout the year at all hours of the day and evening; it is an integral hub in the operation and control of the distribution grid.

500 Commissioners is now 18 years old and, due to its location and other nearby industrial work centers, has shown major signs of aging. To maintain efficient operations, several of the building's systems that are approaching their end of life should be replaced because maintenance can no longer satisfactorily address problem areas. These systems have already undergone repeated repairs and have reached the point at which capital replacement is essential.

14 Carlton

14 Carlton Street is a ten-story office building that was constructed in 1932 to act as Toronto Hydro's original corporate head office. The building was designated a historical site in 1991. It is made up of 179,895 square feet of office space and houses more than 325 employees who work in areas including human resources, finance, law and information technology areas. Like most high rise office buildings, 14 Carlton contains elaborate electrical and mechanical systems spread throughout the building. Over the decades, 14 Carlton has undergone two significant renovations, the most recent of which was completed in 1972.

FIGURE 2: 14 CARLTON STREET (LEFT: FRONT ENTRANCE, RIGHT: REAR ENTRANCE AND PARKING LOT)

Renovating 14 Carlton involves a number of challenges, the most difficult of which is the need to contain and remove asbestos. Asbestos containing materials (ACMs) are found in drainage piping, insulation, floor coverings, wall finishes, electrical panels and heating and cooling systems. Many of these systems need to be replaced, which entails extra cost because of the

legally mandated steps to address ACMs. The renovations to 14 Carlton planned for the 2015-2019 period are needed in order to maintain building comfort, improve safety and decrease costs associated with emergency repairs and maintenance.

60 Eglinton

60 Eglinton Avenue West was constructed in 1954 and operates as a satellite facility that houses 30 employees. The system response group works out of this building throughout the year at all hours of the day and evening. This facility functions as Toronto Hydro's backup control center and houses specialized equipment for power switching functions. The three-storey, 19,626 square feet office building is aging and major system requires replacement, such as the roof, elevator, HVAC and electrical equipment, and interior renovation. Much of the interior to be addressed is known to be affected by ACMs. Investments at 60 Eglinton is designed to maintain occupant safety and comfort and to decrease the cost associated with repairing equipment that lacks readily available replacement parts.

FIGURE 3: 60 EGLINTON AVE. WEST

Stations Facilities

Toronto Hydro has over 215 substations ranging from large scale buildings that house multiple transformers to facilities that resemble small homes with transformer pockets (Figure 4). Toronto Hydro's Distribution System Plan (DSP) includes a separate Stations Building Infrastructure Renewal program (Exhibit 2B, Section E6.18) that addresses the reliability and safety risks associated with aging building infrastructure across the distribution system. The Facilities Management and Security program will focus on security enhancements at a number of stations. Security within these stations is a high priority because they are predominantly unoccupied and remotely monitored. Trespassing on Toronto Hydro properties needs to be prevented in order to maintain public safety and grid integrity.

FIGURE 4: EXAMPLES OF STATIONS FACILITIES

Work in the Facilities Management and Security program can be organized into five major building systems: security, mechanical, electrical, civil and architectural, further explained below.

E8.2.2.1 Security Enhancement

Security enhancements are necessary to protect Toronto Hydro's assets as well as its employees and the general public with up-to-date security equipment and technologies. Toronto Hydro is moving towards North American Electric Reliability Corporation (NERC) standard compliance and is working to implement recommendations noted in the standard surrounding physical security.

Toronto Hydro plans to continue installing pan-tilt-zoom (PTZ) cameras and access control equipment to improve security infrastructure within stations. Since June 2010, Toronto Hydro has been installing cameras and swipe card access at stations to enhance the safety of the facilities, deter crime and provide continuous monitoring. To improve the network, Toronto Hydro intends to expand and install 50 additional cameras at various stations.

In addition, Toronto Hydro plans to replace cameras that have reached or exceeded their life expectancy and are functionally obsolete at 500 Commissioners, 60 Eglinton, and 14 Carlton. These old analogue cameras are set to be replaced with new Internet Protocol (IP) based cameras that have better resolution and offsite, real-time data storage. IP cameras are beneficial because they house data on servers that are centrally located offsite, meaning that the data they collect is protected and easy to monitor remotely. There are a total of 54 Fixed Cameras and 30 PTZ Cameras that Toronto Hydro intends to replace during the 2015-2019 period. Toronto Hydro also plans to make required improvements to the infrastructure that supports these cameras.

Toronto Hydro also plans to install new cameras and security devices to reinforce protection and the safety of critical functions at 500 Commissioners. Toronto Hydro plans on installing the additional cameras in areas that require security improvement such as gate access points, lobbies, entrances, upper level floors and parking lots.

Other projects are needed to prevent and deter unauthorized entries onto Toronto Hydro properties. Toronto Hydro plans to install equipment such as locking hardware, card readers, fencing/gates, lighting, and intercom systems. Toronto Hydro also plans on upgrading vehicle transponders to include the use of a Toronto Hydro badge to open work centre gates. Furthermore, Toronto Hydro plans to renovate the security lobby at 500 Commissioners to accommodate turnstiles and swipe card readers to prevent unauthorized access.

Installing cameras, locking mechanisms, fencing, lighting and signage are expected to provide the following benefits:

- a visual deterrent in crime prevention;
- assists in evidence gathering;
- ensures unauthorized personnel cannot enter restricted areas; and
- helps to improve employee and public safety.

A summary of the forecasted investments for the security projects described in this sub-section is shown below in Table 1.

TABLE 1: SECURITY ENHANCEMENT BUDGET REQUIREMENTS

	2015	2016	2017	2018	2019
SECURITY	$ 2,104,270	$ 2,055,125	$ 202,125	$ 447,125	$ 355,125

/C

E8.2.2.2 Mechanical

Mechanical systems refer to the plumbing, heating, air conditioning, and elevators within a building. A number of mechanical systems and equipment are approaching or have exceeded their life expectancy. Replacing these items is important for reliability, safety and operational readiness. Toronto Hydro plans to replace the mechanical systems and infrastructure at the three buildings outlined below.

500 Commissioners

The Building B HVAC system has reached its end-of-life based on industry standards and requires replacement. Toronto Hydro plans to replace the existing system with a variable air volume (VAV) system. The VAV system is typically found in large office buildings like 500 Commissioners and provides many benefits; it supplies a constant air temperature within the interior of the building while the perimeter zones are heated or cooled as needed, which is a much more efficient design than the existing HVAC system. Maintenance costs are expected to decline because less equipment will be necessary; 35 roof top units in building B are set to be replaced by a few air handling units with a chiller and boiler. Also, a VAV system is more flexible for modifications and expansions purposes if required. To install this type of system, Toronto Hydro needs to remove the existing roof top units and aging Variable Volume and Temperature (VVT) system. Once the existing system is removed, the new air handling system is installed with cooling coils, hot water heating coils, heat recovery wheel, humidification and a fresh air damper.

The emergency exits, overhead doors, dock levelers and yard gates at 500 Commissioners are also in need of replacement. The exits have failed to open during fire drills and the overhead doors and yard gates are frequently breaking down.

Other smaller scale projects include installing new hot water heaters and a steam boiler control. The existing steam boiler control has been turned off due to over humidification.

14 Carlton

The mechanical projects at 14 Carlton focus on replacing items that past end-of-life, functionally obsolete and have a small part supplier network. The projects include:

- Removal and replacement of cast iron drainage. This drainage piping is over 70 years old and there are many cracks that result in leaking sewage. The odour is unpleasant for employees and customers and there is a potential risk of a spill occurring.
- Replace HVAC components that are over 40 years old. These are functionally obsolete as they lack parts and a service network.

60 Eglinton

The projects at 60 Eglinton are smaller in nature and focus mainly on replacing obsolete parts that lack a large supplier network for parts and service. The projects include:

- Replace the parking gate and 10 emergency exit doors. The exit doors are rusted and do not open freely. The doors should be replaced to ensure they open in an emergency. The gate has also reached its end of life.
- Replace condenser and roof top unit. Both are end of life assets that should be replaced since parts are scarce and not available.
- Freight elevator modernization. This will bring the elevator up to current Technical Standards and Safety Authority (TSSA) standards and provide controls and parts that are readily available since the current system is outdated and expensive to maintain.
- Replace chiller and Liebert unit that are at end of life and impacting operating budgets for repairs.

A summary of the estimated cost requirements for all mechanical systems investments is provided in Table 2.

TABLE 2: MECHANICAL PROJECT BUDGET REQUIREMENTS

	2015	2016	2017	2018	2019
MECHANICAL	$ 5,546,000	$ 3,704,500	$ 305,000	$ 165,000	$ 175,000

E8.2.2.3 Electrical

Electrical systems refer to the power distribution system, building automation system (BAS) and the fire and security monitoring system in Toronto Hydro's buildings. The 50-year old panel boards, disconnects and transformers installed at 14 Carlton and 60 Eglinton are obsolete, as many of the breakers, relays and switches are very difficult to source and maintain. Toronto Hydro should not risk using non-standard components in lieu of the Original Equipment Manufacturer (OEM) components since they can potentially cause fires, electrocution and/or additional power outages. Toronto Hydro is also at risk if a failure occurs on one of these long lead, which are special order items that are not found in stock at the wholesalers.

The BAS is an integral part of each facility, as it monitors critical systems and flags issues before failure or damage to other components. The BAS at 14 Carlton and 500 Commissioners is outdated, not centrally located and is difficult to service due to a lack of vendor support. This system has not been very effective in flagging a number of issues within Toronto Hydro buildings. It is the utility's intent to improve the base BAS to expand its capabilities and measure and monitor critical systems within the building with a true BACnet (Building Automation Control)/IP system. This BACnet/IP system is the new industry standard amongst all equipment available on the market. Examples of additional alarms proposed to be installed include:

- floats on sewage ejectors;
- water sensors in critical rooms;
- warning alarms on carbon monoxide levels;
- temperature and humidity probes in critical rooms;
- power failures on critical systems; and
- security breaches.

The potential benefits of a BACnet system include:

- being notified via alarms of critical systems such as floods, sewage back up, high temperatures and system faults;
- scheduling for efficiencies to minimize utility costs during non-business hours;
- trend logs and statistics to help find efficiencies and system faults before failure; and

- connecting all buildings, which helps productivity and efficiency since only one person will be needed to monitor all buildings and flag issues to the building operators.

Other potential electrical projects include the relocation of the emergency lighting and enunciator panel and the replacement of a motor control center panel at 14 Carlton.

The electrical projects within this program are vital to the reliable operation of Toronto Hydro's core business. The BAS upgrades are expected to allow for quicker response times to potential emergencies, and the panel upgrades will minimize risk in buying and waiting for obsolete parts with a shrinking supplier network. The estimated annual costs for the electrical activities in this program are summarized in Table 3.

TABLE 3: ELECTRICAL PROJECT BUDGET REQUIREMENTS

	2015	2016	2017	2018	2019
ELECTRICAL	$ 520,000	$ 22,000	-	$ 170,000	$ 66,000

E8.2.2.4 Civil Work

Civil work refers to the interior and exterior coverings and surfaces of the buildings, access ways, walk ways and windows. The civil work activities in this program are designed to address concerns related to building footprint issues. The projects are also expected to address poor drainage at 14 Carlton where the lobby floods during major storm events, see Figure 17. In 2013, Toronto experienced two particularly severe rain storms, both of which resulted in the main lobby being flooded, where rainwater pooled in the rear stairwell and penetrated through the door opening. In the interim, Toronto Hydro has scheduled expedited and higher frequency catch basin pumping and has sand bags available to seal the rear doorway; however, these are not permanent solutions.

The civil programs Toronto Hydro plans to undertake include:

- Improve storm water management at 14 Carlton by grading and paving the parking lot to stop water infiltration.

- Improve barrier free access at 14 Carlton to allow access for wheelchairs through the rear parking lot. Section 200.15.1.5 of City of Toronto Zoning Bylaw [3] states that accessible parking spaces must be located closest to a main pedestrian access to a

[3] City of Toronto, by-law No. 569-2013, Zoning By-law (9 May 2013). ["City of Toronto Zoning By-law"]

building (specific dimension is not defined). Currently, the barrier-free access directs pedestrians from the rear of the parking lot, through the adjacent alley, and to the front entrance on Carlton Street. Due to the distance between the rear and front of the building, this is not the ideal route for barrier free access.

- Asphalt repair at 14 Carlton's loading dock since it continues to erode, causing large holes. Toronto Hydro plans to initiate a study to determine the cause of the erosion, which could be a damaged water line or artesian well.

- Painting of parking spots and spot numbers at 500 Commissioners.

The forecast cost for the civil works projects are summarized in Table 4 below.

TABLE 4: CIVIL WORKS BUDGET REQUIREMENTS

	2015	2016	2017	2018	2019
CIVIL	$ 395,000	-	-	-	$ 125,000

E8.2.2.5 Architectural

Architectural systems refer to the volumes and functions of a building. Toronto Hydro plans to address issues regarding the foundation and building envelope – in particular, the brick masonry walls, windows and roofs. The described replacement campaigns focus on end of life assets that are becoming increasingly costly to maintain. Proposed projects include:

- Roof replacements at 500 Commissioners, 60 Eglinton and 14 Carlton since Toronto Hydro expects them all to exceed their respective useful lives within the 2015-2019 period. Roof replacements should minimize continuous, expensive and sometimes unsuccessful repairs. Replacing the membranes is expected to provide years of improved protection for the buildings' occupants and assets.

- Repair of the exterior masonry walls and foundation at 14 Carlton; this is expected to eliminate water infiltration into the basement and refresh the appearance of the building, as the exterior walls are severely stained (Figure 25).

- Replacement of the windows at 14 Carlton, as they are producing condensation that stains the masonry walls and creates the conditions for mould growth in the window sills.

Toronto Hydro also plans to renovate the floors at 14 Carlton. The renovation will address issues such as:

- Renewing office space that is past its useful life and no longer suitable for use.
- Populating the now empty 6th floor that has also been stripped to base building foundations in the process of prior asbestos remediation (Figure 18).
- Optimizing the space to the current Toronto Hydro Office Standards.
- Refurnishing the building with standard office furniture, fixtures and finishes.

Each floor currently varies in both age and degree to which ACM's are present. Depending on the floor in question, the construction work required will range from refreshing current finishes that are past their life expectancy to full floor demolition and renovations (Figure 18), which is explained in detail below. Furthermore, the 2nd floor at 14 Carlton houses critical equipment and the floor has many signs of wear including large cracks. The floor must be repaired and reinforced to ensure it can continue supporting this equipment. Floor repair in this room will require special measures to ensure that nearby computer rooms remain free of dust and vibration. /C

The third floor of 60 Eglinton is currently in an inoperable state. It has not been renovated in more than 30 years and the equipment in place is obsolete and not required. The office standards that Toronto Hydro plans to implement at 14 Carlton and 60 Eglinton is currently in place at 500 Commissioners and as a result, the capacity of the building has increased, with the number of occupants in the building rising by approximately 200 employees.

The remaining proposed architectural projects include a number of small scale projects that focuses on common building improvements. These include:

- replacing broken floor tiles and concrete floors at 500 Commissioners to provide clean, smooth floor finishes, which minimize the risk of slips, trips and falls,
- painting at 500 Commissioners,
- washroom renovation at 60 Eglinton,
- removing an abandoned brick chimney at 14 Carlton, and
- structural review at 60 Eglinton, triggered by the fact the building is 60 years old. Performing the study will provide confidence in the buildings integrity and highlight issues Toronto Hydro is not equipped to assess.

The estimated cost of the architectural projects within this program are shown in Table 5 below.

TABLE 5: ARCHITECTURAL PROJECTS BUDGET REQUIREMENTS

	2015	2016	2017	2018	2019
ARCHITECTURAL	$ 7,768,500	$ 3,400,000	$ 1,445,000	$ 1,175,000	$ 1,095,000

/C

In summary, the facilities capital plan focuses on improving building envelopes, properties, equipment and systems. These replacement programs are required to allow Toronto Hydro's core business to operate reliably, efficiently and to comply with legislation.

The following table summarizes the anticipated benefits of this program.

TABLE 6: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Addressing security issues and facility issues can mitigate safety risks to the public and ensures that Toronto Hydro employees are well equipped to provide timely and effective customer service.
Reliability	ƒ Addressing of obsolescent systems which are not functional and unreliable such as BAS upgrades and HVAC/Boiler repair. ƒ Managing risk at facilities reduces risk to system operations and system reliability during event response
Safety	ƒ Security enhancement is a visual deterrent and also increases employee and public safety. ƒ Addressing operational centre issues which pose safety risks (e.g. increased lighting)
Efficiency	ƒ Renovations, heating/cooling to enable greater productivity of employees.

E8.2.3 Why the Program is Needed

Toronto Hydro's Facilities Management and Security program is required to help maintain the safe, reliable and efficient operations of work centers and stations facilities.

E8.2.3.1 Program Drivers

The trigger and secondary drivers of capital investment in this program are summarized in Table 7.

TABLE 6: SUMMARY OF PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	System Maintenance and Capital Investment Support	x Toronto Hydro's various facilities house support functions that are critical to the effective and efficient operation of all facets of the utility's business, including the planning and execution of maintenance and capital investment programs. x A number of critical building assets have reached the end of their expected useful lives and/or are obsolete (i.e. no longer vendor supported). x Failure of old and/or obsolete building assets can hinder the productive operation of Toronto Hydro's business functions. The failure of certain critical facilities assets could directly impact Toronto Hydro's ability to respond effectively to power interruptions or emergency situations. x Toronto Hydro's facilities continue to require investments in security infrastructure in order to align with NERC standards and to help eliminate potential threats to the visiting public and to utility personnel and property.
Secondary Drivers	Safety	x Employees must be safe in the workplace. o Floors at 500 Commissioners are not smooth or free of hazards, which can result in injury. o Unauthorized personnel may be able to enter certain buildings. o Carbon monoxide warning levels are not linked into the BAS system at 500 Commissioners, so a cracked heat exchanger could potentially expel carbon monoxide into the workplace. x The general public should be protected from power outages due to accidental exposure to equipment or deliberate attempts to destroy equipment. o There are 50 stations that are not monitored by CCTV. o Toronto Hydro is at risk of an accidental or deliberate breach that can result in equipment failure. x Occupational Health and Safety compliance. o The temperature of office space at 500 Commissioners and 14 Carlton was not consistently above 18 degrees Celsius during the 2013/14 winter due to several heat exchangers cracking and malfunctioning. o It should be noted that asbestos and other designated substances need to be treated and handled via strict procedures when work commences on these project.

	Drivers	Reasoning
	Failure Risk	x Toronto Hydro buildings feature components that have reached or exceeded their expected useful lives and/or are functionally obsolete. x Maintenance costs for old and obsolete assets are expected to continue to increase over time. o The potential impact on safety and system reliability of certain assets failing is notable. For example, a cracked heat exchanger may allow carbon monoxide (CO) to enter the workplace.
	Reliability	x The capital investment program is required to help ensure that all work centers, stations and the power systems operate as required. o Gates and dock levelers are breaking down due to age, which can delay trucks from getting equipment and leaving the work centers. o Roof top heating units are failing due to age and design and can create unsatisfactory conditions for employees. o Security cameras and equipment are continually breaking down and are not always functioning as required. As of May 23, 2014, there have been 38 camera failures that have been documented for the year.

Each of Toronto Hydro's facilities houses unique support functions that are critical to the ongoing operation, control and administration of the distribution system and other important business functions such as customer service and communications. Every building has specific needs relating to comfort, design and controls depending on the functions housed within. Toronto Hydro believes that it needs to maintain certain basic standards with respect to building attributes so that the employees can continue operating and improving the distribution system and so that they can deliver timely and effective customer service. These standards include:

- a workplace that is heated and cooled to acceptable temperatures;
- building envelopes that do not leak and protect against the elements;
- fresh air that is free of particulates and carbon monoxide;
- hot water faucets and showers for those employees working with controlled substances such as lead;

- unobstructed flooring that does not present tripping hazards;
- properties that are secure against intruders, vandalism and potential injuries; and
- a workplace that is secure and protected from unauthorized individuals.

The following subsections provide a more detailed discussion of the investment drivers behind the planned Facilities Management and Security program, with reference to the trigger and secondary drivers presented in Table 8 above.

Security Deficiencies

Toronto Hydro believes that security enhancement are required to improve public and employee safety, as well as grid integrity. The statistics in Table 8 represent Toronto Hydro's experience with crimes and injuries at all utility sites, including stations. Toronto Hydro is a safety driven organization, the ultimate objective of additional security investments is to eliminate these incidents altogether given the safety and security risks they represent.

TABLE 7: SECURITY INCIDENTS ON TORONTO HYDRO PROPERTY

	2011	2012	2013
Theft	14	21	6
Forced Entry	3	3	5
Vandalism	5	5	6
Injury	14	24	13
Trespass	8	14	5
Threats to Employees	1	7	1

To address critical security and safety concerns at multiple properties and work centres, Toronto Hydro plans to undertake the following projects:

- Installing additional cameras at 500 Commissioners to further improve security of critical functions that cannot be affected.
- Installing additional card swipe access and CCTV camera's at stations. Toronto Hydro should be in a position to monitor the stations and react to safety issues and criminal acts as soon as possible. Card swipe access provides history to track who has been in and out of high voltage areas

- Improve signage at Toronto Hydro stations to ensure the public knows it is private property and cannot be used for recreation, gardening and neighbourhood parties, all of which occurs regularly.
- Install lights to deter break and enters on Toronto Hydro property and neighbouring property.
- Improve and install fencing to ensure people off Toronto Hydro potentially dangerous property.
- Improve security functions in the lobbies and the procedures therein to ensure unauthorized people cannot enter the buildings and areas containing critical components and valuable equipment.

Toronto Hydro has been continuously improving physical security and security policy. It is Toronto Hydro's intent to carry on with upgrades to move toward NERC standards. NERC standards play a significant role in protecting critical infrastructure such as Supervisory Control and Data Acquisition (SCADA) gear and also by layering physical security barriers. Two of the most critical components of the standard ensure that there are video monitoring and access control to monitor who is accessing the equipment and to prohibit unauthorized personnel from entering restricted areas.

Aging and Obsolete Mechanical Systems

Several mechanical systems at 500 Commissioners, 14 Carlton and 60 Eglinton require replacement due to age, lack of parts and functional obsolescence. The major planned projects within this program are the HVAC retrofit at 500 Commissioners, drainage piping at 14 Carlton and doors and gates at 500 Commissioners.

HVAC Systems

Space heating and cooling for the office areas in all three Toronto Hydro owned work centers (500 Commissioners, 14 Carlton and 60 Eglinton) are primarily provided by rooftop HVAC units and VVT damper controls. Most of these units were installed in 1995 or 1996 at 500 Commissioners and in 1970 for 60 Eglinton and 14 Carlton. The existing HVAC units are associated with a number of issues related to age, design and function. Poor design, aging components (Figure 5 below), cracked heat exchangers (Figure 6 below) and high maintenance costs are driving the need to replace this equipment in the 2015-2019 period.

FIGURE 5: RUSTED HEAT EXCHANGERS PRONE TO SPLITTING. COMBUSTION GASES WILL ENTER THE OFFICE SPACE

FIGURE 6: CRACKED HEAT EXCHANGER

From 2011 to 2013, total repair costs associated with HVAC equipment was $472,268 due to over-cycling conditions, further explained below, and the equipment being near its end-of-life based on industry standards.

Problems with the 500 Commissioners HVAC system include:

(1) The duct system is zoned incorrectly between perimeter zones and interior zones. This forces cycling between heating and cooling on a single floor due to the fact that it is hotter near windows in the summer and colder near the windows in winter. The system is satisfying the perimeter temperature needs at the expense of the interior temperatures.

(2) The system is stacked vertically and the three floors continually battle one another between heating and cooling floor to floor, which can affect equipment longevity.

(3) The rooftop units and VVT controls are obsolete and lack a qualified supplier network, making it difficult to obtain spare parts and resulting in extended repair times.

As previously discussed in section E8.2.2.2, to address these issues and provide consistent and comfortable temperatures and functional controls, Toronto Hydro plans to replace the system with a modern VAV system.

Renewal of the HVAC system at 14 Carlton is also recommended. The equipment at 14 Carlton is comprised of central plant equipment, piping distribution of heating and chilled water, and air handling equipment. The air handling systems encompass several outdoor air units, compartment units (one per floor), and perimeter fan coil units for heating and cooling throughout each floor (over 400 units in total). The majority of the air handling equipment was installed in the 1970s and is well past its expected service life. In addition, refurbishment of the chillers are necessary since they are obsolete and past their expected useful life. This was captured on a lifecycle analysis performed in late 2013.

FIGURE 7: CHILLER REPLACEMENT / REFURBISHMENT

Drainage Piping at 14 Carlton

14 Carlton's plumbing systems are insulated with coverings that include ACM's. The drainage piping is, in most cases, the original cast iron piping from 1932 and has become prone to cracking, leading to leaks. Figure 8 shows an example of cracking. The leaks not only produce unsightly stains and spills as shown in Figure 9, but also produce unbearable odours. The drainage system network includes multiple risers throughout the floor plates and is estimated to consist of over 1.25 km of pipe. Due to the age of the drainage piping system, there is also a significant amount of remediation of designated substances such as lead, oakum and asbestos required as part of the replacement work. Failure to replace the piping in a timely manner raises the risk of a major break that could result in a spill that is larger than the one documented in Figure 9.

FIGURE 8: CRACKED DRAINAGE PIPING AT 14 CARLTON.

FIGURE 9: CRACKED DRAINAGE PIPING RESULTS IN STAINS AND SPILLS BASEMENT

Doors, gates and dock levers

Overhead doors are located throughout buildings A, B, and D at 500 Commissioners and were installed in 1995. The automatic doors and associated closing mechanisms that lead to the loading docks and storage areas are showing signs of aging as depicted in Figure 10. Corrosion at the bottom of the door frame can eventually lead to wider door closing gaps and doors not closing completely. Smoke and fire can potentially seep through these gaps, which can possibly undermine the proper fire rating requirements needed to protect individuals and assets. In addition, gaps from doors not fully closed can release heat in the winter. This can create ice, which poses a slipping hazard, strains the heating units, and causes increased demand on natural gas utilities. There are 18 overhead doors in various sizes that Toronto Hydro plans on replacing between 2016 and 2018.

FIGURE 10: CORROSION OF OVER HEAD DOOR FRAME AND RAIL AT 500 COMMISSIONERS.

Exterior doors, which include both single and double doors, are located throughout 500 Commissioners and were installed in 1995. Due to the harsh weather conditions near the lake and the salting of ice, the exterior doors show significant wear and tear, including corrosion. Figure 11 depicts one such example, where both the door and frame are rusted. This type of corrosion resulted in three doors not opening during the 2013 annual fire drill. The affected doors were in the main office and did not open when the occupants were in the stairwell trying to exit. Failing to replace these doors can pose a potential safety risk in the event of a fire.

Figure 12 depicts a door that will not close due to rust. This is a security concern, as these doors can potentially be used to gain unauthorized entry to the building, which in turn puts Toronto Hydro employees and assets at potential risk. There are 44 exterior doors located throughout 500 Commissioners that Toronto Hydro plans to replace during the 2015-2019 timeframe.

FIGURE 11: RUSTED DOOR AND FRAME. THE DOOR PICTURED DID NOT OPEN EASILY AND ONCE OPEN IT DID NOT CLOSE.

FIGURE 12: RUSTED DOOR THAT WILL NOT CLOSE IS A SECURITY AND FIRE HAZARD.

Dock levelers are height-adjustable platforms that are used to bridge the gap between the dock and a truck. Once engaged, fork trucks can load and unload the trucks. Toronto Hydro currently has nine dock levelers and each of them is corroded and have gone through years of wear and tear, as seen in Figure 13 below. Toronto Hydro intends to replace all of these dock levelers between 2015 and 2019 in order to minimize the risk of malfunction and the cost of repair. Figure 14 depicts a locked out dock leveler that is jammed due to corrosion. The parts that are stocked in the warehouse and delivered to the distribution workers rely on the dock levelers daily. In addition, dock leveler design has improved to include better safety features for service.

FIGURE 13: 1 OF 9 DOCK LEVELER'S AT 500 COMMISSIONERS. THEY ARE FAULTING OUT REGULARLY SINCE THEY ARE CORRODING.

FIGURE 14: ONE OF THE DOCK LEVELLERS IS LOCKED OUT DUE TO CORROSION / JAMMING

The gates, like the one shown in Figure 15, and the associated drivers and control units at 500 Commissioners, were installed in 1996 and are expected to reach the end of their useful lives in 2016. The drivers and control units should be replaced to ensure that the eight gates currently in service do not malfunction due to wear and tear, which could cause a delay to construction, line crews and other personnel who rely on fleet vehicles to carry out the day-to-day business of the utility. The gates provide access to Toronto Hydro vehicles and assets such as copper and aluminum, and are therefore critical in preventing trespassing and theft. From January 1 to May 15, 2014 there were 44 work orders to repair four gates at 500 Commissioners, see Table 9 below for details. Of those, 16 of them needed a visit from a gate repair company that resulted in $6,600 worth of repair costs.

Insufficient and Obsolete Electrical Systems

The electrical systems at 500 Commissioners and 14 Carlton are in need of repair and improvement. The projects listed below are required due to functional obsolescence of existing systems and the need for more efficient and effective proactive maintenance planning.

Electrical panel replacements

The 416/240V and 120/208V power distribution system at 14 Carlton is comprised of a number of step-down and step-up transformers, distribution panels, Machine Control Centers (MCC's), panel boards and bus duct with disconnect switches. This equipment was manufactured and installed in the 1960s and has been operating for more than 50 years. The equipment is past its useful life and replacement is needed in order to help avoid power failures and costly maintenance issues. Failure of any part of the components of the system can result in the loss of power to an entire floor, critical mechanical systems or the entire building. Replacement of breakers or disconnect switches is costly and time consuming due to their age, since only refurbished breakers of the same type can be used and obtained from companies specialized in refurbishing old equipment.

The emergency lighting enunciator panel should be moved and consolidated into one panel for certification and permitting.

Building Automation Systems

The BAS is an integral part of each facility, as it monitors critical systems and flags issues before other components experience failure or suffer damage. The current system is outdated and tying in new points and equipment is challenging. When buying and installing new equipment, Toronto Hydro needs to purchase specialized controllers that can communicate with the old BAS. New BAS runs on a BACnet/IP software, which is supported by all current equipment that is available at the present time. Many of the new BASs are capable of tying in more equipment and control. An example of where Toronto Hydro would have benefited from additional controls was a sewage back up at 500 Commissioners. The sanitary sewer was blocked on the city side of the property. The sewage backed up into the central holding tank and overflowed into the parking lot. There were no sensors and alarms available to notify facilities managers before the spill occurred. BACnet compliant high water level sensors could have prevented the spill and improved the utility's response time. This particular example had to be reported to the Ministry of Environment since some of the sewage water entered the storm drains and could have closed the employee

parking lot for remediation. Vehicles around the sewage tank and ejector were evacuated and a comprehensive cleanup was performed. This would most likely cause delays in core services if it was a larger flood, as there are over 500 employees that park their cars in the parking lot.

The BASs at 500 Commissioners and 14 Carlton require improvements in order to tie the new data center and control room into the base building BAS. This process involves new software, controls and equipment. In addition, the current HVAC system is now obsolete and the controls will not tie into the required replacement systems. For instance, the VAV air dampers at 500 Commissioners should be replaced with BACnet/IP controlled equipment that will allow wireless control and monitoring.

Deficient Civil Infrastructure

Storm water retention at 14 Carlton

The employee parking lot at 14 Carlton should be re-graded to more effectively drain storm water away from the building. In 2013 there were two occurrences where the storm drains could not drain the water fast enough (Figures 16 and 17). The water levels increased and water made its way through the rear employee entrance, flooding the lobby. New drainage piping and asphalt surfaces are expected to prevent future disruptions. Since these floods took place, Toronto Hydro has increased the frequency of catch basin cleaning and purchased sand bags as a preventative measure; however, a permanent solution is required.

FIGURE 16: REAR EMPLOYEE ENTRANCE AT 14 CARLTON WHERE WATER POOLS AT THE REAR STAIRWELL.

FIGURE 17: RAINWATER THAT ENTERED THE LOBBY THROUGH THE STAIRWELL

Aging Architectural Systems

The main Architectural projects within this program are: floor renovations at 14 Carlton, roof system replacements at 500 Commissioners and 60 Eglinton, foundation and building envelope repairs at 14 Carlton and renovation of 60 Eglinton's third floor.

Floor Plate Finishes at 14 Carlton and 60 Eglinton

Toronto Hydro believes that floor renovations are required since many of the finishes and furnishings are past their useful lives and are no longer suitable for use. There are also mixtures of furnishing and fixtures that are not readily available and are not standardized throughout 14 Carlton. In order to amalgamate the finishes throughout Toronto Hydro, the facilities group developed standard finishes, colors, coverings, fixtures and furniture that can be implemented at 14 Carlton and 60 Eglinton. Toronto Hydro plans to introduce these new standards wherever existing legacy finishes and furniture are in need of renewal due to age, deterioration or obsolescence. Currently the floors are not common or standard at both buildings. The new standards are illustrated in Figures 18 and 19. 500 Commissioners is the first building that has started to accommodate these standards.

FIGURE 18: COMMON OFFICE AND DESK

FIGURE 19: COMMON OFFICE LAYOUT CONSISTING OF COMMON FURNITURE, LAYOUT AND EQUIPMENT.

Applying these standards corporate wide is needed for several reasons:

- Due to a lack of standardization, Toronto Hydro often faces challenges when trying to adequately addressing ergonomic, light quality and other safety concerns brought forward as safety concerns or WSIB investigations. Having a library of common parts that

passed a rigorous approval process by experts in lighting, ergonomics, interior design and Engineering allows for greater efficiencies in planning future projects and dealing with employee concerns.

- There is inconsistency in floor and office layouts. Common office layouts for managers, supervisors, professional staff, clerks and students are expected to help alleviate the requests for furniture, fixtures and changes.

- The facilities storage rooms are littered with many uncommon parts including lights, ceiling tiles, filters and belts, making them difficult to sort, standardize and clean. Standardizing the components are expected to enable Toronto Hydro to use the warehouse and stock one common part instead of a wide variety.

- Current wayfinding is inadequate, meaning that visitors to Toronto Hydro's various work centers, including employees, customers and service providers, often waste time reaching their destinations.

- Purchasing items in small quantities can be expensive. The reduction in the variety of required equipment and parts could lead to procurements savings from buying bulk items in larger quantities.

Figure 20 depicts the 6th floor at 14 Carlton, which has been renovated to remove ACMs. Toronto Hydro plans to implement the new floor plate finishes described above in this space.

FIGURE 20: 14 CARLTON 6TH FLOOR, MAY 2014.

/C

FIGURE 20: 14 CARLTON 6TH FLOOR, MAY 2014.

The third floor of 60 Eglinton is currently in an inoperable state (see Figure 21 below). This floor was abandoned in places and needs to be improved to allow for planned future occupancy. The doors do not close properly and the finishes, such as tiles and carpets, are deteriorating and have passed their life expectancy. The third floor has not been renovated in more than 30 years and houses critical back-up systems. The renovation is designed to conform to the new standards for square foot optimization and floor plate finishes.

FIGURE 21: 3RD FLOOR OF 60 EGLINTON

Roof Systems

The roof system may be most critical component of a building. There are many important objectives that a roof's design and construction are meant to achieve, including:

- protection of the building and its occupants from wind, rain, sun, snow and ice;
- retention of heat in the building during winter months; and

- drainage of water that accumulates on the roof.

The roof systems at 500 Commissioners, 14 Carlton and 60 Eglinton are in dire need of replacement or repair, as they exhibits many issues including:

- standing water;
- increase in the number of leaks and service calls;
- stained ceiling tiles; and
- cracked and peeled flashing and bubbles in the membrane.

The existing roofs uses an ethylene propylene diene monomer (EPDM) membrane covered with stone ballast (Figures 23 and 24). This design should have a life expectancy of 25 years, but due to the weather conditions at the building's location and the premature wear of the membrane and flashing, the roof should be replaced before 2017. Failing to replace the roof is expected to increase the risk of a failure, which can result in damage to critical infrastructure, systems or functions.

FIGURE 22: CRACKS ALONG FLASHING

FIGURE 23: STONE BALLAST

FIGURE 24: EPDM COMPOSITION.

The roof membranes are tenting around the perimeter and roof leaks are occurring along the flashing and in the central membrane. This has subsequently caused damage to surfaces and assets below. Over the years, many repairs have been done to address the issue but it has now reached a point where repairs are no longer efficient in maintaining the structural integrity of the building. Furthermore, it is very difficult to trace the location of the leak since water will sometimes bypass the membrane under the stone ballast and travel along the vapour barrier and insulation. The leak can then enter the building through a seam in the metal deck a significant distance away

from the actual break in the membrane. Finding and fixing the leaks is time consuming, costly and not always successful.

Foundation and Envelope Repair

The foundation and building envelope at 14 Carlton – in particular, the brick masonry walls and windows – are in need of repair, as observed in Figures 25, 26 and 27. The foundation is leaking and the building envelope (exterior walls, windows, and roof) is deteriorating.

FIGURE 25 - EVIDENCE OF SUSPECTED WATER INFILTRATION IN THE BASEMENT, ADJACENT TO AN AIR HANDLING UNIT

FIGURE 26 - CLOSE-UP OF PEELED PAINT AND DETERIORATED MORTAR JOINTS OF BRICK MASONRY WALL

FIGURE 27 - DETERIORATED BRICK AND MORTAR NEAR THE ROOF LINE ON THE NORTH ELEVATION

The specific issues that Toronto Hydro plans to address are:

- water infiltration into the basement and crawlspace through the exterior wall;
- deterioration of the brick masonry wall on the north elevation and of the penthouse;
- staining of sandstone panels on exterior walls; and
- failure of the glazing seals of the windows.

Repairs are required to mitigate potential hazards such as falling bricks. Replacement of the windows is expected to minimize air/water infiltration into the building and formation of icicles. Failure to address these issues through asset renewal may force Toronto Hydro maintenance staff to handle an increasing number of reactive building maintenance issues. For example, cleaning up problems such as spills, peeling paint and mould are reactive courses of action that use facilities resources. The maintenance staff could otherwise be focusing on preventative

maintenance tasks that keep the critical systems such as the HVAC systems operating without issues.

Interior Renovations

The third floor of 60 Eglinton is currently in an inoperable state since it housed the old critical equipment that is no longer in use. Certain portions of this floor were abandoned and should be improved to allow for future occupancy. The third floor has not been renovated in more than 30 years and houses critical back-up systems. The doors do not close properly and the finishes, such as tiles and carpets, are deteriorating and have passed their life expectancy.

E8.2.4 Timing & Pacing of the Program

As per Table 10 below, Facilities Management & Security investments are forecasted to increase in 2015 and 2016 compared to the steady rate of spending in previous years. Investment is then expected to drop considerably. The initial increase is due in large part to the infrequent replacement of many large building components set to take place in the first two years of the program, as described earlier. For example, the 500 Commissioners roof replacement is estimated to cost $4.8 million, which is nearly equal to the forecasted total expenditures for the program in 2014. Some of the building components, like the drainage piping at 14 Carlton and the roof system at 500 Commissioners have never been replaced or upgraded. They are prone to malfunction and/or they put Toronto Hydro at potential risk of experiencing significant water damage caused by a crack in drainage piping or a leak in the roof system. The increase in spending in 2015 and 2016 is also due to the fact that some of these projects are widespread in nature and address multiple buildings.

TABLE 9: HISTORICAL AND FORECASTED PROGRAM EXPENDITURES

	Historical Spending					Future Spending				
	2010	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
CAPEX ($M)	12.1	8.1	6.6	6.8	7.5	16.5	9.4	2.0	2.0	1.9

/C

Toronto Hydro considers these early program investments to be urgent in nature. A primary concern is that safety is potentially compromised given the current state. In order to provide a safer environment for Toronto Hydro employees and the general public, security enhancements should be undertaken. Currently there are 49 stations with no access control or CCTV cameras. There are no visual deterrents preventing trespassers from entering Toronto Hydro premises.

Trespassers are potentially at risk of injuring themselves, Toronto Hydro employees and the general public by gaining unauthorized access to Toronto Hydro facilities. In addition, with the ongoing consolidation of Toronto Hydro buildings outlined in the Operating Centres Consolidation program (refer to section E8.3), security is of greater concern, as many critical functions will be under one roof and will be in need of enhanced protection.

Major, infrequent equipment replacements (such as the planned HVAC renewal) should be completed as scheduled in order to provide a safer working environment, comply with OHSA standards and minimize the cost of repairs.

E8.2.4.1 Ranking & Prioritization

The sequencing of work within this program is based on the following factors:

- Safety – Projects that are necessary to protect the safety and health of Toronto Hydro employees and customers are generally categorized as highest priority. In particular, the security-related investments planned for 2015-2019 respond to identified gaps in existing security infrastructure, and failure to address these gaps in a timely manner could potentially put the safety and health of employees and customers at risk.

- Protecting Critical Functions and Assets – Toronto Hydro's buildings house many functions and equipment that are essential to the distribution system and the utility's ability to serve its customers. In order to provide these functions, Toronto Hydro employees should be located in buildings that are structurally sound and that provide a safe working environment. In addition, equipment should be secure and protected. Facilities investments that are required to protect the most critical system assets (e.g. stations assets) and utility functions (e.g. control room) will generally be prioritized ahead of less critical capital investments.

- Age and Condition – Equipment and systems that have exceeded their life expectancy, are in poor condition or are otherwise defective or performing to a suboptimal level require timely replacement to avoid the potential service interruptions and costs associated with reactive replacement following failure and growing maintenance costs. Failure to plan and implement replacement in a timely manner can potentially put employee health and safety at risk as well critical business functions and assets. Therefore, assets with the most significant failure risk (i.e. the combination of probability of failure and magnitude of failure impact) are expected to be replaced first. The HVAC

replacements and roof system replacements are two major examples of end of life or poor performing assets that require timely replacement.

- Cost-efficiency: All other factors being equal, Toronto plans investments in a manner that maximizes value, leveraging the pacing of other projects. The timing of the HVAC system replacement at 500 Commissioners is an example of this, where Toronto Hydro's forecast costs include anticipated capital cost savings from engaging the facility contractors who will already be on site in connection with the Operating Centers Consolidation program.

E8.2.4.2 Program Execution

Toronto Hydro maintains strict standards for the execution and construction of facilities-related capital projects. Contractors should be ISNetworld certified, which ensures they maintain strong safety records with minimal lost time injuries, remain in compliance with regulatory standards and possess up-to-date insurance. Competitive bid processes are typically used to tender design firms and construction managers. The current proposed structure utilizes a prime design consultant who manages designs, permits and scope documents. The prime design consultant was awarded the contract via a competitive bid process and is responsible for planning, interior designs, structural engineering, move management, mechanical engineering, electrical engineering and architects. Their work is expected to produce construction prints and scope documents that are handed over to a construction manager. The construction manager is also typically tendered using a competitive bid process. This company is typically responsible for tendering the project to a reputable, preferably low cost bidder, and manages the construction project. The construction manager oversees all trades and sub-contractors.

E8.2.5 Evaluation of Alternatives

The Facilities Management and Security program is needed to help maintain a safe and reliable environment for employees and consumers. The status-quo alternative to carrying-out the investments described throughout this program narrative is explored below.

E8.2.5.1 Quantification/Evaluation of Options

Status Quo Alternative

By maintaining the status quo, Toronto Hydro would delay necessary investments in buildings and stations and instead, would continue to maintain and service the facilities as required. This alternative is not recommended because many assets, such as HVAC equipment, have exceeded their useful lives. In addition, Toronto Hydro would not be able to properly address issues with respect to the safety of Toronto Hydro employees and customers, since some stations would continue to be unequipped with cameras and access control. In addition, maintenance and repair costs are expected to increase. For example, in a four month period, the cost of repairing four gates at 500 Commissioners Street was $6,600. Extrapolating this data, Toronto Hydro can conservatively conclude that it will cost approximately $19,800 per year to repair the gates going forward, and costs would likely increase in future years. This is not an efficient use of Toronto Hydro's resources, as replacing a gate entirely would cost approximately $25,000.

A summary of the issues of maintaining the status quo is provided below.

Not replacing the roof systems at 500 Commissioners and 60 Eglinton can put the continued operations of critical functions at risk, as follows:

- In the event of a major leak, Toronto Hydro may not be able to relocate the call center since it has a specific backup power supply that cannot be duplicated or moved in a timely manner.
- Water leaks could damage critical equipment in the warehouse and transformer rooms.
- Highly specialized equipment that is integral to Toronto Hydro cannot be displaced from their current locations.

Not replacing the drainage piping at 14 Carlton may increase the cost of, and risk the continued operations of critical functions as follows:

- Additional operating expenses related to emergency repairs, displacements and controlled substance removals would be incurred.
- Risk to all building occupants related to water, sewage and controlled substances.

- Risk associated with a major break that can result in damage and/or injury.

A failure to improve and enhance security measures could increase the following potential risks:

- Increasing threat of accidental injuries when individuals access electrical equipment at stations. In addition, service disruptions may occur.
- High security areas like the control center, data center, metering and accounts receivable are susceptible to unauthorized entry putting distribution system operations at risk.
- Failure to meet the recognized need to strengthen efforts to ensure grid security.

E8.2.6 2015 Project Details

The following table lists all of the projects that constitute Toronto Hydro's planned 2015 budget for the Facilities Management & Security program.

TABLE 10: 2015 PROJECTS

500 Commissioners	2015	Reason/Explanation
Base building BAS upgrade	250,000	Obsolete/addition alarms required
floor tile replacement	60,000	Damaged and pose a safety risk
Roof system Building B	2,800,000	Reached end of life and leaking
HVAC Units – Perimeter RTUs	180,000	End of useful life and high repair cost
HVAC system retrofit	1,500,000	End of useful life and high repair cost
Double Exterior Doors	16,000	Rusted and high maintenance cost
Steam Boiler Control	50,000	Equipment is not functional without it
Total	$4,856,000	
14 Carlton	2015	
Due diligence to support parking lot improvement	50,000	Consulting cost
Asphalt settlement near loading dock	60,000	Potential risk for slip, trips and fall
Removal and replacement of parking surface to address drainage/debris	250,000	To prevent flooding inside the building
Concrete ramp for barrier-free access	35,000	To prevent potential risk of injury
Study – Foundation(Subsurface Investigation)	10,000	Identify scope of work for foundation
Repair – Foundation and concrete at grade level	220,000	Insure the foundation is secure
Exterior Brick Wall- Masonry Repainting	10,000	Prevent water infiltration
Exterior Brick Wall- Repainting	40,000	Prevent water infiltration
Exterior Wall-East Penthouse- Partial Brick Replacement	11,000	Repair damaged bricks
Scaffolding to address the above deterioration	80,000	

Study to minimized staining observed on the sandstone panels beneath the windows	10,000	To identify potential water infiltration
Abandoned brick chimney enclosure	7,500	Room required for utilities
Floor plate finishes	800,000	To resurface the old floor plates
drainage Piping	2,900,000	Steel cast drainage system that does not meet standards and contains ACM
2nd floor structural improvement	2,800,000	Remove ACM and concrete floor below a computer room and replace the structural beams and concrete flooring.
Ventilation Equipment	675,000	For better distribution of heat and AC
Cooling/Heating Equipment	110,000	Improve the temperature of building
Cafeteria Exhaust	115,000	Currently obsolete
Total	**$8,453,500**	
60 Eglinton	**2015**	
Structural Review	20,000	Ensure building is structurally sounds
3rd Floor Renovation	900,000	To provide work space for employees
Total	**$920,000**	
Security	**2015**	
Equipment / Install stations	1,500,000	Access control and cameras in stations
Signage	8,550	Increase number of visual deterrents
Cameras Buildings	138,000	Increase security
Cost of Lighting	65,000	Increase safety
Security Infrastructure upgrade	240,000	Improve existing infrastructure for safety
Building Upgrades	93,500	Improve existing infrastructure for safety
	$2,045,050	
Total for internal labour to support projects	**$186,272**	
	$16,460,822	

The list above includes large programs, such as the replacement of the roof, drainage pipe, HVAC equipment and installation of access control and cameras. Delaying these large projects will likely add to the cost of replacement in the future, and the cost of maintenance and repair is expected to increase. For example, the cast steel drainage pipes at 14 Carlton have many cracks, as indicated earlier in Figures 8 and 9; if they are not replaced immediately, the risk of flooding will likely increase and many business units could be affected.

E.8.3 Operating Centers Consolidation Program

E8.3.1 Summary

Program Description

This Operating Centers Consolidation Program (OCCP) concerns the consolidation of Toronto Hydro's operating centers it maintains in the City of Toronto that support core distribution activities. Toronto Hydro's distribution system and business support facilities consist of geographically dispersed, functionally integrated buildings and lands that house customer care, system control, operations and maintenance, distribution engineering and design, system response, business support, and other functions.

Toronto Hydro proposes to exit from four facilities it currently occupies in order to secure tenure at its major northwest and northeast operating centers and mitigate the costs and risks arising from having to relocate its operations in the event that a lease cannot be renewed in the future. Two of the four properties are owned by Toronto Hydro and would be sold, the benefits of which would be returned to ratepayers. The other two properties are under leases set to expire during the 2015 to 2019 period and would be terminated. Staff, equipment and operations at those locations would be relocated to three properties already owned by Toronto Hydro. These facilities require capital investment to be adequately prepared to house these new functions.Program Drivers

The trigger and secondary drivers for this program are summarized below.

TABLE A: PROGRAM DRIVERS

Trigger Driver	Reasoning
System Maintenance and Capital Investment Support	ƒ Securing tenure for Toronto Hydro's major northwest and northeast operating centers. ƒ Transferring uninterruptible Data, Control and Call Centers to locations with certain access to fibre-optic communication facilities.
Secondary Driver	**Reasoning**
Business Operations Efficiency	ƒ Two Toronto Hydro-owned facilities would be sold, the benefits of which would be returned to ratepayers. ƒ Operating costs at disposed properties would be shed. ƒ Utilization of existing facilities would be increased.

Preferred Alternative

Toronto Hydro considered three approaches to this program:

1. **Operations Centres Consolidation (Proposed)**

2. **Status Quo (Base Case):** A general continuation of the status quo, subject to the requirement that Toronto Hydro continue to respond to changing circumstances (e.g., the expiry of existing leases) as well as meeting evolving requirements, such as upgrading and expanding its Data Centre.

3. **Do Nothing**

On a net present value (NPV) basis, the OCCP is expected to reduce Base Revenue Requirements (BRRs) by $23.9 million by the end of 2019 and by $145.3 million over the expected 50 year useful life of the facilities. In contrast, the Base Case scenario increases BRRs over both horizons. /C

Timing and Pacing

This OCCP would be executed in four phases:

(1) The sale of the facility at 5800 Yonge and the transfer of staff, equipment and operations to 500 Commissioners;

(2) The termination of the existing lease at 601 Milner and the transfer of staff, equipment and operations to Toronto Hydro's 715 Milner location subsequent to required capital investment;

(3) The termination of the existing lease at 6 Monogram and the transfer of staff, equipment and operations to Toronto Hydro's 71 Rexdale Boulevard location subsequent to required capital investment; and,

(4) The sale of the facility at 28 Underwriters.

The reduction in BRR includes the costs of making up-front capital investments to adequately prepare the retained facilities for their new use. These investments total $52.2 million during the DSP, as summarized in Table B, and are discussed in further detail on a phase-by-phase basis in Section 8.3.3. /C

TABLE B: HISTORIC AND FUTURE SPENDING

	Historical Spending					Future Spending

E8.3.2 Program Description

E8.3.2.1 Background

The Operating Centers Consolidation Program concerns the consolidation of operating centers to achieve security of tenure at Toronto Hydro's major operating centers supporting distribution system construction and maintenance programs, and to permanently and significantly lower operating center costs. It is also expected to resolve existing requirements and constraints related to expiring leases on existing facilities, and the cessation of critical fibre-optic services at Toronto Hydro's main Data Center. The primary driver for the OCCP is System Maintenance and Capital Investment Support. The secondary, but nevertheless important driver is Business Operations Efficiency.

This program does not involve facilities such as transformer stations, municipal stations, or substations that are integral parts of the distribution system itself. Also it does not pertain to ongoing capital and operating expenditures related to the maintenance and improvement of existing facilities, apart from activities related specifically to the OCCP. Please refer to Facilities Management and Security program (E8.2) for evidence pertaining to distribution system facilities and ongoing support facilities programs.

Toronto Hydro's current operational facilities are described in further detail in the following sub-section. The retained facilities are described in section E8.3.3. Figure 1 below depicts the properties that would be retained and those that would be vacated.

RETAINED  VACATE - SELL / EXIT LEASE

FIGURE 1: TORONTO HYDRO MAJOR OPERATING CENTERS

E8.3.2.2 Toronto Hydro Facilities

Toronto Hydro's distribution system and business support facilities consist of geographically dispersed, functionally integrated buildings and lands that house customer care, system control, operations and maintenance, system response, and other functions.

The OCCP facilities are functionally integrated in that Toronto Hydro conducts various operations and activities to serve its customers, and the overall collection of operations and activities must be housed in suitable facilities. To the extent a given facility is vacated or enlarged, the requirements for the remaining facilities in the portfolio will be increased or reduced accordingly.

In addition, Toronto Hydro considers it vital to maintain operations centers dispersed across the city in order to permit reduced travel times to worksites that are themselves widely dispersed across the city. Toronto Hydro strives to maximize the time spent by crews working directly on the distribution system ("wrench time") and minimize the time spent by crews travelling to the work sites across the City. Because Toronto Hydro's service area is a highly congested urban area,

travel times to work sites become a significant factor in Toronto Hydro's ability to respond to system and customer needs in a necessary and efficient manner.

However, the OCCP does not involve an increase in the number of operating centers (the opposite, in fact), and the locations of future operating centers in the southern, eastern, and western areas of the City will be the same or very close to those of the existing centers.

The existing OCCP facilities, which are the subject of this program, are briefly described below:

5800 Yonge Street

The facility at 5800 Yonge Street (north of Finch Avenue) is owned by Toronto Hydro and currently houses the primary system Control Center and Data Center. Until very recently it also housed the Call Center. The system Control Center is the facility through which Toronto Hydro centrally manages the electricity distribution system and responds to changing system conditions caused by operations and maintenance programs as well as unpredicted outages.

The (internal) Call Center houses Call Center staff and equipment to provide customer care for those customer calls which are not handled through external Call Centers. Generally the internally handled calls relate to more complex issues or larger customers and require a higher level of skill than the outsourced calls.

The Data Center at 5800 Yonge is one of two purposefully redundant Data Centers which house critical information technology equipment vital to the functioning of distribution operations, customer care and billing, and business support functions.

The Call Center, the Control Center, and the Data Center at 5800 Yonge are integral, indispensable parts of Toronto Hydro's operations.

The 5800 Yonge facility also accommodates ancillary requirements such as office space and parking for staff, meeting rooms, and common area facilities. Approximately 300 employees (i.e., Toronto Hydro employees and contract staff) work in or out of 5800 Yonge.

500 Commissioners Street

The facility at 500 Commissioners Street (south of Lakeshore Boulevard at Carlaw Avenue) is Toronto Hydro's largest operations center, comprised of four buildings and associated facilities on 16.8 acres of land. Toronto Hydro owns the buildings and occupies the land under a long-term (99 year) lease signed in February of 1995. It accommodates operations and maintenance staff

and equipment, a materials warehouse, yard, fleet and garage space, the Apprenticeship Training Program, internal staff in Engineering, Field Operations and other departments, and ancillary requirements such as parking and common area facilities. Over 700 employees work at or out of Commissioners.

In emergency or unusual conditions, staff may be dispatched from any operating center to any part of the City of Toronto. Normally, however, the 500 Commissioners facility serves the downtown and southern areas of the city.

601 Milner

The facility at 601 Milner Avenue (between Sheppard Avenue East and the 401, east of Markham Road) is an operations center serving the northeast quadrant of the city. It accommodates operations and maintenance staff and equipment, as well as garage, warehouse and office space, and parking for system and employee vehicles. The property and building are leased by Toronto Hydro, with a lease expiry date of July 2017. Approximately 276 employees work in or out of 601 Milner.

6 Monogram Place

The facility at 6 Monogram Place (at Islington Avenue, south of the 401) is an operations center serving the northwest quadrant of the city. It accommodates operations and maintenance staff and equipment as well as garage, warehouse and office space, and parking for system and employee vehicles. The property and building are leased by Toronto Hydro, with a lease expiry date of November 2016. Approximately 307 employees work in or out of 6 Monogram.

28 Underwriters Road

The facility at 28 Underwriters Road (south of Lawrence Avenue, east of Warden Avenue) is an operations center presently accommodating the centralized System Response function as well as the Investment Recovery (i.e., scrap materials recycling) operation. "System Response" is the collection of activities through which Toronto Hydro responds to and corrects unpredicted faults, outages, and other disruptions to its electricity distribution system.

This facility is owned by Toronto Hydro and consists of two buildings of different vintages (1989 and 1945) situated on 12 acres of land. The System Response operation runs all day, every day and is accommodated with vehicle parking, and material, tool and equipment storage space in the newer building. Investment Recovery operations are conducted in the older building, which has

been partly decommissioned. This site is currently being remediated for the presence of lead and other metals, asbestos, PCBs, and various hydrocarbons.

Approximately 63 employees work in or out of 28 Underwriters. This includes 57 System Response staff and 6 Investment Recovery staff.

E8.3.3 Why the Program is Needed

The purpose of the OCCP is to achieve three primary outcomes:

1) Ensure security of tenure at major crew-supporting operating centers;

2) Ensure the uninterrupted continuation of critical functions (i.e., Data, Control, and Call Centers) by transferring these functions to a location where vital fibre-optic communication facilities and an uninterruptible power supply are certain to be available or can be installed; and,

3) Achieve permanent and significant cost savings for customers through:

    a. Allocating net after-tax gains and related tax savings on sale of properties to ratepayers;

    b. Shedding otherwise ongoing property-related costs associated with the properties to be disposed of; and,

    c. Increasing the utilization of remaining properties.

The OCCP will help ensure Toronto Hydro's security of tenure at its major northwest and northeast operating centers. Toronto Hydro's leases at those two locations are set to expire between 2015 and 2019. By relocating to owned facilities, Toronto Hydro can avoid exposure to unnecessary costs and risks arising from having to relocate its operations in the event that a lease cannot be renewed in the future. For example, standard commercial leases are "free-hold", which require the lessee to return the property back to "ready to lease" state, which can be costly. These costs must be incurred whenever a lease comes up for renewal because there is no guarantee that it will be renewed. Toronto Hydro has protection against such risks and costs at 500 Commissioners due to the unusually long term of lease at that property. The OCCP will extend that protection to its two other crew-supporting centers through ownership.

The crew-supporting operations centers have specialized facility and property requirements compared to centralized administrative operating centers, since they require substantial land for warehouses, zoning for outside storage, and very good access to roads and highways, among other factors. Toronto Hydro expects these attributes to become increasingly scarce in the future.

In addition, the OCCP helps ensure the uninterrupted availability of critical communications facilities and uninterruptible power supply which are vital to the Control Center, Data Center, and Call Center. These functions are essential to Toronto Hydro's continued ability to operate its distribution system safely and effectively, to carry out the billing function and numerous other corporate functions such as payroll and financial reporting, and to provide responsive customer care. It is also expected to resolve existing requirements and constraints related to expiring leases on existing facilities, and the cessation of critical fibre-optic services at the 5800 Yonge Data Center. In addition, it is expected to better match existing and new facilities to system requirements and operations, and enable the relocation and upgrading of Data Center facilities.

By selling properties that become surplus through the execution of the OCCP, Toronto Hydro expects to realize significant net, after-tax gains and related tax savings. Toronto Hydro forecasts that these gains, through the sale of the 5800 Yonge and 28 Underwriters properties, will be approximately [redacted] million dollars. Toronto Hydro proposes that these net, after-tax gains on sale be credited to ratepayers, as described in evidence at Exhibit 8, Tab 1, Schedule 1. This proposal substantially reduces rate impacts associated with Toronto Hydro's overall capital plan.

The execution of the OCCP would result in a net decrease of two operating centers (5800 Yonge and 28 Underwriters). The property-related costs of these operating centers are significant, and disposing of these properties means that Toronto Hydro can permanently shed ongoing operating and capital costs. The substantial cost savings resulting from the disposition of the properties are certain, since the costs are directly tied to the operation of those specific properties, which Toronto Hydro will no longer operate.

The OCCP aims to substantially decrease the total square footage of Toronto Hydro's portfolio of operating centers and will improve space utilization in the remaining facilities. At present, Toronto Hydro's major facilities total 4.2 million square feet inclusive of all indoor and outdoor space. Under the OCCP, square footage is planned to be reduced to approximately 2.6 million square feet, a reduction of 1.6 million square feet or approximately 43%. Total space utilization per person (i.e., total square footage inclusive of all indoor and outdoor space divided by the total number of occupants) is expected to decrease from approximately 2,670 square feet in 2012 to

1,650 square feet in 2017. Existing facilities would be used more intensively and interior office configurations will be updated and standardized to accommodate transferred employees.

The reduction in total square footage is not expected to have adverse effects on Toronto Hydro's performance or cost structure otherwise, since the existing operating centres in the northwest and northeast portions of the City would be replaced by centres that are very nearby and equally advantageous in terms of the efficiency of crew deployment.

The result of these outcomes is expected to deliver a number of benefits, summaries of which are shown in Table 1.

TABLE 1: SUMMARY PROGRAM BENEFITS

Customer Value	ƒ Significant reduction in revenue requirement over the CIR period and for the useful lives of the facilities involved ƒ No expected consequential reduction in operating efficiency or increase in capital and maintenance costs
Reliability	ƒ Maintenance of dispersed operating centres throughout the City enabling more rapid response
Efficiency	ƒ 'Inputs' in the form of support facilities square footage reduced while 'outputs' unaffected ƒ Operational and administrative aspects of facility management streamlined
Other	ƒ Ensures security of tenure at critical crew-supporting operating centres ƒ Improved robustness of critical support facilities enhances readiness to serve customers and respond to system needs in emergency situations

The customer value of the OCCP's proposed approach warrants further detail. The principal aspect of customer value is the significant and enduring reduction in revenue requirements that will result from execution of the program. As set out in detail in the Evaluation of Alternatives section in this schedule, the execution of the OCCP is expected to create a savings of $145.3 million in net present value terms over 50 years relative to a base case. Even over the CIR period, which represents a small fraction of the useful life of the facilities involved, the OCCP creates a reduction in revenue requirements of $23.9 million in NPV terms. /C /C

This benefit is achieved without compromising the ability of Toronto Hydro's operating centres to support its core operations, and without indirectly increasing the costs of those operations.

As noted previously, the actions required to execute the OCCP are as follows:

- The sale of the facilities at 5800 Yonge and 28 Underwriters;
- The termination of existing leases for the 601 Milner and 6 Monogram properties; and,

- Investment in new and existing facilities at 500 Commissioners, 715 Milner Avenue, and 71 Rexdale Boulevard, followed by the transfer of staff and equipment to those properties.

These activities will be executed in four distinct phases. The remainder of this section provides a description and corresponding rationale for each of the four phases.

E8.3.3.1 Phase 1 – Transfer of Staff and Functions From 5800 Yonge to 500 Commissioners

Phase 1 of the OCCP involves the transfer of staff, functions, and assets from 5800 Yonge to 500 Commissioners. 5800 Yonge has historically housed the Call Center, Control Center, and Data Center. All of these are integral and indispensable to Toronto Hydro. The Call Center provides Customer Care. The Control Center centrally manages the distribution system, enabling planned maintenance and construction activities and responding to unplanned outages and other events on the system. The Data Center provides critical IT support to all of Toronto Hydro's functions. In total, approximately 300 employees will be transferred to the Commissioners facility; to date, approximately 170 Call Center employees have been transferred to 500 Commissioners.

At the Commissioners location, the facilities-related infrastructure supporting these functions will be reinforced and enhanced to better facilitate Toronto Hydro's functions under extreme or emergency conditions. These investments include: new electrical power connections, uninterruptible back-up generation, communication links, and security features associated with the Data Center; set-up of the relocated Call Center and Control Center together with associated equipment; and reconfigure office space and provide additional parking for transferred employees. The transfer will also allow critical fibre-optic communications service to continue uninterrupted despite the impending cessation of those services at 5800 Yonge.

This process is complex and many elements overlap; however, a high-level timeline for the project is given below in Figure 2. Toronto Hydro intends to vacate and sell the property by the end of 2015.

Phase 1 Project Time Line											
	2013			2014				2015			
	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4
Design											
Tender/Permits											
Construction											
Staff Relocations to 500 Commissioners											
Prep of 5800 Yonge For Sale											
Sale of 5800 Yonge											

FIGURE 2: PHASE 1 HIGH-LEVEL TIMELINE

Rationale for Vacating 5800 Yonge

There are three major factors that support the vacating and disposing of the 5800 Yonge facility. First, this will create enduring and significant OPEX savings arising from avoided property-related costs, including property taxes, utilities, maintenance, security, and other items. These are expected to be approximately $1.6 million per year on average over the CIR period. In addition, significant capital costs are avoided which are expected to total $16.6 million across the CIR period.

Second, the provision of critical fibre-optic communication facilities, which is necessary to support all three vital functions currently housed at 5800 Yonge, will terminate as of November 2014, pursuant to the contract between Toronto Hydro and the provider.

Third, the opportunity cost to Toronto Hydro of maintaining an owned facility in the intensely developed Yonge Street corridor has significantly increased, due to surrounding development of high-rise condominium and commercial buildings, and the fact that the 5800 Yonge property is the last relatively undeveloped, large property in the area. The 5800 Yonge property consists of the building, but more importantly in the long term, a contiguous parcel of 8.1 acres of land suitable for high-rise development. Toronto Hydro has an opportunity to sell this land for a significant premium over net book value to produce a net, after-tax gain on sale and related tax savings of approximately [redacted] million.

As discussed in detail at Exhibit 8, Tab 1, Schedule 1, Toronto Hydro proposes that the net, after-tax gain on sale of the 5800 Yonge property be allocated to the benefit of ratepayers by means of rate riders.

Preparation of 500 Commissioners to Receive Transferred Staff and Functions

The readying of 500 Commissioners to accept the transferred staff and functions from 5800 Yonge began in 2013 and involves an extensive process of design, procurement and construction to install the various required facilities. The Call Centre was transferred to Commissioners earlier in 2014. The remaining staff and functions are expected to be transferred by the end of 2014.

As set out in further detail below, the capital budget for the modifications at Commissioners is $63.8 million, of which $1.3 million is proposed for the 2015 to 2019 period. The total investment covers diverse items including the reconfiguration of space, provision of facilities and equipment to support the relocated Call, Control, and Data Centres, incremental Data Centre investment and consequential costs such as expanding the employee parking lot. The budget for these expenditures is set out below in Table 2:

/C

/C

TABLE 2: BUDGETED PHASE 1 CAPITAL COSTS FOR 500 COMMISSIONERS

OCCP Budgetr Phase 1		Budget ($000s)

As noted, Toronto Hydro began the process of preparing 500 Commissioners for the transfer of staff and functions in 2013. Table 4 below isolates the items completed to date, and provides the budgeted and actual costs, and variances.

TABLE 4: 500 COMMISSIONERS COMPLETED WORK TO DATE

Name of Project	Status	Budget	Actual Cost	Variance
			$000s	
3rd Fl Conference Rooms	complete	$113.3	$270.4	
3rd Floor Manager Offices	complete	$75.0	$66.6	$8.4
Facilities Space	complete	$169.7	$296.9	
Marshalling Space	complete	$752.0	$869.6	
Supply Chain Space	complete	$466.0	$538.8	
Call Centre	complete	$3,000.0	$2,780.1	$219.9
500C Revitalization	complete	$1,000.0	$408.4	$591.6
Total		$5,576.0	$5,230.7	$345.3

Toronto Hydro has presented the budget for the capital work at 500 Commissioners, but because this project has begun, some amounts will be reflected in 2014 year-end Property, Plant, and Equipment, and some amounts will be reflected in CWIP.

5800 Yonge Decommissioning and Preparation for Sale

After the transfer of staff, functions, and assets from 5800 Yonge to 500 Commissioners, 5800 Yonge would be prepared for sale and marketed. Toronto Hydro anticipates that prospective buyers would wish to purchase the property with the building in a condition appropriate for a short term lease in order to provide cash flow while preparations are made for subsequent development. As such, Toronto Hydro expects to include much of the existing fixtures, furniture, and equipment in the transaction. Toronto Hydro expects to place the 5800 Yonge property on the market by Q2 of 2015 and for the transaction to close by Q4 of 2015.

There are no requirements for significant remediation at 5800 Yonge. However, until the real estate transaction closes, Toronto Hydro will continue to incur costs (which will subsequently be shed) for items including baseline utilities, property taxes, security, and similar items. Toronto Hydro will also incur costs directly related to the marketing and sale of the property, such as real estate commissions. Toronto Hydro estimates the real estate and disposition costs for Phase 1 of the OCCP to be approximately $1.3 million.

Stream of Future Avoided Costs

Table 5 below sets out the categories and amounts of avoided costs Toronto Hydro expects to realize over the CIR period as a result of disposing of the 5800 Yonge property. Over $9.1 million of the $16.7 million capital saving in 2015 is related to capital expenditures on upgrading the Data Centre if Toronto Hydro were to remain at 5800 Yonge. The majority of the remaining capital savings are also IT-related.

/C

TABLE 5: COSTS AVOIDED BY THE DISPOSAL OF 5800 YONGE

Avoided Costsr5800 Yonge Street					
	2015	2016	2017	2018	2019
			$000s		
Operational Savings	$ 843	$ 1,722	$ 1,758	$ 1,795	$ 1,833
Avg 2015r2019	$ 1,590				
Capital Savings	$ 16,722	$ 7,616	$ 7,646	$ 1,517	$ 1,549
Avg 2015r2019	$ 7,010				

E8.3.3.2 Phase 2 – Transfer of Staff and Operations from 601 Milner to 715 Milner

Phase 2 of the OCCP principally involves the transfer of existing staff and functions from the operations centre at 601 Milner to the facility Toronto Hydro owns at 715 Milner. In addition, some staff currently located at 601 Milner would be transferred to 500 Commissioners. No further capital expenditures, apart from those shown for Phase 1, are required for this reason at 500 Commissioners. Some staff from 5800 Yonge will also be transferred to 715 Milner.

A high-level timeline for Phase 2 is presented below in Figure 3.

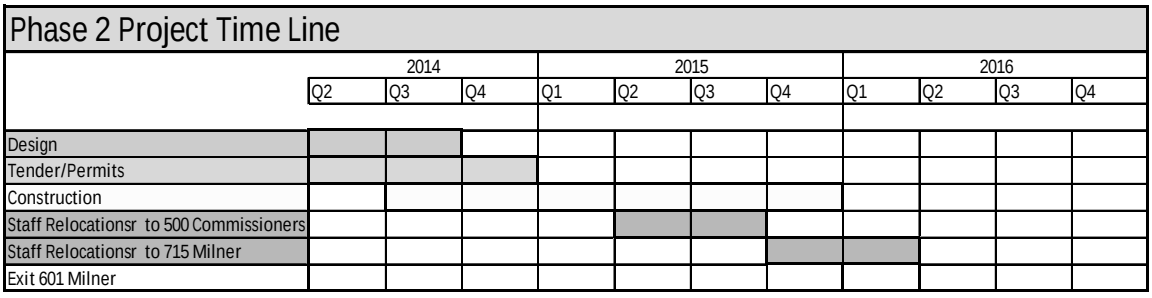

FIGURE 3: PHASE 2 HIGH-LEVEL TIMELINE

Toronto Hydro purchased the 715 Milner property in 2011, with the intention of developing it into an operations center. However, capital constraints have required that development to be postponed until 2014. At present, the building is vacant but it is capable of housing the staff and functions presently accommodated at 601 Milner.

Rationale for Vacating 601 Milner

The principal reasons to vacate 601 Milner and to develop and occupy 715 Milner are to achieve security of tenure for a major operations center and to produce permanent and significant cost reductions.

As noted, by moving to an ownership model for these facilities, Toronto Hydro can avoid unnecessary costs and risks arising from having to relocate its operations in the event that a lease cannot be renewed in the future. Compared to centralized administrative operating centers, the crew-supporting operations centers have specialized facility and property requirements, since they require substantial land for warehouses, zoning for outside storage, and very good access to roads and highways, among other factors.

The lease at 601 Milner expires as of July 2017. Vacating that property is expected to shed significant costs associated with leasing and maintaining that property. Toronto Hydro also plans to terminate the lease at 601 Milner in advance of its expiry. By vacating 601 Milner as of the end of Q1, 2016, Toronto Hydro expects lease savings to cover the cost of early termination of the lease.

The initial capital expenditures necessary to ready 715 Milner are not entirely offset by costs avoided over the CIR period to 2019. However, this is typical for long-term investments in facilities, due to the need to make up-front capital expenditures in order to secure a long-term stream of cost savings. Over the 50 year horizon, the NPV of the reduction in revenue requirement for Phase 2 is [redacted] million.

Preparation of 715 Milner to Receive Transferred Staff and Functions

The building at 715 Milner is essentially vacant at present. Assessment of the building is currently underway to determine exactly what work has to be done to the building envelope to ensure water-tightness, the absence of any contaminants such as mold, and to be energy efficient. It will also determine the need (if any) for structural reinforcement. Several elements of

the building have reached end-of-life and require replacement, including the roof, HVAC units, windows, doors, and seals, and the electrical substation.

Upon completion of the building envelope, the process of fitting the interior space to provide office space and other work facilities will begin. The office space constructed will conform to new standards and configurations also applicable to 500 Commissioners and other operations centers.

Toronto Hydro will renovate the warehouse to provide covered truck parking and upgrade the loading docks. A portion of the existing parking lot will also be converted to outdoor storage.

The budget for the work at this location is $26.8 million, of which $17.8 million is proposed for the 2015 to 2019 period. Further details are set out below in Table 6. Toronto Hydro is expected to complete the readying of 715 Milner to accept the transferred staff and functions by Q4 of 2015.

TABLE 6: BUDGETED PHASE 2 CAPITAL COSTS FOR 715 MILNER

OCCP Budget - Phase 2		Budget ($000s)		
Office Space - Interior Fit-out			$	12,600.0
	Soft Cost for Building Office Fit-out - Incl Furniture	2,700.0		
	Office ground Floor renovated	3,700.0		
	Future IT Space - warehouse unrenovated	250.0		
	Office Ground Floor Warehouse Conversion	2,700.0		
	Swing Space, Second Floor - Renovated	3,250.0		
Warehouse - Interior Fit-out			$	2,750.0
	Soft Cost for Warehouse and Vehicle Storage	300.0		
	Warehouse 1	500.0		
	Warehouse 1	150.0		
	Vehicle Storage	1,800.0		
Parking			$	2,250.0
	Soft Cost for Exterior Parking	200.0		
	LD/MD Parking Exterior	800.0		
	Staff Parking	1,250.0		
Base Building - Building Envelope			$	2,000.0
Ancillary Work - WH Demo			$	400.0
IT			$	3,656.4
Capitalized maintenance during construction			$	3,100.0
		Total Budget	$	26,756.4

Decommissioning of 601 Milner

The costs of exiting the lease at 601 Milner are low. Toronto Hydro will remove its own equipment and fixtures, and perform any other actions pursuant to the requirements of the lease. Most equipment and other chattels, excluding office furniture, will be transferred the short distance to 715 Milner and be reused at that location.

Stream of Future Avoided Costs

Table 7 below sets out the categories and amounts of avoided costs Toronto Hydro expects to realize over the CIR period as a result of disposing the 601 Milner property. The average OPEX cost saving over the 2015 to 2019 period is $2.3 million per year; capital maintenance costs are also avoided. The avoided capital expenditure of approximately $8.8 million relates to the initial capital expenditures on leasehold improvements that are assumed to be necessary when newly occupying a leased facility. Thereafter, capital expenditures resume a normal pattern. The amount was based on historical averages for both the 601 Milner and 6 Monogram facilities.

TABLE 7: COSTS AVOIDED BY EXITING 601 MILNER

Avoided Costs - 601 Milner					
	2015	2016	2017	2018	2019
	$000s				
Operational Savings	$ -	$ 2,057	$ 2,780	$ 3,291	$ 3,360
Avg 2015-2019	$ 2,298				
Capital Savings	$ -	$ 8,850	$ 74	$ 76	$ 78
Avg 2015-2019	$ 1,816				

E8.3.3.3 Phase 3 – Transfer of Staff and Operations from 6 Monogram to 71 Rexdale

Phase 3 involves the transfer of staff and operations from the leased facility at 6 Monogram to the Toronto Hydro-owned facility at 71 Rexdale, which was purchased in June 2014. The reasons for the move from leased facilities to owned facilities in the northwest quadrant of the City are the same as those of Phase 2; the objectives are to achieve security of tenure and long-term cost savings. A high-level timeline for Phase 3 is presented in Figure 4 below.

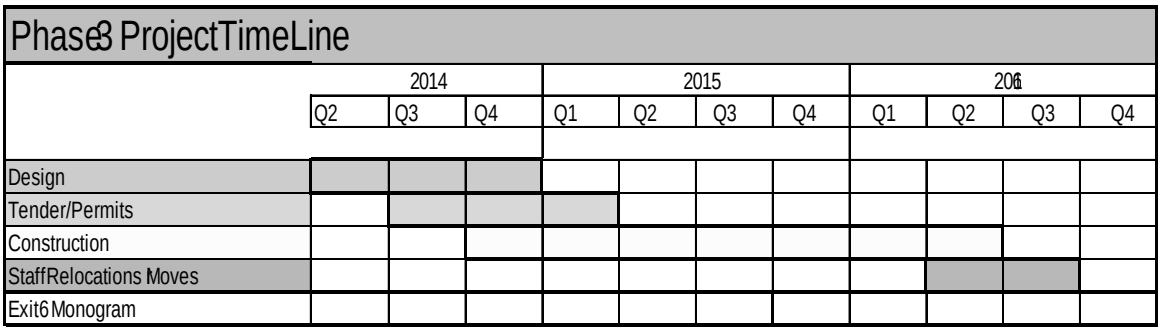

FIGURE 4: PHASE 3 HIGH-LEVEL TIMELINE

Rationale for Vacating 6 Monogram

Toronto Hydro has become aware that the current owners of the property at 6 Monogram intend to sell it. As a result, there is a reasonable likelihood that Toronto Hydro will not be able to renew its lease at the property, which expires in November 2016. Due to the long lead times involved in securing another property, making necessary modifications to it, and transferring staff and functions, Toronto Hydro could not risk waiting until notice is given to it under the terms of the lease for 6 Monogram. As such, it was necessary for Toronto Hydro to acquire a substitute property in the same general location to accommodate staff and functions currently housed at 6 Monogram.

Toronto Hydro needs to maintain a base of operations in the west sector of the city in order to optimize its construction and maintenance programs in that area (for example, by reducing travel time and thereby increasing wrench time). For reasons of tenure security, Toronto Hydro sought to purchase rather than lease a property.

After engaging a firm specializing in commercial real estate, Toronto Hydro was able to purchase the property at 71 Rexdale Boulevard, very nearby the 6 Monogram facility. In May of 2014, Toronto Hydro offered $12.8 million for the property at 71 Rexdale, and after clearing inspection and due diligence, the transaction closed June 13, 2014.

The Rexdale property is a highly suitable replacement for the Monogram facility. It offers excellent access to major roads and is zoned to permit outside storage. The Rexdale property occupies a total of 11.59 acres and is zoned E1, which permits outside storage. Outside storage

is a more economical way to meet Toronto Hydro's storage requirements than having to provide inside storage. Toronto Hydro intends to fully or partially demolish the existing structure and erect a new building designed to meet its needs.

FIGURE 5: 71 REXDALE – DETAILED MAP OF LOCATION

Due to the very recent acquisition of the property, Toronto Hydro has not been able to develop detailed budgets for its development. However, based on initial estimates to construct and fit out office space, warehouse space, and parking, as well as demolition, and the acquisition of the property, Toronto Hydro estimates the Phase 3 capital budget to be approximately $52.1 million,

of which $33.2 million is proposed for the 2015 to 2019 period. The preliminary budget for the construction necessary at Rexdale is set out below in Table 8.

TABLE 8: PRELIMINARY BUDGET FOR COMPLETION OF REXDALE PROPERTY

OCCP Budget - Phase 3	Budget ($000s)
Office Space - Constuction and Fit-out	$ 15,500.0
Warehouse - Constuction and Fit-out	$ 10,500.0
Parking	$ 3,500.0
Ancillary Work - WH Demo	$ 500.0
Land and Building	$ 13,600.0
IT	$ 4,136.4
Capitalized maintenance during construction	$ 4,400.0
Total Budget	$ 52,136.4

Stream of Future Avoided Costs

Table 9 below sets out the categories and amounts of avoided costs Toronto Hydro expects to realize over the CIR period as a result of disposing of the 6 Monogram property.

The avoided capital expenditure totals $9.1 million over the 2015 to 2019 period. The majority of this ($8.9 million) relates to the initial capital expenditures on leasehold improvements that are assumed to be necessary when newly occupying a leased facility; thereafter, capital expenditures resume a normal pattern. The amount was based on historical averages for both the 601 Milner and 6 Monogram facilities.

[redacted]

TABLE 9: COSTS AVOIDED BY EXITING 6 MONOGRAM

Avoided Costs - 6 Monogram						
	2015	2016	2017	2018	2019	
	$000s					
Operational Savings	$ r	$ 321	$ 4,521	$ 4,616	$ 4,713	
Avg 2015-2019	$ 2,834					
Capital Savings	$ r	$ 8,850	$ 74	$ 76	$ 78	
Avg 2015-2019	$ 1,816					

E8.3.3.3 Phase 4 – Disposal of Surplus Property at 28 Underwriters Road

Phase 4 of the OCCP involves vacating and selling the facility at 28 Underwriters Road. This location has historically housed the System Response and Investment Recovery functions.

System Response is the collection of activities through which Toronto Hydro responds to unplanned outages and other trouble events on its system. Independent of the OCCP, Toronto Hydro has begun the process of de-centralizing the System Response function to dispersed System Response sites throughout the City to improve response times to those calls, reduce outage times (i.e., SAIDI) and improve customer service.

Investment Recovery is the activity through which Toronto Hydro recycles metals and other materials from its operations. Toronto Hydro also plans to outsource the Investment Recovery operation thereby eliminating the need to provide space within Toronto Hydro facilities for that function.

These two processes are expected to be complete by the end of 2014. As a result, the Underwriters facility will become surplus to Toronto Hydro's operating requirements. Toronto Hydro proposes to dispose of the property and return the estimated net, after-tax gains on sale of approximately [redacted] million to ratepayers. Toronto Hydro expects the transaction to close by 2014 year end or Q1 of 2015.

Rationale for Disposing of 28 Underwriters

As noted, 28 Underwriters is no longer required to support the System Response and Investment Recovery functions it has housed. Selling the property would realize permanent and significant cost savings from shedding the costs of holding and maintaining the property, and to make net after-tax gains on sale from the sale of Underwriters available to ratepayers. The cost savings over the CIR period are approximately $0.8 million per year, and the net, after-tax gain on sale for distribution to ratepayers is forecast to be approximately [redacted] million.

Decommissioning of 28 Underwriters

28 Underwriters has historically been used as an industrial site. It is currently undergoing environmental assessment and remediation for the presence of lead and other metals, asbestos, PCBs, and various hydrocarbons.

Upon completion of the remediation process, and the transfer of System Response equipment and staff, 28 Underwriters will be prepared for marketing. Toronto Hydro intends to market the property in clean, vacant, but otherwise "as is" condition, and does not anticipate any modifications to or demolition of either of the buildings on the site by Toronto Hydro.

Toronto Hydro anticipates that the work to prepare 28 Underwriters for sale (including transfer of the System Response function) will be complete by the end of Q3 2014, and that closing of the sale transaction could occur by the end of 2014 or Q1 of 2015. During the interim period between the vacating of 28 Underwriters and closure of the sale transaction, Toronto Hydro will continue to bear property-related costs, although at a reduced level reflecting vacant, baseline maintenance of the facility.

Stream of Future Avoided Costs

By disposing of the Underwriters property, Toronto Hydro expects to save approximately $800,000 per year in operating costs, as well as a further $100,000 per year in capitalized maintenance costs.

Table 10 below sets out the categories and amounts of avoided costs Toronto Hydro expects to realize over the CIR period as a result of disposing of the Underwriters property.

TABLE 10: COSTS AVOIDED BY DISPOSING OF 28 UNDERWRITERS

Avoided Costs – 28 Underwriters						
	2015	2016	2017	2018	2019	
	$000s					
Operational Savings	$ 750	$ 766	$ 782	$ 798	$ 815	
Avg 2015-2019	$ 782					
Capital Savings	$ 100	$ 102	$ 104	$ 106	$ 109	
Avg 2015-2019	$ 104					

E8.3.4 Timing & Pacing of the Program

Timing and Pacing of the OCCP

The expected timelines for the OCCP are detailed on a phase-by-phase basis in Section 8.3.3.

E8.3.5 Program Execution

E8.3.5.1 Program Management

Toronto Hydro has assembled a team composed of internal staff and external, contracted resources to manage the execution of the OCCP from initial stages of requirements identification through to completion of construction and occupation of the re-developed facilities.

Toronto Hydro has significant internal expertise in managing its own facilities and has relied on internal staff in Customer Care, Information Technology, and Operations and Maintenance, to identify requirements. Toronto Hydro's internal team consists of representatives from these areas as well as staff and executives specifically charged with overseeing each aspect of the project and the overall project itself.

In three principal areas Toronto Hydro does not maintain internal expertise since needs are transient and are not core to distribution activities. These are real estate evaluation, acquisition, and disposition; facilities design; and facilities construction management. In these areas Toronto Hydro has secured responsible contractors through competitive tendering practices conducted in accordance with Toronto Hydro's procurement policy.

Toronto Hydro has established an Integrated Project Team (IPT) consisting of internal staff and representatives of the contractors to manage the overall project. The structure of the IPT is shown in Figure 6.

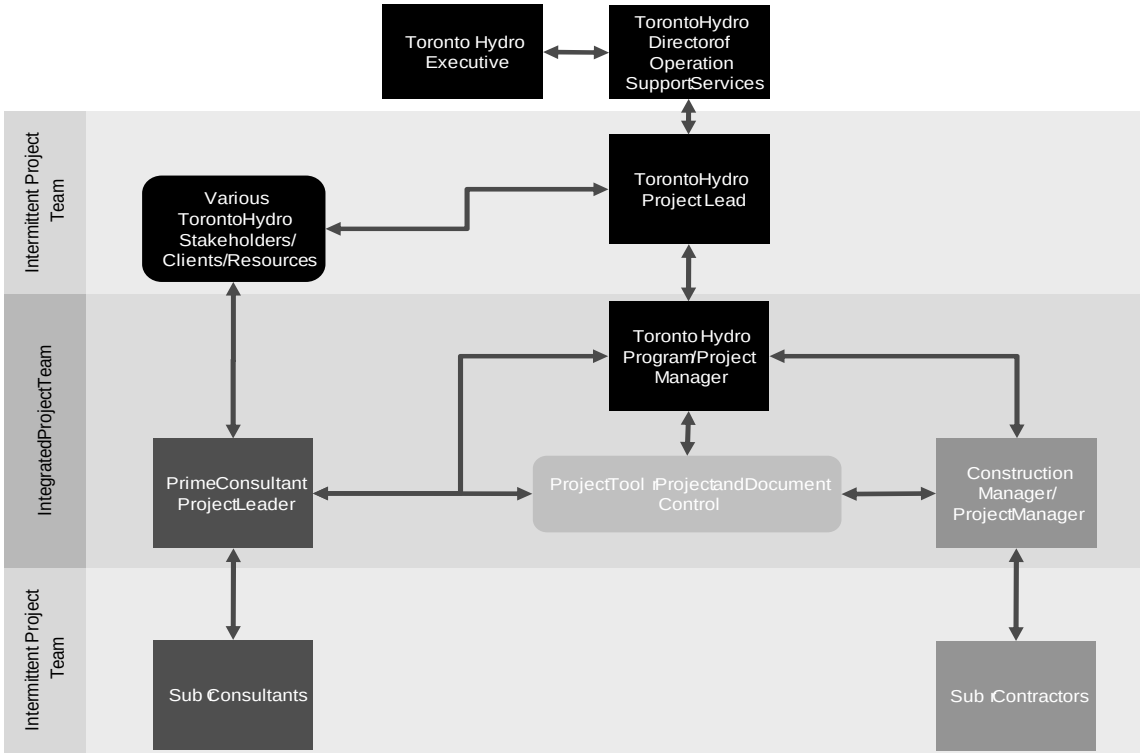

FIGURE 6: INTEGRATED OCCP TEAM

Toronto Hydro Oversight

The Toronto Hydro OCCP team consists of the Integrated Project Team (IPT) dedicated to the project as well as various internal resources including members of the Executive, client groups, and staff with special expertise in areas such as information technology, and environment, health, and safety. The IPT will serve as the single point of contact for external contractors and will ensure that schedule, cost, and quality requirements are met throughout the project.

External resources are also engaged, with a summary of their roles below:

- Real Estate
  - DTZ Canada Inc. has been engaged through a competitive procurement process to provide services related to the disposition of the 5800 Yonge and 28 Underwriters properties, and the sourcing of the Rexdale property.

- Prime Consultant
  - Bennett Design Associates has been engaged through a competitive procurement process to provide the comprehensive design components of the program delivery.
- Sub-Consultants
  - Engaged by the Prime Consultant to support and provide specialized expertise on an as required basis through the life cycle of the program.
- Construction Manager
  - Govan Brown Construction Managers has been engaged through a competitive procurement process to deliver the comprehensive construction and physical implementation components of the program delivery
- Sub-Contractors
  - Competitively procured and contracted by the Construction Manager to supply and install the physical construction on a per trade or discipline basis through the lifecycle of the program.

E8.3.5.2 Program Risks

Toronto Hydro's OCCP is exposed to risks that are commonplace in construction projects. No unusual or elevated risks have been identified. Nevertheless, Toronto Hydro is acting to mitigate existing risks to the degree reasonably possible, by, for example, applying for permits and required approvals as early as possible and on a phased basis where possible.

Phase 1

There is a risk that some required materials and equipment may not be available on a timely basis. Some aspects of Phase 1 construction and equipment installation involve complex equipment such as generators and electrical substations. Manufacturers of this equipment are operating at or close to capacity to meet growing global demand, and long lead times are required for certain types of equipment and materials. Toronto Hydro has pre-ordered material where it has been possible and prudent to do so.

Phase 2

There is a risk that final construction could be delayed due to the discovery of conditions requiring remediation at the site. As noted above, Toronto Hydro is conducting testing and analysis of current building conditions at 715 Milner to obtain early information on any conditions (for example, the presence of mold or other toxic substances) that would have to be remediated prior to final construction. Toronto Hydro is also pre-arranging the installation of the required fibre-optic cable to ensure its availability at the time of occupation.

Phase 3

There is a risk that Toronto Hydro may have to vacate 6 Monogram before the 71 Rexdale property is ready to be occupied. The 71 Rexdale property will be extensively re-developed and as such requires site plan approval from the City, which can take between 5 and 11 months for the entire site. Toronto Hydro will re-use as much of the existing building as possible to minimize the scope of the required construction and will apply for permits on a phased basis to allow the work to proceed in stages.

E8.3.6 Evaluation of Alternatives

Development and Definition of Alternatives

Toronto Hydro developed the four phases of the integrated OCCP in response to requirements and opportunities it faced concerning its portfolio of operating centers. For each Phase, Toronto Hydro examined its existing assets in conjunction with requirements, constraints, and opportunities, and developed what it considers to be the optimal response in each case.

The main facility-related requirements for Toronto Hydro were to ensure the uninterrupted ability to accommodate all of its staff (including contractors), equipment and other assets, and operations in facilities that were adequate and appropriate to the purpose, and to maintain the same basic distributed geographic configuration for its operating centers supporting its planned construction and maintenance activities.

For its northwest and northeast operating centers, Toronto Hydro faced constraints due to expiring leases on the properties involved. However, Toronto Hydro also had opportunities in the form of being able to dispose of potentially surplus properties at 5800 Yonge and 28 Underwriters, and utilizing the property it already owned at 715 Milner.

While in theory there are an indefinite number of alternatives that Toronto Hydro might have been able to pursue, the existence of these requirements, constraints, and opportunities substantially narrowed the range of consideration.

Toronto Hydro proposes the OCCP because it believes that it is the optimal response to the conditions that Toronto Hydro faces. However, for purposes of analysis, Toronto Hydro has also defined two alternative scenarios: a "Base Case" scenario and a "Do Nothing" scenario.

The Base Case essentially represents a continuation of the status quo, subject to the requirement that Toronto Hydro continue to respond to changing circumstances (e.g., the expiry of existing leases) as well as meeting evolving requirements, such upgrading and expanding its Data Centre. The Base Case does not involve the disposition of 5800 Yonge and assumes that the northwest and northeast operating centres continue to be leased. The Base Case assumes moves to new leased facilities for the northern operating centres would be required every ten years. Under the Base Case, significant capital expenditures would be required at 5800 Yonge to compensate for deferred capital maintenance over the past several years in anticipation of disposition, to provide expanded and upgraded facilities required for the Data Centre and for other IT-related investments. /C

Toronto Hydro also defined a "Do Nothing" alternative strictly for the purpose of providing a point of reference. The Do Nothing alternative is untenable because it exposes Toronto Hydro to unacceptable risks of being displaced from its northwest and northeast operating centres, and fails to meet evolving requirements around its technology infrastructure. Under the Do Nothing scenario, Toronto Hydro would passively rely on being able to renew existing leases on its northwest and northeast operating centres indefinitely into the future. Under commercially available terms of lease, Toronto Hydro would be subject to the unacceptable risk that either or both of those leases would not be renewed, with insufficient notice to enable Toronto Hydro to arrange even temporary alternative accommodation.

In addition, the Do Nothing scenario does not provide for required expansion and upgrading of Toronto Hydro's Data Centre at 5800 Yonge. Toronto Hydro's ability to provide basic IT infrastructure support to its core operations would decline over time to unacceptable levels in the face of growing requirements for that infrastructure.

Because the Do Nothing alternative is untenable, Toronto Hydro has not developed detailed financial forecasts based on it. However, Toronto Hydro has conducted detailed analysis of the OCCP in comparison to the Base Case. The results of this analysis are presented below.

E8.3.6.1 Quantification/Evaluation of Options

Introduction

Toronto Hydro has conducted a detailed financial analysis of the incremental costs of the OCCP and of the Base Case. The term "incremental costs" means costs that would be incurred or avoided relative to the level of costs currently embedded in Toronto Hydro's rates, inclusive of all elements of capital-related costs (return, taxes, depreciation) as well as all elements of OPEX, which when combined constitute the incremental base revenue requirement that would be created by either the OCCP or the Base Case, in isolation from all other elements of the total base revenue requirement.

The capital-related costs of the incremental investment in the improvements and expansions at 500 Commissioners are treated as a virtual facility, since the pre-OCCP Commissioners facility will continue to exist in any case. Otherwise, the incremental cost analysis includes the incremental capital-related costs of keeping 5800 Yonge, 71 Rexdale, and 715 Milner in ratebase, inclusive of any further investments that need to be made to those facilities (depending on the scenario involved).

Definition of Base Case

Phase 1

Under the Base Case, the facility at 5800 Yonge would be retained and continue to house the functions historically situated there. In addition to the normal OPEX associated with running that facility, incremental maintenance capital would be invested to compensate for maintenance that has been deferred in anticipation of selling the property. In addition, capital expansions and upgrades related to the Data and Control Centers would be made.

The 500 Commissioners facility would remain unchanged from its pre-OCCP state and would attract no incremental costs.

Phase 2

The facility at 601 Milner would continue to be leased until 2016, at which time an alternate facility would be leased for ten years, then replaced by a further alternate facility, with the 10-year cycle continuing for 50 years until 2064. Upon the initial leasing of each successive facility, capital

investments in leasehold improvements are assumed. The last change of facility within the horizon occurs in 2056. Incremental operating costs for the facility are included.

The facility at 715 Milner is assumed to be excluded from ratebase and attracts no capital-related or operating costs.

Phase 3

The treatment of the northwest operating center is parallel with that of the northeast facility.

The facility at 71 Rexdale is assumed to be excluded from ratebase and attracts no capital-related or operating costs.

Phase 4

The facility at 28 Underwriters is assumed to be retained to house the Investment Recovery function, which would be transferred to the north building. The south building would be demolished as it is not cost-effective to undertake the significant repairs that would otherwise be required. The property would continue to attract moderate incremental OPEX and CAPEX costs.

Common Assumptions

Toronto Hydro applied common parameter assumptions and methodology to both the OCCP and Base Case scenarios throughout the analysis. Major assumptions and parameters are listed below:

- Basic Analysis Horizon: 50 years, set to match the expected useful lives of the facilities involved
- Short Analysis Horizon: 5 years, set to cover the CIR period and isolate effects occurring within that horizon
- Capital structure: equal to current (60 debt: 40 equity)
- ROE: equal to current (9.55%)
- Discount Rate: the discount rate used for calculating the NPVs of the cost streams is 6.06%, equal to Toronto Hydro's current weighted average cost of capital

- OPEX Cost and Escalation Rate: OPEX costs are based on historical rates per square foot and escalated at the forecast rate of inflation
- CAPEX Cost and Escalation Rate: CAPEX costs are based on historical expenditures and escalated at the forecast rate of inflation
- Statutory Tax Rate: 26.5% throughout

RESULTS OF THE FINANCIAL ANALYSIS OF OPTIONS

The financial analyses (i.e., benefit cost analysis, or BCA) are set out in Appendix A for the OCCP and Appendix B for the Base Case. Each case is reviewed over two horizons: the five-year period of 2015 to 2019, the CIR term; and the 50-year period of 2015 to 2064 period), which is the expected useful life of the facilities. The tabs break out the summed costs and benefits by building and by phase.

BCA RESULTS

In net present value terms, the OCCP offers significant reductions in Base Revenue Requirements (BRRs) over both analysis horizons (i.e., to 2019 and 2064). In contrast, the Base Case scenario produces increases in BRRs over both horizons. Table 11 below summarizes these differences.

TABLE 12: SUMMARY OF BCA NPV RESULTS FOR OCCP AND BASE CASE SCENARIOS

[redacted]

In most instances, business cases involving front-end capital expenditures, made to produce cost savings that follow, exhibit weaker or even negative results as the horizon is shortened. This is because shortening the horizon has the effect of excluding future benefits that, while being generated by the initial investment, occur beyond the horizon. It is notable in the case of the

OCCP that a net reduction in the NPV of the BRR occurs even over the short horizon (to 2019), due to the sale of the property.

SUMMARY

The OCCP is expected to yield significant benefits to ratepayers and to Toronto Hydro. For ratepayers, substantial ongoing cost reductions is expected to occur without causing the costs of Toronto Hydro's capital renewal and maintenance programs to increase. In addition, ratepayers would enjoy the benefit of rate riders estimated to exceed [redacted] million dollars.

Both ratepayers and Toronto Hydro will benefit by the security of tenure at major crew-supporting operating centers, and the improved robustness of infrastructure supporting critical Toronto Hydro functions. This is especially important during emergency conditions.

E8.4 IT Hardware Refresh

E8.4.1 Summary

Program Description

Toronto Hydro uses numerous information technology ("IT") systems that support and in many cases, are critical to the execution of various business processes. These IT systems enable Toronto Hydro employees to execute tasks and perform activities that are essential to the proper functioning of the utility, including accounting, customer care and distribution grid management. In addition, these IT systems increase the efficiency of business processes and streamline reporting for both internal and external purposes.

Toronto Hydro employees interact with technology on a daily basis through: (1) endpoint hardware such as desktop computers, laptops, telephones, and printers; and (2) back-end hardware such as servers, local area networks and data storage. Through the IT Hardware Refresh Program, Toronto Hydro plans to replace, maintain and manage its IT hardware over the 2015 to 2019 period in accordance with best practices and standards. In executing the program, Toronto Hydro will efficiently maintain existing IT hardware where possible and will replace IT hardware as it approaches end-of-life.

Toronto Hydro needs to undertake this program in order to maintain the reliability of its IT hardware. Reliable IT hardware enables Toronto Hydro to efficiently and effectively plan and execute capital and operational programs and to fulfill its obligations to customers and applicable regulatory bodies. In addition to providing reliability benefits, this program is expected to mitigate risks to the utility's operations and cyber security and to facilitate the development of technological solutions to address emerging business needs and requirements.

Hardware components addressed in the program can be split into two categories:

(i) Endpoint assets

a. Responsible for computing and printing

b. Desktop computers, laptops, telephones, and printers

(ii) Core Backend Infrastructure assets

a. Rresponsible for computing, storage and communication

b. Servers, local area networks and data storage

The following table summarizes the anticipated benefits of the IT Hardware Refresh program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Updated hardware assets help maintain accurate customer billing. ƒ The hardware refresh will provide additional data storage and processing capabilities to respond to customer growth demands. ƒ Newer hardware has a lower risk of failure, supporting faster restoration times and shorter outages. ƒ The risk of compromise to sensitive customer data is lowered by updated IT hardware assets. ƒ Customer interfaces such as online billing and online customer account information are better supported by updated hardware assets.
Reliability	ƒ Updated hardware assets enable core business activities that are necessary to maintain a reliable distribution system for customers.
Efficiency	ƒ IT hardware supports the automation of business processes, which results in more efficient use of employee time. ƒ New hardware assets are less prone to fail and require less maintenance; this reduces the employee time is managing new hardware assets

Safety	ƒ Updated hardware helps ensure the cyber security of Toronto Hydro's distribution system, and guard against unauthorized access to distribution systems and assets. ƒ Updated hardware assets support environmental health and safety systems and processes in the work place and at the job site, such as the completion of the job site conditions and safety forms and safety audits.
Other Benefits	ƒ Updating hardware assets ensures that support services are available, which reduces the costs associated with specialized technical resources. ƒ Updated hardware systems enables Toronto Hydro to comply with the regulatory requirements of bodies such as Measurement Canada, the OEB and the IESO.

Program Drivers

The trigger and secondary drivers for this program are outlined in Table A below.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
System Maintenance and Capital Investment Support	ƒ IT hardware must be periodically refreshed to ensure the high availability of the systems that support Toronto Hydro's core operations and to minimize risk of failure impact to the business. ƒ Toronto Hydro relies on this technology to satisfy its obligations to customers and to comply with existing and emerging requirements of the various regulatory bodies that govern the utility's operations.
Secondary Drivers	**Reasoning**
Cyber Security Risks	ƒ IT Hardware must be kept current to mitigate the risk of malicious cyber attacks that can compromise sensitive customer data, operational and employee information, as well as the integrity of the distribution system.
Business Operations Efficiency	ƒ IT Hardware supports the automation of core processes and functions, such as customer billing and outage management. It also enables the utility to manage new business objectives and requirements, such as the need for additional data storage and processing capabilities to respond to customer growth demands.

Preferred Alternative

In developing the program, Toronto Hydro evaluated a number of alternatives with respect to both endpoint assets and core backend infrastructure assets.

Alternatives for endpoint assets:

(1) Run the assets to failure and react as needed; or

(2) Install new hardware based on asset lifecycle management methodology.

Alternatives for core backend infrastructure assets:

(1) Run the assets to failure and react as needed;

(2) Implement an externally hosted and managed solution; or

(3) Adopt an internally hosted and managed solution based on asset lifecycle management methodology.

Toronto Hydro determined that the preferred alternatives are to replace the endpoint assets through the "New Hardware" approach and replace the core backend infrastructure through the "Internally Hosted and Managed" approach. Toronto Hydro expects that this course of action will minimize the risk of interruptions to operations and core processes caused by IT hardware failure, in addition to mitigating cyber security risks and increasing the overall security of the utility's IT system.

Timing and Pacing

The forecasted total cost of the IT Hardware Refresh program over the 2015 - 2019 year period is $36.7 million. The program is comprised of multiple projects and the cost breakdown by asset category is as follows:

- Endpoint Assets: $ 9.06 million; and
- Back-end Hardware: $ 27.62 million.

The estimated future cost of the IT Hardware Refresh program is between $5.6 million and $9.8 million per year over the 2015 to 2019 time period. These figures are based on Toronto Hydro's asset lifecycle manager policies for IT hardware. For additional discussion of timing and pacing, refer to section E8.4.4 below. The historical and estimated costs of the IT Hardware Refresh program are provided in Table B below.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Forecasted Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Total Annual Spend ($M)	-	6.62	6.39	5.4	6.03	5.87	7.99	7.41	9.79	5.63

E8.4.2 Program Description

IT systems, comprising of both software and hardware components, support most of Toronto Hydro's operations. Software components are intangible assets such as Microsoft ("MS") Word and Adobe Acrobat applications that enable users to perform specific functions. Toronto Hydro utilizes many software applications to automate processes and efficiently execute required tasks such as preparing customers' bills and dispatching crews to respond to outages. These applications run on core backend infrastructure assets such servers, storage disks and computers, and are operated by employees via end-point assets such as desktops, laptops and tablets. The IT Hardware Refresh Program addresses the renewal and maintenance of these hardware assets. Software upgrades and enhancement are addressed by the IT Software Upgrades, Enhancements and Analytics Program, filed at Exhibit 2B, E8.5. The relationships and dependencies between software and hardware assets are illustrated in Figure 1 below:

FIGURE 1: IT HARDWARE MAPPING WITH UTILITY APPLICATIONS AND PROCESSES

IT hardware components are the building blocks of the overall IT System. IT hardware investments must be planned and implemented with regard to both current and future utility needs and operational requirements in order to enable Toronto Hydro to execute its plans and programs securely and efficiently, and to pursue its short and long-term objectives. IT hardware standards must be continually reviewed, assessed and implemented based on the utility

requirements from an operational, regulatory and customer service perspective. This requires Toronto Hydro to continuously invest in its IT hardware assets.

IT hardware assets are classified either as Endpoint Assets or Core Backend Infrastructure Assets. Endpoint Assets are the assets that the end-user interfaces with to execute, process, complete and review business tasks and operations, while Core Backend Infrastructure Assets are responsible for the computation, storage and communication necessary to support IT systems. Based on their functionality, these assets in this program can be further categorized as follows:

- Endpoint Assets:
  - Computing assets support the execution of business processes, data transactions and analysis - desktops, laptops and tablets used by employees.
  - Printing assets allows the representation of electronic documents such as engineering drawings, standards and contracts on paper and photocopying, scanning and faxing capabilities - printers and plotters.
- Core Backend Infrastructure:
  - Servers manage access to centralized resources and services in the network and security appliances secure the network from unwanted traffic.
  - Storage assets enable the secure retention of digital data such as customer information. Disk and flash arrays store records for access by servers.
  - Communication assets facilitate the exchange of data within and between the core backend assets and the endpoint assets, so that can user can access information in a central IT system. Network and telephony assets enable computers, services and storage devices to exchange data and manage communication services.

To illustrate the relationship between core backend infrastructure assets and endpoint assets, consider an employee in a call centre accessing the Customer Information System (CIS) while interacting with a customer. The employee uses his or her endpoint (i.e. desktop or laptop) to access the CIS application that runs on a server. The application retrieves the necessary data from the storage assets. The network assets facilitate the connection between all the

components of the system. This diagram below depicts the typical structure and dependency of the system:

FIGURE 2: TYPICAL ENDPOINT ASSET TO CORE INFRASTRUCTURE RELATIONSHIPS

Toronto Hydro has over 2,000 endpoint assets and over 1,500 core backend infrastructure assets. To effectively manage its IT hardware infrastructure, the utility has implemented a structured asset management approach that is aligned with industry best practices, vendor lifecycle recommendations and Toronto Hydro empirical data. To learn more about Toronto Hydro's IT asset management methodology, refer to Exhibit 2B, D4.

The lifespan of the assets targeted by this program is in the four to seven year range which is considered within industry norms. After four to seven years, the hardware assets risk of failure increases significantly and could impact core business processes. To determine the refresh cycle of existing hardware, Toronto Hydro maintains an inventory of its hardware assets that includes technical details and lifecycle information such as date of implementation and end of vendor support. This approach ensures that IT hardware assets are available to support the effective and efficient execution of utility's operations.

Furthermore, Toronto Hydro has a cautious approach to implementing any new technology hardware. Toronto Hydro requires reviewing the hardware specifications and testing hardware performance prior to approval for implementation. As a result, the hardware implemented in

Toronto Hydro is typically not the latest vendor released version. This ensures the systems have an acceptable performance and there is minimal impact to operational processes.

The high level scope of the different initiatives in the program is presented below:

- Identify the specific assets in the scope of the planned hardware refresh;
- Verify the technical requirements and compatibility of the proposed hardware;
- Provision for the assets per the published IT Technical Standards;
- Install and test the new hardware using Standard Operating Procedures;
- Test compatibility, redundancy, and integration as per the IT Testing Standard;
- Upgrade Operating Systems of virtual systems on legacy hardware if required to move to the new Hardware; and
- Migrate virtual systems to the newly deployed Hardware.

The table below presents the approximate breakdown of programs costs by asset type. The total estimated program cost for the 2015 to 2019 period is $ 36.69 million.

TABLE 1: ESTIMATED COST BREAKDOWN BY ASSET TYPE

No.	Asset Class	Hardware Function and Assets	Total ($ M)
1	End point Assets	Compute Desktops laptops, tablets Print Printers and plotters	$ 9.06
2	Core Back-end Infrastructure Assets	Compute Servers	$ 9.37
3		Storage Disk arrays and flash arrays	$ 6.69
4		Communication Network and telephony assets	$ 9.75
5		Miscellaneous Items	$ 1.81

No.	Asset Class	Hardware Function and Assets	Total ($ M)
		Ancillary items needed for the functioning of the above hardware components	
		TOTAL	$ 36.69

The following table summarizes the anticipated benefits of the Hardware Refresh Program.

TABLE 2: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Updated hardware assets help maintain accurate customer billing. ƒ The hardware refresh will provide additional data storage and processing capabilities to respond to customer growth demands. ƒ Newer hardware has a lower risk of failure, supporting faster restoration times and shorter outages. ƒ The risk of compromise to sensitive customer data is lowered by updated IT hardware assets. ƒ Customer interfaces such as online billing and online customer account information are better supported by updated hardware assets.
Reliability	ƒ Updated hardware assets enable core business activities that are necessary to maintain a reliable distribution system for customers.
Efficiency	ƒ IT hardware supports the automation of business processes, which results in more efficient use of employee time. ƒ New hardware assets are less prone to fail and require less maintenance; this reduces the employee time is managing new hardware assets
Safety	ƒ Updated hardware helps ensure the cyber security of Toronto Hydro's distribution system, and guard against unauthorized access to distribution systems and assets. ƒ Updated hardware assets support environmental health and safety systems and processes in the work place and at the job site, such as the completion of the job site conditions and safety forms and safety audits.
Other Benefits	ƒ Updating hardware assets ensures that support services are available, which reduces the costs associated with specialized technical resources. ƒ Updated hardware systems enables Toronto Hydro to comply with the regulatory requirements of bodies such as Measurement Canada, the OEB and the IESO.

E8.4.3 Why the Program is Needed

The IT Hardware Refresh Program is needed to maintain the reliability of the IT hardware systems that enable Toronto Hydro to efficiently and effectively plan and execute capital and operational programs and to fulfill its obligations to customers and regulatory bodies.

The IT Hardware Refresh Program plans the refresh of IT Hardware within the 4 to 7 year timeline. This duration is determined based on the asset type, asset sub-type and the acceptable performance of the hardware asset in terms of the expected hardware failure rate and the resulting impact to business operations. Based on the asset type and asset sub-type, beyond the 4 to 7 year timeline, it is expected that the hardware failure rate will significantly impact core business processes and will need a higher overhead to maintain and manage the hardware. This concept is explained in terms of the Bathtub Curve in the E8.4.4 Timing & Pacing of the Program section of this narrative. In the absence of the rigour in maintaining assets by a defined lifecycle, there is a significant risk to interruption of core business operations. There is a support risk from management of hardware assets by exception and increased overhead costs in the management of the hardware assets.

E8.4.3.1 Purpose

The table below summarizes the trigger and secondary drivers of the IT Hardware Refresh Program:

TABLE 3: PROGRAM DRIVERS

	Drivers	Reasoning
Trigger Driver	System Maintenance and Capital Investment Support	› IT hardware must be periodically refreshed to ensure the high availability of the systems that support Toronto Hydro's core operations and to minimize risk of failure impact to the business. x Toronto Hydro relies on this technology to satisfy its obligations to customers and to comply with existing and emerging requirements of the various regulatory bodies that govern the utility's operations.

	Drivers	Reasoning
Secondary Drivers	Cyber Security Risks	› IT Hardware must be kept current to mitigate the risk of malicious cyber attacks that can compromise sensitive customer data, operational and employee information, as well as the integrity of the distribution system.
	Business Operations Efficiency	› IT Hardware supports the automation of core processes and functions, such as customer billing and outage management. It also enables the utility to manage new business objectives and requirements, such as the need for additional data storage and processing capabilities to respond to customer growth demands.

This program directly impacts customer experience because Toronto Hydro's IT hardware infrastructure assets support a number of customer service functions. Currently, approximately 93,000 customers use the online electronic billing function and approximately 72,000 customers have accounts through which they can complete key self-serve functions, such as management of account details, customer moves, payment options and landlord information. Hardware assets also support a number of customer interfacing applications and processes delivered via telephony through the Toronto Hydro Call Centre. If the hardware assets supporting these functions were to fail, customers would be unable to access these systems, and could experience a significant delay in completing routine transactions. This would impact customer service satisfaction and would likely lead to increased volume of calls and complaints to Toronto Hydro's call center.

Hardware assets support systems that are used to manage the field crews and respond to outages. By providing distribution grid management employees real-time access to crew availability, geographic outage location and crew location, these systems enable Toronto Hydro to efficiently and effectively deploy crews to restore power to customers in a timely fashion. In the event of core backend infrastructure failure, the functionality of these applications would be impaired, and as a result, Toronto Hydro's outage response time would be negatively affected. This program therefore has direct impact on the duration of outages and the reliability of the distribution system.

The hardware assets in this program also support environmental health and safety systems and processes in the work place and at the job site. The processes range from completion of the job

site conditions and safety forms, review of the Material Safety Data Sheets (MSDS), safety and environmental audits and incident and claims investigation. In the event of an IT Hardware failure, employees may not have access to the information required to make informed decisions about environmental and health and safety issues that may arise, potentially leading to unsafe work conditions and/or resulting in inadvertent breaches of key obligations and requirements.

IT hardware assets contribute to operational efficiency by reducing manual processing times and ensuring consistency in the execution of operational task and processes. In the event of a hardware asset failure, business processes could be significantly affected. For example, Toronto Hydro uses a Customer Information and Billing system to process and generate customer bills. If the hardware supporting this system were to fail, Toronto Hydro could lose important data and experience notable delays in processing billing. In the worst case scenario, employees would need to revert back to manually processing billing data for thousands of customers, which would increase the time and cost associated with the billing process, as well as the likelihood of errors.

This program is needed to mitigate the following risks associated with aging IT Hardware Assets:

- Business Continuity: Use of obsolete IT hardware exposes users to unreliable system and application performance resulting, and increases the likelihood of interruptions to core processes that the utility relies on to effectively and efficiently execute its capital plans and operational programs.

- Cyber Security Risks: Obsolete IT hardware exposes Toronto Hydro to cyber security threats because it impairs the ability of system administrators to apply necessary service packs, security patches and upgrades to the operating system and the applications that are critical to maintaining a robust security posture. If this risk materializes, sensitive customer, operational and employee information could be compromised.

- Inability to Support Business Needs and Pursue Operational Efficiency: Business needs and operational efficiency drive the implementation of software solutions to enhance and automate processes. Due to compatibility issues, obsolete hardware assets could limit Toronto Hydro from implementing new solutions to achieve its business goals and objectives. If this risk materializes, Toronto Hydro would have to respond to emerging business needs on a case-by-case basis. This could result in poor response times for implementing new initiatives, and could create a fragmented hardware infrastructure that will become increasingly difficult and expensive to maintain and support as time passes.

- Lost Opportunity Cost: If Toronto Hydro does not effectively and efficiently manage its assets in a structured way, it will add new IT hardware assets in an ad hoc fashion based on immediate short term requirements. There will be lost opportunity cost to consolidate the infrastructure in a "Pooled or Farm" based concept. A "Pooled or Farm" based concept is a collection of hardware resources to complete desired computing operations that exceed the requirements of a single hardware machine. The pooled farm based concept simplifies applying services packs, patches and bug fixes from a gain in economies of scale. In the absence of the pooled farm based concept, the burden of managing hardware assets increases significantly as does the risk of IT hardware not being effective to support new business requirements.

E8.4.4 Timing & Pacing of the Program

The timing and pacing of the program for each asset sub-type is driven by the asset lifecycle defined in the respective standards. The standards are designed to extract maximum value of hardware asset and minimize negative impact of potential asset failures. This is explained through the concept of the "Bathtub Curve".

FIGURE 3: IT HARDWARE ASSET LIFECYCLE FAILURE RATE OVER TIME

As illustrated above, the bathtub curve breaks life-cycle of an asset into three distinct areas:

- Decreasing Failure Rate: This is the region of the curve associated with the reducing failure rate over time. This is typical of new IT hardware. The vendor quickly releases service packs, patches and bug fixes that reduce the IT hardware failure rate.

- Constant Failure Rate: As the failure rate decreases it comes to a stage when it stabilizes and it is almost constant. The cost of ownership in this area of the bathtub curve is steady and the considered financially optimal.

- Increasing Failure Rate: As the IT hardware ages beyond useful life, the failure rate starts to increase again. This is attributed to the general operational wear and tear of the asset as well as vendor focus on development of new products, in essence, lack of investment in obsolete products. The system failures and associated maintenance costs start to rise steeply in this portion of the bathtub curve.

Toronto Hydro's IT standards attempt to define asset lifecycles so that assets operate within the "Constant Failure Rate" region of the bathtub curb where they enjoy the lowest failure rate. This approach minimizes the strain on Toronto Hydro's operational support resources and leads to a reduction in hardware support costs.

Toronto Hydro also considers forecasted capacity requirements to ensure it has the necessary IT hardware to support general business growth and associated increased data storage and data processing requirements. The forecasts are based on the analysis of the following factors:

- Historic trends of current assets capacity versus utilization by existing information technology systems;

- Asset resource requirements to support system enhancements and new initiatives; and

- New operational requirements that necessitate increased hardware resources. An example of this is the estimated increase in storage resources required to account for an increase defined by the retention policy of electronic records.

Toronto Hydro maintains a centralized registry of all hardware. This includes dates the hardware assets were implemented in Toronto Hydro. This information is used in conjunction with the applicable IT standard(s) and the forecast capacity requirements to determine the replacement quantities and schedules over the 2015 to 2019 period.

The approximate breakdown of the annual costs of the program by the IT Hardware Sub-Type is presented in the table below . Details of the 2015 replacement are presented at the end of this document in Table 7.

TABLE 4: ESTIMATED COSTS BY IT HARDWARE SUB-TYPE

No.	Hardware	Hardware Sub-Type	Approximate Annual Spend ($,M)			TOTAL ($,M)		
			2015	2016	2017	2018	2019	
1	End-point Assets	Desktop, Laptops, Tablet, Printer and Plotter assets	1.78	1.77	1.84	1.82	1.84	9.06
2	Core Back-end Infrastructure Assets	Servers and Security Appliances	1.33	3.32	2.20	1.71	0.82	9.37
3		Disk and Flash Storage Assets	0.34	0.71	1.67	3.14	0.83	6.69
4		Network and Telephony Assets	1.68	2.05	1.57	2.71	1.74	9.75
5		Miscellaneous Items (Accessories, Power etc.)	0.74	0.13	0.14	0.40	0.40	1.81
TOTAL			5.87	7.99	7.41	9.79	5.63	36.69

Endpoint Assets

It is expected that all endpoint assets would reach end of life within the 2015 to 2019 period. Toronto Hydro estimates that it will replace approximately an equal number of endpoint assets each year. The annual of forecasted cost associated with replacing these assets is therefore consistent over the 2015 to 2019 period.

Servers and Security Appliances

Per the server asset lifecycle, no major server and appliance replacements are needed in 2019, this results in a smaller estimated spend in 2019. The increase in spend in 2016 and 2017 is attributed to the lifecycle replacement of security appliances.

Disk and Flash Storage Assets

Toronto Hydro's forecast expenditures relating to storage assets are highest in year 2017 and 2018 since these investments are timed and paced in accordance with a four to six year replacement schedule.

Network and Telephony Assets

Expenditures relating to the renewal of specific network assets are forecast to be the highest in the year 2018, consistent with their asset lifecycle management of five years.

Miscellaneous Items

The estimated expenditure towards miscellaneous items is higher in 2015 in comparison to other years due to the planned lifecycle of hardware accessories such as racks, cables and tools.

Summary

There is a difference in forecasted spend between years 2018 and 2019 of approximately $4.16 million. This difference is largely attributed to the higher spend in 2018 in storage assets and network and telephony assets. To reduce this difference, Toronto Hydro would need to defer some of the investments relating to the refreshment of storage and network and telephony assets beyond their planned lifecycle. This would significantly increase the likelihood of storage and network and telephony asset failure, which is a risk that Toronto Hydro is unprepared to take because these assets are critical to the proper functioning of the IT systems that the utility relies upon.

Historical Spend

As provided in the figure below historic spend from 2010 to 2014 varied between $5.19 million and $10.6 million averaging $7.72 million annually. The estimated future cost of this program over the 2015 - 2019 period range between $5.63 million and $9.79 million per year, with an average of $7.34 million. Some of the highlights of the proposed spend are presented below:

- The planned refresh of IT storage assets and network and telephony assets coincide in 2018. This results in a high estimated spend in 2018.
- The planned network and telephony asset replacement coincides with the planned security appliance refresh in 2016 that results in a high estimated spend of $7.99 million in 2016.

TABLE 5: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Forecasted Future Spending				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	10.60	9.39	7.41	6.00	5.19	5.87	7.99	7.41	9.79	5.63

E8.4.4.1 Ranking & Prioritization

In determining the priority of the investments in this program, failure impact is the main consideration that Toronto Hydro takes into account. If endpoint assets such as laptops, desktops or printers fail, the impact would be localized to a specific user(s), and in most cases, it would be possible to provide the affected users with a corresponding replacement asset in a timely fashion. Although it is likely that some re-work would be required to configure the corresponding assets for the user, the impact would likely be manageable and minimal. As the likelihood of failure of the endpoint assets would increase with the increase in asset age, Toronto Hydro would need to keep more assets as "standby" to minimize impact to the business users.

In contrast, the failure of core backend infrastructure could lead to the failure of entire IT systems, and could have a profound impact on core operations and business processes or could affect a large number of users. Such a failure could lead to a loss of productivity and/or the unavailability of core system(s) while the workarounds and fixes are being developed and implemented. Because the impact to the utility is likely more profound in event a core backend infrastructure failure, these assets are given a higher priority than endpoint assets.

Within the endpoint assets, there are two asset sub-types, computers, and printers and plotters. The impact of failure to Toronto Hydro from printer and plotter failure is smaller than that from computer failure. In the event of printer and plotter failure, business users would have the opportunity to use alternative endpoint printers and plotters within the utility premises to complete the print function. While this could potentially delay completion of business processes, this failure does not cause employee downtime. In case of computer failure, there is some employee downtime before the employee can commence execution of duties. Therefore, at the endpoint asset layer, the compute assets are more critical than print assets.

Within the core backend infrastructure assets, there are three sub-types of assets: servers, storage and network assets. Restoration of servers, while tedious, can be completed with some

employee downtime. In case of network and telephony asset failure, the immediate impact is to users in a specific location. Restoration of service typically involves replacement of the faulty asset with a corresponding new asset. Employees would be unable to access IT systems running on servers and storage assets. This will cause considerable employee downtime. Finally, in case of failure of storage assets, the impact is very serious and significant as a large number of users, would be affected. There would likely be data corruption issues and data loss. There would also be a considerable delay in the restoration of IT systems to resume regular business operations and processes.

Given the above considerations, the hardware assets to be addressed by this program are provided below, in order of highest to lowest priority.

1. Core Backend Infrastructure Assets
    1.1. Servers
    1.2. Network and telephony assets
    1.3. Storage assets
2. Endpoint Assets
    2.1. Printers and plotters
    2.2. Compute devices - Desktops, laptops and tablets

E8.4.5 Program Execution

The program will be executed through multiple projects. The high level steps in executing the projects within this program are presented below:

- Identify the specific assets in the scope of the planned hardware refresh project - Determine the IT hardware assets that need to be replaced based on the defined IT hardware asset standard lifecycle. This step will define the project scope in terms of the required IT hardware specifications and quantity of IT hardware assets that need to be managed.
- Verify the technical requirements and compatibility of the proposed hardware with other interdependent components - In this step, Toronto Hydro will review the hardware technical specifications of new hardware that would replace the existing IT hardware. This will ensure the ongoing optimal performance of the assets. Toronto Hydro will also ensure the hardware compatibility with dependent components. As an example,

in case of new servers, the Toronto Hydro would ensure compatibility with the applications, databases and storage assets.

- Provision the assets per the published IT Technical Standards - Toronto Hydro will initiate the process to procure the required IT hardware assets. Toronto Hydro will issue tenders to invite competitive bids from vendors. On the successful selection of the vendor, Toronto Hydro will purchase and provision the assets needed.
- Install and test the new hardware using the Standard Operating Procedures - In this step, Toronto Hydro would implement the new hardware and validate the hardware installation steps per the established Standard Operating Procedures.
- Test compatibility, redundancy, and integrat ion as per the IT Testing Standard - In this step, Toronto Hydro would test the new hardware in the IT system for security, performance and architectural compliance. Through security testing, it is determined that the applicable security controls are in place and the security posture is validated; in performance testing, the hardware performance criteria is validated with load and stress tests; and architectural compliance testing ensures the solution is appropriately designed and validates the design with appropriate simulation of failure scenarios for Disaster Recovery purposes.
- Upgrade Operating Systems of virtual systems running on legacy hardware if required to move to the new Hardware - This additional step is completed in case of legacy hardware. This step requires to upgrade the operating system to a new version to allow the virtual system to be reassigned to the enables the upgrade
- Migrate virtual systems to the newly deployed Hardware - In this step the infrastructure teams will complete the deployment of the new IT hardware in the IT system. The applications, databases and middleware are migrated to the newly deployed hardware.

(i) Program Risks

The program faces several risks that could impact the program in terms of scheduling and sequencing of work, program costs and quality of work. The potential impact of program risks is presented below:

TABLE 6: RISKS AND CONSEQUENCES

Risk	Potential Consequences	Mitigation Measures
Internal Resource Availability: insufficient resources to complete the planned program tasks and activities	Schedule Risk of delay to interdependent and downstream program/ project activities Cost: project costs could increase due to the need to procure temporary skilled resources at a premium.	› Adopt a long term resource plan based on project tasks and activities that Toronto Hydro plans to undertake over the next five years x Ensure appropriate responsibility overlaps between labour resources to minimize impact from attrition
Vendor Management: vendor does not meet its program delivery obligations, or changes the product cost structure	Schedule vendor is unable to provide the product according to the project schedule Quality: the vendor does not deliver per the product specifications. Cost: program costs could vary significantly from the program budget.	› Clearly state expected timelines and have resolution clauses to address delays x Delineate an escalation path to quickly resolve conflicts and discrepancies x Enforce short interval control through vendor project status updates and reports x Complete comprehensive due diligence of scope and requirements prior to undertaking projects and incorporate findings in the tender documentation x Enter into long term

Risk	Potential Consequences	Mitigation Measures
		contracts, where appropriate, with vendors and suppliers to ensure costs are fixed over a long period of time x Solicit vendor responses to competitive bids
Overall Program Schedule r Toronto Hydro is at risk of missing the program timelines from the volume of work in the program	This risk might impact the defined project and program timelines, deliverables and costs.	› Closely monitor the project progress and project deliverables through monthly Project Status Reviews with senior management and executives

(ii) External Constraints

The planned IT Hardware Refresh program faces a number of external constraints that could impact program schedule, budget and/or the quality of work.

- Vendor Strategy: Changes to the vendor planned hardware release dates or product strategy could impact the project schedules. The changes to the release schedule of a specific hardware component will impact other interdependent hardware component activities and projects in scope of this program. This will risk delays to the planned program schedule. Likewise, if a vendor decides to terminate a product line, Toronto Hydro would have to review the planned project scope and it will impact program quality. Similarly, should the vendor change its product strategy it would likely have an impact on the planned hardware asset management. For example, the vendor might terminate a product line that would require a review of the planned project scope and impact program quality. Toronto Hydro continually monitors changes to the technology landscape that might impact its program plans. Toronto Hydro will adhere to its internal architecture framework for standards and associated specifications which would redefine the program scope and timelines.

- Technical Compatibility: Each hardware component needs to be compatible with the underlying interdependent hardware components. Should the technical requirements of the hardware components in this program change, there could be potential impact to the interdependent hardware components needed to successfully complete the IT hardware refresh program. For example, servers need to be compatible with storage hardware and, to a lesser extent, the underlying network components. Should the technical compatibility requirements of the server assets change, it will force a review of the architecture. This might result in the unplanned procurement of a new suite of flash and disk array storage assets. This will affect the overall program costs.

Technology evolves at a fast pace with new products frequently entering the technology market space. It is likely that new technologies will become available to Toronto Hydro in the 2015 to 2019 period. Toronto Hydro will evaluate these new technologies with respect to product stability, benefit to business units, and alignment with Toronto Hydro's technology standards and long term technology strategy. Should the evaluation deem that the new technologies would be beneficial to Toronto Hydro, it would impact the planned scope and quality of this program. Toronto Hydro will adhere to the internal governance framework in the implementation of changes to the planned hardware refresh.

(iii) Standard & Regulation Adherence

The program is broadly governed by the following regulations and standards:

External Regulations and Standards:

This refers to the legislation and directives provided by bodies such as the Ontario Energy Board and Measurement Canada.

Toronto Hydro will also adhere to the following standards and legislation:

- National Institute of Standards and Technology (NIST) SP800-82 - This standard provides the guidance for establishing industrial control systems. This standard applies to the Supervisory Control and Data Acquisition (SCADA) systems used in Toronto Hydro to complete remote switching operations on assets in the distribution grid network. Toronto Hydro must ensure that the products purchased as part of this program comply with the NIST SP800-82 requirements.

- North America Electric Reliability Corporation (NERC) Critical Infrastructure Protection (CIP) 002-009 - The NERC CIP 002-009 provides the guidance to ensure the protection of the critical cyber assets which control or affect the reliability of North America's bulk electricity systems. This standard applies to the SCADA systems used in Toronto Hydro to complete remote switching operations on assets in the distribution grid network. This standard requires the identification of critical assets; the protection and classification of the assets, the appropriate personnel training, the appropriate access controls and vulnerability assessments, the implementation of a broad range of measures to secure critical and non-critical assets, the maintenance of a response plan and retention policy of the documentation, and the review of recovery plans that includes backup and recovery of cyber assets. Toronto Hydro must ensure that the NERC CIP requirements can be appropriately applied to the hardware in scope of this program.
- NIST Interagency or Internal Reports (NISTIR) 7628 - This standard presents the analytical framework to develop effective cyber security strategies to mitigate Smart Grid risks and vulnerabilities. Toronto Hydro uses this standard in the metering process that measures, gathers and analyzes energy consumption. Toronto Hydro must ensure that the hardware in this program supports the applicable security frameworks.
- NIST SP800-53 - This standard stipulates the security controls for IT systems to protect the confidentiality, integrity and availability of the overall system and the information contained within it. This standard applies to the hardware of IT systems that support business operations such as finance, billing and accounts receivable.
- The Personal Information Protection and Electronic Documents Act [1] - This Act was enacted by the Government of Canada to regulate the collection, use, disclosure, retention, access and security of personal information in conducting commercial activities. This pertains to the management of personal customer and employee information as part of billing and payroll processes, respectively. Toronto must ensure that the hardware in this program support the systems that comply PIPEDA.

Internal Standards:

Toronto Hydro develops technical standards for computers, servers, storage devices and network devices govern and simplify hardware management and to gain economies of scale in hardware management. Collectively, these standards and regulations will provide the technology framework for the proposed hardware management.

[1] S.C. 2000, c. 5. ["PIPEDA"].

The following standards are the foundation of the Hardware Refresh program:

- Toronto Hydro Desktop and Laptop Standards:

  This standard provides requirements on the types of desktops and laptop hardware to provision, the base software that should be deployed to the desktops and laptops, the general management practices to use the hardware and the asset replacement lifecycle.

- Toronto Hydro IT Infrastructure Provisioning Standards:

  This standard provides the requirements to provision IT infrastructure components to provide a highly available, scalable and manageable platform for business applications deployed. The standard also documents the lifecycle for the assets, patches and capacity of the different components within the infrastructure such as server and storage assets.

- Toronto Hydro Core Backend Network Architecture and Provisioning Standard :

  This standard stipulates the hardware and feature specifications that must be deployed to deliver consistent and predictable levels of performance, capacity and availability from the Core Backend Network Assets and the associated Architecture.

- Toronto Hydro Testing Standard :

  This standard establishes the scope and methodology of non-functional or System Acceptance Testing for IT system in Toronto Hydro. The standard enumerates the categories of tests to be used to prepare detailed test plans during the implementation of IT projects.

E8.4.6 Evaluation of Alternatives

Toronto Hydro evaluated its alternatives based on asset type.

Endpoint Assets:

In case of endpoint assets, Toronto Hydro considered the following alternatives to refresh its desktops, laptops, tablets, printers and plotters:

(1) Do Nothing - Run Assets to Failure

(2) Install New Hardware - Standards Based Asset Lifecycle Replacement

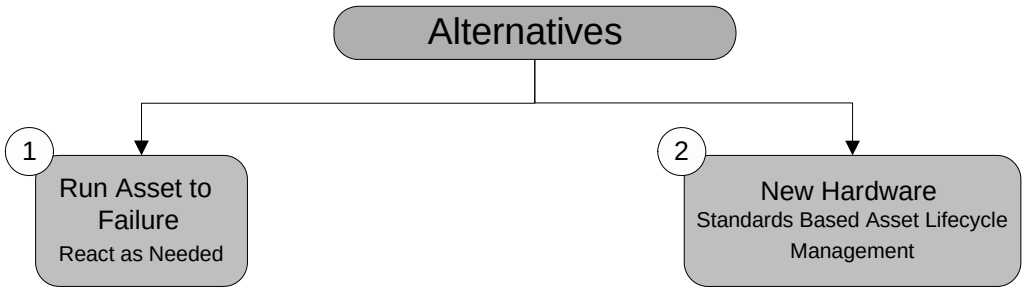

FIGURE 4: CONCEPTUAL REPRESENTATION OF ALTERNATIVES TO EXECUTE THE ENDPOINT ASSET REFRESH

Core Backend Infrastructure Assets:

In case of core backend infrastructure, Toronto Hydro considered the following alternatives to refresh its servers, security appliances, disk arrays, flash arrays, network and telephony assets:

(1) Run Asset to Failure - React as Needed

(2) Externally Hosted and Managed - Outsourced IT Hardware

(3) Internally Hosted and Managed - Asset Management Methodology

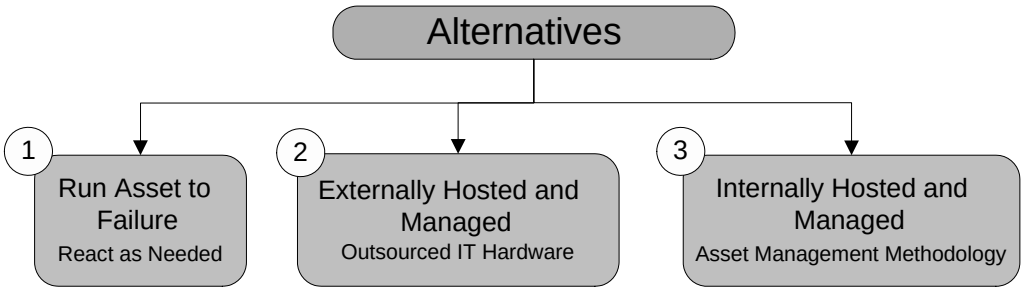

FIGURE 5: CONCEPTUAL REPRESENTATION OF ALTERNATIVES TO REFRESH CORE BACKEND INFRASTRUCTURE ASSET

E8.4.6.1 Quantification/Evaluation of Options - Endpoint Assets

Presented below is the analysis of the options with respect to Endpoint Assets:

1 Run Assets to Failure - React as Needed

In this alternative, Toronto Hydro would not upgrade and/or refresh the existing IT hardware endpoint assets in the 2015 to 2019 period. Within this period, all hardware will reach and pass its respective useful life. As such, Toronto Hydro would run outdated hardware and associated operating systems. Given the typical usage of the IT endpoint hardware, equipment suffers wear and tear with age. This will increase the probability of hardware failure. Any hardware refresh would be completed in a reactive and ad hoc fashion based on hardware asset failure. This could also lead to budgetary issues.

Running assets to failure and reacting as needed is not a preferred solution for the following reasons:

- Toronto Hydro would need to procure and stock assets at high costs to complete asset management activities on an expedited basis.
- There is high risk exposure to core business operations and processes and user experience from endpoint asset failure. The user will experience poor system response times to the commands and functions executed. There is a significant cost of failure from impacted business processes and employee downtime. There is a risk that the users would lose data that would need re-work that would further impede employee productivity.
- While this option entails the lowest upfront capital expenditure, it is offset by high operational expenditures related to maintenance/support and employee downtime. There is also a risk of unexpected increase in future capital expenditure to replace hardware on an expedited schedule.

2 New Hardware - Standards Based Asset Lifecycle Replacement

In this alternative, Toronto Hydro would refresh its computer endpoint assets per the lifecycle requirements stated in the desktop and laptop standard and refresh the printer endpoint assets per the vendor lifecycle recommendations. Each year, Toronto Hydro would procure a designated number of endpoint assets and deploy them to the business users and to designated Toronto Hydro locations, as required. Based on the typical computer hardware lifecycle, it is expected that all user endpoint devices will be replaced in the 2015 to 2019 period.

Toronto Hydro prefers this option for the following reasons:

- Reduced employee downtime from isolated incidents of endpoint failure. The endpoint assets would be replaced before asset performance is affected from wear and tear, age and general usage. This mitigates the risk of employee downtime and mitigates the risk of re-work and data loss from failure of endpoint assets.

- Reduced need to procure new endpoint assets on an expedited basis from vendors, or to maintain a large number of standby devices to address potential failure.

E8.4.6.2 Quantification/Evaluation of Options - Core Backend Infrastructure Assets

Presented below is the analysis of the options with respect to the core backend infrastructure assets:

1 Run Assets to Failure - React as Needed

In this alternative, Toronto Hydro would not upgrade and/or refresh the existing IT hardware in the 2015 to 2019 period. Within this period, most hardware would reach or pass its respective useful life. Toronto Hydro would run outdated hardware and associated operating systems. After a certain date, vendors would not provide any further service packs and patches, increasing the risk of hardware failure. Vendors typically offer support on a best effort basis with no assurances of turnaround times to fix hardware failure. Internally Toronto Hydro would need to develop workarounds to respond to hardware failure. As well, Toronto Hydro would need to procure specialists to support the archaic hardware. Any hardware refresh will be completed in a reactive and ad hoc fashion based on hardware asset failure.

This alternative is not preferable for the following reasons:

- Toronto Hydro would need to procure assets and labour resources at high costs to complete asset management activities on an expedited basis.

- IT systems are susceptible to malicious cyber attacks that could compromise sensitive customer, operational and employee information, or the integrity of the distribution system.

- The risk exposure to core business operations and processes is very high. There is a significant cost of failure from impacted business processes and employee downtime.

- While, this option entails the lowest upfront capital expenditure, it is offset by high operational expenditures related to maintenance/support and employee downtime.

Toronto Hydro will need to stock a larger quantity of replacements parts. In the worst case, Toronto Hydro will need to expedite the purchase of new equipment that will cause unexpected increases in the planned capital expenditure.

2 Externally Hosted and Managed - Outsourced IT Hardware

In this option, the core backend infrastructure assets would be housed in an environment that is outside Toronto Hydro. In this model, Toronto Hydro would stipulate the desired level of hardware availability and level of service. While the service provider is responsible for the provisioning, maintenance and support of the hardware, Toronto Hydro is responsible for network connectivity to the vendor infrastructure.

Toronto Hydro would stipulate the applicable security standards, desired service quantity and quality via specifications of infrastructure required to provide a business solution. Under this approach, Toronto Hydro has limited control and role in project implementation of hardware assets in the vendor infrastructure. The project must provision for high network availability and secure high volume connections between Toronto Hydro's network and the vendor infrastructure. System integration in this model will tremendously increase costs and complexity.

The hardware would be supported by two distinct groups. Toronto Hydro would provide the first level of support to address business queries and to verify the root cause as hardware issues. The vendor would then offer detailed technical support such as setting up a server, increasing storage and compute resources and addressing technical issues. The desired service levels and system availability would be detailed in the contract at differing price points.

The service provider would be responsible for the management of the core backend infrastructure assets. The service provider would also determine maintenance windows to apply service packs, patches, upgrade assets and increase compute resources as needed. The service provider would provide appropriate notices of the planned infrastructure outages.

This is not a preferred option for the following reasons:

- There is a risk to end user experience in performance issues from increased latency and lag in response time. This risk stems from the traffic load on the connection between the hosted environment and Toronto Hydro, and from the increased distance between hardware and the user than in the current internally hosted environment.

- The onus of data security is entirely on the service provider. Toronto Hydro runs the risk of misuse of data, data loss and cyber security in this option. Toronto Hydro will not have the details of the service provider security vulnerabilities and the mitigation strategies and activities.

- Toronto Hydro will not have the desired support and flexibility in managing maintenance windows with the service provider planned window. During system maintenance, the system is typically unavailable to business users, while it is patched, upgraded and applications System / application unavailability would severely hamper the distribution grid restoration effort In case the maintenance window coincides with a time of widespread distribution grid outages from ice storms and flooding.

- The service provider would not be in a position to offer an integrated IT strategy that aligns both hardware and software components. The vendor may decide to upgrade the core backend infrastructure without consideration of the applications running on it. This creates an interoperability risk between vendor hardware and Toronto Hydro systems running on them.

- Should Toronto Hydro decide to terminate the contract with the service provider, Toronto Hydro will need to provision and setup the hardware assets in a short period of time prior to the date of contract termination. This will result in inordinate costs in the IT hardware asset procurement and the labour needed to standup the new hardware asset environment and associated penalties from contract termination and migration delays.

- This option has the highest overall costs. Toronto Hydro will incur operational expenditures with respect to the vendor hosting the infrastructure assets in contrast to the current capital expenditures to refresh and maintain its hardware assets. Further to this, Toronto Hydro will incur huge operational expenditures related to network costs from Internet Service Providers (ISPs), who will provide the connectivity and bandwidth required between Toronto Hydro and the vendor infrastructure. This model would increase Toronto Hydro's annual operational expenditures.

- In the implementation of this approach, there is a risk of disruption of business operations from system outages. There would be considerable change in the management of infrastructure assets and their ongoing support. The adoption associated with this option will delay realization of any benefits from this option.

3 Internally Hosted and Managed - Asset Managed Methodology

In this option, Toronto Hydro would refresh hardware assets that will be hosted internally in Toronto Hydro premises. The core backend infrastructure assets are refreshed based on an asset management methodology; the applicable asset lifecycles are defined in Toronto Hydro's IT technical standards..

Toronto Hydro would be responsible for IT hardware asset management that includes upgrades, adding compute resources, replacement of hardware assets as they approach the end of useful life and leveraging the appropriate technology to gain operational efficiencies. Toronto Hydro would utilize internal resources to complete project tasks and activities.

The technical standards and age of existing hardware determine the hardware assets to be replaced and upgraded. Each year Toronto Hydro would draw near term IT hardware asset management plans in alignment with the long term plan and execute applicable projects to the plan.

Toronto Hydro would gain the necessary expertise to support the hardware in project implementation.

Toronto Hydro prefers this alternative for the following reasons:

- Toronto Hydro will have a granular view of project tasks and activities. This is critical to manage the project and program level schedules with the ability to remediate and mitigate shortfalls and risks that might impact the program.
- This option obviates the need of a secure connection between Toronto Hydro's network and externally hosted infrastructure to allow users to interact with different systems. This mitigates cyber security risks and exorbitant network connectivity costs.
- There system response time to the end user would be unchanged. Unlike the externally hosted and managed – outsourced IT hardware option, there will be no risk from system latency and lag in system response times.
- This option has the least risk of all alternatives. Toronto Hydro has the flexibility to modify hardware asset maintenance windows on an as needed basis. As well, Toronto Hydro will have the ability to quickly respond to hardware outages and to quickly internally escalate hardware asset issues for resolution, thereby efficiently supporting business

needs. This option will also mitigate risks and potential delays resulting from communicating with an external vendor in an emergency situation.

- This option offers least disruption to business operations. Furthermore, there is minimal change to internal support processes within IT.

2015 ASSET REPLACEMENT DETAILS

TABLE 7: 2015 ASSET REPLACEMENT DETAILS AND FORECASTED COSTS

No.	Asset Type	Asset Sub-Type	Project/Task	Total ($ M)
1	Core Backend Infrastructure	Server and Security Appliances	Threat, Risk, Control Infrastructure Lifecycle	$0.326
			Identify Access Management Infrastructure Lifecycle	$0.2
			Threat, Risk, Control Infrastructure Growth (Netmotion, SSL VPN)	$ 0.015
			VMware Additional CPU Licenses	$0.12
			x86 Blade and Rack server refresh	$0.393
			IBM million TPC Licenses	$0.15
			Citrix Licenses	$0.1
2	Core Backend Infrastructure	Disk and Flash Storage Assets	Brocade DCX SAN switch blade refresh	$0.085
			EMC VNX organic capacity growth	$0.08
			IBM million TEST/DEV Storage organic capacity growth	$0.016
			IBM million SVC Licence capacity upgrades	$0.05
			Backup Infrastructure Licenses	$0.1
3	Core Backend Infrastructure	Network and Telephony Assets	Data Network Environment Lifecycle	$0.5
			Upgrade from Layer 2 to Layer 3 networking	$0.25
			Voice (IPT/Call Center) Environment Lifecycle	$0.3
			Radio Network Environment Lifecycle	$0.092
			Telecom Environment Lifecycle	$0.204
			Data Network Environment Growth	$0.06
			Voice (IPT/Call Center) Environment Growth	$0.045

No.	Asset Type	Asset Sub-Type	Project/Task	Total ($ M)
			Radio Network Environment Growth	$0.06
			Telecom Environment Growth	$0.045
			Additional Voice Radio Mobiles & Portables	$0.063
			Telecom (Fiber/Optic) Repair supplies	$0.03
4	Core Backend Infrastructure	Miscellaneous Items	UPS Batteries Lifecycle	$0.03
			UPS Lifecycle (Does not include facilities work)	$0.26
			Data Centre UPS Capacity & Availability growth	$0.15
			Racks/Cables/PDUs/Tools/Patch Panels/Floor Tiles	$0.04
			Electrical works related to growth	$0.02
			DCI million Tool	$0.22

E8.5 IT Software

E8.5.1 Summary

Program Description

Toronto Hydro relies on various Information Technology ('IT') software systems to efficiently manage core operations and business processes and to execute planned programs relating to Distribution Grid Infrastructure Design and Construction, Distribution Grid Operations, Customer Billing and Service and Corporate Services. By automating and streamlining operations, IT software systems enable safe and efficient execution of numerous activities across the organization. Without these systems, a utility of Toronto Hydro's size and complexity would encounter significant challenges in operating its electricity distribution system, delivering its capital programs and satisfying its obligations to customers and other parties that it interacts with.

The IT Software program is composed of two sub-programs:

(i) Software Upgrades; and

(ii) Software Enhancements and Regulatory Compliance.

As software vendors release new product versions, they also terminate support for older products, which means that a vendor no longer provides any periodic software system upgrades, security upgrades and fixes for known issues. Software vendors do not guarantee any service

levels as time goes on, and the risk of running out of technically-qualified support personnel increases. In the event of a system's failure, there is a high risk that Toronto Hydro may experience prolonged restoration time and pay premium costs to procure specialized labour resources. Moreover, in the course of day-to-day operations, there is a high level of security risk when Toronto Hydro's software system may get exposed to an increased level of cyber attacks due to the lack of timely security upgrades. Thus, Toronto Hydro must upgrade its IT systems to ensure their availability to meet operational needs, and to protect itself against cyber threats that could jeopardize the security of the distribution system and the privacy of sensitive operational, customer and employee information. In addition, Toronto Hydro must explore IT software solutions and enhancements to existing applications to address evolving business needs and external requirements.

The following table summarizes the anticipated benefits associated with this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ Updated software maintains accurate customer billing. ƒ Increased cyber security better protects customer information from unauthorized access. ƒ Newer software enables streamlined and simpler integration, which prevents delays in restoring outages and completing necessary maintenance for customers and enables new services.
Reliability	ƒ By automating and streamlining operations, IT software systems enable safe and efficient execution of numerous activities across the organization that are necessary to maintain a reliable distribution system for customers. ƒ Increased cyber security protects against threats to the distribution system, helping ensure reliability.
Efficiency	ƒ Automation of business processes improves employee efficiency. ƒ Consolidation of multiple application interfaces into fewer applications improves employee efficiency. ƒ Allow the seamless migration of business applications as Toronto Hydro migrates Operating Systems from Windows XP to Windows 7, reducing employee time spent troubleshooting migration issues. ƒ Analytics in relation to these new applications can provide Toronto Hydro with critical information about managing resources and restoring power to customers in emergency events such as the recent July flood and December ice storm in 2013
Safety	ƒ Updated software helps ensure cyber security of Toronto Hydro's distribution system. ƒ Increased cyber security mitigates the risk of unauthorized access to distribution systems and assets.

Other Benefits	ƒ Updating software ensures that support services are available from the vendor, which reduces the costs of specialized technical resources ƒ Updated software enables Toronto Hydro to comply with the regulatory requirements of bodies such as Measurement Canada, the OEB and the IESO.

Program Drivers

The trigger and secondary drivers for this program are outlined in Table A below.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
System Maintenance and Capital Investment Support	ƒ IT systems support core business operations and planned work programs. These systems must be maintained and upgraded in order to mitigate failure risk, which could jeopardizes the utility's operations, and its ability to execute planned work programs. Applications must be periodically enhanced and modified to provide additional functionalities and support evolving requirements and operational needs.
Secondary Drivers	**Reasoning**
Cyber Security	ƒ Ensure IT systems are upgraded, patched and secure from cyber attacks and that any vulnerabilities are addressed
IT Systems Compatibility	ƒ Software applications and the underlying components (e.g. servers and operating systems) must be compatible to ensure uninterrupted IT system operations and deliver the desired end user experience and functionality.
Regulatory Compliance	ƒ IT systems enable adherence to the requirements of regulatory bodies such as Measurement Canada, the OEB and the IESO.

Preferred Alternative

The Software Upgrades sub-program includes the regular upgrades of more than 70 software applications that support Toronto Hydro's core functions and processes. The following alternatives were analyzed and evaluated for the Software Upgrades sub-program:

(1) Do Nothing - Run Asset to failure and react accordingly

(2) Managed Services - Outsourced Management of IT Applications

(3) Standards based asset lifecycle management - Asset Management Methodology

Option 3, "Like for Like Upgrades" of the software asset systems, is the preferred alternative because:

- It has the lowest cost and shortest implementation time
- It poses the lowest risk to ongoing core business operations
- It offers the most straightforward change management process
- It is the most secure option from a cyber security perspective

The Software Enhancements and Regulatory Compliance sub-program includes work that is required to optimize or enhance business operations, or to comply with external requirements provided by entities such as Measurement Canada and Ontario Energy Board (OEB). Given the diverse and reactive nature of these investments, Toronto Hydro does not have a pre-defined options analysis. In planning and executing these initiatives, Toronto Hydro intends to rely on its internal governance processes to ensure that appropriate options are considered and evaluated for each specific initiative.

Timing and Pacing

The total estimated cost of the IT Software program over the 2015-2019 period is $81 million, consisting of $51.87 million for the Software Upgrades sub-program and $29.13 million for the Software Enhancement and Regulatory Compliance sub-program.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending ($M)					Forecasted Future Spending ($M)				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Software Upgrades	12.48	2.66	1.49	3.13	5.55	9.68	10.50	9.91	10.93	10.85
Software Enhancements	7.65	18.35	11.34	4.46	3.50	4.22	4.16	4.31	4.28	4.32
Regulatory Compliance	2.06	0.15	1.60	2.01	1.05	1.55	1.52	1.57	1.56	1.58
TOTAL	22.20	21.17	14.45	9.61	10.11	15.46	16.19	15.81	16.78	16.76

The program covers planned IT systems upgrades, enhancements and analytics, as well as modifications to existing IT systems or new IT systems which are required to comply with regulatory obligations. The estimated annual cost of the program is in line with historical trends. For Software Upgrades, the forecasted costs are based on detailed asset level information that Toronto Hydro maintains in its IT Inventory system (for more information, refer to IT Asset Management Strategy at E8-4). Due to funding limitations in 2013-2014, Toronto Hydro had to defer certain software upgrades, resulting in a forecasted increase in these types of investments over the 2015 to 2019 period.

E8.5.2 Program Description

The utility plans to undertake numerous IT software projects over the 2015-2019 period, all of which will involve intricate planning, testing, and execution. Toronto Hydro plans to execute these projects under the following sub-programs: 1) Software Upgrades, and 2) Software Enhancements and Regulatory Compliance.

1) Software Upgrades

This Software Upgrades sub-program includes the planned lifecycle upgrades of applications that support core functions and processes relating to Distribution Grid Infrastructure Design and Construction, Distribution Grid Operations, Customer Service and Billing, and Corporate Services. As illustrated in the Figure 1 below, multiple software systems are embedded in each of these core processes and functions.

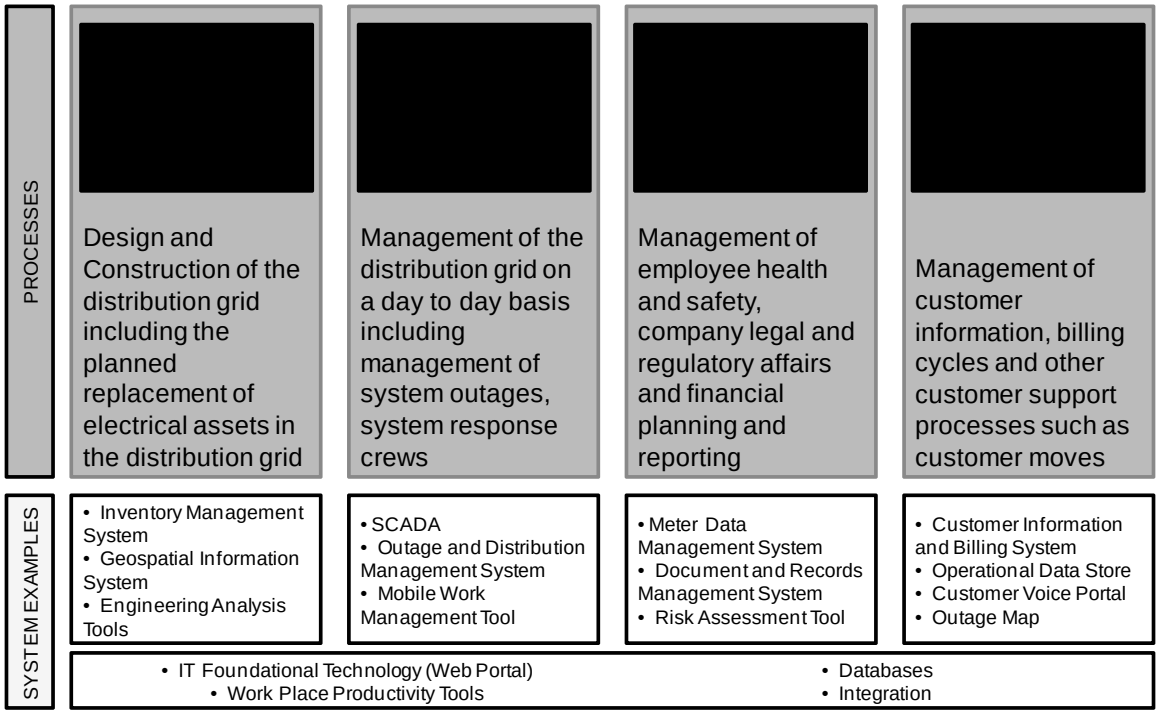

FIGURE 1: CORE PROCESSES AND FUNCTIONS

To execute its capital plans and programs and adequately serve its customers in an uninterrupted manner, Toronto Hydro must upgrade all of its software applications (approximately 70) during the 2015 to 2019 period. These investments will be made in accordance with the asset lifecycle

and other key information that Toronto Hydro maintains as part of it IT Inventory system (refer to IT Asset Management Strategy at Exhibit 2B, Tab 4, Section D, Schedule 4).

The projects in this sub-program typically include the following activities:

- Engage vendor(s) to provide upgrade assistance
- Upgrade the underlying infrastructure
- Configure the application to ensure compatibility with underlying components
- Configure the application to meet Toronto Hydro business requirements
- Integrate with other utility IT systems, as needed
- Complete regression testing to ensure the upgrade is successful
- Train the business users of the new features and functionality
- Change Management activities to minimize impact to the business users
- Deploy the new systems and release it to the business users

2) Software Enhancements and Regulatory Compliance

As the name suggests, this sub-program consists of two categories of projects: Software Enhancements, and Regulatory Compliance projects. Software Enhancement projects are designed to improve existing systems and processes, develop new reports and functionalities, provide business analytics, and integrate IT systems and software applications. Regulatory compliance projects enable the utility to adhere to the requirements of regulatory bodies such as Measurement Canada, the OEB and the IESO.

Over the 2015-2019 period, Toronto Hydro plans to undertake software enhancements and regulatory compliance projects pursuant to the four-step process described below (see Figure 2). The utility intends to evaluate each project through a rigorous exercise, whereby it will identify operational requirements, define the scope, assess options and validate benefits before it proceeds with the project.

FIGURE 2: COMPLIANCE PROJECTS PROCESS

Evaluate:

The IT group validates the proposed project, and works with the designated business subject matter experts to determine the project scope, business requirements, current state business processes, future state business processes, the options to achieve the future state and the preferred approach. The relevant business units commit to tangible and measurable benefits and intangible benefits from the implementation of the new initiative.

Align:

Toronto Hydro reviews the proposed project to ensure the following:

- Governance, due-diligence, rationale and accuracy of the project costs and benefits
- Strategic alignment with utility objectives (e.g. value for money)
- Effect of newly-deployed software system on Toronto Hydro's risk profile (e.g. cyber security)

Prioritize:

Toronto Hydro prioritizes the project based on project dependencies, costs, benefits, strategic alignment and risk assessment.

Execute:

Project execution typically consists of the following steps:

- Engaging the vendor to provide application enhancement and analytics
- Gathering more detailed user and technical requirements
- Developing and/or procuring the application as needed

- Provisioning the infrastructure to host the application
- Configuring the application(s) to meet the business requirements
- Testing the application for compatibility with Toronto Hydro's infrastructure
- Engaging users to test that the application meets their business and functional requirements
- Training the users about the features and functionality of the application; Implementing the application across the appropriate utility departments

The following table summarizes the anticipated benefits of the Software Upgrade Program.

TABLE 1: SUMMARY OF PROGRAM BENEFITS

Customer Value	• Updated software maintains accurate customer billing. • Increased cyber security better protects customer information from unauthorized access. • Newer software enables streamlined and simpler integration, which prevents delays in restoring outages and completing necessary maintenance for customers and enables new services.
Reliability	• By automating and streamlining operations, IT software systems enable safe and efficient execution of numerous activities across the organization that are necessary to maintain a reliable distribution system for customers. • Increased cyber security protects against threats to the distribution system, helping ensure reliability.
Efficiency	• Automation of business processes improves employee efficiency. • Consolidation of multiple application interfaces into fewer applications improves employee efficiency. • Allow the seamless migration of business applications as Toronto Hydro migrates Operating Systems from Windows XP to Windows 7, reducing employee time spent troubleshooting migration issues. • Analytics in relation to these new applications can provide Toronto Hydro with critical information about managing resources and restoring power to customers in emergency events such as the recent July flood and December ice storm in 2013
Safety	• Updated software helps ensure cyber security of Toronto Hydro's distribution system. • Increased cyber security mitigates the risk of unauthorized access to distribution systems and assets.
Other Benefits	• Updating software ensures that support services are available from the vendor, which reduces the costs of specialized technical resources • Updated software enables Toronto Hydro to comply with the regulatory requirements of bodies such as Measurement Canada, the OEB and the IESO.

E8.5.3 Why the Program is Needed

This program is needed to support Toronto Hydro's operations and processes. In addition, periodically upgrading applications minimizes the risk of system integration challenges, cyber security risk and reduces maintenance costs by keeping applications current with the supporting infrastructure and aligned with vendor support cycles.

The applications in this program are important in the execution of utility processes. Application failure must be avoided in order to mitigate the following impacts:

- Employee downtime and loss of productivity;
- Potential delays in completion of core business processes such as customer billing; and
- Operational risks such as the inability to respond to outages in a safe, timely and effective manner.

This program is also needed to minimize the financial risks associated with running application past the expiry of the vendor support cycle. If an application is not upgraded before the vendor support cycle expires, Toronto Hydro may have to procure specialized technical resources to maintain and support the application (i.e. resolve incidents, address issues, or customize/enhance the application to suit the utility's needs).

Furthermore, Toronto Hydro may have to put in place additional contingencies to accommodate the outdated application and supporting infrastructure. These contingencies include standalone environments of legacy applications. In stand alone environments, the applications are run on server infrastructure that hosts the desired applications in a separate environment with compatible technology. To allow the seamless migration of business applications as Toronto Hydro migrates Operating Systems from Windows XP to Windows 7, a number of applications are hosted in standalone environments. Toronto Hydro needs to gradually reduce the footprint of standalone environments to reduce the burden of maintaining parallel infrastructure.

E8.5.3.1 Purpose

The purpose of the program is to upgrade the IT systems that support Toronto Hydro's core business operations and enable the utility to execute planned work programs. This program also mitigates risks relating to cyber security, ensures the compatibility of IT systems, facilitates regulatory compliance and enables process improvements and operational efficiencies.

The chart below outlines the trigger and secondary drivers of the program:

TABLE 2: PROGRAM DRIVERS

Trigger Driver	Reasoning
System Maintenance and Capital Investment Support	• IT systems support core business operations and planned work programs. These systems must be upgraded in order to mitigate failure risk, which could jeopardizes the utility's operations, and its ability to execute planned work programs. • Applications must be periodically enhanced and modified to provide additional functionalities and support evolving requirements and operational needs.
Secondary Drivers	**Reasoning**
Cyber Security	• Ensure IT systems are upgraded and secure from cyber attacks and that any vulnerabilities are addressed
IT Systems Compatibility	• Software applications and the underlying components (e.g. servers and operating systems) must be compatible to ensure uninterrupted IT system operations and deliver the desired end user experience and functionality.
Regulatory Compliance	• IT systems enable adherence to the requirements of regulatory bodies such as Measurement Canada, the OEB and the IESO.

System Maintenance and Capital Investment Support

To ensure the safe and efficient execution of its capital plans and operational programs, Toronto Hydro must maintain and enhance the software systems that support its core processes and operations. When IT systems are beyond the period of extended vendor support, the vendor and the market place do not guarantee availability of qualified resources and expertise needed to resolve any potential issues. As a result, if these systems fail, it typically take a longer time to restore, which can have a significant effect on the utility's operations and its ability to execute planned work programs and deliver service to its customers.

For example, control room operators and dispatchers rely extensively on the Outage and Distribution Management System and Mobile Network Management System to access to real time outage data and to view the location and status of field crews. Upgrading these systems ensures Toronto Hydro's continued ability to respond to outages in a safe, timely and efficient manner. In addition, system enhancements and analytics in relation to these applications can

provide Toronto Hydro with critical information about managing resources and restoring power to customers in emergency events such as the recent July flood and December ice storm in 2013.

Engineers, designers, and field crews depend on IT systems such as the Geospatial Information system and the Distribution Network Analytical Tool to access important information about assets across the distribution system, and to develop asset replacement plans, determine project detail estimates and review the conditions of assets prior to physical intervention.

Likewise, to execute planned work programs and to respond to outages in a timely fashion, Toronto Hydro's construction project teams and outage response teams must have access to various materials. The inventory management system facilities this by managing asset inventory levels across multiple warehouse locations, and enabling the delivery of materials at job sites and key locations across the system. A failure of this system could lead to potential errors in entering material information that could affect asset costing information, or even worse, may jeopardize the safety of employees using these materials. Delays in the delivery of materials to project sites could also hamper the utility's ability to respond to outages and to execute planned work in a timely and efficient manner.

Toronto Hydro's customer service teams also rely on IT software systems, such as Customer Care and Billing system, to access important customer information (e.g. customer addresses, billing information, and account history) in providing efficient and effective service to customers. The older versions of the systems present Toronto Hydro with increased security risks as they require the more frequent installation of security patches. This is an especially serious issue as security breaches can potentially compromise confidential customer information, e.g. customer bank accounts, SIN's, etc. As the customer care systems are aging, the probability of their failure is increasing. The potential failure of the Customer Care and Billing system presents a financial risk to Toronto Hydro as the utility will not be able to bill customers and can lose its revenue for the duration of these systems failure. Toronto Hydro expects that upgrades to this system will provide call center employees better functionality to effectively manage customer queries and relations, and associated IT systems enhancements and analytics are expected to provide the management with operational insights to better manage customer service.

There are many other IT software systems that are embedded into Toronto Hydro's operational processes and the majority of these systems are interconnected. The failure of any of these systems can potentially disrupt the supported process and negatively impact Toronto Hydro's overall operations.

Cyber Security Risks

When applications are used beyond the extended vendor support, the vendor no longer provides security upgrades or patches and performance upgrades or fixes for the software, which makes the application more vulnerable to cyber security risks. Each month, Toronto Hydro's IT security team successfully blocks, on average, over 50,000 "Exploit" type attacks and over 2,000 "Denial of Service" type attacks. "Exploit" type attacks seek to compromise IT systems, gain unauthorized access to confidential information and services, or tamper with normal IT system operations by exploiting known or potential system vulnerabilities. The "Denial of Service" attacks attempt to make a machine or network resource unavailable to its intended users. For example, a successful "Exploit" type cyber attack on the Customer Information and Billing System would compromise customer usage and billing data, and customer information. Any stolen data can be used in fraud and identity theft. Similarly, a leak of Toronto Hydro operational information could lead to malicious attempts to jeopardize day–to-day operations and, in extreme cases, a system vulnerability could lead to mass outages across the grid.

IT System Compatibility

Software applications and the underlying components (e.g. servers and operating systems) must be compatible to ensure uninterrupted IT system operations and deliver the desired end user experience and functionality. In many cases, the IT systems and their underlying components are on different lifecycles because the applications hosted in-house are purchased from the software product vendors and the underlying components are purchased from the hardware product vendors.

The ongoing use of applications past end of useful life leads to retention and maintenance of standalone underlying components that lag vendor support lifecycles. This exposes the IT systems to security and failure risks from the underlying components. Toronto Hydro must address these risks by upgrading its applications to maintain compatibility with underlying with infrastructure. The utility plans to do so in accordance with its IT Asset Management Strategy. To learn more about this strategy please refer to Exhibit 2B, Section D4.

Regulatory Compliance

Each year, Toronto Hydro must make changes to its business processes in order to comply with emerging regulatory requirements imposed by various regulatory bodies such as the OEB and

Measurement Canada. These changes must be reflected in the IT systems that support the relevant business processes. Examples of major past projects include the following:

- Creation of a new rate class for 30,000 customers who were billed using specialized suite meters, reflecting an OEB decision.
- Development of operational capability and reporting for Low-Income Energy Assistance Program (LEAP) customers.
- Development of operational processes and system functionality to implement the Ontario Clean Energy Benefit.
- Modification of operational process and systems functionality to support a 3000 kWh cap on the Ontario Clean Energy Benefit.
- Enhancements to Regulated Price Plan functionality to true up customer accounts based on updated OEB regulation.
- Redesign of the Non Billed Budget customer letters to match updated OEB regulations.

E8.5.3.2 Development of systems, self-service capabilities and internal control to manage operations in accordance with Canadian Anti Spam Legislation

All the IT software applications that Toronto Hydro owns and maintains (approximately 70 applications) are in the scope of this program.

Enterprise Applications describes a collection of computer programs built with the aim to display, process and store the large amounts of complex data to support enterprise-wide business processes.

Enterprise application software performs business functions such as procurement, scheduling, customer information management, energy management and accounting. It is typically hosted on servers and provides simultaneous services to a large number of users, typically over a computer network. This is in contrast to a desktop single-user application that is executed on a user's personal computer and serves only one user at a time.

Toronto Hydro's classifies its enterprise applications in two categories: Tier 1 and Tier 2.

The "Tier" nomenclature denotes the application importance or operational criticality.

- Tier 1 applications enable Toronto Hydro's operations and support utility-wide processes. They are functionally integrated with other applications, and are supported by complex underlying infrastructure such as databases, middleware, storage and network. As a result, Tier 1 applications generally have higher maintenance costs and a large user base. In a disaster scenario, the recovery point objective is less than 4 hours. Examples of Tier 1 applications include the ERP (Enterprise Resource Planning) System and Geospatial Information System.

The table below demonstrates that all the major IT systems (Tier 1 applications) in scope of this program and their underlying infrastructure will reach their end of life in the 2015 to 2019 period and must be upgraded:

TABLE 3: TIER 1 IT SYSTEMS DETAILS

System Name	System Age in 2015	Vendor End of Extended Support	Infrastructure End of Life
Financial Planning and Forecasting Tool	14 years	2012	2014
Inventory Management System	3 years	2013	2015
Geospatial Information System	12 years	2010	2012
Supervisory Control and Data Acquisition System (SCADA)	7 years	2015	2015
Distribution Network Management System	10 years	2011	2012
Mobile Work Management Tool	5 years	Not Applicable[1]	2015
Customer Information and Billing System	4 years	2015	2012
IT Foundational Technology	4 years	2013	2012

The IT systems and underlying infrastructure are on different end-of-life and vendor support cycles. This is a well understood reality in the IT industry because the systems hosted in-house are purchased from the software product vendors and all the underlying hardware infrastructure those systems are running on (e.g. servers, network devices, etc.) are purchased independently from the hardware product vendors. This practice explains the fact that, for example, the Customer Information and Billing System will be past of vendor support in 2015, whereas its underlying infrastructure reached its end of life in 2012.

[1] Mobile Work Management Tool is a system developed in house

- Tier 2 applications enable specific divisional and departmental processes. These applications have little to no integration with other enterprise applications, and are typically supported by simple infrastructure. In a disaster scenario, the recovery point objective is less than 24 hours. Tier 2 applications generally have lower maintenance costs, and cater to a smaller user base than Tier 1 applications.

The table below provides examples of Tier 2 applications and explains how these application support business processes:

TABLE 4: TIER 2 APPLICATIONS

Business Area	Examples of Business Processes	Examples of Tier 2 Applications
Customer Service	1. Processes supporting customer self-services	1. TorontoHydro.com – used to enable various web services to customers including access to their accounts and ability to complete transactions
Operations	1. Processes supporting engineering design of Toronto Hydro electric distribution infrastructure	1. Computer Aided Design (CAD) Software – used to design and create work prints for electrical distribution system
Corporate Services	1. Process to manage payroll of Toronto Hydro employees 2. Process to manage workplace accidents	1. Payroll Application – used to extract employee pay data from Enterprise Resource Planning system and transmit the data to ADP (the payroll services company) to process payroll and transfer funds to various employee bank accounts 2. Workplace Incident Management Program –used to keep track of incidents, claims, and investigations relating to workplace accidents
Information Technology	1. Processes to manage IT user requests 2. IT Incident and Problem Management	1. Service Request Management Tool – used to track corporate-wide requests to IT 2. IT Central Data Repository – used to maintain information about IT assets and their relationships to each other

The typical lifecycle of a Tier 2 enterprise application is 2-5 years. This means that software vendors release the new versions of their systems once every 2-5 years. As the current

Distribution System Plan covers the period of 5 years, Toronto Hydro plans to upgrade all Tier 2 applications during the 2015-2019 period.

The table below (Table 5) presents the approximate number and percentage of the number of the Tier 2 applications that Toronto Hydro intends to upgrade each year:

TABLE 5: PLANEED TIER 2 APPLICATION UPGRADES

Tier 2 Enterprise Applications to be Upgraded	Year				
	2015	2016	2017	2018	2019
Approximate percentage	25%	20%	20%	14%	21%
Approximate number	15	12	12	9	13

Although Toronto Hydro makes its best efforts to distribute the upgrades and associated investments evenly during the 5-year period, the historical evolution of the IT landscape overtime and the uneven deployment of new systems in the past few years explains the increase in the number of assets to be upgraded in 2015 and explains the drop in the number of assets to be upgraded in 2018.

IT Software Enhancement

When any enterprise application is initially deployed, the pre-built functionality of this application is typically limited and does not provide sufficient analytics and reporting. To overcome the above-mentioned limitation, Toronto Hydro utilizes in-house and external IT developers to enhance application functionality and create customized reports to:

- Meet growing business needs
- Supply Toronto Hydro's leadership with the data to help them make informed business decisions
- Provide services to customers
- Provide management with short-interval process measurements and controls to achieve strategic and tactical goals

For example, the enhancements to the reporting functionality in the Attendance Management System in Toronto Hydro gave middle and senior management visibility in employee attendance records. The analytics were effectively used to improve Toronto Hydro's employee engagement.

This functionality enabled Toronto Hydro to achieve above average industry results with respect to absenteeism. For more information, refer to the Human Resources and Safety Program at Exhibit 4A, Tab 2, Schedule 18.

E8.5.4 Timing & Pacing of the Program

The total estimated cost of the IT Software Program is $81.0 million. The annual project costs over the 2015 – 2019 period is between $15.46 million and $16.78 million, and the average annual cost is $16.20 million. The table below (Table 6) provides the estimated cost breakdown by year from 2010 to 2019:

TABLE 6: HISTORICAL AND FUTURE SPENDING

CAPEX / ACTIVITY	Historical Spending ($M)					Forecasted Future Spending ($M)				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Software Upgrades	12.48	2.66	1.49	3.13	5.55	9.68	10.50	9.91	10.93	10.85
Software Enhancements	7.65	18.35	11.34	4.46	3.50	4.22	4.16	4.31	4.28	4.32
Regulatory Compliance	2.06	0.15	1.60	2.01	1.05	1.55	1.52	1.57	1.56	1.58
TOTAL	22.20	21.17	14.45	9.61	10.11	15.46	16.19	15.81	16.78	16.76

The program covers planned IT systems upgrades, software enhancements and analytics, as well as IT investments which are required to comply with regulatory obligations. The total forecasted program costs are consistent with historical trends. For software upgrades, the forecasts are also based on the asset lifecycle and other key information that Toronto Hydro maintains with respect to its IT assets in the IT Inventory System (refer to Exhibit 2B, D4). Due to funding limitation, Toronto Hydro had to defer certain upgrades in 2013 and 2014, and as a result, there is a forecasted increase in software upgrades investments in 2015-2019 period.

The timing and pacing of the software upgrade program is also influenced by a number of factors, including co-ordination with the proposed Enterprise Resource Planning (ERP) program, application complexity, and resource balancing.

Integration with the ERP Program:

Some of the applications in this program, such as the Mobile Work Force Management Tool and the Customer Information and Billing System must be integrated with Toronto Hydro's ERP system. As a result, the utility plans to defer upgrading certain applications until the ERP Program is completed in order to reduce duplicative efforts of integrating these applications with the existing ERP, and subsequently with the new ERP. All the IT application upgrades that are dependent on the ERP Program have been scheduled accordingly.

Application Complexity:

The IT software systems differ by the level of criticality and complexity.

Toronto Hydro classifies its enterprise applications in two categories: Tier 1 and Tier 2. The "Tier" nomenclature denotes the application importance or business criticality.

- Tier 1 applications enable Toronto Hydro's operations and support utility-wide processes. They are functionally integrated with other applications, and are supported by complex underlying infrastructure such as databases, middleware, storage and network. As a result, Tier 1 applications generally have higher maintenance costs and a large user base. In a disaster scenario, the recovery point objective is less than 4 hours. Examples of Tier 1 applications include the ERP System and the E-Mail System.

- Tier 2 applications enable specific divisional and departmental processes. These applications have little to no integration with other enterprise applications, and are typically supported by simple infrastructure. In a disaster scenario, the recovery point objective is less than 24 hours. Tier 2 applications generally have lower maintenance costs, and cater to a smaller user base than Tier 1 applications.

As a common IT industry practice, the most critical Tier 1 applications take priority while scheduling the IT software upgrades. For example, several applications at Toronto Hydro integrate with the IT Foundational Technology. The IT Foundational Technology provides the necessary software layer to run enterprise applications and cross-platform solutions. Toronto Hydro must upgrade the IT Foundation Technology first, prior to upgrading other applications that integrate to it. This sequence is important because if the integrated to IT Foundational Technology applications were to be upgraded first, Toronto Hydro would duplicate the amount of integration work: first, to integrate the less complicated applications after they are upgraded to IT

Foundational Technology, and then, to integrate them again after the IT Foundational Technology is upgraded.

Similarly, dependencies exist between different projects within this program. For example, a Finish to Start dependency exists between the Outage and Distribution Management System Upgrade and the Geospatial Information System Upgrade. This means, the Geospatial Information System Upgrade can commence only after the Outage and Distribution Network Management System Upgrade project completes.

Resource Balancing:

The projects are timed to ensure Toronto Hydro engages a steady level of available resources throughout the 2015 to 2019 period. This approach allows the utility to achieve a relatively stable annual capital expenditure plan over the 2015 to 2019 period, and reduces the cost pressures associated with the need to procure temporary resources to meet peak resource demands from projects.

E8.5.4.1 Ranking & Prioritization

As detailed in the IT Asset Management Strategy filed at Exhibit 2B, D4, Toronto Hydro employs a robust process in making decisions about which IT initiatives to pursue in a given time period. In accordance with this strategy, the utility plans to rank and prioritize the initiatives in this program by weighing the following considerations, and their effect on the utility's operations.

- Compliance with regulatory requirements: Regulatory bodies such as Measurement Canada and the OEB periodically review and amend regulations, standards and policies that govern Toronto Hydro operations. Toronto Hydro must take necessary steps to comply with the revised requirements to mitigate the risks of regulatory non-compliance which could result in financial penalties and legal repercussions.

- Core business operations and planned work programs: Toronto Hydro relies on IT systems to run its core business operations and to execute its capital plans and operational program. In case of an IT system failure, the affected business processes can become completely impaired, which could have a significant effect on Toronto Hydro's operations, its ability to serve customers and employee productivity. The utility must ensure that IT systems are available to support key business processes.

- Data security from cyber attacks: IT systems house important and highly sensitive information about utility's operations, and its customers and employees. This data must be secure against external cyber threats. The systems and underlying components must be upgraded and kept current to receive the latest security upgrades and service packs that ensure a strong cyber security posture.

- Impact to customer service: To sustain and improve the current levels of customer service, Toronto Hydro must ensure that its IT systems are available to support core customer service processes and functions. In some cases, Toronto Hydro must upgrade its applications to provide customers with new functionality, to maintain the security of these systems and to protect customer personal information.

E8.5.5 Program Execution

(i) Program Risks

The program risks can be categorized as follows:

Costs:

The program cost is based on estimates of internal labour, external labour and software costs over the 2015 to 2019 period. While Toronto Hydro can make confident estimates for the 2015 period this program is subject to greater price fluctuations over the 2016-2019 period. For example, there is a risk that vendors may increase software costs over the 2016 to 2019 period. This risk is mitigated by building the long term relationships with software vendors and including the appropriate clauses into the contractual agreements.

In addition, the absence of appropriate resources could be a risk to the cost of this program. In the event of resource shortages, Toronto Hydro will need to procure temporary skilled labour. Temporary skilled resources for projects needed at short notice cost a premium. To mitigate this risk, Toronto Hydro intends to procure resources for the 2015 to 2019 period based on long term program requirements.

Schedule:

Resource availability is critical to this program as the absence of appropriate resources could significantly impact the program schedule. This risk is mitigated through the development of

resource requirement plans for each year based on planned project load, and by spacing the initiatives over the 2015 to 2019 period to ensure there is a steady annual resource requirement.

Quality:

The two major risks to project quality stem from the following:

- IT System Integration: The IT systems in this program are tightly integrated with other IT systems across the utility, and the current levels of integration must be maintained in order to sustain existing processes. If the program fails to deliver the existing level of integration, business processes could be impeded and process inefficiencies could be introduced from manual data updates to and from other utility IT systems. The risk is mitigated by careful consideration and analysis of the new underlying component configurations in defining project scopes.

- Project Delivery: IT systems support core business processes, and as such, the delivery of a new IT system version to business units poses a risk to these processes. To mitigate these risks, the project plans include extensive regression testing and user testing, prior to rolling out the final upgrade to the business units. In addition, risks are mitigated through appropriate user engagement and communication, and project governance including contingencies to minimize the impact to the business users in the final implementation.

(ii) External Constraints

The planned scope of this program may be limited by the external constraints summarized below. Toronto Hydro intends to monitor these potential external constraints to ensure that sufficient time is available to plan and react in a way that minimizes the impact to this program.

Changes in the Technology Landscape

Toronto Hydro will monitor the technology landscape to ensure the most appropriate application meeting Toronto Hydro's business requirements is selected and implemented. Prior to each upgrade, Toronto Hydro will scan the product category to validate that the planned software upgrade is the most appropriate choice for Toronto Hydro. Should a superior alternative emerge, Toronto Hydro may consider implementing the better alternative software. The costs associated with the new software could impact the overall project costs.

Software Release Dates

Any changes to the application version release dates will impact the project schedule and potentially impact downstream projects in the program. For example, there exists a Start to Finish dependency between the Outage and Distribution Management System and Geospatial Information System; the latter cannot be upgraded until the former system is successfully upgraded. In this case, a delay in the release of the new version of the Outage and Distribution Management System Upgrade will delay the planned upgrade of the Geospatial Information System.

Standard & Regulation Adherence

All projects that form part of this program are governed by the external or internal standards and regulations. Collectively, these standards and regulations provide the technology framework for the proposed Software Program.

External standards and regulations include technology and information standards and regulations issued by bodies such as the OEB and Measurement Canada. For example, some Measurement of Canada recent regulations have led to Toronto Hydro's IT system changes:

- Modification of data collection, billing processes and core systems to bill customers based on register reads
- Customization of residential customer bills to display line loss and related units of measure

Internal standards include standards developed by Toronto Hydro for its servers, databases, middleware and network to effectively govern their selection, simplify the maintenance of solution components, and reduce the burden of managing unique stand-alone IT systems. To learn more about IT standards, refer to the IT Asset Management Strategy at Exhibit 2B, D4

E8.5.6 Evaluation of Alternatives

Toronto Hydro considered the following alternatives in relation to the Software Upgrades sub-program:

(1) Do Nothing - Run assets to failure and react accordingly.

(2) Managed Services - Outsource management of IT applications

(3) Standards based asset lifecycle maintenance - Asset Management Methodology

E8.5.6.1 Quantification/ Evaluation of Options

1. Do Nothing - Run assets to failure and react accordingly

Under this alternative, Toronto Hydro would not undertake any planned projects to upgrade its applications, but rather would run the applications to failure. After a certain period of time (typically after 2-5 years after the application is released), the software vendor would issue a new version of the application and would no longer provide support for the old version. When a software application is out of vendor support, it does not receive any security upgrades or service packs from vendors. As a result, Toronto Hydro would not be able to upgrade any underlying components, would become exposed to operational risks associated with application failure, and would be vulnerable to cyber security threats.

Project Implementation:

No projects are planned under this option. However, it is expected that Toronto Hydro would need to execute ad hoc projects to upgrade existing solutions on a reactive basis. The project budgets, timelines and scope will be determined on an as needed basis.

Change Management:

In theory, the Change Management requirement of this option is the lowest because Toronto Hydro would continue to use the same applications in the 2015 to 2019 period. However, it is likely that Toronto Hydro would need to upgrade existing IT systems or implement new IT systems in a reactive manner when an existing IT system fails. This would create change management issues in user adoption of the new or upgraded IT system and in users fully utilizing the features and functionalities in the new version or IT system. The reactive nature of this implementation would create additional change management challenges, i.e. limited time for testing, training, contingencies, etc.

Customizations:

It would become increasingly difficult to customize IT systems under this option due to compatibility issues related to the obsolescence of the IT system. For the same reason, it would be expensive to procure the necessary resources and skill sets to implement future customizations.

Ongoing Maintenance:

In this option, once the application is past its useful life, and out of guaranteed vendor support, Toronto Hydro would be responsible for maintaining the application and dealing with all the application issues. This would necessitate developing workarounds to known problems rather than long term solutions.

Risk:

This option has the highest risk exposure, as business processes and operations could be severely affected by the failure of the IT systems which support them. In addition, this option poses a significant cyber security risk because outdated systems are more vulnerable to cyber attacks and compromises. There is also a financial risk from the labour and vendor charges in undertaking unplanned and ad hoc projects to upgrade IT system(s) when they fail.

2. Managed Service

In this alternative, Toronto Hydro would enter into contractual agreements with a number of vendors to manage its software applications. Toronto Hydro would provide the requisite underlying components, but an external vendor would administer and maintain the applications that the utility requires to carry out its business processes and executed its plans and programs. The external vendor would also apply the necessary service packs, security upgrades and bug fixes, and upgrade the software as needed.

Project Implementation:

The vendor and Toronto Hydro would collaborate to determine the appropriate product upgrade schedule to be undertaken in the 2015 to 2019 period. The vendor would complete the software upgrade activities, in collaboration with the relevant Toronto Hydro teams responsible for the underlying components. Toronto Hydro would be responsible for providing necessary customization requirements and completing user acceptance testing of the new software version, but could not directly control delivery timelines.

Change Management:

The change management impact of this option would be the highest out of all alternatives. First of all, the whole interaction process between the IT division and the business users of the systems would need to be re-designed as the IT division would no longer be responsible for the systems'

performance and on-going maintenance. Second, the managed service model will affect the structure, roles and responsibilities of the IT division. In dealing with IT systems failures, as opposed to completing detailed investigations and fixing the issues at the time of incidents, the business users will need to report of incidents to vendors and manage communication with them.

Customizations:

In this model, Toronto Hydro would need to engage the vendor to customize the software, as the vendor would have the required expertise with respect to the configuration of the IT system, its features and functionalities, as well as the database structure. This approach can potentially complicate the coordination of all involved stakeholders and prolong the execution timelines.

Ongoing Maintenance:

This option presents Toronto Hydro with the least control over the maintenance of its IT software applications. Over time, Toronto Hydro would lose the knowledge and expertise in maintaining its IT systems. Should there be a need to quickly resolve a number of IT systems incidents simultaneously, as is usually the case during emergency events (e.g. storms, flooding, etc.), there is a significant risk that the third-party vendors would not be able to accommodate the demand in a timely manner. As a result, Toronto Hydro could experience prolonged IT systems outages and, by necessary implication, customers could experience prolonged electricity outages. Since the vendor would be responsible for the overall management of the application, the Operational Expenditure in this option would be very high.

Risks:

Vendor management is a key risk that the utility has to consider under this option. If Toronto Hydro terminates the contract with a vendor or vice versa, there is a risk that the IT system would be unsupported until a suitable support alternative is found. This situation could prolong the duration of IT system failures and jeopardize the continuity of Toronto Hydro's business operations. There are increased risks to data security from vendor data accessibility and vendor cyber security risks.

3. Like-for-Like Upgrades - Asset Management Methodology

In this alternative, Toronto Hydro will upgrade the software and the underlying components to more recent and stable vendor supported versions. Toronto Hydro policy is to stay one version behind the latest release, but not to exceed two versions behind the latest release. This allows a

sufficient stabilization period for the IT system prior to an upgrade by Toronto Hydro and allows for the development of any necessary performance and security fixes to minimize interruptions to the utility's operations and planned work programs.

Project Implementation:

From a project implementation perspective, this option will deliver the projects relatively quickly. This option reduces the time and effort needed to evaluate different IT system options and negotiate new contracts. Toronto Hydro has considerable knowledge in understanding the project effort, duration, and complexity involved in upgrading existing IT systems.

Change Management:

A Like-for-Like upgrade ensures minimal impact to processes and incremental changes to business user experience. Toronto Hydro will implement new features that would provide incremental benefits to existing processes. Upgrading existing IT systems minimizes the effort required to overcome challenges from change management and re-training of business users on new IT systems. This ensures a higher rate of user adoption and a more successful upgrade. This option also minimizes the re-training needed for IT staff to support the new IT systems.

Customizations:

The existing system integration and configurations will be migrated to the next version. Since the integration and configurations are within the same product, the effort needed to duplicate this effort for a new version is less than that required for a new IT system. Extensive regression testing will be needed to ensure no bugs are introduced in the upgrade.

Ongoing Maintenance:

This option gives Toronto Hydro control over the maintenance of the software and its underlying components. By retaining and building upon the detailed knowledge of its IT systems, this option enables Toronto to quickly resolve incidents and known errors, and to manage and respond to emergencies and other urgent situations more effectively and efficiently than a third party vendor could. Under this option, Toronto Hydro will control the IT system maintenance windows, which allows the utility to address underlying component needs and compatibility considerations, and better manage data security issues.

Risk:

This option offers the lowest risk of all options. Toronto Hydro will mitigate to the risk of IT system outages that could impact core operations and business processes by carefully planning and scheduling applications' upgrades. This option ensures the overall IT system is up to date, and secure from malicious cyber security threats.

The table below (Table 7) summarizes the analysis of the alternatives and presents Toronto Hydro's recommendation:

TABLE 7: OPTIONS EVALUATION

Criteria	Option 1 Do Nothing - Run assets to failure and react accordingly	Option 2 Managed Services - Outsource management of IT applications	Option 3 Standards based asset lifecycle maintenance - Asset Management Methodology
Ease of Project/ Upgrade Implementation	N/A	high	high
Change Management	medium	high	low
Ease of Customizations	low	low	high
Ease of Ongoing Maintenance	medium	high	low
Risk	high	medium	low
Recommendation			X

For the investments in the Software Enhancements and Regulatory Compliance sub-program, which are more diverse and reactive in nature, Toronto Hydro will leverage the governance process described above in section E8.5.2 and the IT Asset Management Strategy filed at Exhibit 2B, D4, to assess the scope and evaluate the technical alternatives for each proposed initiative. This process will help ensure that Toronto Hydro considers relevant options, and makes the most prudent decision with respect to these types of investments.

E8.5.7 2015 Projects

Software Upgrades

1) OMS / DMS Upgrade
2) Web Portal Foundation
3) JBOSS Interface Migration
4) ODS Upgrade
5) ARIS Upgrade
6) AP Link (RBC Express)
7) Iteraplan Upgrade
8) Microsoft SharePoint 2013 Migration
9) Websphere (WAS)
10) SPI SPOKE interface upgrade
11) Data Package Reporting System (DPRS) Upgrade
12) Mercury / HPQC Upgrade
13) Microstation Design Tools Upgrade
14) SRR (eSRR) – System Response Report Upgrade
15) Admin Studio Upgrade
16) Visual Studio Upgrade

E8.6 Enterprise Resource Planning Program

E8.6.1 Summary

Program Description

Enterprise Resource Planning (ERP) systems are Information Technology (IT) tools that perform critical "back-office" processes, such as finance, human resource and supply chain activities, to support Toronto Hydro's core utility operations. Toronto Hydro's end-of-life ERP, Ellipse, was introduced in 2002 and will soon no longer be supported by its vendor. The cessation of this support will introduce a number of technical risks that severely restrict the ongoing sustainability of Ellipse.

To meet evolving statutory, regulatory and operational demands, Toronto Hydro implemented additional applications to complement Ellipse where its functionality was insufficient. While this approach extended the life of Ellipse, it created an IT framework that is challenging and expensive to support and inhibits Toronto Hydro's ability to add new functional requirements in a cost-effective manner. Moreover, many of those applications face sustainability issues of their own.

Toronto Hydro's preferred approach is to replace Ellipse and 30 other applications ("Legacy Systems") with a new, fully-supported ERP. The new ERP would incorporate new functional requirements that deliver incremental benefits such as cost savings and process improvements. This approach would also allow Toronto Hydro to remove Ellipse and the Legacy Systems from its operations, avoiding the need to make technical upgrades to address its sustainability issues.

Program Drivers

The trigger and secondary drivers for this program are summarized below.

TABLE A: PROGRAM DRIVERS

Trigger Driver	Reasoning
Functional Obsolescence	ƒ Between 2015 and 2019, Ellipse and many of Toronto Hydro's Legacy Systems, will no longer be supported by vendors. ƒ Cessation of vendor support raises a number of critical risks, including cybersecurity.

Secondary Driver	Reasoning
Business Operations and Efficiency	ƒ Toronto Hydro has identified a number of key processes that could be made more efficient if supported by an IT solution.

Preferred Alternative

Toronto Hydro considered four approaches to this program:

(1) Technical Upgrade (Base Case): Executing technical upgrades of Ellipse and the Legacy Systems.

(2) Ellipse and Legacy System Renewal: Executing technical upgrades of Ellipse and the Legacy Systems and further customizing these applications to deliver the new functional requirements.

(3) ERP Implementation (Proposed): Replace Ellipse and the Legacy Systems with a new ERP that delivers the new functional requirements.

(4) Extended ERP Implementation: Replace Ellipse, the Legacy Systems and three additional applications with a new ERP that delivers the new functional requirements.

Option 3, "ERP Implementation", delivers the highest net present value of the four options considered. On this basis it is Toronto Hydro's preferred option.

Timing and Pacing

Toronto Hydro's proposed ERP Program consists of a single project culminating in the implementation of a new ERP during the 2015 to 2019 period. This project is scheduled to be completed by end of 2016. A four-phase implementation approach will be adopted that emphasizes an integrated design process and requirements definition prior to the selection of a system. These phases are:

(1) Initiation: During the Initiation Phase, Toronto Hydro developed the program's high-level implementation approach and timeline to give structure and direction to the remaining phases of the project. Resources required to execute the subsequent stages were also defined.

(2) Strategize & Architect: The purpose of the Strategize & Architect phase is to identify, define and verify the functional requirements of the program. Once the functional requirements are determined, the benefits associated with each improved process will be estimated.

(3) Design, Realize & Deploy: This phase encompasses the standard phases of an ERP Implementation, including detailed design, configuration, testing, training, data cleansing and conversion and all associated change management activities.

(4) Support & Optimize: The objectives of this phase are to stabilize the ERP System, to embed the new processes into day-to-day operations, and to capture unanticipated system or process inefficiencies for subsequent resolution.

As shown in Table B, Toronto Hydro plans to spend $51.3 million to implement this program during the DSP period.

TABLE B: HISTORIC AND FUTURE SPENDING

	Historical Spending					Forecasted Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	1.8	0.9	17.7	33.6	0	0	0

E8.6.2 Program Description

The Enterprise Resource Planning Program (the "ERP Program") proposes to replace Ellipse, Toronto Hydro's current end-of-life ERP system, and 30 other "back-office" information technology systems (together the "Legacy Systems") with a single ERP application.

An ERP System is an integrated suite of applications covering broad operational end-to-end utility processes, such as those found in finance, human resources, distribution, project systems, maintenance service and the supply chain. ERP tools share a common process and data model which allow operational transactions to be linked to financial transactions, specifically general ledger transactions, in real time.

Toronto Hydro's current ERP system, Ellipse, was implemented in 2002 and is a legacy from the period of IT system renewal undertaken following the amalgamation of Toronto Hydro's predecessor utilities. That period of system renewal was focused on replacing the predecessor utilities' outdated information technology applications, and synthesizing their back-office systems. At the time of purchase, Ellipse was classified as an ERP system, however the industry has developed significantly since then to the point where Ellipse is no longer considered an ERP.[1]

Since 2002, Toronto Hydro's operating environment has undergone considerable change due to evolving legislative, regulatory and operational requirements. Moreover, Toronto Hydro has undertaken an increasingly complex and demanding capital renewal program and is constantly working to meet evolving customer needs. This evolving utility landscape has demanded new or different functionality from what Ellipse was capable of providing. For example, Toronto Hydro must publish financial reports using multiple accounting rules, including the simultaneous production of USGAAP, IFRS and regulatory accounts, a function that Ellipse is unable to execute.

To fulfill these incremental requirements in a cost-effective manner, Toronto Hydro opted to extend the lifespan of its existing system by implementing new applications networked with Ellipse as they were needed. To modernize its accounting practices in response to the new financial requirements, SAP was introduced to meet those needs.

[1] In a 2013 review of ERP systems by Gartner, a leading IT research and advisory firm, for companies like Toronto Hydro, Ellipse was omitted from that list.

Consequently, Ellipse and the Legacy Systems form a substantial part of an integrated application topology that performs crucial back-office tasks that support the core financial, human resource, work execution and safety processes that are essential to Toronto Hydro's operations.

Figure 1 illustrates the current topology of Toronto Hydro's back-office systems, including Ellipse and the Legacy Systems which are proposed for replacement under this program. A brief description of each of the 30 Legacy Systems can be found in Appendix A.

FIGURE 1: A VISUALIZATION OF THE TOPOLOGY OF ELLIPSE AND OTHER IT SYSTEMS

Like all information technology applications, as Ellipse and the Legacy Systems age, they must be maintained on an ongoing basis to ensure that they continue to operate efficiently and

securely. For example, in 2006 Toronto Hydro undertook a mid-lifecycle technology upgrade of Ellipse. Among other things, this step ensured Toronto Hydro could obtain security patches and other kinds of technical support, extending the functional life of Ellipse.

However, the version of Ellipse currently used by Toronto Hydro is once again functionally obsolete, exposing the utility to a number of technical risks that must be addressed. These risks, discussed in greater detail in the Needs section of this case, are:

- Operation on uncertified hardware
- Application capability limitations
- Technology limitations that impede operational efficiency
- Cybersecurity

The functional gaps between Ellipse and Toronto Hydro's operational requirements create further issues for the ongoing sustainability of Ellipse and the Legacy Systems. As shown in Figure 1, Toronto Hydro now uses a suite of applications to complement the functionality of Ellipse. Toronto Hydro must maintain 31 software interfaces to ensure that existing back-office utility operations are supported. However, securing and maintaining seamless processes across these applications becomes increasingly complex and resource-intensive with each additional application.

The constraints imposed by Ellipse and the Legacy Systems are problematic because Toronto Hydro has identified a number of operational processes that require the back-office IT support. These processes, discussed in further detail in the Needs section of this case, are:

- Planning;
- Record-to-Report;
- Human Capital Management;
- Asset Plan, Build, Maintain
- Source to Pay; and,
- Customer Connection.

Replacing Ellipse and the Legacy Systems with a new ERP is an effective means of addressing functional obsolescence. Under this program, Toronto Hydro would remove Ellipse and the Legacy Systems from its operations and replace them with a single ERP system that is equipped to meet the utility's operational needs for serving its customers. The incremental functionality required by these processes would be incorporated at the design phase of the ERP development process.

Toronto Hydro expects its selected ERP approach to provide it with the opportunity to achieve benefits that fall into three primary categories:

- cost savings;
- cost avoidance; and,
- process improvements.

Cost savings can be obtained in moving away from Ellipse and the Legacy Systems to a new ERP by eliminating the need to do certain tasks or activities. This includes the savings expected to materialize through no longer needing to support Ellipse, the Legacy Systems and many existing software interfaces. By comparison, the topology centred around the new ERP would be far simpler, as shown in Figure 2. The number of interfaces that require ongoing support and maintenance would be reduced by more than half, from 31 to 14. As a result, Toronto Hydro would require fewer resources to provide the necessary support to the new ERP, and would require fewer specialized skills that are otherwise necessary to maintain Ellipse and the Legacy Systems. Table 1 lists the applications that would be retired with Ellipse upon implementation of the new ERP.

FIGURE 2: NEW IT TOPOLOGY UPON IMPLEMENTATION OF THE NEW ERP.

TABLE 1: LEGACY SYSTEMS PROPOSED FOR REPLACEMENT IN ADDITION TO ELLIPSE

1. Asset Management Portal	16. New Location Request Application
2. Attendance Management System	17. On-Line Hold Off Request Form
3. Cable Failure Web Application	18. Picking Slip Application
4. Confined Space System	19. Reclaim Equipment Application
5. Employee Moves	20. Resource Requisition (RRAP)
6. Ellipse Management Reporting System (EMRT)	21. Return Slip Application
7. Equipment Without Maintenance Scheduled Tasks	22. SAP
8. Feeder Information System	23. Scope Planning
9. Feeder Operating Conditions	24. Support Point Paniva
10. Hyperion	25. TeamMate Audit Management
11. IT Time Sheet	26. Timelink
12. Labour/Vehichle Costing Application	27. Treasury Manager
13. Maintenance Schedule Task Application	28. Unit Price Contract Management System
14. Material Reference Book	29. Work Activity Log
15. Material Requirements Planning and Forecasting	30. Work Request System

Implicit in implementing a new ERP is the avoided cost of the otherwise necessary remedial action need to address the functional obsolescence of Ellipse and the Legacy Systems. This work, discussed in further detail under in the Evaluation of Alternatives section, constitutes the basis for comparing the various options considered under this case.

It is also expected that the new ERP would deliver process improvements by reducing the amount of time required to undertake tasks in the new ERP environment. Process improvements are expected in each of the six functions identified above. This includes the benefit of the projected increase in the reliability of Toronto Hydro's IT systems.

The ERP Program is forecast to require capital expenditures of approximately $51.3 million in the 2015 to 2019 period, as outlined in Table 2. The total cost of the program, inclusive of pre-2015 capital expenditures, includes Software and User Licenses of approximately $5.1 million, computer hardware and other required technical infrastructure of approximately $3.4 million and system implementation resources and services of approximately $45.4 million. A description of how Toronto Hydro intends to execute the program is included in the Program Execution section.

Appendix B contains a summary of the projected costs and benefits of implementing the proposed ERP Program over its expected ten-year life.

TABLE 2: EXPECTED CAPITAL EXPENDITURES – ERP IMPLEMENTATION

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	1.8	0.9	17.7	33.6	0	0	0

E8.6.3 Why the Program is Needed

Toronto Hydro implemented its current ERP system, Ellipse, in 2002. Since then, Toronto Hydro has taken steps to maintain Ellipse as a cost-effective, secure, reliable and relevant component of its back-office IT infrastructure. These steps included performing a mid-lifecycle technology upgrade on Ellipse in 2006 and adding applications to leverage or to supplant Ellipse's capabilities when Ellipse on its own could not deliver the required functional improvements.

While Toronto Hydro's investments in Ellipse and the Legacy Systems provided value to the utility and ratepayers, they can no longer prudently satisfy the utility's operational, statutory, or regulatory requirements, nor is there any prudent means of further extending their useful lives. Material risks of continuing to operate Ellipse and the Legacy Systems in their current state include inadequate availability of support resources, performance and cybersecurity risks. In order to mitigate these risks and achieve additional operational efficiencies, Toronto Hydro proposes to replace Ellipse and the Legacy Systems within the 2015 to 2019 period.

E8.6.3.1 Program Drivers

TABLE 3: PROGRAM DRIVERS

Primary Driver	Reasoning
Functional Obsolescence	ƒ Between 2015 and 2019, Ellipse and many of Toronto Hydro's Legacy Systems, will no longer be supported by vendors. ƒ Cessation of vendor support raises a number of critical risks, including cybersecurity.
Secondary Drivers	**Reasoning**
Business Operations and Efficiency	ƒ Toronto Hydro has identified a number of key processes that could be made more efficient if supported by an IT solution.

E8.6.3.2 Functional Obsolescence

Vendor support for Toronto Hydro's version of Ellipse is coming to an end which, if unaddressed, would render it functionally obsolete.

Ellipse is a "Commercial Off-the-Shelf" (or "COTS") software application. A major advantage of purchasing a COTS application, as opposed to developing an application in-house, is the availability of vendor support for the application and its underlying database and operating system for the duration of the General Support period.

Ellipse's General Support, provided by its vendor, Ventyx, was crucial to the system's ongoing usefulness to Toronto Hydro. While Ellipse was in General Support, Ventyx developed some of the functionality required to comply with new legislative, regulatory and operational requirements in a timely fashion.[2] They quickly identified and resolved system issues and security vulnerabilities in the application's source code. Periodically, they also certified new database, operating system and hardware configurations to ensure system performance.

Similarly, Toronto Hydro had a General Support Agreement in place with Oracle to support Ellipse's Oracle database. This helped ensure that newly discovered database bugs and security vulnerabilities were resolved in a timely manner through patches.

While General Support provides significant benefits to application users, these agreements are only available for a limited time, as application vendors do not offer indefinite support arrangements.[3]

As Table 4 illustrates, Ellipse's Oracle 9i database has been out of General Support since July 2007, while General Support for the application itself expired in March 2008.

TABLE 4: ELLIPSE SOFTWARE COMPONENTS –SUPPORT STATUS

	Software	End Of General Support	End Of Sustaining Support
Application	Ellipse 5.2.3.7	Q1 2008	Q2 2015
Database	Oracle 9i	Q2 2007	Indefinite

Once the General Support period for a software product ends, vendors typically offer Sustaining Support. However, Sustaining Support is subject to time and scope limitations and other exclusions and limitations. These departures from the General Support terms reduce the value of vendor support, but not its cost. Over time, continued reliance on Sustaining Support means that

[2] As detailed above, this functionality was not delivered to the extent required by Toronto Hydro.
[3] While arrangements vary from vendor to vendor, the typical or "industry standard" General Support period is 5 years, followed by an additional 3 to 5 year period of Sustaining Support (also sometimes called Extended Support).

the value-for-money of the investment consistently diminishes.[4] Given these considerations, it is not prudent for Toronto Hydro to continue operating current versions of Ellipse or the Oracle database beyond the actual or effective expiration of their respective Sustaining Support periods.

One alternative to vendor Sustaining Support is to provide those critical services either by a suitably qualified third-party or from within Toronto Hydro's Information Technology department. However, Toronto Hydro expects that obtaining replacement services will be increasingly challenging and costly. Moreover, the efficacy of this increased effort and expenditure would also likely be limited, particularly with respect to the certification of hardware and the maintenance application and database security as these sorts of activities are highly specialized and therefore not feasible to maintain "in-house".

The functional obsolescence of Ellipse introduces the following technical risks:

- Operation on uncertified hardware;
- Application capability limitations;
- Technology limitations that impede operational efficiency; and
- Cybersecurity.

Operation on Uncertified Hardware

Retaining General Support for an information technology application is valuable because the vendor will certify that their applications will operate properly on certain hardware. Certification is essential because applications require processors, disk drives and other physical internal systems to reliably and accurately gather, process or transmit information properly. Vendors' support contracts specify that support will not be provided for technical issues that occur on unsupported hardware. Information technology vendors will also cease to certify a version of their software to operate on any new hardware once that version's General Support period ends.

No hardware released in the last five years is certified by Ventyx to run the version of the Ellipse application currently used by Toronto Hydro. The lack of certification for new equipment would not be an issue if the physical hardware required to operate Ellipse had an indefinite life. However, information technology equipment eventually degrades and requires replacement. Ellipse's

[4] Oracle's Software Technical Support Policies are indicative of the kinds of restrictions that take effect upon the expiry of General Support. See the following link for more information: http://www.oracle.com/us/support/library/057419.pdf. Accessed June, 2014.

original server became less reliable over its 12 years of service, with its disk drives and readers wearing out and its power supplies degrading. Because the hardware was no longer manufactured, replacement parts for these critical components also became difficult to obtain.

To mitigate the risk of a physical server failure, Toronto Hydro migrated Ellipse to unsupported servers in November 2013. While necessary and carefully planned, tested and executed, Ellipse's migration onto these unsupported servers raised the risk that Ellipse may not function properly in certain situations due to incompatibility between the application and its uncertified physical hardware.

There is already some evidence that the new server components supporting Ellipse are unable to efficiently execute the instructions sent by Ellipse in certain circumstances. For instance, since the migration onto the new hardware took place, the nightly update processes required to ensure that Ellipse and the other Legacy Systems that receive data from it are ready for the start of the next business day take approximately one hour longer to complete. Given that those nightly processes must be complete before the next day's processing can begin, Toronto Hydro's ability to use Ellipse at the start of the next business day could be compromised if performance deteriorates further. This could result in a significant loss of operational efficiency.

Moreover, in the absence of vendor support for new hardware certification in the future, Toronto Hydro cannot eliminate the possibility that additional and more serious software or hardware compatibility issues will emerge when the next server change is required to address the risk of hardware failure.

Application Capability Limitations

Today, Ellipse's software platform presence in North America generally, and within the utility industry more specifically, is very limited. This reduced industry footprint raises two important sustainability issues for Toronto Hydro.

First, the release of new application functionality for Ellipse is lagging when compared to its competitors, diminishing the breadth of Ellipse's solution-offering over time. As a result, Toronto Hydro has been forced to look to other providers for cost-effective, back-office information technology solutions to fulfill operational requirements. For example, in 2009 Toronto Hydro implemented SAP's Finance module because Ellipse was unable to support the simultaneous use of USGAAP and IFRS accounting rules in a timely manner. Toronto Hydro also implemented Timelink's timekeeping solution in 2012 because Ellipse's functionality was inadequate. It is likely

that Toronto Hydro will be forced to continue to develop or purchase additional software in the future to meet new operational requirements, which is not prudent given the level and specialized nature of resources required to maintain this topology.

The second sustainability issue that arises from Ellipse's reduced industry footprint concerns the timely availability of application support. Since implementing Ellipse in 2002, it has been difficult to locate qualified Ellipse support staff, especially those capable of supporting and integrating the utility's aging version of the application. This situation continues to worsen with time.

The application support risk stemming from the very small number of resources with sufficient skills in Ellipse is significant to Toronto Hydro because it requires specialized skills to repair the Ellipse system. These skills are not always available and can be expensive when they are. Without access to that talent, Toronto Hydro will be far less likely to be able to effectively support Ellipse over time.

Finally, it is reasonable to expect that the utility may experience challenges with the provision of Oracle database resources in the future, since Oracle's Sustaining Support service does not guarantee that necessary information and skills will be available. Future resourcing issues are likely to emerge as the Oracle database version used by Toronto Hydro ages.

Technology Limitations that Impede Operational Efficiency

The version of Ellipse used by Toronto Hydro has four other technical limitations that prevent or impede the development of more efficient and secure processes.

- Absence of a Standard Application Programming Interface: Toronto Hydro integrates Ellipse with the Legacy Systems to fulfill its operational process needs. Integrating applications improves the accuracy and security of the data contained within it. However, while necessary to ensure operational efficiency, the integration between Ellipse and the Legacy Systems is often complex and costly to undertake because the older version of Ellipse used by Toronto Hydro, unlike many other ERP systems, does not have a standard Application Programming Interface (API) to facilitate the technical work required. Consequently, all integration to and from Ellipse must be custom-developed, tested and implemented. This is a more costly and time-consuming approach than would be the case if an API was available in the application. Moreover, interface support costs are further increased because of the need to retain relevant skill sets and to monitor of number of complex, interdependent

interfaces. The lack of integration capability within Ellipse is a significant barrier to integrating new applications that are necessary for Toronto Hydro to operate efficiently and effectively.

- No Lightweight Directory Access Protocol Support: One of the measures Toronto Hydro uses to maintain the effectiveness of its information security administration is a centralized user account/privilege repository known as the Lightweight Directory Access Protocol (LDAP). LDAP was implemented to help Toronto Hydro information technology staff better manage user access across all systems. However, the version of Ellipse currently used by Toronto Hydro cannot be integrated with LDAP and so additional manual effort to manage users and permissions in Ellipse is required. These extra measures substantially increase the required security management oversight, necessitating frequent audits to ensure that application access privileges are not granted in error to users that are not entitled to receive them. This extra effort raises the cost of sustaining Ellipse.

- "All or Nothing" Access to Operational Functions and Data: The ability of Ellipse to segregate access to operational data and functions on a sufficiently granular level is limited, making it difficult to restrict user access in certain areas, modules and situations. This "all or nothing" access to data and operational functions creates a number of issues including the inability to limit access to human resource or financial data to a single department of the organization or to only certain users. This technical limitation means that the utility has to decide between not fully leveraging Ellipse's capabilities, or losing internal control over the use of data.

- No Cross-functional workflow: Cross-functional workflow capability would allow the utility to define, sequence and monitor tasks performed by different actors across operational functions. Ellipse has only primitive workflow management capabilities and, as a result, instead of implementing automated workflows to orchestrate efficient processes, Toronto Hydro must rely on manual systems to facilitate the integration of tasks that cross utility functions. For example, within the purchasing area, manager approvals are required when purchase orders exceed prescribed thresholds, but there is no way to automatically route these approval requests to the relevant manager from within the version of Ellipse used by the utility. As a result, Toronto Hydro employs a manual system using e-mail to perform this function. This approach increases the effort required to monitor the process, raises the likelihood of errors

and introduces delays that would not occur if a fully-automated and fully integrated workflow management solution was available.

Cyber Security

During the course of its operations Toronto Hydro gathers, processes and stores large amounts of confidential financial, asset and human resources data within Ellipse. Protecting this information from unauthorized disclosure or use is a key priority for Toronto Hydro, especially given the rising threat posed by increasingly sophisticated malicious parties. As the Independent Electricity System Operator (IESO) notes in its "Cyber Security Threat Overview" the number and complexity of cyber attacks by individual, sub- or pan-national interest groups and rogue states grew by 42% in 2012, with the Energy/Utilities sector being the 5th most targeted industry.[5]

Toronto Hydro recognizes that an information technology security breach could have material adverse effects on the utility and its ability to deliver essential services. It mitigates this risk by using layers of technical and management controls to prevent or to detect and limit the extent of any breach. These efforts include:

- Using security event management tools ("firewall") to assess network activity and to detect and prevent intrusion;
- Applying security patches provided by vendors to applications and databases;
- Performing regular vulnerability assessments on critical IT assets;
- Implementing corrective measures where vulnerability assessments indicate a weakness;
- Conducting periodic system scans for known cyber threats and signatures of malicious traffic; and
- Training staff in information security awareness.

The protection measures applied to the Ellipse application and its database are not keeping pace with new threats. Ellipse's application and database software have received Sustaining Support since Q1 2008 and Q2 2007 respectively, which does not require the vendors (Ventyx and Oracle respectively) to search for undiscovered vulnerabilities or provide the patches to fix them. This lack of regular security support by the vendor leaves Ellipse more vulnerable to potentially significant information security breaches than it would be if such support was provided. While

[5] Hammerschmidt , Jason D. "Cyber Security Threat Overview" IESO PowerPoint Presentation ., p. 7, 10,& 12.

developing in-house application and database security capacity is technically an option, doing so would likely be prohibitively expensive and, given the large number of threats to identify and remedy, likely less effective than vendor-led efforts.

For these reasons, Toronto Hydro is becoming increasingly dependent upon its corporate firewall and other compensating controls to ensure Ellipse's security. If these measures are circumvented, both the application and its database would be more susceptible to virus, malware and other hacking exploits than if vendor support for information security patching was provided. Consequently, there is a heightened risk that Ellipse may experience database damage, information leakage or externally caused system failure in the future.

E8.6.3.3 Legacy Systems – Sustainability Issues

Since Ellipse's implementation, Toronto Hydro has had to implement many COTS and custom-developed information technology applications to address the utility's evolving operational needs. While these applications enabled Toronto Hydro to leverage and prolong the life of Ellipse, many of these solutions now have sustainability issues of their own.

Table 5 briefly describes the applicable sustainability issues and indicates which custom-developed Legacy Systems are impacted:[6]

TABLE 5: CUSTOMIZED LEGACY SYSTEM SUSTAINABILITY ISSUES

Issue	Description	Legacy Systems Impacted
End of Extended Support for Oracle Databases	Oracle's support for the databases that now support most of the Legacy Systems is now in the Sustaining Support Phase. While this support is "indefinite", it does not include security patch updates to close newly discovered security vulnerabilities. Unpatched security gaps make the system increasingly vulnerable to a cyber intruder. In addition, if database	ƒ Asset Management Portal ƒ Attendance Management System ƒ Cable Failure Web Application ƒ Confined Space System ƒ Employee Move Form ƒ EMRT ƒ Equipment without Maintenance Schedule Tasks ƒ Feeder Information System ƒ Feeder Operating

Delays in acquiring these resources may impact Toronto Hydro's ability to fulfill its core mandate in a timely and efficient manner in the future.	
End of Support for Access 2003	Microsoft's support for Access 2003 has also now ended, causing to two sustainability issues. First, Microsoft no longer provides security patch updates to close newly discovered security vulnerabilities. Unpatched security gaps make the system increasingly vulnerable to a cyber intruder. Second, the Scope Planning System is now ageing. Acquiring and maintaining resources with the requisite technical skills to maintain	ƒ Scope Planning System

Issue	Description	Legacy Systems Impacted
	these programs is expected to be challenging moving forward. Delays in acquiring these resources may impact Toronto Hydro's ability to fulfill its core mandate in a timely and efficient manner in the future.	

In addition to the issues described above, four of Toronto Hydro's COTS Legacy Systems are experiencing sustainability issues today or will experience them in the 2015 to 2019 period. These issues are briefly described in Table 6.

TABLE 6: COTS LEGACY SYSTEM SUSTAINABILITY ISSUES

System	Status
Hyperion	Hyperion 9.3.1 is in sustaining support, and Oracle no longer provides security patch updates to close newly discovered security vulnerabilities in the application or the database. Absent implementing a new ERP, this application would require an upgrade.
Panviva	The version of Panviva used by Toronto Hydro is no longer supported by the vendor. Absent implementing a new ERP, this application would require an upgrade.
Team-Mate	Support for this application is set to expire in May 2016. Absent implementing a new ERP, this application would require an upgrade at that time.
Timelink	Timelink was acquired by a competitor in July 2013 and its new owner has not committed to developing or supporting the application after the end of the existing support period.

E8.6.3.4 Business Operations and Efficiency

Toronto Hydro identified eight primary operational needs that could be made more effective or efficient through improved IT capability. At present, Ellipse and the Legacy Systems perform most or all information processing requirements for six core back-office functions:

- Planning;
- Record-to-Report;

- Human Capital Management;
- Asset Plan, Build, Maintain
- Source to Pay; and
- Customer Connection.

Ellipse and the Legacy Systems also perform tasks related to Toronto Hydro's Meter-to-Cash and Event Management processes.

These functions enable Toronto Hydro to support the core financial, human resource, work execution and safety processes that are essential to its operations. However, the complex topology of Ellipse and the Legacy Systems limit Toronto Hydro's ability to add new functionality in response to changing operational, statutory and regulation requirements in a prudent fashion. With such an array of applications, providing the necessary support and administrative oversight is resource intensive both in terms of the level and specialized nature of those resources. Technical expertise in COTS applications and development technologies such as Cold Fusion, Visual Basic and Access 2000 would need to be retained in the absence implementing a new ERP.

By implementing a new ERP, there are opportunities to improve each of these operational processes by removing these general limitations in addition to those specific to each function. These are described in greater detail below.

Planning

The Planning function allows Toronto Hydro to perform and maintain governance over a number of planning-related tasks across the utility's operations, including:

- Integrating planning activities with Human Capital management (HCM) and Asset Management Systems;
- Performing long term planning based on historical trends;
- Preparing Operational and Capital Expenditure Forecasts;
- Creating Planned Projects;
- Planning for asset decommissioning and de-recognition;

- Planning for property disposition, pre-capitalized inventory, and Asset Retirement Obligation; and
- Controlling and monitoring planning changes.

Executing these tasks often relies on data contained within other systems. To date, it was not cost effective to develop a common planning user interface for these disparate systems. This gap significantly complicates data transfers and process tracking and necessitates the use of extensive manual processes in order to meet the utility's regulatory and reporting requirements.

By integrating these functions into a common platform, the new ERP system is expected to mitigate those issues and deliver new planning capabilities, including:

- Improving centralized planning governance and processing and incorporating change controls;
- Integrating Finance, HCM and Asset Management organizational planning activities in one system;
- Improving project type and delivery traceability across multiple plans;
- Generating multiple plans based on different accounting standards; and
- Implementing real-time reporting with flexibility to meet regulatory and operational requirements.

Record-to-Report

The Record-to-Report function provides centralized governance over the collection, analysis, distribution and publication of Toronto Hydro's financial filings and management reports. Since Ellipse was implemented in 2002, Toronto Hydro's financial and regulatory reporting requirements have increased considerably, but Ellipse's native financial and regulatory reporting capabilities did not. As a result, Ellipse's inherent reporting capabilities are no longer sufficient to meet the utility's basic financial and regulatory reporting obligations.

Tasks currently being performed that are expected to be retained by the new ERP include:

- Producing statutory, regulatory, management and operational financial reporting (including US GAAP and IFRS report requirements);

- Managing on-going and periodical financial postings and accruals (including fiscal period opening and closing);
- Managing cash flow and other Treasury functions;
- Calculating Payments in Lieu of Corporate Taxation, Property Taxes and other taxes; and,
- Managing the Fixed Assets Sub-ledger, asset accounting and costing.

The new ERP system is expected to add new Record-to-Report capabilities, such as:

- Establishing a centralized repository of all financial data, with real-time, automated updates to the General Ledger;
- Improving controls over versioning and accounting ledgers;
- Automating fixed asset sub-ledger activities (including project traceability, energization, costing, de-recognition, reporting and regulatory compliance); and,
- Implementing real-time reporting with flexibility to meet new regulatory and operational requirements.

Human Capital Management (HCM)

HCM encompasses strategic human capital planning functions and the processing of day-to-day human resource transactions. Ellipse currently contains employee demographic data and information storage capabilities, allowing it and the Legacy Systems to provide many HCM tasks, including:

- Planning retirement projections and roll-out retirement details;
- Developing headcount and succession plans as well as associated budgets;
- Managing timesheets and process payroll, expenses, compensations and benefits;
- Storing and updating employee information (union and non-union); and,
- Coordinating employee on-boarding, cross-boarding and off-boarding.

However, the limitations of Ellipse and the Legacy systems require a number of manual tasks to be complete, introducing inefficiencies and data quality risks. The new ERP would address these limitations by incorporating new functionality, including:

- Performing organizational structure management across the utility, including the ability to assign and reassign employees, in a more timely and accurate manner;
- Improving workforce planning functionality, including: retirement projections, headcount planning and budgeting, succession planning and career development, skills and training, and job design;
- Implementing workflow management for resource requisition, on-boarding, cross-boarding, off-boarding, leave request and approval, timesheet follow-up and job changes;
- Establishing a single point-of-entry for time and attendance with integration to payroll/finance and ADP for payments;
- Enhancing Human Capital Management process audit capabilities to ensure adherence to policies and procedures; and
- Implementing real-time reporting with flexibility to meet new regulatory and operational requirements.

Asset Plan, Build and Maintain

The Asset Plan, Build and Maintain function encompasses long-range distribution asset planning capabilities and the ongoing management of asset renewal programs and projects for which Ellipse and the Legacy Systems are used to:

- Make long term asset plans;
- Perform Program scoping and project design as well as create packaged estimates;
- Initiate, manage and track asset construction;
- Establish asset maintenance plans/schemas and perform asset maintenance;
- Prioritize work, planning and scheduling to support asset life cycle operations;

- Capture planned and actual labour effort and resource utilization and associated internal and external costs; and
- Enhance employee and public safety.

Currently, these functions require the significant use of other work management application such as Microsoft Project, Microsoft Access, Excel and other software to overcome the shortcomings of Ellipse. The new ERP system is expected to add significantly to the work that could be undertaken through the ERP, including:

- Improving project management capabilities with the ability to:
  - compare Quoted Pricing between contractors
  - categorize projects and programs
  - track task completion, progress and actuals versus planned in real-time
  - identify risks, delays, and resource availability
  - generate notifications when project timelines are at risk
  - publish updated project schedules
  - automatically close a project for capitalization for ISAs
- Adding new Workflow Management capabilities including the ability to:
  - automate workflow in design
  - assign scopes and projects to supervisors and construction electronically
  - track scope and design performance
  - generate reports on scope status in the work queue
  - provide notifications for milestones in design and construction
- Improving productivity management functionality, including the ability to create work schedule and measure productivity based on labour rates.

- Providing a central repository for project documentation and data, enabling planning, design, and construction documentation to be shared amongst different groups more easily.

Event Management

The Event Management function encompasses long-range forecasting and program development as well as the day-to-day intake, resolution and management of system events.

The new ERP system is expected to enable the Event Management function to:

- Improve Event Management work tracking capabilities including the ability to:
  - create a Service Notifications or a Work Order based on a triggering event in OMS
  - link work orders to a master event to capture time, cost and materials when multiple resources are required to complete work or where work is referred to another work group for follow up
  - upload digital files (e.g., pictures) into Event Management Work Orders
- Optimize communication for all field personnel using laptops and tablets to enable real-time work order execution functionality;
- Extract and interface available crew and skill set information to the OMS.

Source to Pay

The Source-to-Pay function supports Toronto Hydro's material and service purchasing capabilities at the strategic and day-to-day level. Ellipse and the Legacy Systems are used to:

- Perform sourcing, vendor management, contract management and procurement operations;
- Manage material inventory (including receiving, shipping and stock transfer operations);
- Manage repairs, returns and warranties;
- Perform vehicle maintenance operations;

- Track crew, fleet and tools/equipments assignments; and
- Manage PO and GR based accounts payables and standalone accounts payables.

However, many of these tasks are not fully automated and require manual processes for execution. The new ERP system is expected to integrate new functionality into the Source-to-Pay function, allowing Toronto Hydro to:

- Link product failures back to their original purchase and warranty terms;
- Implement electronic request functionality, including storing request templates, tracking request gates, and managing request-related vendor correspondence;
- Roll out self-serve procurement for non-inventory items with automatic Purchase Order creation;
- Group approvals of non-order invoice payments;
- Manage Consignment Inventory;
- Integrate Contract Management functionality with Purchase Orders;
- Approve RFP and sole source documentation with automated workflows; and
- Enhance Vendor Master search functionality.

Customer Connection

Ellipse and the Legacy Systems support Customer Connections processes, including billing and account management functions that are required to connect new customers and to provide additional supply to existing customers. These functions are essential to fulfilling Toronto Hydro's mandate to connect and serve its customers.

However, Ellipse is not able to manage the full end-to-end Customer Connection process. Instead, Toronto Hydro uses separate systems for specific tasks, such as logging certain technical requirements. This is another example how the limitations of Ellipse introduce inefficiencies and the potential for data issues to current processes. The new ERP system is expected to improve the Customer Connection function by:

- Automating the customer design deposit and Offer to Connect (OTC) processes;

- Automating the Net Present Value calculation for customer work;
- Tracking charges by all departments to a customer connection;
- Implementing Work Flow Management for OTC processes; and,
- Time Stamping all system based handoffs between Toronto Hydro and Customers.

Meter to Cash

While the majority of Meter-to-Cash processes are supported by Toronto Hydro's Customer Care and Billing System (CC&B), Ellipse is used to initiate, process and track non-electricity customer accounts receivable related to the payment of customer-initiated capital work and other ancillary services. However, its functionality in this regard is limited. For example, Ellipse is unable to accept interim or staged payments that are otherwise permitted or automatically calculate and charge the interest on unpaid balances. Instead, manual processes are relied upon.

The new ERP system would remedy the limitation of the Meter to Cash function by:

- Improving non-electricity billing functionality including the ability to:
  - track information such as labour, material, fleet, contracts against a work order or invoice calculation
  - capture customer bill format preference
  - automatically apply late payment charges
- Automating the collection process;
- Automating the deposit interest calculation process;
- Including an on-demand deposit interest calculation capability;
- Automating the trigger to review the customer's commitment for capital contribution;
- Accepting general ledger account entry adjustments from the CC&B system; and,
- Accepting accounts payable entries at the sub-ledger level, including appropriate taxes.

E8.6.4 Timing & Pacing of the Program

The timeline in Figure 3 reflects Toronto Hydro's current expectations for the timing and pacing of the four phases of this program. The four phases of the program are described in the Program Execution section below.

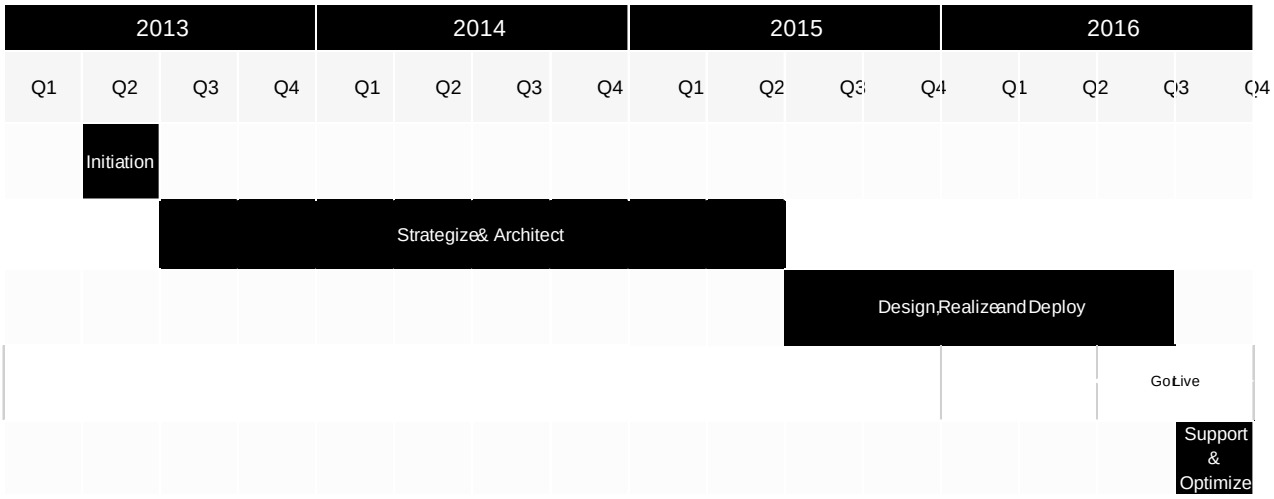

FIGURE 3: EXPECTED TIMELINE FOR NEW ERP IMPLEMENTATION.

E8.6.5 Program Execution

Toronto Hydro's proposed ERP Program consists of a single project culminating it the implementation of a new ERP during the 2015 to 2019 period. Toronto Hydro has adopted a four-phase implementation approach that emphasizes an integrated design process and requirements definition prior to the selection of a system.

This approach is represented at a high level in Figure 4 and explained in more detail below.

FIGURE 4: FOUR PHASES OF THE PROPOSED PROGRAM EXECUTION APPROACH.

Initiation

During the Initiation Phase, Toronto Hydro developed the program's high-level implementation approach and timeline to give structure and direction to the remaining phases of the project. Resources required to execute the subsequent stages were also defined.

Strategize & Architect

The purpose of the Strategize & Architect phase is to identify, define and verify the functional requirements of the program prior to the Design stage when making changes to the requirements is far more costly. Consequently this phase was entirely "paper-based".

Once the functional requirements were determined, the benefits associated with each improved process were estimated. At this stage of the program, estimates were made without reference to any particular information technology approach or system, recognizing the fact that various approaches or vendor technologies could be used to fulfill operational requirements.

The next step was to identify the preferred technical approach to deliver the required functionality. Here, the technical and operational merits of each approach were considered and costs were thoroughly compared. At the conclusion of this process, the recommendation to implement an ERP with the necessary incremental functionality was made.

The process of selecting an ERP system and a system integrator to assist Toronto Hydro with the Program's subsequent phases would be undertaken subsequent to regulatory approval.

Design, Realize and Deploy

The Design, Realize and Deploy Phase encompasses the standard phases of an ERP Implementation, including detailed design, configuration, testing, training, data cleansing and conversion and all associated change management activities.

During this phase, Toronto Hydro will be supported by System Integrator and Vendor resources to ensure that the functional requirements identified in the previous phase are seamlessly implemented in the ERP solution. Using a System Integrator and Vendor resources provide valuable experience from other ERP projects during this phase of the program, which can help to minimize implementation costs.

This phase ends at the time the ERP system goes live.

Support and Optimize

The Support and Optimize phase commences immediately after the ERP System becomes functional and continues for approximately three months.

The objectives of this phase are to stabilize the ERP System, to embed the new processes into day-to-day operations, and to capture unanticipated system or process inefficiencies for subsequent resolution.

During this phase support will be provided to end-users through an "ERP Help Desk" staffed during business hours, in-department "super-users" and proactive and reactive post-"Go-Live" user training and follow-up sessions.

It is at this point that Ellipse and the Legacy Systems would no longer be used to support Toronto Hydro's operations.

E8.6.5.1 Program Risks

Toronto Hydro identified a number of risks to the successful completion of the new ERP and is taking a proactive approach to mitigating them.

Solution Fit to Utility Requirements

The processes proposed for incorporation into the new ERP must be able to deliver the functionality Toronto Hydro requires to meet its operational, legislative, regulatory and customer obligations. A design approach that considers functionality as silos is particularly risky.

Toronto Hydro made efforts to fully consider all areas of its operations before any configuration or coding has taken place. All processes and system requirements are defined and documented by Toronto Hydro prior to system selection and integration. End-to-end operational process scenarios will be used in the testing phase of the new ERP.

Functional Obsolescence

The new ERP system selected by Toronto Hydro must be able to deliver the functionality Toronto Hydro requires while the system is in use, including requirements that are not known or anticipated at this time.

Toronto Hydro is mitigating the risk that the new ERP will not be able to fulfill unforeseen future needs by selecting its solution from those offered by top-tier ERP Vendors with a large presence in the utilities industry. The selection of a financially strong vendor with robust application capabilities and a commitment to meeting its utility sector customers' future needs will mitigate the risk the new ERP would be unable to meet functional requirements that are not known at this time.

E8.6.7 Evaluation of Alternatives

E8.6.7.1 Quantification/Evaluation of Options

Option Identification

Toronto Hydro developed four options that consider different approaches to addressing the program drivers identified in the Needs section.

To address the primary driver, functional obsolescence, Toronto Hydro could:

(1) Execute a Technical Upgrade of Ellipse and the Legacy Systems to a version or release fully supported by its vendor.

(2) Replace Ellipse and the Legacy Systems with a new ERP system, thereby avoiding the need to perform the Technical Upgrade.

To address the secondary driver, business operations and efficiency, Toronto Hydro could:

(1) Customize Ellipse further by developing or purchasing new applications that deliver the required functional improvements.

(2) Implement a new ERP that integrates the required functionalities into the system at the design phase.

Toronto Hydro considered four options, as summarized in Table 7 and described in further detail below. Option 3 is the preferred option, as described extensively in the Program Description section.

TABLE 7: SUMMARY OF THE FOUR OPTIONS CONSIDERED IN THIS PROGRAM.

	1. Technical Upgrade (BASE CASE)	2. Ellipse & Legacy System Renewal	3. ERP Implementation (PROPOSED)	4. Extended ERP Implementation
Is Technical Upgrade Required?	Yes	Yes	No	No

	1. Technical Upgrade (BASE CASE)	2. Ellipse & Legacy System Renewal	3. ERP Implementation (PROPOSED)	4. Extended ERP Implementation
Delivers new required functionality? If so, how?	No	Yes, Appended	Yes, Integrated	Yes, Integrated
Which IT systems are retired?	None	None	Ellipse, Legacy Systems	Ellipse, Legacy Systems + 3 applications

The costs and benefits of each of these options were estimated over a 10-year period, the expected life of the proposed new ERP, and are summarized in Appendix B.

(i) Option 1 (Base Case): Technical Upgrade

To address the functional obsolescence of Ellipse and the Legacy Systems, Toronto Hydro must at a minimum upgrade those systems to a version or release fully supported by their vendors. Upgrading these systems to a supported version would allow Toronto Hydro to continue to apply security patches to maintain the application and database security and ensure that vendor support for current hardware is maintained.

The Technical Upgrade option is projected to require a capital investment of $13.2 million in the 2015 to 2019 period.

This option would not deliver incremental value for ratepayers and the utility, as it would not satisfy Toronto Hydro's operational needs and would leave material risks and challenges unaddressed. Specifically, this option would not address the technical issues with respect to interfaces, the implementation of LDAP support or data access and segregation concerns present in Ellipse today.

In addition, this option would not deliver any incremental functional capabilities needed to improve the operational efficiency of the utility. Toronto Hydro's corporate processes would remain unchanged if this option was adopted, and existing inefficiencies and data quality risks would go unabated. All applications as well as the interfaces between Ellipse and the Legacy Systems would be maintained "as is."

Under this approach, Toronto Hydro would still have a complex application environment to administer and support after the successful completion of this initiative. At a minimum, patches for each unique application, technology or database in the current IT topology would need to be checked for and applied. Similarly, Toronto Hydro would remain responsible for maintaining the 31 interfaces. Together, these undertakings would be complex and time consuming and, as a result, gaps in the timely application of security patches and the timely development of interface changes are likely.

Toronto Hydro would also remain responsible for designing, developing, testing, implementing and supporting any additional tax, legal or regulatory requirements that pertain to the 24 custom applications retained in this scenario. This would require additional incremental expenditures over time. Finally, a high degree of Vendor Relationship Management will be required to establish the boundaries and the accountabilities of the application, technology and database vendors contributing to this solution.

(ii) Option 2: Ellipse & Legacy System Renewal

Like the Technical Upgrade, this option would upgrade Ellipse and each of the Legacy Systems to a version or release fully supported by its vendor, allowing Toronto Hydro to continue to issue security patches and to obtain vendor support. In addition to undertaking these technical upgrades, the new functional requirements would be incorporated through additional configuration within Ellipse, further custom development of the Legacy Systems and new integration improvements.

Toronto Hydro estimates that implementing this option would require capital expenditures of $71.6 million in the 2015 to 2019 period.

Implementing this option would deliver the same incremental efficiency benefits (i.e., cost savings, cost avoidance and process improvements) of the preferred option, but with one exception. Because Ellipse and the Legacy Systems would continue to be used for Toronto Hydro operations, the improvements made to those systems would not improve the reliability of Toronto Hydro's IT infrastructure to the same extent as a new ERP. Accordingly, only a share of that benefit would be obtained through this approach.

There are other, cost-related drawbacks with this option. The resulting application topology would be a far more complex system to operate, administer and support than the system that exists today or that would be implemented through a new ERP. For example, System Security staff

would still have to, at a minimum, check for and apply patches for each unique application, technology or database. This is a complex and time consuming undertaking and gaps in the timely implementation of security patches are likely to arise as a result.

Interface support requirements would also increase if this option is adopted as additional integration will be required to incorporate the new functionality discussed in the proposed option. For example, eliminating the use of excel-based data transfers in the Planning, Record to Report and Human Capital Management functions would require the building of additional interfaces to securely transmit information between Ellipse, SAP and Hyperion.

If this option was implemented, Toronto Hydro would remain responsible for designing, developing, testing, implementing and supporting any additional tax, legal or regulatory requirements that pertain to the 24 custom applications retained in this scenario. Development work in excess of what is currently necessary would be required.

(iii) Option 3 (Preferred): ERP Implementation

The implementation of a new ERP is the option described in this exhibit and is Toronto Hydro's preferred option. As noted, Toronto Hydro estimates that implementing this option would require capital expenditures of $51.3 million in the 2015 to 2019 period. The total cost of this option is estimated to be $54.0, inclusive of pre-2015 capital expenditures.

(iv) Option 4: Extended ERP Implementation

Like the proposed Option 3, in this scenario Toronto Hydro would replace Ellipse and the Legacy Systems with a single ERP system. This would address all of the sustainability, security and efficiency issues identified earlier.

This initiative would also replace all other applications within the current ERP that could be replaced with an ERP. These functions provided by these applications, including Toronto Hydro's Current Warehouse Management System (Red Prairie), its Safety Incident Recording System (Intelex) and its Performance Management System (Halogen), would be integrated into with the new ERP as standard functionality.

Toronto Hydro estimates that implementing this option would require capital expenditures of $65.5 million in the 2015 to 2019 period.

It is unlikely that that this option would provide any incremental benefits when compared to the proposed option. In Toronto Hydro's view, these additional systems are operating as required and no material functional improvements associated with incorporating these systems into the ERP were identified.

Options Analysis

To compare each of the options on a consistent basis, Toronto Hydro estimated the prospective costs and benefits of each of the four options over the expected 10-year period, corresponding to the expected life of a new ERP.

The basis of comparison is the Technical Upgrade, Option 1, which represents the work that Toronto Hydro must at a minimum execute to address the serious risks posed by the functional obsolescence of Ellipse and the Legacy Systems. For options that do not require the Technical Upgrade there is an associated cost avoidance benefit equal to the amount of that upgrade.

Table 8 summarizes the net present value (NPV) calculation associated with each of the four options. In Option 2, the cost of incorporating the new functional capabilities by further customizing Ellipse and Legacy Systems does not outweigh the benefits of doing so. In Option 4, the cost of expanding the scope of the ERP beyond what is required does not deliver incremental value.

By delivering the incremental monetary benefits and process improvements in a cost-effective fashion, Option 3 is optimal approach to addressing the functional obsolescence and inefficiencies of Ellipse and the Legacy Systems. On this basis, Option 3, implementing a new ERP with the new required functionality, is the proposed option.

TABLE 8: NPV COMPARISON OF THE FOUR OPTIONS CONSIDERED FOR THIS PROGRAM.

	1. Technical Upgrade (BASE CASE)	2. Ellipse & Legacy System Renewal	3. ERP Implementation (PROPOSED)	4. Extended ERP Implementation
Net Capital Investment	This option used as basis for comparison	$71.6M	$54.0M	$65.5M
Expected 10 yr NPV: Monetary benefits only		($31.2M)	($15.3M)	($25.4M)
Expected 10 yr NPV: Monetary and Process benefits		($16.5M)	$4.9M	($5.3M)

APPENDIX A

Table 1 lists and describes the Legacy Systems which would no longer be required for Toronto Hydro's operations upon implementing the new ERP.

TABLE 1: A SUMMARY OF THE 30 APPLICATIONS THAT MAKE UP THE LEGACY SYSTEMS.

Legacy System	Function
Asset Management Portal	ƒ Provides access to a number of applications and forms used to manage the inspection process for approximately Toronto Hydro distribution system assets.
Attendance Management System	ƒ Enables supervisory staff to monitor the frequency and severity of employee absences and to analyze the associated trends.
Cable Failure Web Application	ƒ Retrieves cable failure data stored in the EMRT and provides multiple parameters to enable standard analysis or to export into Excel for custom analysis.
Confined Space System	ƒ Tracks hazards in confined spaces in the old City of Toronto.
Employee Moves	ƒ Facilitates a variety of Human Resource processes (e.g., employee changes, transfers, salary changes, and terminations).
Ellipse Management Reporting System (EMRT)	ƒ Provides users with pre-defined analytical, operational, financial reports as well as an ad-hoc reporting tool that can be used to query the database.
Equipment Without Maintenance Scheduled Tasks	ƒ Reports all assets that do not have a Maintenance Schedule Tasks and provides multiple parameters to enable standard analysis or to export into Excel for custom analysis. Works with EMRT.
Feeder Information System	ƒ Manages requests from designers when new loads are to be added on feeders.
Feeder Operating Conditions	ƒ Analyzes current loading on the Toronto Hydro's feeders for planning purposes.
Hyperion	ƒ Produces annual budgets and monthly, quarterly and year-end financial reports.
IT Timesheet	ƒ Captures and approves time and attendance data for Toronto Hydro Information Technology employees and contractors.
Labour/Vehicle Costing Application	ƒ Tracks labour and vehicle costing, crew overtime and other data against Work Orders.

Legacy System	Function
Maintenance Schedule Task Application	ƒ Produces paper-based inspection form unique to a specific equipment type.
Material Reference Book	ƒ Combines description of an item from the Ellipse catalogue with a corresponding photo of the item to allow staff to select the correct material for every task.
Material Requirements Planning and Forecasting	ƒ Provides Inventory Analysts with visibility into the material requirements for planned work.
New Location Request Application	ƒ Allows users to reserve a location number and create locations for assets in Ellipse.
On-Line Hold Off Request Form	ƒ Enables crews to request in advance non-switching planned work based Hold-Offs.
Picking Slip Application	ƒ Provides an interface to select materials for planned work and to generate an Issue Requisition (IREQ) in a fashion that ensures defined operational processes are followed.
Reclaim Equipment Application	ƒ Creates a new asset for reclaimed equipment that can be refurbished.
Resource Requisition (RRAP)	ƒ Used to deploy forms and workflows to support the on-boarding process for new employees.
Return Slip Application	ƒ Used to manage the return of inventory to the warehouse.
SAP	ƒ Toronto Hydro fulfills its Ontario Securities Commission, Accounting Standards Board, and Ontario Energy Board financial reporting requirements using a combination of Ellipse and SAP's Finance Module.
Scope Planning	ƒ Creates and tracks future project information for regulatory filings.
Support Point- Paniva	ƒ Delivers role-specific user documentation for the Ellipse application.

Legacy System	Function
TeamMate Audit Management	ƒ Provides a streamlined application for managing internal audits.
Timelink	ƒ Performs Time and Attendance, Workforce Scheduling, Absence Management, and Labour Planning functions.
Treasury Manager	ƒ Manages and reports cash inflows and outflows, including bill payments, payroll withdrawals, vendor payments and customer bill payments.
Unit Price Contract Management System	ƒ Manages and administers civil and electrical work assigned to external contractors.
Work Activity Log	ƒ Manages the Street Lights Trouble Call Center.
Work Request System	ƒ Schedules and coordinates primary feeder work.

APPENDIX B

On the following pages, Tables 1 through 4 enumerate the costs and benefits of Options 1 through 4 respectively.

As noted in the Evaluation of Alternatives section, Options 2 through 4 consider not having to undertake Option 1, the Technical Upgrade, as a cost avoidance benefit. The NPVs of Options 2 through 4 are therefore relative to Option 1. As it serves as the baseline for comparison, the NPV of Option 1 is axiomatically zero.

	Net Present Value (NPV)										
10-yr: Monetary only	-31.2										
10-yr: Monetary and Process	-16.5										

[7] Option 2 entails a renewal of Ellipse and the Legacy Systems which includes the work required to perform technical upgrades those systems. The cost of doing this upgrade work is incorporated in the Expenditures lines, but to ensure that the NPV calculation reflects only the incremental work relative to the Technical Upgrade option, those costs are offset by the Cost Avoidance line. Further, as discussed in the Evaluation of Options section, it is estimated that process improvements delivered by increased IT infrastructure reliability is 55% of what is likely to be achieved by a replacement ERP system.

TABLE 2: EXPECTED COSTS AND BENEFITS OF OPTION 3 – ERP IMPLEMENTATION

A. EXECUTIVE SUMMARY

SUMMARY

Toronto Hydro has prepared a submission to the Ontario Energy Board for the implementation of an ERP solution to replace their legacy Ventyx Ellipse system due to significant operational, security and functional gaps in that system.

InfoTech was asked to review the submission to provide an opinion on the feasibility of the approach, the recommendation, and the options for the Ellipse replacement. InfoTech is an independent IT research and advisory firm operating globally in support of its members, and focusing on the practical and pragmatic operations of IT within complex environments. InfoTech is not associated with any software or hardware firms, and does not implement any systems, including ERP systems.

InfoTech reviewed the replacement of the Ellipse system in the context of the large utilities and determined that the approach was consistent with the rest of the utility industry. InfoTech also notes that SAP and Oracle are the dominant ERPs in that segment of the utility industry and, as such, should be the primary -considered solutions to take advantage of industry ERP supported capabilities.

InfoTech reviewed the four options presented by Toronto Hydro and recommends, in concurrence with Toronto Hydro, that Option 3, with the replacement of base or core functionality with either SAP or Oracle, is preferred. Option 1, which includes the continued use of the Ellipse system, does not address concerns with the security capability of Ellipse or the creation of needed business functionality. Option 2 has some security advantages over Option 1 but increases the complexity of the technology environment for both the implementation and the ongoing operation. Option 4, which extends the use of the ERP to include three other areas of functionality, does not include strong business value creation at this time and should be deferred until and unless a new business case is presented.

InfoTech has also reviewed the cost models for the four options and found the methodology, completeness, and quality to be reasonable.

As a result, InfoTech is in agreement with 7 R U R Q W R + \ G U R ¶ V U H F R P P H Q G D W L R Q for Option 3 of this submission: the purchase and implementation of an enterprise ERP, at a cost of $54 million over four years.

B. INTRODUCTION

APPROACH OVERVIEW

This review of the Toronto Hydro ERP submission encompassed three main areas of investigation:

1. Does the preferred approach align with the utility industry IT strategies and actions?
2. Does the preferred option meet reasonable implementation, sustainment, and business requirements?
3. Does the pricing methodology and analysis of all four options meet a reasonable and supportable level of quality?

This document aligns with the investigation approach laid out above and discusses at a high level each of the topics above. The materials used to support that investigation are noted with footnotes at each of the sections, although all topics required a level of experience and expertise to put facts into context.

C. INDUSTRY BACKGROUND

ERP SYSTEMS IN UTILITIES

Companies that generate, transmit, distribute, and sell energy are encountering two primary challenges: the need to manage and reduce costs and the management of large amounts of essential data in terms of both governance and quality. As the needs of the industry evolve, ERP has become a top priority for utility investment. Mature utilities are looking to enhance existing ERP systems to support broader business goals and support organizational excellence. In emerging or small markets, utilities are building ERP systems for the first time in order to enhance corporate services and develop competencies.

Of the systems used by utilities to achieve these goals, operational systems are playing less of a central role with further emphasis being placed on business processes outside of the WUDGLWLRQDO DVVHW GULYHQ ³FRUH´ RI WKH XWLOLWLHV LQGXVWU\ 6 analytics, maintenance budgeting, corporate governance, human capital management, and procurement have become part of the overall integrated information technology solutions. In the past, these functions and others have been owned by a number of separate systems with varying degrees of integration. Much of the drive behind the adoption or expansion of ERP is the ability to have each of these processes as part of a single system. Utilities are moving towards having a single, unified view of the organization to better identify opportunities for achieving more demanding goals in a more complex technology world.

There is a growing concern within the utility industry, and rightfully so, about the potential for cyber attacks and malicious hacking. The difference between these two is that a cyber attack is an external attack while malicious hacking is usually internal. While the first is about breaching the firewall that surrounds the systems, the second can be an attack inside the firewall, targeting systems that do not maintain adequate internal security or access segregation.

The value of resources and data maintained by electric utilities means that cyber attacks from outside parties present a significant operational risk. In 2012, cyber attacks were the sixth highest cause of incidents affecting user connections ±up 81% from 2010 [1]. Utilities were also the fifth most attacked industry in the same year. Underscoring this threat is the IDFW WKDW RI DOO GDWD EUHDFKHV LQ ZHUH GXH WR KDFNHU DF SXEOLF´ DQG ³WKHIW RU ORVV´ DFFRXQW [2]. Utilities are increasingly efforts to guard against cyber attacks in order to avoid loss of data and control over crucial systems.

ERP LANDSCAPE

Toronto Hydro is currently using the Ellipse system, with significant customizations and integrated point solut ions, as their ERP. Initially classed as an Enterprise Resource Planning solution focusing on asset -centric industries, Ellipse is no longer considered a full ERP system by the IT industry and the owners of Ellipse.

Since the acquisition of parent compa ny Mincom by ABB, the renamed Ventyx Ellipse has been marketed as an Enterprise Asset Management point solution. While Ellipse has a strong utility record in its home country of Australia and has seen some success in South Africa and the U.K., it has had a limited presence in North America [3]. This means that there is a small resource pool, especially in Canada, that is qualified to implement and support Ellipse. The acquisition by ABB has resolved the financial issues faced by Ellipse, but the number of new sales to utilities has been in decline.

As the industry evolved, the capabilities of Ellipse eroded to the point where it could no longer compete in the ERP market. In the case of Mincom and other smaller players, their products were purchased and used t o reinforce the existing solution capabilities of larger companies. While some legacy solutions have remained as independent systems, many have been merged into existing ERP capabilities. This shrinking of the number of ERP market players has created more robust single solutions supporting a greater range of processes. The overall shrinking of the ERP industry has also led to a skills commoditization in the North American market, benefiting utilities with an available and lower cost, technology workforce.

The primary ERP systems in use in large utilities in North America, similar in size to Toronto Hydro, are Oracle and SAP. These two ERP systems dominate the large enterprise space beyond just utilities and have become the standard options for large enterprises looking for a new ERP. In utilities SAP has a large presence in Canada with utilities such as Hydro One, Hydro Quebec and BC Hydro and a global presence of over 20% in the utilities industry [4]. Oracle is similarly present in the US with many l arge utilities but a somewhat smaller global presence. These two systems dominate the large enterprise space in almost every industry and both systems maintain utility specific industry support, industry enhancements and industry user groups.

This type o f large scale support and investment for industry development and industry support is essential for the utility industry that is going through complex changes toward utilizing Smart Meter/Smart Grid capabilities.

[4] SAP for Utilities ± Executive Overview (SAP AG, 2013) p. 43.

FUTURE CONSIDERATION

Many electric ut ilities have , or are in the process of , implementing smart grid and smart meter infrastructure. Utilities are faced with the task of collecting and analyzing up to 3,000 times more data than ever before [5]. With this reality comes a host of data management concerns. While ERP systems are not the primary systems that support this new capability, the underlying data bases, infrastructures and capabilities need to adapt to this new environmental reality [6].

The need for integration between smart grid systems, operational systems, planning systems, and financial systems to support t hese developing requirements , continue s to put pressure on older and less able legacy systems and infrastructures. ERP system implementations are often used to eliminate a large number of older and less capable systems to improve the flexibility and adap tability of the technology platforms , as well as to formalize data governance rules and methods within the new environment [7]. These seemingly unconnected modernizations also improve the overall ability of the utility to implement these new systems .

An emerging trend in the utility technology market is that of Mobile ERP enabled by a highly capable ERP system. Especially in an organization with a highly mobile workforce such as the utility maintenance crews, Mobile ERP can lead to improvements in productivity and efficiency. This technology can further streamline business processes by providing real time access to information for those who previously did not have it [8]. These capabilities have been expensive to develop independently but utilities are now using standard ERP functionality that is shared by the entire industry. These capabilities are supported by SAP and Oracle ERP systems.

Ultimately, utilities are recognizing the need to develop cohesive and industry aligned strategies for managing their IT assets. Unlike assets used in energy distribution, it is no longer a GHTXDWH WR PDQDJH ,7 DVVHWVDZQLQWKD PE3XLXQG WLWW IDVL0RX QHHG LW mentality . Unlike other assets in the utility industry, the asset life in the IT Infrastructure world is defined by the outside environment instead of the asset itself. As the security attacks become more sophisticated, the hardware assets become obsolete, not because parts fail, but because the asset can no longer function securely . Similarly as the need for complex integration arises, the software assets become obsolete, not b ecause the software can no longer be changed, but it can no longer communicate to other software at a reasonable cost or with reasonable performance.

The impact of a single asset failing, be it hardware or software, is too significant to the organiza tion with automated systems fundamental to the operations of the utility business . The loss of any one system can impact processes from customer billing to power distribution itself. While some assets could be used indefinitely, their effective life is oft en much shorter

as the environment that they operate in changes . Hardware and software become unsupported by their respective vendors, increasing the overall risk of operation.

The typical life spans of IT assets are shrinking as the complex utility technology world evolves from stand alone systems run by engineers and accountants with paper, to that of a fully integrated, data driven, technology managed utility. This has changed the typical lifespan of infrastructure from 10 years to 3 to 5 years, ERP systems from 20 years to 10 years, and system portfolio lifecycle reviews from 5 years to yearly. Storage is another area that has not reached any stable or predictable lifespan with storage reviews and storage operational enhancements occurring monthly as data capture and data analysis has become the new norm for utilities and businesses around the world.

C. REVIEW OF THE NEED FOR INVESTMENT

CRITICAL CONCERNS WITH THE CURRENT OPERATION

The current Ventyx Ellipse system has some critical areas of concern, based on our analysis of the ERP submission supporting documents, that require immediate action to sustain a reasonable risk profile for the Toronto Hydro operation. These areas are:

- The lack of vendor support for the current Ellipse system and the Oracle database with security patches not being provided, opening the systems up to both penetration hacking and malicious hacking
- The operation of the current Ellipse system on uncertified hardware which could cause significant operational downtime or prevent a timely restart in the event of a system failure or shutdown
- The inability of the current Ellipse system to connect with LDAP (Lightweight Directory Access Protocols) for access control which increases the potential failure points in granting, but more importantly, denying access for departing employees or contractors
- The inability of the current Ellipse implementation to practically segregate access to operational data and functions, increasing the risk severity of malicious hacking or inappropriate access to data.

Toronto Hydro represents these as major issues that drive the need for investment and we agree. In particular, the negative implication to the security profile of Toronto Hydro is substantial and is not considered prudent practice in any industry.

The lack of security patching in these systems means that the Toronto Hydro technology environment is highly dependent on the reliability of the external firewall and supporting manual processes to keep external attackers out of the systems. Once inside the firewall, the vulnerabilities of the Ellipse system can be exploited, and because there is no segregation of data and functionality access, the ability of a hacker to cause maximum damage is enhanced. The ability of sophisticated hackers to breach firewalls is well documented with an average of over 20 major data breaches occurring per month over the last year.

In addition, the combination of the use of manual processes to manage the system access on-boarding and off-boarding of employees, with a lack of segregation of access to data and functionality within Ellipse, means that malicious hacking by current or future employees or contractors, with the intent to damage Toronto Hydro, is a significant risk. Lack of segregation of data access also means that malicious hackers could release private or confidential data to unauthorized parties or gain a competitive advantage in contract or procurement negotiations with the use of insider knowledge.

While productivity improvements are an important element of any IT operating strategy, and 7RURQWR +\GUR LV DOVR IDFLQJ LQFUHDVHG RSHUDWLRQV FRPSOH[LW\ QRWKLQJ´ LQ WKH IDFH RI VXFK PDMRU VHFXULW\ ULVNV VXFK DV WKHVH LV QRW DQ DSSURSULDWH UHDVRQ IRU LQYHVWPHQW. InfoTech agrees that at minimum the systems need to be updated and brought to industry standards of regular patching, LDAP compatibility and segregation of data access.

C. REVIEW OF THE FOUR OPTIONS

RISK DISCUSSION

InfoTech uses a COBIT 5 framework as the basis for all of its research and for the creation of operational methodologies for its 34,000 client members. The COBIT 5 framework is an IT industry supported open standard that is used globally to enable users to establish complete, risk governance processes for the effective management of Information Technology in the Enterprise.

As a result, the discussions below are framed within a risk context. While InfoTech maintains extensive risk tools to assess the detailed plans for implementation and sustainment, the business risks noted below represent the assessment of options within the industry context. In the interest of clarity, the summaries of the risk assessments are presented below in the options review. The definitions used of the risk levels are in the table below:

Definition			
Risk Element	Low	Medium	High
Implementation	x Minimal development x Stabilization of existing application footprint	x Configured Commercial Off The Shelf (COTS) applications or ERP x Integration through adaptors or Service Oriented Architecture (SOA) and Enterprise Service Bus (ESB)	x Extensive custom development x Complex point-to-point integration
Sustainment	x Large ERP footprint x Minimal integration points x Stable, well-supported solutions	x Multiple point solutions x Multiple integration points x Stable solutions	x Multiple point solutions x Complex integration x New / non-stable solutions requiring specialized and rare skill sets
Business	x Meets all identified future business needs	x Meets some future business needs	x Does not meet future business needs

OPTION 1

Option 1 is th e upgrade of the Ventyx Ellipse, its Oracle Database and the associated legacy systems.

This option is expensive , without any functionality enhancements , and does not address two of the critical areas of concern that were noted in the earlier sections. This option will not address the lack of integration to an LDAP system and will not improve the lack of segregation of functionality or data access. While this option mitigates the risk of external hacking it does not address any of the concerns of potential malicious hacking.

In addition, from a strategic point of view, Ellipse remains a system with little to no future in the utilities industry in North A merica, without sufficient functionality to market their Ellipse system as an ERP. Investing significantly more money into this system without a near term exit strategy being prepared is not prudent. The momentum in the large utility industry is toward S AP and Oracle, and this will likely push this system, like so many others before it, into extinction.

The technical risk of the implementation of Option 1 is relatively low. The upgrade path with few enhancements will be a standard process supported by the Ventyx Ellipse software company. These standard upgrades are usually well tested and, although slow to implement and requir ing extensive testing, will generally be completed on time and on budget. There is a lack of implementation resources with Ellipse experience so this may increase the risk of the price of the resources and require scarce experienced resources to be obtained globally (Australia) instead of locally as is common practice. This h as been adequately reflected in the pricing model.

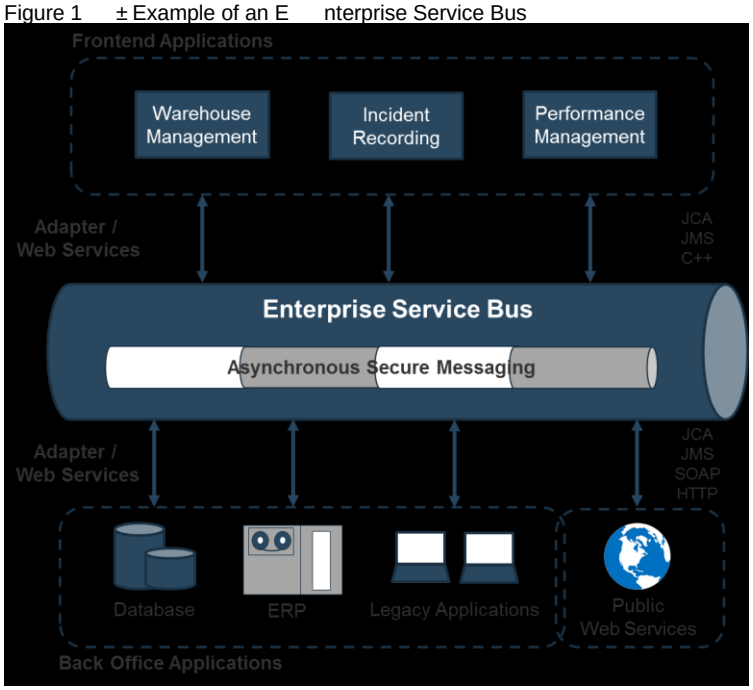
The technical risk of the sustaining operation of Option 1 would be considered medium. The collection of systems used to operate the back office of Toronto Hydro will remain a patchwork of point solution s with Ellipse in the middle. The number of integration points will remain the same and the sophistication of the integration will remain low (point to point integrations always act as individual programs that need ongoing monitoring, testing and upgradin g).

The business risk of Option 1 would be considere d high. This approach will not deliver the identified functionality needed for Toronto Hydro and there is no path forward that provides the functionality without significant cost or significant time. In addition, the Ellipse system remains in the portfolio, managing the operations of Toronto Hydro, without a plan to replace as it approaches functional obsolescence.

InfoTech does not recommended this option as a viable solution for Toronto Hydro and does not view this option as prudent investment considering that critical security concerns will still remain within the IT portfolio.

OPTION 2

Option 2 is t he upgrade of the Ventyx Ellipse, its Oracle Database and associated legacy systems plus the custom development of additional external functionality.



This option will take the application environment and extend the back office system landscape with additional point systems to achieve the enhanced functionality that Toronto Hydro is look ing to build. While my comments on the future desirability of the Ellipse system still stand, there are additional concerns with this approach.

The IT industry, as a whole, is moving away from custom developed software for many good reasons. The costs t o build, maintain and operate these systems have been extensive and often underestimated. The legacy portfolio of systems and their multiple point to point integrations have become barriers to build ing new functi onality or extending functionality in busin esses. As a result, many IT groups have become expensive barriers to progress instead of enablers of progress .

One of the key considerations in building business capabilities is the need to test all of the systems and integrations within the interconne cted system portfolio. This is the point where costs of implementations become prohibitive and sometimes IT groups take risks to push systems into production instead of incur or recognize these costs. Unforeseen issues arise during these types of operations that create either failure to achieve on -time and on -budget results or downtime due to quality issues that were moved into production before technical readiness.

There is a potential technical solution to help mak e these legacy systems more manageable and more adaptable. , 7 D U F K L W H F W V K D Y H E H H Q X V L Q J D V W D Q G D U G V \ V W H P Enterprise Service Bus or ESB (see Figure 1) . This additional off -the -shelf system creates a standardized means of connecting a nd monitoring all of the integrations needed between the legacy portfolio of systems. During any changes, builds or upgrades, the testing only includes the new functionality itself and the connection to the Enterprise Service Bus. This simplifies and red uces the risks of both implementation and testing of a large portfolio of legacy systems. This has not been included in the proposal for Option 2.

Figure 1 ± Example of an E nterprise Service Bus

The technical risk of the implementation of Option 2 is high. While the necessary upgrade is of low complexity, the build out and integration of point solutions to integrate with Ellipse is complex, uncertain and involves the creation of many additional systems. This would all be custom development undertaken by Toronto Hydro at a time when the industry is moving solidly away from that approach. The proposed Option 2 does not include an ESB within the architecture and seems to be treated as equivalent in implementation risk to the other options.

The techni cal risk of the sustaining operation of Option 2 is high. The collection of systems used to operate the back office of Toronto Hydro will increase the patchwork of point solutions with Ellipse in the middle. The number of integration points will increase greatly and the sophistication of the integration will remain low (point to point integrations always act as individual programs that need ongoing monitoring, testing and upgrading).

The business risk of Option 2 is als o high. While Toronto Hydro will achieve the functionality it needs today, it will be building a large barrier to progress for future enhancements and business functionality as it adapts to Smart Grids and other industry changes. The cost of future enhan cements will continue to escalate based on the investments made toward this type of IT system architecture.

As a result of this risk profile, we recommend the addition of between $10 million and $15 million in project costs to either manage the risk of the implementation through extension of testing resources, timing and ongoing support, or through the addition of an ESB purchase and implementation into the system architecture for this solution. InfoTech would highly recommend the addition of an Enterp rise Service Bus if this option is selected.

InfoTech does not recommend Option 2 for Toronto Hydro. The creation of an increasing portfolio of disconnected systems runs counter to the architectural recommendations in the

IT industry and even though the expense is very high, the resultant system will likely require replacement well ahead of a more conventional ERP approach.

OPTION 3

Option 3 is the elimination of Ellipse, elimination of the current legacy portfolio and the replacement with an integrated ERP.

This reduction of the number of systems and the number of integrations is standard good practice within the IT industry as it reduces operating costs and complexities, and increases the ability and flexibility of the organization to respond to changes if the replacement systems are chosen with care and diligence. It is also common practice that all IT investments are challenged to not only deliver functionality but to reduce the IT system portfolio size, complexity, manag eability and average age.

The implementation of a leading ERP system will be supported with extensive experienced industry implementation teams and well tested suppo rting processes. In addition, if an ERP system is chosen that has a significant footprint in the utility industry in North America (usually SAP or Oracle) then future functional improvements are shared across the industry and the burden would not solely f all on the need for custom development at Toronto Hydro.

The technical risk of the implementation of Option 3 is medium. The implementation of an ERP system is complex and requires both experienced and disciplined teams. The governance structure should be in place from the inception of the project and that needs to continue unabated throughout the life of the system. The practices in the industry have varied throughout ERP implementations and the results have not always been successful. A conservative and thoughtful approach without arbitrary timelines has provided the most success in implementation. These costs have been reasonably represented in the pricing model for Option 3.

The technical risk of the sustaining operation of Option 3 is low. The reduction of the integration points, the support of a leading ERP provider and the availability of standard support processes and systems are all positive enhancements for Toronto Hydro compared to the current state or Options 1 or 2 . The use of a main s tream ERP also increases the options for Toronto Hydro with infrastructure, employees, contractors and consultants allowing future cost containment.

The business risk of Option 3 is also low. Toronto Hydro will achieve the functionality it needs today an d will benefit from the utility base of the chosen system to achieve future functionality as part of standard upgrades. In addition the system portfolio landscape will be simplified and costs of future enhancements will be delivered with lower risk and, p otentially, lower cost.

Option 3 represents the best use of funds for investment with a managed transition to a more robust IT portfolio, enhanced functionality and a strong alignment to the utility industry IT leading practices.

OPTION 4

Option 4 includes the replacement of the current legacy portfolio with SAP as well as extending the implementation to cover other areas of Warehouse, Safety and Performance Management.

This option would extend the functionality of the SAP system to eliminate three additional legacy systems that would have major operational affects across the employee user base in Toronto Hydro.

This option increases the risk of implementation by touching many more users than the Option 3 functionality which remains essentially a back office capability. In addition to expected professional users in Option 3, this option will have a wide spread impact on front line workers. As a result the need for enhanced training and organizational change management is important for Option 4.

Since these targeted-for-replacement systems are also relatively new to the Toronto Hydro system portfolio and appear to be working at this time, the value of including them at this time with the increased churn that will occur during this major project appears low.

The technical risk of the implementation of Option 4 is high. The inclusion of significant numbers of front line workers to the training and organizational process change will increase the likelihood of increased costs without being able to establish a clear message to the workforce for the need of a change, when these current systems are functioning reasonably well.

The technical risk of the sustaining operation of Option 4 remains low. The reduction of the integration points, the support of a leading ERP provider and the availability of standard support processes and systems are all positive enhancements for Toronto Hydro compared to the current state or the Option 1 or Option 2. The use of a main stream ERP also increases the options for Toronto Hydro with infrastructure, employees, contractors and consultants allowing future cost containment.

The business risk of Option 4 remains low. Toronto Hydro will achieve the functionality it needs today and will benefit from the utility base of the chosen system to achieve future functionality as part of standard upgrades. In addition the system portfolio landscape will be simplified and costs of future enhancements will be delivered with lower risk and, potentially, lower cost.

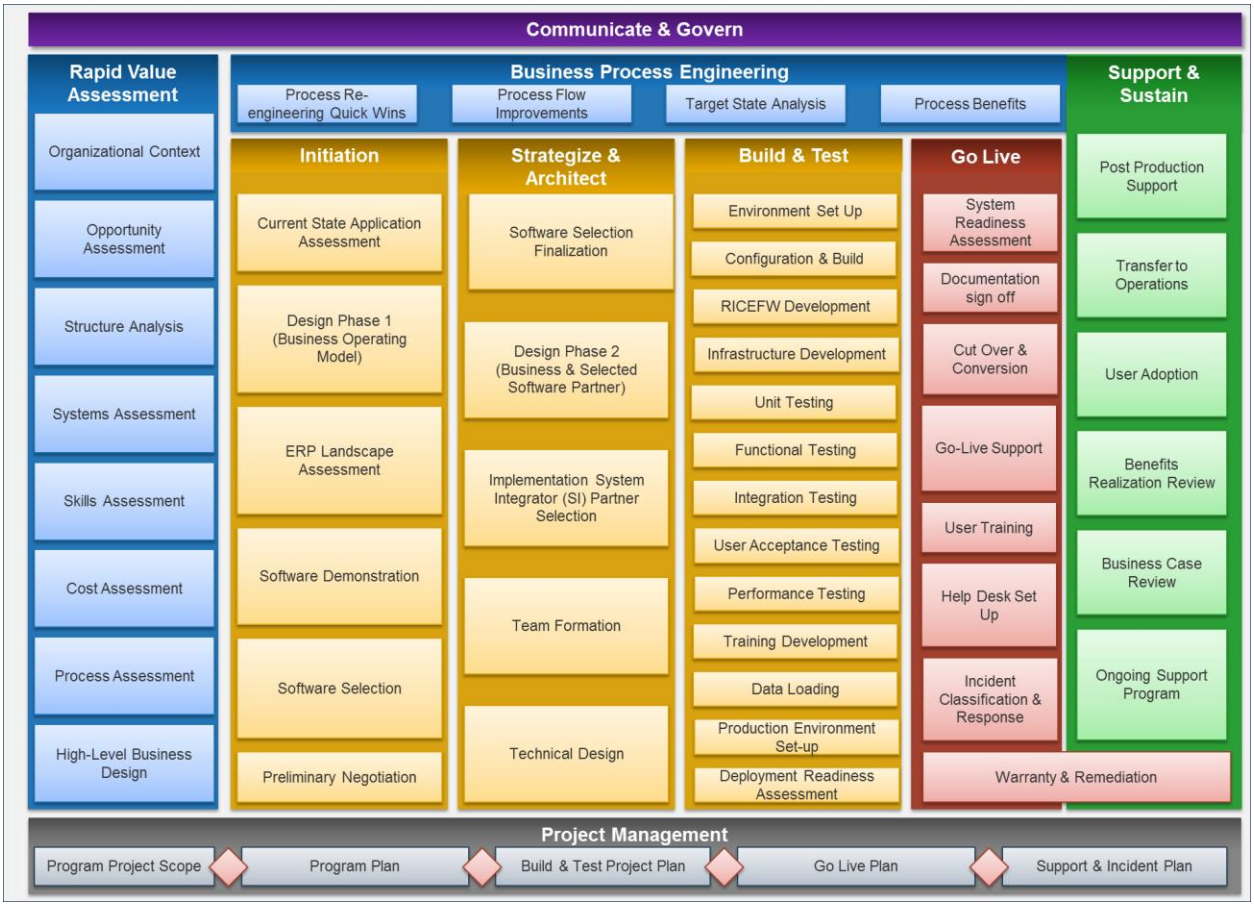
As a result of the risks of implementation, InfoTech recommends an increase of training and organization change management costs to the cost of the Option 4. It would be prudent to expect that a dedicated change management team would be added to the project team to deal with the implementations in the warehouse, safety, and operational management functionality. InfoTech expects that this would require an additional $1 million to $2 million in costs.

InfoTech does not recommend Option 4, as the increase in investment does not appear to support business value creation and appears to minimally reduce the cost of IT sustainment. The increased value in the replacement of those three other systems can be reviewed at a

future time when the IT portfolio is being reviewed for either functionality improvements or cost reduction requirements.

RISK SUMMARY

RISK ELEMENTS			
Option	Implementation	Sustainment	Business
1	Low	Medium	High
2	High	High	High
3	Medium	Low	Low
4	High	Low	Low



Definition			
Risk Element	Low	Medium	High
Implementation	x Minimal development x Stabilization of existing application footprint	x Configured Commercial Off The Shelf (COTS) applications or ERP x Integration through adaptors or Service Oriented Architecture (SOA) and Enterprise Service Bus (ESB)	x Extensive custom development x Complex point-to-point integration
Sustainment	x Large ERP footprint x Minimal integration points x Stable, well-supported solutions	x Multiple point solutions x Multiple integration points x Stable solutions	x Multiple point solutions x Complex integration x New / non-stable solutions requiring specialized and rare skill sets
Business	x Meets all identified future business needs	x Meets some future business needs	x Does not meet future business needs

C. PRICING REVIEW

PRICING METHODOLOGY

The pricing templates provided were reviewed for completeness against the standard ERP implementation framework that InfoTech uses to support and advise its members. The items included in the pricing model used by Toronto Hydro are complete and sufficient to provide an adequate and responsible project budget for all options.

,QIRTECH (QWHUSULVH 6\VWHP 'H

LICENSING COSTS

The licensing costs for the ERP systems were compared to published materials from the key ERP providers in the utility industry (SAP and Oracle) . These costs were compared on average to those included in the proposal and InfoTech views the submission costs as adequate and responsible for the purposes of the ERP submission .

There are many factors that will go into the completion of the contracted licensing costs including the potential that these costs can be reduced with professional negotiation. These costs may provide a small upside depending on the commercial environment at the time of negotiations.

SERVICES COSTS

The costs to implement the projects through the use of service providers was reviewed by three competent and experienced ERP strategic, planning and implementation advisors, includi ng the author of this review. All the advisors have experience in utilities and ERP within the Toronto and North American market.

The costs of the services appear to be reasonable and prudent. The costs of the services for Option 3 and 4 are more predictable as they will draw on a large and well established pool of talent for a major ERP in a major market.

In all four cases the size of the projects and the variability of resources required will require prudent and comprehensive project management which has been included in the pricing of all four Options.

D. CONCLUSION

InfoTech can support the following conclusions:

1. The selection of a major ERP (either Oracle or SAP) will support the functional needs for Toronto Hydro as stated in the submission and will resolve the major security concerns that are inherent in the current state systems.

2. Neither the upgrade of the Ellipse and legacy systems (Option 1) nor the replacement and enhancement of the Ellipse and legacy systems (Option 2) are recommended for reasons that include security profile, cost, lack of functionality , and increased complexity of system sustainment.

3. The pricing model for Option 2 should include an additional $10 million to $15 m illion in costs to either include an Enterprise Service Bus or additional costs in testing and sustainment because of the comp lexity of the integration environment being created.

4. The pricing model for Option 4 should include an additional $1 million to $2 m illion in support for training and change management for the front line workforce who will be experiencing significant proce ss changes on three additional systems.

5. Other than those additions, the pricing methodology is complete and reasonable based on the information presented on the scope and complexity of the projects.

6. InfoTech concurs with Toronto Hydro that Option 3 repre sents the best use of investment funds that meets the necessary security requirements and aligns best to the needs of the large utility industry.

E8.7 Voice Radio System Upgrade Program

E8.7.1 Summary

Program Description

The objective of this program is to upgrade Toronto Hydro's existing voice radio system. Toronto Hydro needs to upgrade the existing system in a timely manner because the key infrastructure components will not be supported or maintainable beyond 2016.

The two way radio is used to:

- establish and ensure protection of exposed workers,
- establish hold-offs; in addition to protecting the plant from possible damage, establishing a hold-off informs the control authority of the presence of workers in a specific location which is critical should an emergency occur,
- ensure orders to operate (OTO) are followed correctly and both the control authority and workers are in continual contact during the execution of an OTO, and
- summon help in an emergency through the mayday protocol.

The following table summarizes the anticipated benefits associated with this program.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ This technology enables Toronto Hydro to safely and effectively respond to trouble calls, resulting in shorter restoration times in the event of an outage. ƒ The new system is expected to have lower maintenance costs than the current aging system.
Reliability	ƒ Facilitates faster restoration times, thus increasing system reliability. ƒ Protects the integrity of the distribution system by keeping the Control Centre up to date on conditions that pose a reliability threat ƒ Radio communication is required for field work operations, which support overall system reliability. ƒ Cell phone service is often unavailable during an emergency due to overloads on telecommunications networks, while radio communications remain operational.
Efficiency	ƒ This technology enables Toronto Hydro to better coordinate responses to trouble calls. ƒ Upgrading the radio system will increase efficiency by reducing the time it takes for field crews to receive instructions from the Control Centre and begin work – work that must be stopped if the radio system is down. ƒ The new equipment will facilitate multiple calls from the field at one time, unlike the existing Control Centre radio equipment. ƒ Enables communication between workers in below grade situations, which enables the efficient completion of field work.
Safety	ƒ Reliable communications with the Control Centre will help create safer working conditions for Toronto Hydro employees by keeping crews updated about changing conditions in an emergency situation. ƒ Real-time information communicated through the radio system about the energization status of equipment helps reduce the risk of injury to field workers. ƒ Enables communication in below grade situations, which is essential to worker safety. ƒ The radio system is relied upon to contact emergency response crews in the event of an incident.
Other Benefits	ƒ The new system has readily available technical support. The specialized labour required to the maintain old system is in short supply, which causes delays to field work when the radio system requires maintenance but support is unavailable. ƒ The availability of spare parts for the old system is diminishing, which will result in longer and more frequent radio outages. Spare parts are readily available for the new system.

Program Drivers

As the voice radio system serves a number of critical safety-related functions, Toronto Hydro requires all field operations to be stopped when the system is down, and requires that field work

only resume after the system has been completely restored. This an important precaution in mitigating a multitude of potential safety risks associated with field work, including:

- inadvertently operating equipment that is energized,
- not being readily informed of changing conditions on the system that could pose a threat,
- not being able to contact the Control Centre or emergency services for help when needed, and
- other precarious circumstances that may arise while working on the overhead or underground distribution plant.

The trigger and secondary drivers for this program are outlined in Table B below.

TABLE B: PROGRAM DRIVERS

Trigger Driver	Reasoning
Safety	Maintain the high reliability and availability of critical voice communications to Toronto Hydro field crews to protect them from injury or harm, and to provide them priority access to emergency services
Secondary Drivers	**Reasoning**
Capital and Maintenance Program Support	The voice radio system is essential to Toronto Hydro's core distribution operations as it enables the utility to safely and effectively deliver its planned capital and maintenance programs in the ordinary course and to respond to trouble calls in a safe, timely and efficient manner
Obsolescence	The radio system infrastructure cannot be supported or maintained beyond mid-2016

Preferred Alternative

Toronto Hydro considered the following options to address the risks associated with the aging voice radio system infrastructure:

(1) maintain the existing system beyond 2016 on a "best effort" basis;

(2) migrate to a contracted radio service;

(3) replace the existing analog system with new digital radio system TETRA ; or

(4) upgrade the existing analog system to new digital radio system P25 .

Toronto Hydro evaluated the alternatives and determined that option 4 - "Upgrade the existing analog system to digital radio system P25" is preferred because Toronto Hydro expects it to be the most cost-effective solution for addressing the risks of the current system and is designed to optimize the continuity of Toronto Hydro's core operations by:

- allowing Toronto Hydro to leverage the existing radio infrastructure and re-use some of its components, and, thereby, it helps minimize program execution costs and timelines, and
- enabling Toronto Hydro to execute upgrades in phases, which is expected to minimize the interruption of Toronto Hydro's operations.

Timing and Pacing

Due to the majority of the voice radio system infrastructure components aging by 2016, Toronto Hydro must upgrade the system. The implementation cannot be delayed as it creates potential safety risks to Toronto Hydro crews. The historical and estimated costs of the Voice Radio System program are provided in Table C below.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Forecasted Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019

E8.7.2 Program Description

The objective of this program is to upgrade Toronto Hydro's existing voice radio system. Toronto Hydro needs to upgrade the existing system in a timely manner because the key infrastructure components will not be supported or maintainable beyond 2016. Toronto Hydro estimates that this program will cost approximately $20.41 million and that the work will be completed in 2015 and 2016.

The two way radio is used to:

- establish and ensure protection of exposed workers,
- establish hold-offs; in addition to protecting the plant from possible damage, establishing a hold-off informs the control authority of the presence of workers in a specific location which is critical should an emergency occur,
- ensure orders to operate (OTO) are followed correctly and both the control authority and workers are in continual contact during the execution of an OTO, and
- summon help in an emergency through the mayday protocol.

Toronto Hydro has set following requirements to the voice radio system to enable its employees to successfully and safely perform their job functions:

TABLE 1: VOICE RADIO REQUIREMENTS

Business Requirement/ System Feature	Toronto Hydro Employees who Require the Feature	Why it is important for Toronto Hydro's operations	Current State Challenges	Mitigation due to the Voice Radio System Upgrade
1. Provides a reliable city wide wireless voice communication that field crews can access readily.	All Toronto Hydro crews and contractors working in the field: x Emergency response overhead and underground crews, x Construction and maintenance	Whenever Toronto Hydro's field crews enter or access distribution system plants, they need to notify the Control Centre. The voice radio system is a dedicated system that allows this type of	The presence of "dead zones" in some parts of Toronto where the radio signal is weak or absent.	Yes: The program provisions for additional radio sites to address the weak radio signal issues and improve the city wide coverage.

Business Requirement/ System Feature	Toronto Hydro Employees who Require the Feature	Why it is important for Toronto Hydro's operations	Current State Challenges	Mitigation due to the Voice Radio System Upgrade
	overhead and underground crews, and x Stations crews	communication.		
2. Supports emergency communication and signaling procedures, which are required to satisfy 'mayday' contingency protocols.	All Toronto Hydro crews and contractors working in the field: x Emergency response overhead and underground crews, x Construction and maintenance overhead and underground crews, and x Stations crews	› This feature enables the quickest priority access to the Control Centre with the press of an Emergency Button x No other known technology, except for the voice radio system, is capable of providing this benefit.	No challenges	Yes: This feature is available in the upgraded system.
3. Enables below grade communications in confined spaces such as ground vaults, cable chambers and other underground structures.	Toronto Hydro underground crews and contractors working in the field: x Emergency response underground crews, and x Construction and maintenance underground crews	This is one of the most essential features, as the underground distribution system assets covers approximately 57% of the total distribution system within the City of Toronto and any work on these assets require the use of below ground radio communication.	During the implementation of the voice radio system in 2001, Toronto Hydro selected the best available technology at that time and enabled below grade communication through installation of vehicular repeaters on utility trucks. As a result, the operating procedure required to enable the below grade radio communication is	Yes: x The upgraded system is expected to provide seamless below grade voice radio communication, which will simplify its use by field employees.

Business Requirement/ System Feature	Toronto Hydro Employees who Require the Feature	Why it is important for Toronto Hydro's operations	Current State Challenges	Mitigation due to the Voice Radio System Upgrade
			manual and tedious.	
4. Provides sufficient call r management tools that enable Toronto Hydro personnel to effectively manage voice radio communications with Toronto Hydro field operatives and external contractors.	Power System Controllers and Dispatch Operators.	This feature allows the Control Centre Operators to respond to the radio call of the field crews to issue instructions, hold o-offs and emergency calls.	Radio calls to the Control Centre are often queued. This occurs because up to six Power System Controllers service the same area, yet only one call can be active at any time as a result of the fact that all users of the area share a single radio talk group. This situation leads to a call processing time of 30 -60 minutes.	Yes: Existing desktop radios in the Control Centre are expected to be replaced with proper dispatch consoles, which, unlike the desk top radios, offer features such as call management tools and user r friendly interfaces.

The existing system was installed in 2001 and will not be maintained and supported by the vendor beyond 2016. Due to its age and the lack of vendor support, Toronto Hydro expects that the existing system will not be able to satisfactorily support its operations beyond 2016. To address this issue, Toronto Hydro plans to upgrade the voice radio system infrastructure over the course of the next two years. The chart below summarizes the work that Toronto Hydro proposes to complete as part of this program, and the estimated costs of completing the work.

TABLE 2: 2015 -2019 COST SUMMARY

		Estimated Costs for 2015-2019, $M					
Infrastructure Type	Asset Type	2015	2016	2017	2018	2019	Total
Data Network and Facilities At high site locations (Non-Toronto Hydro premises)	• Facilities Assets (UPS, Generator, A/C) • High-speed IP Network (Fiber Optic)	3.6					3.60
Backend Infrastructure and Labour	• Core Equipment • Antenna Site Base Stations • Gateway Devices		8.64				8.64
Below-Grade Infrastructure and Labour (old city of Toronto only)	• Antennae/ Base Stations for additional sites		2.03				2.03
Front-end Infrastructure and Labour	• Dispatch Consoles • Radios	3.08	3.05				6.13
TOTAL		6.68	13.73				20.41

The following table summarizes the anticipated benefits of the Voice Radio System Upgrade Program.

TABLE 3: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ This technology enables Toronto Hydro to safely and effectively respond to trouble calls, resulting in shorter restoration times in the event of an outage. ƒ The new system will have lower maintenance costs than the current aging system.
Reliability	ƒ Facilitates faster restoration times, thus increasing system reliability. ƒ Protects the integrity of the distribution system by keeping the Control Centre up to date on conditions that pose a reliability threat ƒ Radio communication is required for field work operations, which support overall system reliability. ƒ Cell phone service is often unavailable during an emergency due to overloads on telecommunications networks, while radio communications remain operational.
Efficiency	ƒ This technology enables Toronto Hydro to better coordinate responses to trouble calls. ƒ Upgrading the radio system will increase efficiency by reducing the time it takes for field crews to receive instructions from the Control Centre and begin work – work that must be stopped if the radio system is down. ƒ The new equipment will facilitate multiple calls from the field at one time, unlike the existing Control Centre radio equipment. ƒ Enables communication between workers in below grade situations, which enables the efficient completion of field work.
Safety	ƒ Reliable communications with the Control Centre will help create safer working conditions for Toronto Hydro employees by keeping crews updated about changing conditions in an emergency situation. ƒ Real-time information communicated through the radio system about the energization status of equipment helps reduce the risk of injury to field workers. ƒ Enables communication in below grade situations, which is essential to worker safety. ƒ The radio system is relied upon to contact emergency response crews in the event of an incident.

Other Benefits	ƒ The new system has readily available technical support. The specialized labour required to the maintain old system is in short supply, which causes delays to field work when the radio system requires maintenance but support is unavailable. ƒ The availability of spare parts for the old system is diminishing, which will result in longer and more frequent radio outages. Spare parts are readily available for the new system.

E8.7.3 Why the Program is Needed

The voice radio system is essential element in Toronto Hydro's ability to execute its core distribution operations because it helps facilitate the safety of employees, contractors, third party workers entering Toronto Hydro's plant, and protects the integrity of the distribution system. Field crews rely on the voice radio system to communicate with the Control Centre prior to initiating and completing work, to receive instructions and clarifications from their supervisors, and to contact emergency response services in the event of an incident. Since the voice radio system serves these critical functions, Toronto Hydro requires all field operations to be stopped when the system is down, and requires that field work may only resume after the system has been completely restored. This an important precaution in mitigating a multitude of potential safety risks associated with field work, including:

- ƒ inadvertently operating equipment that is energized,
- ƒ not being readily informed of changing conditions on the system that could pose a threat,
- ƒ not being able to contact the Control Centre or emergency services for help when needed, and
- ƒ other precarious circumstances that may arise while working on the overhead or underground distribution plant.

As previously mentioned, Toronto Hydro plans to upgrade the existing system as soon as possible because the vendor will not support the system beyond 2016. Spare parts are no longer being manufactured for this system, and the inventory of available parts is rapidly depleting. If the key components of the voice radio system cannot be maintained, the risk of system failure increases significantly. Given the critical function of this technology in Toronto Hydro's core distribution activities, such a failure could result in a prolonged interruption of the utility's

operations and potentially create safety concerns for field crews who rely on this infrastructure. To mitigate this risk, Toronto Hydro proposes to promptly undertake the work under this program.

The diagrams below illustrate that over the past few years, the performance of the aging voice radio system is steadily degrading and associated maintenance costs have increased significantly. Costs have increased because the vendor's technical specialists are no longer trained to provide technical support on this technology. As a result, specialized labour needs to be procured to support this system. Such labour comes at a higher cost, and more importantly, cannot be guaranteed by the vendor. As such, Toronto Hydro bears the increasing risk of not being able to obtain the desired support when needed.

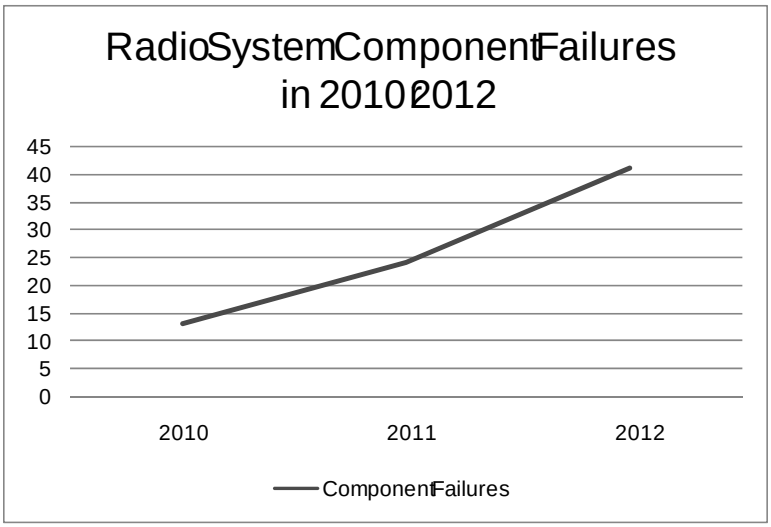

FIGURE 1: VOICE RADIO SYSTEM COMPONENT FAILURES IN 2010-2012

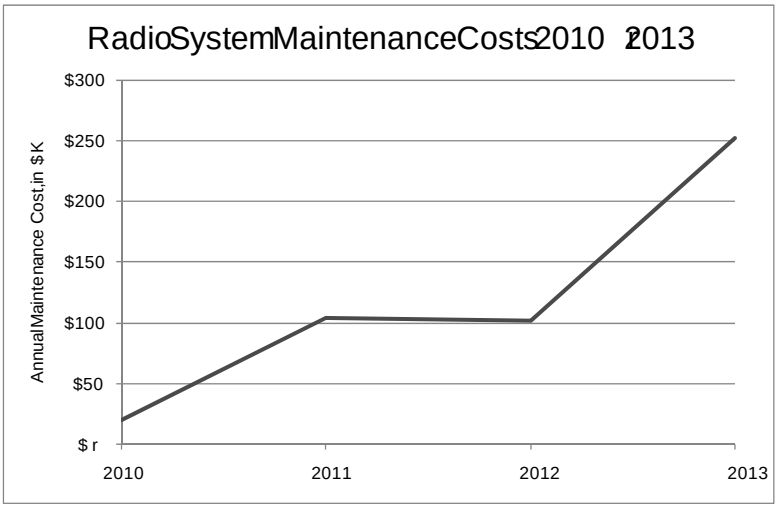

FIGURE 2: VOICE RADIO SYSTEM MAINTENANCE COSTS IN 2010-2012

In addition to the deteriorating system's performance and increasing maintenance costs, there are a number of technical issues related to the aging voice radio system that can be resolved through this program:

(1) Due to the growing number of high-rises under construction in the city, there are several radio frequency dead zones with poor or no radio signal;

(2) The underground radio coverage is unreliable because it connects two radio systems that are not designed to work together through vehicular repeaters. The more elements any system contains, the higher the probability of system failure;

(3) 81% of the radio units are past their end of useful life and should be replaced;

(4) The Control Centre operators do not possess the technical ability to inform field crews where they are in the call queue in the current system;

(5) All conversations between the field crews and the Control Centre are taped. However, the existing technology does not enable Toronto Hydro to tag or identify recordings in any way that allows for categorizations of conversations or for it to be able to find a particular conversation sometime in the future. Where an accident occurs, it is very difficult and laborious to locate the conversations related to the event in questions, information that is necessary for safety investigations and labour disputes;

(6) The Control Centre radio equipment lacks proper call management functionality and capacity to take more than one call at a time.

Due to the recent developments and innovations in the radio industry and based on the preliminary research of the standard capabilities of the upgraded radio system offered by the vendors in Canada, Toronto Hydro plans to resolve all of the above-mentioned issues with the proposed upgrade solution.

Toronto Hydro expects that the upgraded voice radio system will enable the Control Centre to manage voice radio communications with Toronto Hydro field crews and external contractors more efficiently. A particular challenge with the existing system is that calls are often queued. This occurs because up to six Power System Controllers service the same area, yet only one call can be active at any time because all users of the area share a single radio talk group. This configuration leads to a call processing time of 30-60 minutes. The system that Toronto Hydro plans to install addresses this problem by upgrading the existing desk top radios in the Control Centre with proper dispatch consoles, which, unlike the desk top radios, offer features such call management tools and user-friendly interfaces that provide the controller and dispatchers increased flexibility and functionality.

E8.7.3.1 Purpose

The purpose of the program is to ensure that Toronto Hydro has access to reliable voice radio communications, to better protect the safety of Toronto Hydro's field workers and to ensure the continuity of the Toronto Hydro's core operations.

The chart below outlines the trigger and secondary drivers of the program:

TABLE 4: DRIVERS

Drivers		Reasoning
Trigger	Safety	Maintain the high reliability and availability of critical voice communications for Toronto Hydro field crews in order to protect them from potential injury or harm, and to provide them priority access to emergency services.
Secondary	Capital and Maintenance Program Support	The voice radio system is essential to Toronto Hydro's core distribution operations as it enables the utility to safely and effectively deliver its planned capital and maintenance programs in the ordinary course and to respond to trouble calls in a safe, timely and efficient manner.

Drivers		Reasoning
	Obsolescence	The radio system infrastructure cannot be supported or maintained beyond mid-2016.

E8.7.3.2 Asset Details

TABLE 5: ASSETS TO BE REPLACED BY ASSET CLASS

Asset Class	Infrastructure Type	Asset Type	Costs for 2015-2019, $M					
			2015	2016	2017	2018	2019	Total
Radio Hardware: SAP Activity Code 1760; SAP Asset Class Code 3360	Data Network and Facilities	• Facilities Assets (UPS, Generator, A/C) • High-speed IP Network (Fiber Optic)	3.60	-	-	-	-	3.60
	Backend Infrastructure and Labour	• Core Equipment • Antenna Site Base Stations • Gateway Devices	-	8.64		-		8.64
	Below-Grade Infrastructure and Labour (old city of Toronto only)	• Antennae/ Base Stations for additional sites	-	2.03		-		2.03
	Front-end Infrastructure and Labour (Dispatch Consoles only)	• Dispatch Consoles • Radios	3.08	3.05		-		6.13
	TOTAL		6.68	13.73		-	-	20.41

(i) Asset Lifecycle

The two major technical components of the system are the infrastructure equipment and subscriber gear (radio units). The vendor has indicated that these components will not be

supported and maintained beyond 2016. The radio system component lifecycle is presented in the table below:

TABLE 6: LIFE CYCLE

Product	Year of Deployment by TH	Product Lifecycle in Years	Support Details
2-way Fixed Network Equipment (Infrastructure)	2001	15 Years	End of support in 2016
Mobile/ Portable 2-way Radios	Various years	10 Years	81% of radios are out of support

(ii) Asset Failure Impacts

Voice radio communications are critical for Toronto Hydro because a failure of the system can potentially result in the failure of business operations and increased safety risks for Toronto Hydro employees.

If the voice radio system fails, emergency response crews have to use cellular phones as a back-up option. This is a very unreliable means of communications, especially during large power outages, for several reasons:

- The cellular phone system can be overloaded with customer calls and can become inaccessible, particularly during major events such as storms and floods;
- The cellular phone system can be inaccessible if is affected by a power outage;
- In case of an emergency call made from a cell phone, there is no way for a Power System Controller in the Control Centre to identify the urgency and criticality of the call, which potentially creates additional safety concerns for Toronto Hydro field employees.

The two way radio system has proven to be the only reliable means of communicating between the field crews and the Control Centre. Without a functional two way radio system, the safety issues associated with restoring power can worsen.

E8.7.4 Timing & Pacing of the Program

Toronto Hydro has a window of approximately 36 months to upgrade the voice radio system before the system's major components will longer be supported and maintained by the vendor. Toronto Hydro should not defer or delay this work beyond 2016 because a failure of the voice

radio system creates potential safety risks for Toronto Hydro's crews and compromises the utility's ability to sustain its core operations.

Toronto Hydro plans to implement this Program in the following stages:

Project Phase	2015				2016	
	Q1	Q2	Q3	Q4	Q1	Q2
Network & Facilities Infrastructure						
Backend Infrastructure						
Deploy Below Grade Infrastructure						
Purchase Radio HW (Handsets and Dispatch Consoles)						

FIGURE 3: PROGRAM IMPLEMENTATION

As a reference, historical CAPEX spending incurred and the forecasted future CAPEX spending is presented in the table below:

TABLE 7: HISTORICAL AND FUTURE SPENDING

	Historical CAPEX Spending, $M					Future CAPEX Spending, $M				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Total Annual Spend ($M)	0.02	0.1	0.1	0.25	0.12	6.68	13.73	0.0	0.0	-

E8.7.5 Program Execution

Toronto Hydro considered and evaluated the following program execution options:

- "Big bang" implementation which refers to the simultaneous upgrade of all radio system components; and
- Phased implementation, which refers to a gradually sequenced upgrade of the radio system components.

A "big bang" approach is not a viable or prudent option for Toronto Hydro for the following reasons:

- It would require the installation of a new radio system in parallel with the present radio system. This option is not desirable because it does not allow for the re-use of any existing equipment, requires significant capital investments into the new radio system and adds maintenance costs to support the old radio system during the transition period;

- Since there is not enough space to install the new radio sites and other equipment without de-commissioning the old infrastructure, additional sites would have to be secured and validated. This is not desirable because it could impose both schedule risks and substantial costs on Toronto Hydro;

- There is a higher level of potential safety risk associated with this option, as handheld radio devices and dispatch consoles in the Control Centre also would have to be duplicated and used in parallel during the time of system replacement (for several months), which necessitates considerable training efforts, physical inconvenience and increases the risk that the devices will be mixed and used erroneously.

Toronto Hydro plans to upgrade the existing radio system in phases. This approach is optimal for the following reasons:

- it minimizes the potential safety risks because a large portion of the equipment can be re-used and the employees are familiar with this equipment and of how to operate it;

- it minimizes the effect of the upgrade process on business continuity because the radio system components can be upgraded gradually, likely causing minimal to no interruption to business operations, and

- it minimizes the deployment costs as some radio system infrastructure components may be re-used.

The proposed phases of the program are:

- Phase 1: Connect the existing Smartnet 3.Z system to a P25 Core via a SmartX gateway, which will allow the Smartnet infrastructure to operate as a component of the new P25 infrastructure. Toronto Hydro does not expect this transition to affect the operation of the system. From a business continuity perspective, Toronto Hydro expects that this phase will only require a short downtime of approximately 2-4 hours.

- Phase 2a: Replace the existing dispatch radios with proper dispatch consoles and gradually replace the radio units used by crews in the field. Toronto Hydro expects that

the implementation of this phase will not exceed 12-18 months, and that it will not affect business continuity.

- Phase 2b: Implement additional radio sites to improve the radio coverage. Toronto Hydro expects to complete this phase in approximately 16-18 months.
- Phase 3a: Complete the gradual replacement of the radio units. This phase can occur in parallel with phases 1 and 2 above.
- Phase 3b: Install the new P25 radio sites at the same locations as the existing Smartnet sites and switch over each site from Smartnet to P25, thereby completing the system upgrade.

(i) Program Risks

Toronto Hydro does not foresee any major risks to the execution of this Program. Minor risks that Toronto Hydro plans on addressing include:

(1) Provisioning of the backhaul infrastructure (e.g. fibre optics), and

(2) Receiving Construction Permits from the City of Toronto.

To mitigate these risks, Toronto Hydro plans to proactively engage the City of Toronto and put the necessary contractual provisions in its agreements with the selected vendor.

E8.7.6 Evaluation of Alternatives

E8.7.6.1 Quantification/ Evaluation of Options

Toronto Hydro considered a number of alternatives for addressing the safety and operational risks associated with the aged voice radio system infrastructure:

(1) maintain the existing system beyond 2016 on a “best effort” basis;

(2) migrate to a contracted radio service;

(3) replace the existing analog system with new digital radio system TETRA; or

(4) upgrade the existing analog system to digital radio system P25.

Option 1: Maintain the existing system beyond 2016 on a "best effort" basis

Toronto Hydro considers this option infeasible for the following reasons:

- Maximum Safety Risk: In this option, Toronto Hydro would not upgrade or replace the existing voice radio system from 2015-2019. Within this period, all voice radio system components will reach the end of their useful lives, increasing the risk of failure. Any failure of voice radio system generates potential safety issues because they can potentially affect the emergency communication between the field crews and the Control Centre

- Maximum Vendor Risk: The vendor may offer support on a "best effort" basis without any service levels guarantees. There is a high risk that in the near future, the spare parts for the antiquated radio system will not be available.

- Medium Operational Risk: With the foreseen scarcity of technical and labour resources to resolve the voice radio system component failure due to the lack of vendor guaranteed support, the time required to resolve the program could be substantial, which may threaten the continuity of Toronto Hydro's operations whenever employees need to contact the Control Centre via the radio system.

- Medium Amount of Investments: Toronto Hydro would likely incur additional costs to procure obsolete radio system components as well as technical specialists to support the voice radio system on a "best effort" basis.

Option 2: Migrate to a contracted radio service

Under this option, Toronto Hydro would migrate to managed or contracted services, including outsourcing critical voice radio communication activities to the external supplier, which will own the radio system and would be accountable for the functionality and performance of this system.

Toronto Hydro considers this option infeasible for the following reasons:

- Maximum Potential Safety Risk: No known external vendors' radio system provides below-grade capability. The lack of below-grade coverage by the two-way voice radio system provided by the external vendor could expose Toronto Hydro to an unacceptable level of potential safety risk. Below-grade communication capability is one of the most essential features of Toronto Hydro's voice radio system as underground distribution

system assets covers approximately 57% of the total distribution system within the City of Toronto.

- Maximum Vendor Risk: The concept of managed service is based on the pre-requisite of attracting the sufficient number of customers to guarantee the availability of radio system to the organizations lacking in-house radio expertise at a reasonable cost. A number of organizations in Ontario have contemplated this option as their radio communications systems reached their "end of life" cycle. Currently, Bell Mobility Radio is the only service provider of managed radio services. Bell Mobility Radio serves six governmental stakeholders: Ontario Provincial Police (OPP), Ministry of Health (MOH), Ministry of Transportation (MTO), Ministry of Natural Resources (MNR), Ministry of Correctional Services (MCS), and Guelph Police and Fire. Bell Mobility's current contract with the Ontario Government expires in 2016, and their efforts to secure customers for a future shared vendor-managed solution have not produced any commitments to date. If Bell Mobility is not be able to subscribe new customers or renew the contract with the Ontario Government, their offering of the managed radio services is at risk.

- Maximum Operational Risk: In the absence of a below-grade communication feature, Toronto Hydro cannot use the contracted radio system to manage its field operations, which presents a high operational risk.

- Medium Amount of Investments: The switch to the contracted radio services is costly and, should Toronto Hydro decide to move to the in-house radio system at a later time, would likely require substantial additional investments.

Option 3: Replace the existing analog system with new digital radio system TETRA

Terrestrial Trunked Radio (TETRA) (formerly known as Trans-European Trunked Radio) is a professional mobile radio and two-way transceiver specification and a European Telecommunications Standards Institute (ETSI) standard published in 1995. TETRA was specifically designed for the use by government agencies, emergency services (police forces, fire departments, ambulance), by public safety networks, rail transportation, transport services and the military in Europe. The development of TETRA standard was driven by the need to standardize radio communication across the European Union and across various industry groups. TETRA is a new standard; the only way to transition to it is by replacing the existing radio system completely in one stage (http://www.tandcca.com).

Toronto Hydro considers this option infeasible for the following reasons:

- Maximum Potential Safety Risk: During the deployment phase, for example, field employees must carry two radio units, which can be confusing and can result in mistakes being made, while using a new system entirely presents an unacceptable level of potential safety risk in case of emergency radio communication.

- Maximum Vendor Risk: As the TETRA standard was developed in Europe, there are no vendors in North America which supply radio systems based on this standard.

- Maximum Operational Risk: There is an unacceptable level of operational risk associated with this option as all the existing radio system infrastructure components, as well as radio units, have to be scrapped and re-installed from scratch. This cannot be accomplished without significant interruptions to Toronto Hydro's field operations.

- Maximum Amount of Investments: During the deployment period, the whole voice radio system must be duplicated, which likely requires substantial investments and additional system maintenance costs. Toronto Hydro expects that the replacement of the existing radio system with a completely new system would not allow for the re-use of the existing radio infrastructure, which makes its deployment prohibitively expensive.

Option 4: Upgrade the existing analog system to digital radio system P25

Toronto Hydro considers this is a preferred alternative for the following reasons:

- Minimum Potential Safety Risk: The upgrade of the existing analog system to digital radio system P25 presents a minimal safety risk because it allows using some existing equipment while upgrading certain other components. The radio system users are familiar with the equipment and know how to operate it.

- Minimum Vendor Risk: P25 is a suite of standards for radio communications for use by federal, state/ province and local public safety agencies in North America to enable them to communicate with other agencies and mutual aid response teams in emergencies. The P25 system fills the same role in North America that the European Terrestrial Trunked Radio (TETRA) standard fills in Europe (http://www.motorolasolutions.com). There are several well-established and reputable vendors in Canada that provide P25 voice radio systems. Toronto Hydro intends to go through a competitive bidding process to select the vendor who most satisfies the utility's requirements.

- Minimum Operational Risk: Toronto Hydro believes that upgrading the existing system to P25 technology is the options associated with the least interruption to Toronto Hydro's operations, as it offers a gradual transition from the present state to the future state radio system by upgrading certain radio system components one-by-one with the simultaneous re-use of other components that end users are familiar with. In addition, Toronto Hydro expects that it will be easier to implement because it optimizes the opportunity for training and minimizes the impact to end users, as it presents them with an opportunity to gradually adjust to the new operating environment.

- Minimum Amount of Investments: The ability to re-use existing radio infrastructure is important because Toronto Hydro will likely be able to leverage some of its existing assets throughout the upgrade process; for example, 19% of radio units may be re-used. Coupled with reduced training efforts in comparison with options two and three, the equipment re-usability opportunity makes this option most economically efficient.

Preferred Alternative

The assessment of four considered alternatives is summarized in the table below. Based on the analysis, Option 4 is Toronto Hydro's preferred alternative because of the minimal level of safety, vendor and business continuity risks it presents and because it is the most economically viable option:

TABLE 8: ALTERNATIVES EVALUATION

Criteria	Option 1: maintain the existing system beyond 2016 on a "best effort" basis	Option 2: migrate to a contracted radio service	Option 3: replace the existing analog system with new digital radio system TETRA	Option 4: upgrade the existing analog system to digital radio system P25
Potential Safety Risk	maximum	maximum	maximum	minimum
Vendor Risk	maximum	maximum	maximum	minimum
Operational Risk	medium	maximum	maximum	minimum
Amount of Investments	medium	medium	maximum	minimum
Recommendation				X

E8.8 Program Support

E8.8.1 Summary

Program Description

Toronto Hydro's Distribution System Plan (DSP) has been developed through a series of asset management processes, tools, systems and resources, as identified within Section D (Asset Management Process). Key outputs of the Asset Management Process include both long-term capital programs and discrete capital projects contained within those programs. The proposed Program Support expenditures will allow for continued refinement and improvements to the development of capital projects within the five-year period along with future development of capital programs from 2020 and beyond, through the execution of two key support studies: a climate adaptation study and a customer interruption cost (CIC) study. Table A provides a summary of this program's benefits.

TABLE A: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ CIC study is expected to further enhance the Feeder Investment Model (FIM) with localized outage costs ƒ System improvements based on the studies will facilitate the reduction of customer impacts due to extreme weather events and climate change
Reliability	ƒ Proposed studies will support efforts towards reduction in the frequency and duration of adverse-weather related outages ƒ The development of localized customer interruption costs would further enhance Toronto Hydro's capability to manage system reliability in a

	customer-focused manner
Safety	ƒ Proactively targeting areas vulnerable to extreme weather and climate change impacts is expected to reduce crews' exposure to work on the system during severe weather events
Efficiency	ƒ Enhancements to localized outage costs are expected to further enhance Toronto Hydro's business case evaluation (BCE) process, facilitating an enhanced economic evaluation of capital investments. ƒ Storm hardening improvements to the distribution system will help mitigate the risks associated with extreme weather events, creating opportunities for cost reductions of weather-related service restoration.

Program Drivers

The trigger driver for this program is summarized in the following table.

TABLE B: PROGRAM DRIVER

Trigger Driver	Reasoning
System Maintenance and Capital Investment Support	ƒ Plans based on the climate adaptation study are planned to be executed in both Overhead and Underground Circuit Renewal Programs ƒ Update localized outage costs into the Feeder Investment Model

Preferred Alternative

In the absence of the proposed studies, adaptation to climate change within Toronto Hydro's distribution system can be derived solely from historical information and trends in weather-related events. Similarly, Toronto Hydro would continue to use existing customer interruption cost (CIC) inputs as part of their Feeder Investment Model (FIM) and business case evaluation (BCE) process. This option is not preferred as it does not address the expected impacts of climate change and would not allow for the continuous improvement of the FIM approach.

Timing and Pacing

Both studies comprising this program are planned to be conducted in the first two years of the DSP period. After the completion of the climate adaptation study, Toronto Hydro plans to review the plans completed through the FIM, as well as compare the climate change adaptation study results to the existing programs being executed, to benefit from any cross-program synergies or to build on existing programs that may already be investing in system resiliency. The CIC study is

planned for completion in 2015 because the localized outage costs calculated would have to be tested and gradually incorporated into the FIM to further enhance the model in preparation of prioritization of projects in the later years of the DSP period. Toronto Hydro proposes to spend $1.7 million for this program as shown in Table C.

TABLE C: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	1.2	0.5	0	0	0

E8.8.2 Program Description

The objective of Program Support program is to enhance Toronto Hydro's long-term and short-term asset management planning processes, and ultimately enhance capital program and capital project development through the execution of the key planning studies. These studies include a climate adaptation study and a customer interruption cost (CIC) study. The climate adaptation study would permit Toronto Hydro to enhance its standards and design practices with storm-hardening capabilities, while also identifying specific areas within the distribution system that face an elevated amount of weather-related risks. The CIC study is expected to enhance a key input that is used as part of Toronto Hydro's Feeder Investment Model (FIM) decision-support system, such that the overall business case evaluation (BCE) process will be further improved.

E8.8.2.1 Climate Adaptation Study

Toronto Hydro plans to conduct climate adaptation study in 2015 and 2016 to assist with engineering analysis, informed decision-making and standards for overhead and underground capital programs. The study will focus specifically on identifying areas of the distribution system that are vulnerable to extreme weather and climate change. Figure 1 shows an example of reconfiguring the distribution system to move it outside of a flood plain, which is an example of the type of work that could be carried out as result of climate adaptation study. As recommendations from the climate study become available, pilot projects will be conducted as part of the studies to test the recommendations. The purposes of including the pilot projects as part of the studies is to finalize the climate adaptation solutions before programs are carried out at a system level.

FIGURE 1: RECONFIGURING DISTRIBUTION SYSTEM OUTSIDE OF FLOOD PLAINS

E8.8.2.2 Customer Interruption Costs (CIC) Study

The proposed Customer Interruption Costs (CIC) study is a survey-based interruption cost study to estimate outage costs specific to the City of Toronto context. This study would survey various customer classes, Toronto Community Councils, and Business Improvement Areas (BIAs). Surveying across different customer demographics ensures that Toronto Hydro's diverse customer base is captured in this study. In addition, the proposed study would also ask each survey participant about their expectations (i.e. the frequency and duration of outages that customers consider acceptable) and perceptions (i.e. how satisfied customers are with the level of reliability they currently experience) of service reliability.

The selected vendor for this study would recommend outage scenarios and their proposed cost estimation methodology based on the diversity of survey participants. The different outage scenarios would include a combination of seasonal (summer/winter), weekly (weekend/weekdays), and daily (morning/afternoon/night). As shown in Figure 1, based on historical data, there is no single hour that accounts for more than 7% of outages or less than 2% of outages. Accordingly, the study must be designed to capture information across all time

periods. Finally, each set of these scenarios will need to include durations of 5 minutes, 1 hour, 4 hours, 8 hours and 24 hours[1].

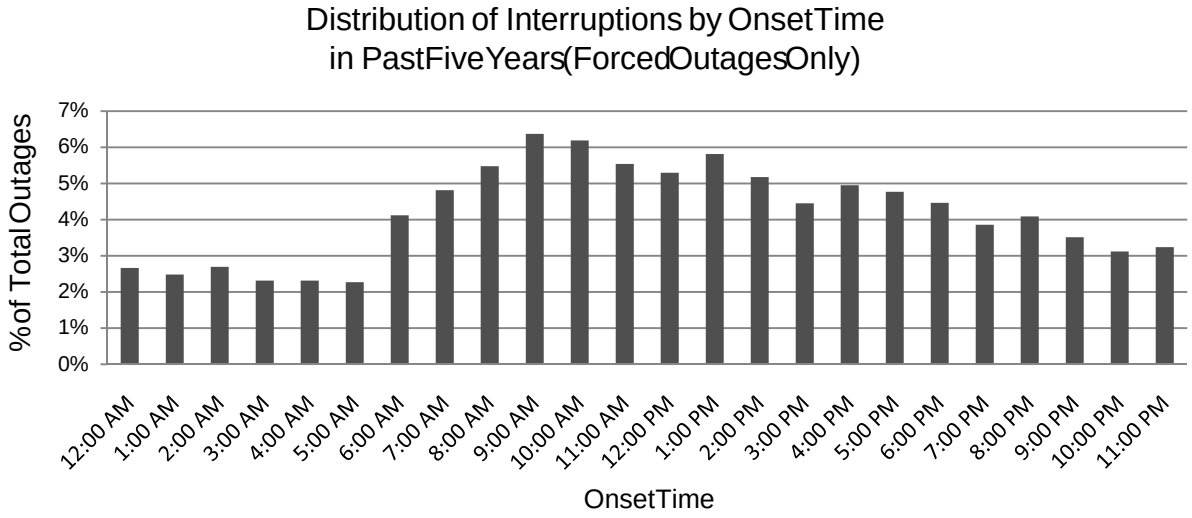

FIGURE 2: DISTRIBUTION OF INTERRUPTIONS BY ONSET TIME IN PAST FIVE YEARS

The different cost estimation methodologies are willingness-to-pay (WTP), willingness-to-accept (WTA), and direct-worth[2]. WTP cost estimations involve measuring the amount that customers would be willing to pay to avoid experiencing a service interruption; WTA involves measuring the level of compensation that customers would require to avoid a service interruption. Both of these approaches contribute to understanding how much customers would pay to avoid service interruptions. As costs for residential customers are mostly an inconvenience or hassle, they are often intangible and difficult to estimate using a direct-worth method. The combination of WTP and WTA approaches is a rigorous way of determining these implied costs. The direct-worth (DW) method involves asking customers to estimate the direct costs they would experience during a service interruption. These include outage related costs (e.g. labour and material costs incurred during an outage), lost production, cost to operate backup generation equipment,

[1] M.J. Sullivan and D.M. Keane, Outage Cost Estimation Guidebook (Electric Project Research Institute Research Project 2878-04 Final Report) (San Francisco Freeman, Sullivan and Company, 1995).
[2] Leona Lawton et al., A Framework and Review of Customer Outage Costs: Integration and Analysis of Electric Utility Outage Cost Surveys (Berkley: Population Research Systems, LLC and Lawrence Berkeley National Laboratory, 2003), online: Consortium for Electric Reliability Technology Solutions <http://certs.lbl.gov/pdf/54365.pdf>.

material costs to restart the production processes, etc. The DW approach is recommended for non-residential customers, i.e. small, medium, and large commercial and industrial (C&I) users.

This proposed study would survey customers across the Toronto Hydro service territory to determine system-wide values along with an analysis showing the confidence level of the values. Once these outage costs are calculated, they will be used in the FIM described in Section D3.

The anticipated benefits of this program are summarized in Table 1.

TABLE 1: SUMMARY OF PROGRAM BENEFITS

Customer Value	ƒ CIC study is expected to further enhance the FIM with localized outage costs ƒ System improvements based on the studies would help reduce customer impacts due to extreme weather events and climate change
Reliability	ƒ The studies would help achieve a reduction in the frequency and duration of adverse-weather related outages ƒ The development of localized customer interruption costs would further enhance Toronto Hydro's capability to manage system reliability in a customer-focused manner
Safety	ƒ Proactively targeting areas vulnerable to extreme weather and climate change impacts would help reduce crews' exposure to work on the system during these events
Efficiency	ƒ Enhancements to localized outage costs would allow Toronto Hydro to further enhance its business case evaluation (BCE) process, facilitating enhancements to the economic evaluation of capital investments. ƒ Storm hardening improvements to the distribution system would help mitigate the risks associated with extreme weather events, facilitating reductions in weather-related reactive work.

E8.8.3 Why the Program is Needed

The purpose of the two studies in this program is to assist Toronto Hydro in preparing for climate change and mitigate its impacts and to enhance the FIM by reflecting the localized interruption costs for Toronto Hydro's customers. The climate adaptation study would include detailed engineering analysis and development of climate adaptation plans as well as pilot project testing based on recommendations from the study's findings. Localized customer interruption costs would help Toronto Hydro enhance the FIM, which is used to prioritize future projects.

E8.8.3.1 Program Drivers

As shown in Table 2, the trigger driver for this program is System Maintenance and Capital Investment Support. This driver classifies the program in the General Plant category. These two key support studies would allow for the continued refinement and improvements of the development of the capital projects within the five-year period along with future development of capital programs beyond 2020.

TABLE 2: PROGRAM DRIVER

Trigger Driver	Reasoning
System Maintenance and Capital Investment Support	ƒ Plans based on the climate adaptation study ware planned to be executed in both Overhead and Underground Circuit Renewal Programs ƒ Update localized outage costs into the Feeder Investment Model

(i) Climate Adaptation

On July 8, 2013, and December 22, 2013, (shown in Figure 3), the City of Toronto was hit with two different types of extreme weather that adversely affected Toronto Hydro's distribution system.

FIGURE 3: FALLING BRANCH ON STREET ENTANGLED WITH CONDUCTOR [3]

[3] "Photos: Toronto coated in ice following destructive winter storm", Windsor Star (22 December 2013) online: Windsor Star <http://www.windsorstar.com/news/national/cms/binary/9318821.jpg?size=640x420>.

Based on the information outlined in the AECOM-Toronto Hydro report entitled Future Impacts of Climate Change on Toronto Hydro's Distribution System (filed at Appendix A to this schedule), extreme weather events of this nature adversely affect Toronto Hydro's distribution system and will continue to do so in the future. The proposed climate adaptation study and pilot project would analyze, develop and test plans to make Toronto Hydro's distribution system more resilient to weather induced failure by reducing the time for restoring service to customers.

Toronto Hydro uses two fundamental measures of outage durations and outage frequency, namely System Average Interruption Index (SAIDI) and System Average Interruption Frequency Index (SAIFI). One of the sub-categories for both SAIDI and SAIFI tracks the impact of adverse weather specifically. In both metrics major event days (MEDs) (i.e. atypical events that are beyond the design or operational limits of the system) are put aside from historical tracking because they can distort perception of the utility's reliability performance. However, because of the nature of the climate adaptation study, it is relevant to look at how MEDs affect Toronto Hydro's distribution system.

Table 3 shows the total annual SAIDI for adverse weather excluding MEDs, and the average annual SAIDI from 2000-2013 for these values.

TABLE 3: AVERAGE ANNUAL SAIDI DUE TO ADVERSE WEATHER

Year	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
Total Annual SAIDI excluding MEDs (min)	40.5	33.3	35.6	35.0	18.4	19.8	26.9	26.5	26.6	28.9	32.8	38.2	16.8	30.5
Average Annual SAIDI from 2000 to 2013, excluding MEDs = 29.3 minutes														

By definition, MEDs can have a significantly higher than average impact on SAIDI. Toronto Hydro experienced two MEDs recently: the July 8, 2013, flood with a SAIDI total of 197.26 minutes, and the December 21 to the 26, 2013, ice storm with a preliminary SAIDI total of 990.7 minutes. Both MEDs far exceeded the average adverse weather SAIDI count for an entire year, demonstrating the extreme impacts adverse weather has on Toronto Hydro's distribution system. For further information on recent weather events affecting network performance refer to Future Impacts of Climate Change on Toronto Hydro-Electric System Limited (Appendix A)

The proposed climate adaptation study would assist Toronto Hydro in the implementation of the overhead and underground programs by focusing on the identification of areas of the system that are vulnerable to extreme weather. This will consist of a logical breakdown of the distribution system at a system level and a matrix comparison between different weather scenarios, highlighting areas affected by changing climate.

Other electrical utilities have also conducted studies on climate adaptation and have developed climate adaptation programs based on the findings to move underground equipment out of flood plains, or elevate equipment where possible to remove the hazard. Where removal of equipment is not possible, equipment upgrades could be implemented in flood zones to incorporate submersible equipment that would not be as vulnerable to the water. For more detail on what other electrical utilities are developing for climate adaptation please refer to (Future Impacts of Climate Change on Toronto Hydro-Electric System Limited in Appendix A). Overhead equipment, which endures the most pressure from extreme weather, would also be examined; in certain areas where power supply is critical, system reconfiguration may be used to increase reliability and the integrity of the overhead distribution system.

Future increases in temperature could have adverse effects on the Toronto Hydro distribution system as well. It is forecasted that in 100 years, increased temperatures could produce a 10 percent reduction in efficiency of the distribution system. Potential mitigation programs can look at changing the amount of energy consumed by customers through new technologies.

The proposed climate adaptation study would include pilot projects to test feasibility of the recommendations. The benefit of testing the study's recommendations before system level implementation is to ensure the most effective solutions go forward. These proposed pilot projects are included in the forecasted expenditures for the program.

At this point in time, there are many solutions Toronto Hydro could use to mitigate climate change impacts. However, in order to ensure the correct steps are taken, two years of studies and pilot projects will be used to identify the critical path for future climate adaptation programs.

(ii) Customer Interruption Costs

The proposed CIC study would help further enhance customer interruption cost inputs used within the Feeder Investment Model (FIM), which is further detailed in Section D3. Customer Interruption Costs are defined as a measure of the monetary losses for customers due to an interruption of

electric service. The inconvenience and damage encountered by customers involves three periods:

(1) The first period is immediately after power interruption. Customers need to take the necessary action to mitigate the immediate effects of the interruption risks to health and welfare of employees, tenants or the public, production impacts, and other business and non-business activities. This first period can be monetized as per the formula shown below:

(a) Event Cost = $(SAIFI_{EFFECT})$(Total Load)

Where:

- $SAIFI_{EFEECT}$ ($30) represents the cost associated with this first period of the interruption.
- Total Load represents the peak load that will be interrupted due to the outage event.

(2) The second period follows, with on-going disruption to production, sales, office work and entertainment. In this period the customer interruption cost is proportional to the duration of power failure. This second period can be monetized as per the formula shown below:

(a) Duration Cost = (SAIDIEFFECT)(Total Load)(Outage Duration)

Where:

- $SAIDI_{EFEECT}$ ($15) represents the cost associated with this second period of the interruption.
- Total Load represents the peak load that will be interrupted due to the outage event.
- Outage Duration represents the average duration of the outage event in hours.

(3) The third period is after the restoration of power when customers take action to resume normal production.

As noted above, Toronto Hydro has adopted the use of a $30/kVA (peak load) customer interruption cost value to represent the first period of the outage (the "Event") and a $15/kVA-hour (peak load) customer interruption cost value to represent the second period of the outage (the "Duration"). These costs were developed with input from consultants, who have worked with other

utilities in establishing similar parameters. Reliability valuation studies, such as those from Roy Billinton, were used to aid in the development of these parameters, which are applied consistently to quantify power interruptions to all types of customers. Due to the immediate termination of regular activities involving electricity during the first period of the outage, it is expected that the costs associated with this period will be larger in comparison to the second period, where the customer has now re-adjusted their activities to account for the loss of electricity. It is during the second period, however, that the inconvenience and disruption associated with the outage will continue to grow as the outage continues to linger. Therefore, the monetized value associated with this stage will be multiplied with the duration of the outage, in hours.

The customer interruption cost study proposed within Program Support will further enhance the $SAIFI_{EFFECT}$ and $SAIDI_{EFFECT}$ inputs through the development of a localized customer survey for the City of Toronto, which will better reflect the specific needs and preferences of Toronto-area customers. Furthermore, it should be noted that during the ICM interrogatories, both the interveners and the OEB Staff[4] recommended that Toronto Hydro look into the "use of surveys on the various customer classes to determine the units of [outage costs per customer class] as recommended by experts in that field". Toronto Hydro believes that conducting this study will help in the development of localized outage costs that address these concerns from various stakeholders.

E8.8.4 Timing & Pacing of the Program

Toronto Hydro plans to conduct these two studies to help mitigate the impact of the extreme weather and further enhance the FIM through localized outage costs. The spending forecast for the five-year period starting in 2015 is shown below in Table 4.

TABLE 4: HISTORICAL AND FUTURE SPENDING

	Historical Spending					Future Spending				
Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
CAPEX ($M)	0	0	0	0	0	1.2	0.5	0	0	0

Toronto Hydro plans to conduct the climate adaptation study in 2015 and 2016 while the CIC study is expected to be completed in 2015. The proposed total costs for climate adaptation study is $1.0 million over the two years with a budget of $0.5 million each year, while the CIC study is expected to cost $0.7 million.

[4] EB-2012-0064, Board Staff Submission (September 30, 2013), at page 13.

It is preferable to complete the climate adaptation study in the first two years of the DSP period. Upon completion of the climate adaptation study, Toronto Hydro would review its existing plans through the FIM, and compare the results to existing programs Toronto Hydro is currently executing, to benefit from any cross-program synergies or to build on exist existing programs that may already be building on system resiliency. The CIC study is planned for completion in 2015 because the localized outage costs calculated will have to be tested and gradually incorporated into the FIM to further enhance the model in preparation of prioritization of projects in the later years of the DSP period.

E8.8.5 Program Execution

Both of the studies in this program are planned for the first two years (2015-2016) of the DSP period as shown in Table 5. The climate adaptation and the CIC studies are expected to be completed in 2015-2016 and 2015 respectively. Toronto Hydro plans to contract out both studies on a competitive bid basis, while working closely with the vendors to provide the required data and direction.

TABLE 5: PROPOSED WORK PLAN

Year	Program Support
2015	CIC Study
2015	Climate Adaptation
2016	Climate Adaptation

The climate adaptation study in 2015 and 2016 would focus on identifying areas of vulnerable to extreme weather and climate change in the distribution system. The starting point of the studies would pick up where previous programs have left off. (Refer to Toronto Hydro's Actions to Date in Appendix A; Future Impacts of Climate Change on Toronto Hydro-Electric System Limited). Specifically, the study would start by looking at extreme weather event scenarios that are expected to increase in future climate change projections. These scenarios include but are not limited to flooding, freezing rain, increase in temperature, and ice-storm etc. In each scenario thresholds and boundaries would have to be created to identify what areas of the distribution system will be affected. In some cases where information is not readily available external parties will be engaged. Once thresholds and boundaries of each extreme weather scenario are known, a detailed engineering analysis of impacts from each event will be created.

For the CIC study, a vendor would be selected based on past experience conducting extensive outage costs surveys for different scenarios and across different customer demographics. Most

importantly, the preferred vendor should possess sufficient experience with the cost estimation methodologies described earlier in the narrative. Due to the survey nature of this study and Toronto Hydro's customer base, it is critical to ensure adequate customer representation and random sampling to mitigate sampling bias in the survey participants.

Following vendor selection, Toronto Hydro would work with the vendor to develop the questionnaire and expects to complete the survey by end of Q3 2015. The vendor would be expected to process the surveys and analyze the results and provide a final report. The goal is to complete the survey by end of Q4 2015.

E8.8.5.1 Program Risks

Both studies in this program would require external the involvement of external experts with proven experience in their fields. This is especially important for the CIC study. The CIC study requires a group with background in statistics (to ensure the right sample mix and no sampling bias exists), economics (quantify outage costs), survey design and execution. Toronto Hydro plans to reach out to authors of previous CIC studies, among other potential vendors.

E8.8.6 Evaluation of Alternatives

E8.8.6.1 Quantification/Evaluation of Options

(i) Status Quo

In the absence of these two proposed studies, plans to adapt to climate change within Toronto Hydro's distribution system would be derived solely from historical information and trends in weather-related events. Table 2 illustrates how customer interruptions associated with weather events would continue to increase due to the higher frequency of extreme weather. Similarly, Toronto Hydro would continue using existing customer interruption cost (CIC) inputs as part of their Feeder Investment Model (FIM) and business case evaluation (BCE) process.

This option is not preferred as it does not address the expected impacts of climate change and would not allow for the enhancement of CIC estimates.

(ii) Execution of Program Support

Through the execution of this program, Toronto Hydro would improve its Asset Management capabilities, including long-term and short-term planning processes, thereby allowing for improvements to capital programs and projects respectively.

Executive Summary

This document provides an overview of how the impacts of climate change are likely to affect Toronto Hydro's electrical distribution network. It also outlines the need for, and process by which, Toronto Hydro can continue its efforts to better understand its risks, take proactive steps to manage the risks and enhance the resilience of its electrical distribution system to climate change.

Toronto Hydro and the City of Toronto

Toronto Hydro is a part of the electricity network that includes generators (supply-side), transmission and distribution companies and consumers (demand-side). Each element of the network is interdependent, and decisions by, or impacts to, any element will affect the others. Reliable electrical supply is a central element supporting the activities, economy and people of a resilient city.

Toronto Hydro serves the City of Toronto, Canada's largest city and home to over 2.5 million people. The city is the capital of the province of Ontario, a major North American financial centre, and an important air, road and rail transportation hub. The following factors present unique challenges for Toronto Hydro in the provision and maintenance of electricity, as well as the response to emergency events and outages:

- Dense inner city development;
- Significant transportation infrastructure (e.g. road, subway and rail); and,
- Complex networks of above and below ground utility systems (e.g. water, stormwater, sewer, gas and telecommunications).

The climate is changing

There is a significant body of evidence indicating that the weather affects the performance and reliability of the electricity network. There is also a significant body of evidence that global and regional climate has changed and will continue to change over the coming century.

Since the middle of the 20th century the weather has changed with recorded increases in daily temperature, heat waves, precipitation, droughts and frequency of tropical cyclones in the North Atlantic (Flato, et al., 2013). Specific to Toronto, the climate is projected to continue to change with:

- Continued increase in average temperatures;
- Increase in extreme maximum temperatures;
- Increase in the number days over 35°C per year;
- Increase in total annual rainfall;
- Decrease in the total annual snowfall; and,
- Increase in the intensity of rainfall events (SENES Consultants Limited, 2011).

Weather and climate change will impact the reliability of the electrical system

The weather (e.g. heat, precipitation and wind) has direct and significant impacts on the performance of all elements of the electricity network. The weather's influence on the system is not new and is actively managed by companies through design and operational activities. For example, components of the network (e.g. transformers and conductors) are designed to achieve a minimum standard of performance up to a particular wind or temperature threshold. However, in the face of projected changes in climate, electrical distribution companies like Toronto Hydro will be placed in the predicament of having to manage assets that were not designed for future climate conditions.

There have been numerous recent examples of how the weather has affected Toronto's network performance including:

- Severe Thunderstorms, August 2005;
- Hurricane Sandy, October 2012;
- Extreme Rainfall, July 2013; and,
- Ice Storm, December 2013.

Each event produced significantly greater than average outages to the network. In the case of the August 2005 and July 2013 events the weather surpassed previous records.

Without intervention, Toronto Hydro will continue to experience increased physical impacts to its network due to severe weather and a changing climate, generating significant operational and maintenance costs and disrupting the supply of electricity to communities and businesses.

Globally – Utilities are responding to changing climate

Many infrastructure utility owners and operators (including electrical utilities) around the world are experiencing significant damage and disruption to their infrastructure as a result of extreme weather events. In addition to recognizing current weather vulnerabilities, many utilities are also acknowledging that the climate will continue to change, and that they should take steps to better understand the likely impacts to their systems, assets and services, and plan to adapt to a changing climate.

The following examples demonstrate how some of these utilities, with a focus on the electrical sector, are addressing the issues presented by climate change around the world. While the projected changes in climate and the impacts to infrastructure differ across regions, in general, there is increasing action to better understand the impacts and invest in measures that will improve the resilience of networks. Case studies presented in this document illustrate the following:

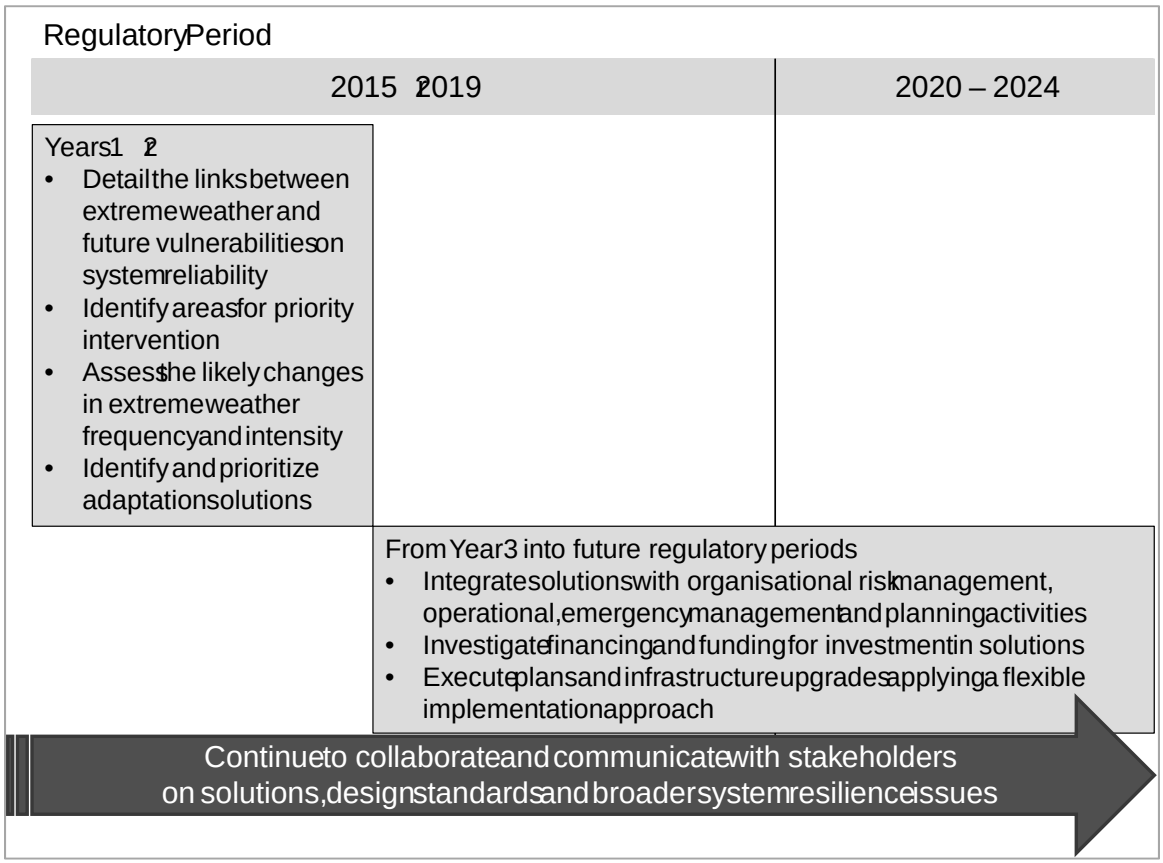
- In Canada at the national level, there is acknowledgement that climate change presents potentially significant risks to critical public infrastructure and that there is a need to better understand the risks to enable proactive management. This is demonstrated by the Natural Resources Canada report From Impacts to Adaptation: Canada in a Changing Climate 2007 and the completion of 25 climate change risk assessment case studies across multiple sectors including one of which involved Toronto Hydro's electrical distribution assets;
- In Ontario, Horizon Utilities conducted an assessment in 2012 of climate change related risks to its business and developed a twenty-year adaptation strategy and action plan addressing assets, operations and procurement practices;
- In California, a study has quantified the impacts that climate change may have on electrical network performance. The study showed likely increases in outages and reduced performance as temperatures increase;
- Consolidated Edison of New York Inc. illustrates how stakeholder interest and pressure contributed to the adoption of regulatory requirements for considering climate risks and investment in resiliency projects and support from the regulatory authority with $1billion approved to support implementation;
- The UK case study illustrates how regulatory requirements have driven assessments of climate risk on electrical utilities and provides examples of the approach used to fulfill the requirements; and
- In Australia, significant disruptions to electrical networks in two regions stemming from extreme weather were documented. Approaches to building resilience (both direct and seeking regulatory support) were presented.

Toronto Hydro is already resp onding to a changing climate

Toronto Hydro recognizes that a changing climate will have an impact on its operations, assets, and system reliability. Toronto Hydro's efforts to understand and address climate change have included:

- Adopting an Environmental Policy outlining its commitment to environmental stewardship. The policy includes a principle to ensure that environmental considerations are integrated into its business processes. Toronto

Hydro's commitment to environmental stewardship is closely aligned with addressing the issue of climate change, as the latter has the potential to disrupt business operations and electrical supply, which may result in detrimental impacts to the environment;
- Collaborating with government, private and non-profit organisations through the WeatherWise Partnership and the Canadian Electricity Association (CEA) Roundtable Initiative on Climate Adaptation; and,
- Commencing the process of understanding the impacts of climate change on Toronto Hydro Distribution Assets by undertaking a climate change risk assessment in collaboration with Engineers Canada.



These efforts indicate that Toronto Hydro has taken initial steps in its journey towards building a resilient network for the City of Toronto. However, there are limitations in Toronto Hydro's current understanding of its potential network vulnerabilities in the face of climate change. Notably, much of the work to date remains at a preliminary phase and further detailed work is still required to understand the impacts of a changing climate including how the climate will evolve locally as well as developing, prioritizing, costing and financing the potential adaptation solutions to enhance the resilience of the electrical distribution system to climate change.

An Adaptation Plan to move forward

In order to address these limitations a logical, considered and flexible plan should be developed and implemented to guide Toronto Hydro's efforts in improving the resilience of its electrical network. The key elements of this plan are (refer to Figure 1):

- Enhancing understanding of the projected changes in extreme weather event frequencies and intensities (e.g. extreme heat, ice storms);
- Detailing the links between the climate (e.g. extreme weather events and longer term changes in climate) and future vulnerabilities on system reliability by undertaking detailed assessments of component and system vulnerabilities (e.g. interdependencies, redundancies, equipment condition and age, climate induced changes in energy demand profile);
- Projecting impacts of climate change on the number of customer service interruptions and quantifying through reliability measures (i.e. SAIDI, SAIFI) and the costs of outage events;
- Identifying areas for priority intervention in consultation with the City of Toronto based on electrical system vulnerabilities, vulnerable populations, and priority service areas (e.g. emergency response and health facilities, shelters etc.);
- Identifying adaptation solutions, which include engineering actions, maintenance and operations measures, procurement specifications, emergency response and recovery measures, and increased risk tolerance and insurance measures. These solutions must be identified in conjunction with community and stakeholder engagement and an assessment of organisational and community risk tolerances;
- Evaluating and prioritizing adaptation solutions based on evaluation of costs and benefits, system vulnerabilities, and priority geographic areas for intervention;
- Investigating financing and funding for investment in solutions;
- Developing implementation plans describing solutions, timelines and budgets for implementation. Incorporate flexibility into plans to allow the implementation process to integrate, in so far as possible, advancements in scientific understanding of climate change, ongoing evaluations of system performance, funding opportunities and scheduled upgrade opportunities on which to 'piggyback' integration of climate change resilience measures;
- Integrating solutions within organisational risk management, current operational and maintenance programs, and emergency response management and planning activities;
- Executing plans and infrastructure upgrades in accordance with the flexible implementation approach described above;
- Continuing to monitor system performance and reliability on an ongoing basis; and,
- Reviewing and updating design standards in collaboration with other utilities and the Canadian Standards Association.

Figure 1 Overview of the Proposed Next Steps for Toronto Hydro's Adaptation Planning

Adapting to Climate Change, an Ongoing Challenge

In summary, while the climate has and will continue to affect the reliability and performance of Toronto Hydro's network, with thoughtful planning, preparation and investment, Toronto Hydro can proactively address the issues presented by climate change and continue to support the reliability and resilience of Toronto's electrical system.

This document demonstrates Toronto Hydro's recognition of the importance of understanding, planning and acting to address climate change. Toronto Hydro should seek the support of the regulator in its efforts to systematically advance the resilience of the electricity network to increasing risks posed by climate change.

Having an Adaptation Plan that is logical, considered and flexible is the most sensible path to manage this new challenge. There are many actions that can be incorporated within business as usual operating constraints, but many others require new research, technologies, targeted investment and collaboration amongst agencies.

Toronto Hydro should fully develop its Adaptation Plan, carry out further detailed studies, and seek funding support for enhancing the resilience of its electrical network. Toronto Hydro should also seek longer term support for ongoing consideration of climate change in future operational and investment planning.

Flexibility in the development and execution of the Adaptation Plan is necessary to ensure that the results of further detailed studies (that are not known at this time) can direct investment towards identified high priority, and / or pilot projects to boost the reliability of its network to both gradual climate change related impacts as well as those stemming from increasingly severe weather events. Finally, the Adaptation Plan and measures developed and implemented by Toronto Hydro could be used as a template and guide to help other utilities across the electricity distribution sector to enhance the resilience of their systems to climate change.

1.0 Introduction

The climate is changing and increasing the risks of damage to, and disruption of, critical infrastructure including the electricity network. This has significant implications for the resilience of communities and the economy.

The electricity network is made up of generators (supply-side), transmission and distribution companies and consumers (demand-side) (Figure 2). Each element of the network is interdependent, and decisions and actions made by one element will affect the others. For example, disruptions to the generation of electricity will affect the ability of transmission and distribution companies to provide electricity to consumers. Likewise, if consumers change their demand profile, it will place pressure on transmission and distribution infrastructure and may also influence operational and investment decisions made by generators.

Figure 2 Overview of the Electricity Network

Much of the activities of public and private sector organisations or individuals are dependent on reliable electricity supply, as illustrated by Figure 3. For example businesses and industry need electricity to produce goods or make transactions, while households need electricity for many recreational activities and heating and cooling. In addition, electricity supports food production and storage, water supply and treatment, and transportation systems (e.g. powering trains, providing lighting and signals on roads, and communications for air traffic control). During times of emergency the need for reliable electricity is even more apparent; it plays a critical role in:

- supporting communications in preparing for an event and during response and recovery activities;
- supporting mitigation efforts, for example flood control pumps;
- providing lighting for emergency management, repair and recovery activities; and,
- heating and cooling during extreme cold or warm periods.

Reliable electrical supply is central to the resilience of a city and community.

Toronto Hydro serves the City of Toronto, Canada's largest city and home to over 2.5 million people. The city is the capital of the province of Ontario, a major North American financial centre, and an important air, road and rail transportation hub. The following factors present unique challenges for Toronto Hydro in the provision and maintenance of electricity, as well as the response to emergency events and outages:

- Dense inner city development;
- Significant transportation infrastructure (e.g. road, subway and rail); and,
- Complex networks of above and below ground utility systems (e.g. water, stormwater, sewer, gas and telecommunications).

The weather (e.g. heat, precipitation and wind) can have direct and significant impacts on the performance of the electricity system, from the efficiency of generators to the ability to distribute electricity to consumers and ultimately the level of consumer demand. The influence of the weather on the system is actively managed by companies through design and operational activities. For example, design standards are used for network components to achieve acceptable performance up to a particular wind or temperature threshold.

Generally, maintenance regimes are set to monitor the condition and performance of components over a given timeframe. Assets may be replaced based on their specified design life, but may also be repaired or refurbished to extend operational life beyond original design specifications. These types of maintenance, refurbishment and replacement decisions have traditionally been informed by standards and practices that are based on historical climate records.

Asset failure occurs when weather events exceed the design capacity / threshold of system components. The weather can also affect assets by directly, or indirectly damaging assets (e.g. flood waters inundating a substation, wind-blown debris bringing down power lines). There have been many recent examples of how extreme weather has affected the network in the Greater Toronto Area (GTA), including severe storm and flooding events in 2005, 2012 and 2013.

The climate has changed over the last 50 years and is projected to continue to change over the lifespan of assets that are critical to the electricity network. When combined with other circumstances such as changes in policy affecting demand and generation profiles, changes in the frequency and intensity of extreme weather events and longer term changes in the climate (e.g. average temperatures) will have significant, broad ranging impacts to all elements of the electricity network.

Changes in the projected average temperature and average precipitation can result in significant changes in the frequency or intensity of extreme events. As a result of the projected changes in climate, it is possible that the lifespan of assets will be shortened as they operate under greater stress, or may fail more frequently as their design thresholds are exceeded more often.
